- Log in to FusionInsight Manager, choose **Cluster > Services > Redis**, and click **Instance** to view the IP addresses of instances running in the cluster.
- On Redis nodes, the port number used by role **Redis\_1** is **22400**, and that used by role **Redis\_2** is **22401**. The others follow the same rule.
- **userName** indicates the cluster user. **redisuser** is for reference only.
- **realmsName** indicates the cluster domain name. **HADOOP.COM** is for reference only. You can log in to FusionInsight Manager and choose **System > Domain and Mutual Trust** to view the actual domain name of the cluster.
- **krbConfPath** and **keyTabFile** indicate the locations of the user authentication files decompressed from **krb5.conf** and **user.keytab** on the Linux server, respectively. **/opt/test** is used as an example.
- **principal** is in the format of **Username@Domain name**. **redisuser1@HADOOP.COM** is for reference only.

Perform the following steps to run the code:

**Step 1** Create a directory on the Linux node, for example, **/opt/test**, and create the **/config/auth.conf** file. The file content is as follows:

```
userName = redisuser
storeKey = true
realmsName = HADOOP.COM
useKeyTab = true
keyTabFile = config/user.keytab
krbConfPath = config/krb5.conf
```

**Step 2** Decompress the downloaded user authentication file to obtain **krb5.conf** and **user.keytab**, and move them to the **/opt/test/config** directory.

**Step 3** Change the values of **Const.IP\_1** and **Const.PORT\_1** in the preceding sample code based on the site requirements.

**Step 4** Package the application by referring to [Commissioning an Application in Linux](#).

**Step 5** Run the following command to run the application:

```
java -cp .:lib/* com.huawei.redis.security.SecureJedisClusterDemo
```

----End

### 1.18.3.3 Global Authentication Through APIs

You can access the Redis service by setting global authentication information. The sample codes are as follows:

```
public class SecureJedisClusterDemo2 {
    public static void main(String[] args) {
```

```
System.setProperty("java.security.krb5.conf", "krb5.conf file path");
AuthConfiguration authConfiguration = new AuthConfiguration("keytab file path", "principal");
GlobalConfig.setAuthConfiguration(authConfiguration);
// System.setProperty("SERVER_REALM","HADOOP.COM");

Set<HostAndPort> hosts = new HashSet<HostAndPort>();
hosts.add(new HostAndPort(Const.IP_1, Const.PORT_1));
JedisCluster client = new JedisCluster(hosts, 5000);

client.set("test-key", System.currentTimeMillis() + "");
System.out.println(client.get("test-key"));
client.del("test-key");
client.close();
}
}
```

Perform the following operations to run the application:

- Step 1** Decompress the downloaded user authentication files to obtain **krb5.conf** and **user.keytab**, and upload them to the Linux server where the sample runs, for example, **/opt/test**.
- Step 2** Change the values of **java.security.krb5.conf**, **krb5.conf file path**, **principal**, **Const.IP\_1** and **Const.PORT\_1** in the preceding sample codes based on the site requirements.
- Step 3** Refer to the packing operations described in [Commissioning an Application in Linux](#).
- Step 4** Run the following command to run the application:

```
java -cp ..lib/* com.huawei.redis.security.SecureJedisClusterDemo2
----End
```

#### 1.18.3.3.4 Authentication Through the jaas.conf File

Use the specified **jaas.conf** file to access the Redis server. The sample codes are as follows:

```
public class SecureJedisClusterDemo3 {
    public static void main(String[] args) {
        System.setProperty("redis.authentication.jaas", "true");
        System.setProperty("java.security.auth.login.config", "jaas.conf file path");
        System.setProperty("java.security.krb5.conf", "krb5.conf file path");
        // Section name of the jaas.conf file. The value is case sensitive. The default value is Client.
        // System.setProperty("redis.sasl.clientconfig", "redisClient");
        // System.setProperty("SERVER_REALM","HADOOP.COM");
        Set<HostAndPort> hosts = new HashSet<HostAndPort>();
        hosts.add(new HostAndPort(Const.IP_1, Const.PORT_1));
        JedisCluster client = new JedisCluster(hosts, 5000);

        client.set("test-key", System.currentTimeMillis() + "");
        System.out.println(client.get("test-key"));
        client.del("test-key");
        client.close();
    }
}
```

Perform the following operations to run the application:

- Step 1** Decompress the downloaded user authentication files to obtain **krb5.conf** and **user.keytab**, and upload them to the Linux server where the sample runs, for example, **/opt/test**. Generate the **jaas.conf** file by referring to [Preparing Authentication Mechanism Code](#).

**Step 2** Modify the preceding sample codes based on the content of the **jaas.conf** file generated in [Step 1](#).

**Step 3** Refer to the packing operations described in [Commissioning an Application in Linux](#).

**Step 4** Run the following command to start the application:

```
java -cp .:lib/* com.huawei.redis.security.SecureJedisClusterDemo3
```

----End

### 1.18.3.3.5 Independent Authentication Through APIs

You can use APIs to access Redis servers using different usernames in the same application. The following sample code is used to access two Redis logical clusters at the same time in the same application. You need to download the authentication information of the two Redis logical clusters.

```
public class SecureJedisClusterDemo4 {  
  
    /**  
     * Default connection timeout  
     */  
    private static final Integer TIMEOUT = 3000;  
  
    /**  
     * Maximum retries  
     */  
    private static final Integer MAX_ATTEMPTS = 1;  
  
    public static void main(String[] args) throws KeyManagementException, NoSuchAlgorithmException {  
        // Create a Kerberos authentication object.  
        AuthConfiguration authConfiguration = new AuthConfiguration("path1/krb5.conf", "path1/  
user.keytab",  
            "user@HADOOP1.COM");  
        authConfiguration.setServerRealm("HADOOP1.COM");  
        authConfiguration.setLocalRealm("HADOOP1.COM");  
        // Create a second Kerberos authentication object.  
        AuthConfiguration authConfiguration2 = new AuthConfiguration("path2/krb5.conf", "path2/  
user.keytab",  
            "user@HADOOP.COM");  
        authConfiguration.setServerRealm("HADOOP.COM");  
        authConfiguration.setLocalRealm("HADOOP.COM");  
        // Add the IP addresses and port numbers of the cluster.  
        Set<HostAndPort> hosts = new HashSet<>();  
        hosts.add(new HostAndPort("Const.IP_1", Const.PORT_1));  
        Set<HostAndPort> hosts2 = new HashSet<>();  
        hosts2.add(new HostAndPort("Const.IP_2", Const.PORT_2));  
  
        // Initialize the connection pool.  
        JedisPoolConfig jedisPoolConfig = new JedisPoolConfig();  
        jedisPoolConfig.setMinIdle(3);  
        jedisPoolConfig.setMaxTotal(100);  
        jedisPoolConfig.setMaxIdle(100);  
  
        // Create SSL sockets.  
        boolean ssl = false;  
        final SSLSocketFactory socketFactory = SslSocketFactoryUtil.createTrustAllSslSocketFactory();  
  
        // Initialize the jedisCluster connection.  
        writeCluster(hosts, jedisPoolConfig, socketFactory, ssl, authConfiguration);  
        // Connect to the second JedisCluster.  
        writeCluster(hosts2, jedisPoolConfig, socketFactory, ssl, authConfiguration2);  
    }  
}
```

```
* Connect to a Redis cluster.  
*  
* @param hosts      Indicates the primary instance list.  
* @param jedisPoolConfig  Indicates the connection pool configuration.  
* @param socketFactory  socket factory class  
* @param ssl          Specifies whether to enable SSL.  
* @param authConfiguration  Indicates the security authentication configuration.  
*/  
private static void writeCluster(Set<HostAndPort> hosts, JedisPoolConfig jedisPoolConfig,  
    SSLSocketFactory socketFactory, boolean ssl, AuthConfiguration authConfiguration) {  
    JedisCluster client = new JedisCluster(hosts, TIMEOUT, TIMEOUT, TIMEOUT, MAX_ATTEMPTS,  
    jedisPoolConfig, ssl,  
        socketFactory, authConfiguration);  
    client.set("test-key", System.currentTimeMillis() + "");  
    System.out.println(client.get("test-key"));  
    client.del("test-key");  
    client.close();  
}  
}
```

Perform the following operations to run the application:

- Step 1** Decompress the downloaded user authentication files of the two Redis logical clusters to obtain **krb5.conf** and **user.keytab**, and upload them to the Linux server where the sample runs, for example, **/opt/test**.
- Step 2** Change the values of **krb5.conf**, **user.keytab**, **HADOOP1.COM**, **principal**, **Const.IP\_1**, **Const.PORT\_1**, **Const.IP\_2**, and **Const.PORT\_2** in the preceding sample code based on the site requirements.
- Step 3** Package the application by referring to [Commissioning an Application in Linux](#).
- Step 4** Run the following command to run the application:

```
java -cp ..:lib/* com.huawei.redis.security.SecureJedisClusterDemo4
```

----End

### 1.18.3.4 Connection to Redis in Security Mode Using Other Languages

#### 1.18.3.4.1 Connection to Redis in Security Mode Using Python 3.x

##### Overview

This section describes how to use Python 3.x in a Linux operating system to connect to a Redis instance in security mode. Currently, Windows operating systems are not supported.

##### Prerequisites

- SSL channel encryption has been disabled.  
Log in to FusionInsight Manager and choose **Cluster > Services > Redis**. Click **Configurations** then **All Configurations**, search for **REDIS\_SSL\_ON**, and set this parameter to **false**, and click **Save**. Restart the service for the configuration to take effect.
- Create a Redis role and user on FusionInsight Manager, for example, create **redisuser**. For details, see [Development and Operating Environment](#). Download the authentication file of the user.

- This section takes a CentOS 7.6 running on a x86 server as an example. The **python-gssapi** package for Python Kerberos authentication is required. You need to install the authentication package and set up other basic Python environments. To install Kerberos authentication packages, perform the following steps:

**Step 1** Run the following command to install the packages on the client to be authenticated:

```
yum install cyrus-sasl cyrus-sasl-lib cyrus-sasl-gssapi cyrus-sasl-plain krb5-devel krb5-libs
```

**Step 2** Run the following command to install the Python basic package on the client to be authenticated:

```
yum install python3-devel python-kadmin
```

**Step 3** Run the following command to install the Python packages required for Kerberos authentication on the client to be authenticated:

```
pip3 install gssapi subprocess struct redis
```

**Step 4** Install the client of the current cluster to a specified directory, for example, **/opt/hadoopclient**. For details, see [Preparing Operating Environment](#). Run the following command to add environment variables:

```
source /opt/hadoopclient/bigdata_env
```

**Step 5** Download the Redis user credential, decompress it to obtain the **krb5.conf** and **user.keytab** files, and upload the files to the **/srv/project/krb5-example** directory on the client server.

----End

## Kerberos Authentication

The following code is used as an example to connect to a Redis instance with Kerberos authentication enabled using Python 3.x. Modify the parameters in the example as needed by importing the dependency.

```
import gssapi
import os
import redis
import subprocess
import struct
#Change the values of KRB5CCNAME, KRB5_CONFIG, and KRB5_KTNAME as needed.
os.environ["KRB5_KTNAME"] = "/srv/project/krb5-example/user.keytab"
os.environ["KRB5_CONFIG"] = "/srv/project/krb5-example/krb5.conf"
os.environ["KRB5CCNAME"] = "/srv/project/krb5-example/krb5cc_0"
#Change the domain name.
realm = "HADOOP.COM"
#Change the username and domain name.
principal="redisuser@" + realm
store = {'ccache': os.environ["KRB5CCNAME"], 'keytab': os.environ["KRB5_KTNAME"]}
#Service IP address and port number for connecting to the Redis instance. You can change them as needed.
r = redis.Redis("192.168.20.238", 22400)
conn_pool = r.connection_pool
conn = conn_pool.get_connection("_")
subprocess.run(["kinit", "-kt", os.environ["KRB5_KTNAME"], principal])
server_principal = "redis/hadoop." + realm.lower() + "@" + realm
service_name = gssapi.Name(server_principal)
cname = service_name.canonicalize(gssapi.MechType.kerberos)
```

```
client_creds = gssapi.Credentials(usage='both', store=store)
client_ctx = gssapi.SecurityContext(name=cname,
                                    flags=gssapi.RequirementFlag.mutual_authentication,
                                    mech=gssapi.MechType.kerberos,
                                    creds=client_creds)
SASL_QOP_AUTH = 1
server_token = None
while not client_ctx.complete:
    client_token = client_ctx.step(server_token)
    client_token = client_token or b''
    conn.send_command("authext", client_token)
    auth_response=conn.read_response()
    server_token=auth_response[4:]

msg = client_ctx.unwrap(server_token).message
qop = struct.pack('!B', SASL_QOP_AUTH & msg[0])
msg = qop + msg[1:]
msg = client_ctx.wrap(msg + principal.encode(), False).message
conn.send_command("authext", msg)
auth_response=conn.read_response()
print(auth_response)

conn.send_command("config", "get", "maxmemory")
auth_response=conn.read_response()
print(auth_response)
```

#### NOTE

- **KRB5\_KTNAME** and **KRB5\_CONFIG** indicate the locations where the user authentication files decompressed from **user.keytab** and **krb5.conf** are uploaded, respectively, on the Linux server.
- **KRB5CCNAME** indicates the path of the cache file generated after you log in to Kerberos.
- **realm** indicates the cluster domain name. **HADOOP.COM** is for reference only. You can log in to FusionInsight Manager and choose **System > Permission > Domain** and **Mutual Trust** to view the actual domain name of the cluster.
- **principal** is in the format of *Username@Domain name*. **redisuser@" + realm** is for reference only.
- Obtaining the instance service IP address: Log in to FusionInsight Manager, choose **Cluster > Services > Redis**, and click **Instance** to view the IP addresses of instances running in the cluster.
- Obtaining the port number: On Redis nodes, the port number used by role **Redis\_1** is **22400**, and that used by role **Redis\_2** is **22401**. The others follow the same rule.

## Debugging Program

- Step 1** Log in to the server where the Redis client is deployed as the **root** user.
- Step 2** Save the modified Python sample code as **krb5test.py** and upload it to the **/srv/project/krb5-example** directory on the server.
- Step 3** Run the following commands to change the permission on the **krb5test.py** file to **700**:
- ```
cd /srv/project/krb5-example
chmod 700 krb5test.py
```
- Step 4** Run the following command to run the sample Python program:
- ```
python3 krb5test.py
```

**Step 5** The command output is as follows:

```
...  
b'authok'  
[b'maxmemory', b'1073741824']
```

----End

### 1.18.3.4.2 Connection to Redis in Security Mode Using C and C++

## Overview

This section describes how to use C and C++ to connect to Redis in security mode to implement Kerberos authentication. This section is implemented based on the environment listed in the following table. Other environments are similar and are not described. Note that some commands in the guide do not support the Debian OS.

**Table 1-167**

Environment	Version information
GCC	7.3.0
CMake	3.22.1

This chapter describes how to log in to the Kerberos service using **kinit**, whose login duration is 24 hours. You can periodically update the login information of **kinit** based on the site requirements to prevent Redis access failures caused by login information expiration.

## Prerequisites

- SSL channel encryption has been disabled.  
Log in to FusionInsight Manager and choose **Cluster > Services > Redis**. Click **Configurations** then **All Configurations**, search for **REDIS\_SSL\_ON**, and set this parameter to **false**, and click **Save**. Restart the service for the configuration to take effect.
- A Redis role and user has been created on FusionInsight Manager, for example, create **redisuser**. For details, see [Preparing Operating Environment](#). The authentication file of the user has been downloaded.
- The Hiredis source code package has been downloaded to the local environment in advance because it is used to access the Redis service in this test example. The download address is <https://github.com/redis/hiredis/tree/v1.0.2>. Click **Download ZIP** to download Hiredis 1.0.2 to the local environment.
- The Kerberos dependencies have been installed. EulerOS is used as an example here.

**yum install cyrus-sasl cyrus-sasl-devel cyrus-sasl-lib**

 NOTE

Debian OSs do not support the preceding commands. You need to install Cyrus and krb5 dependency packages.

## Kerberos Authentication

The following code is used as an example to connect to the Redis instance in security mode using C/C++. Modify the parameters in the example based on the site requirements.

```
#include <stdio.h>
#include "kerberos.h"
#include "hiredis/hiredis.h"
#include "hiredis/sds.h"

#define CRLF      "\r\n"
#define AUTH_OK    "authok"
// auth continue
#define ACT_PREFIX  "act:"
#define CRLF_LEN   2
#define AUTH_OK_LEN 6
#define ACT_PREFIX_LEN 4

/* Error codes */
#define C_OK        0
#define C_ERR       -1

int sds2str(char *s, long long value) {
    char *p, aux;
    unsigned long long v;
    size_t l;
    /* Generate the string representation, this method produces
     * a reversed string. */
    v = (value < 0) ? -value : value;
    p = s;
    do {
        *p++ = '0' + (v%10);
        v /= 10;
    } while(v);
    if (value < 0) *p++ = '-';
    /* Compute length and add null term. */
    l = p-s;
    *p = '\0';
    /* Reverse the string. */
    p--;
    while(s < p) {
        aux = *s;
        *s = *p;
        *p = aux;
        s++;
        p--;
    }
    return l;
}
/**
 * Send authentication information to the server.
 * @param c Redis connection information
 * @param datalen ticket length
 * @param data ticket content
 * @return Whether the message is sent successfully
 */
int sendAuthReq(redisContext *c, size_t datalen, char *data) {
    sds cmd = sdsnew("*2\r\n$7\r\nnauthext\r\n");
    char buf[32] = {0};
    long len = 0;
    len = sds2str(buf, (long long )datalen);
```

```
cmd = sdscatlen(cmd, "$", 1);
cmd = sdscatlen(cmd, buf, len);
cmd = sdscatlen(cmd, CRLF, CRLF_LEN);
cmd = sdscatlen(cmd, data, datalen);
cmd = sdscatlen(cmd, CRLF, CRLF_LEN);
if (redisAppendFormattedCommand(c, cmd, sdslen(cmd)) != REDIS_OK) {
    return C_ERR;
}
return C_OK;
}
/**
 * Obtain the returned authentication information.
 * @param c Redis connection information
 * @return Ticket information returned during authentication
 */
sds getAuthReply(redisContext *c) {
    redisReply *reply;
    if (redisGetReply(c, (void **)(&reply)) == REDIS_ERR) {
        printf("reply error\n");
        return NULL;
    }
    if (reply->type == REDIS_REPLY_ERROR) {
        printf("(error) %s\n", reply->str);
        freeReplyObject(reply);
        return NULL;
    }
    sds ticket = sdsnewlen(reply->str, reply->len);
    if (!strncmp(ticket, AUTH_OK, AUTH_OK_LEN)) {
        return ticket;
    }
    // Delete useless information returned by the server: act:
    sdsrange(ticket, ACT_PREFIX_LEN, -1);
    freeReplyObject(reply);
    return ticket;
}
int main() {
    // Initialize the Kerberos authentication information when the client is started.
    initializeClient();

    redisContext *c = redisConnect("Instance service IP address", Port number);
    int finished = 0;
    char* full_server_realm = "hadoop.Domain name";
    printf("full_server_realm=%s\n", full_server_realm);
    struct client_state state = {
        .auth_started = 0,
        .auth_complete = 0
    };
    // Start authentication.
    gss_result result = start(full_server_realm, &state);
    if (result.code != 0) {
        printf("error:%s", result.message);
        return -1;
    }
    while (!finished) {
        sendAuthReq(c, result.len, result.response);
        sds reply = getAuthReply(c);
        if (reply == NULL) {
            return -1;
        }
        if (!strncmp(reply, AUTH_OK, AUTH_OK_LEN)) {
            finished = 1;
            continue;
        }
        result = step(reply, sdslen(reply), &state);
        if (result.code == -1) {
            printf("error:%s\n", result.message);
            return -1;
        }
        if (result.response == NULL) {
```

```
        result.response = "";
    }
}
printf("auth ok%\n\n");
printf("authed user=%s\n", state.username);
redisCommand(c, "set %s %s", "b", "bbbbbb");
redisReply *reply = redisCommand(c, "get %s", "b");
printf("b=%s\n", reply->str);
return 0;
}
```

#### NOTE

- Obtaining the instance service IP address: Log in to FusionInsight Manager, choose **Cluster > Services > Redis**, and click **Instance** to view the IP addresses of instances running in the cluster.
- Obtaining the port number: On Redis nodes, the port number used by role **Redis\_1** is **22400**, and that used by role **Redis\_2** is **22401**. The others follow the same rule.
- Format of **full\_server\_realm**: "*hadoop.Domain name*". You can log in to FusionInsight Manager and choose **System > Permission > Domain** and **Mutual Trust** to view the cluster domain name of the cluster.

## Running the Sample

**Step 1** Upload the modified sample code to the **/srv/cKerberos** directory on the Linux server.

**Step 2** Decompress the downloaded Hiredis package and upload the decompressed code to **/srv/cKerberos/src/hiredis**.

```
[root@192-168-150-7 cKerberos]# ls src/hiredis/
adapters alloc.h      async.c  async_private.h CMakeLists.txt dict.c examples hiredis.c
hiredis.h   hiredis_ssl-config.cmake.in hiredis_ssl.pc.in net.c read.c README.md sds.c sockcompat.c
ssl.c test.sh
alloc.c appveyor.yml async.h CHANGELOG.md  COPYING      dict.h fmacros.h hiredis-
config.cmake.in hiredis.pc.in hiredis_ssl.h      Makefile    net.h read.h sdsalloc.h sds.h
sockcompat.h test.c win32.h
```

**Step 3** Create the **/srv/cKerberos/build** folder.

```
mkdir -p /srv/cKerberos/build
```

```
cd /srv/cKerberos/build
```

**Step 4** Compile the sample code.

```
cmake -DTEST_ENABLE=true .. && make
```

The compilation result is as follows:

```

```

**Step 5** Run the sample code.

```
source Client path/ bigdata_env
kinit Redis user
./kerberosTest
```

**Step 6** Check the command output, as shown in the following figure.

```
[root@100-85-150-7 build]# ./kerberosTest
full_server_realm=hadoop.HADOOP.COM
auth ok

authed user=redisuser@HADOOP.COM

b=bbbbbb
[root@100-85-150-7 build]#
```

#### 1.18.3.4.3 Connection to Redis in Security Mode Using Node.js

##### Overview

This section describes how to use Node.js to connect to a Redis instance in security mode. Currently, the development environment running Windows is not supported.

This chapter describes how to log in to the Kerberos service using **kinit**, whose login duration is 24 hours. You can periodically update the login information of **kinit** based on the site requirements to prevent Redis access failures caused by login information expiration.

##### Prerequisites

- SSL channel encryption has been disabled.  
Log in to FusionInsight Manager and choose **Cluster > Services > Redis**. Click **Configurations** then **All Configurations**, search for **REDIS\_SSL\_ON**, and set

this parameter to **false**, and click **Save**. Restart the service for the configuration to take effect.

- A Redis role and user has been created on FusionInsight Manager, for example, create **redisuser**. For details, see [Preparing Operating Environment](#). The authentication file of the user has been downloaded.
- This section takes a CentOS 7.6 running on a x86 server as an example. The basic Node.js environment has been installed. The current example uses Node.js to call the binary library and you need to install authentication-related packages before authentication.  
**yum install cyrus-sasl cyrus-sasl-devel cyrus-sasl-lib**
- The Node.js dependencies have been installed.  
**npm install node-gyp -g**

## Kerberos Authentication

The following code is used as an example to connect to the Redis instance in security mode using Node.js. Modify the parameters in the example based on the site requirements.

```
"use strict";

const stream = require("net");
const {genCommand} = require("./redisProtocol")
const Krb5 = require("./kerberosAuth")
const {initParser} = Krb5

let realm = "HADOOP.COM";
let username = "flinkuser" + "@" + realm;
// Initialize Krb5Auth.
let auth = new Krb5.Krb5Auth("./krb5.conf", "./user.keytab", realm, username);
auth.setCCname("/srv/kerberos-auth/flinkuser_10000");
auth.kinit();
let connectionOptions = {
    "port": Port number,
    "host": Service instance IP address
};
// Connect to the Redis service.
const client = stream.createConnection(connectionOptions);
// Initialize the Redis return value parser.
const authParser = initParser(auth);
// Start authentication.
auth.authStart(client);
let count = 1;
client.on("data", (buffer) => {
    authParser.execute(buffer);
    if (auth.error) {
        console.log("error");
        return;
    }
    if (count <= 0) {
        // After the authentication is successful, the system sends a password and exits. This parameter is invalid.
        process.exit();
    }
    if (auth.authed) {
        // After the authentication is successful, the service command starts to be sent. The following uses config get maxmemory as an example.
        console.log("send info");
        client.write(genCommand("config", ["get", "maxmemory"]));
        count--;
    } else {
        // Before the authentication is successful, obtain the ticket from the server, verify the ticket, and
```

generate a ticket from the client until the authentication is successful. This process takes about two to three times.

```
        auth.authTicket(client);
    }
});
```

#### NOTE

- Obtaining the instance service IP address: Log in to FusionInsight Manager, choose **Cluster > Services > Redis**, and click **Instance** to view the IP addresses of instances running in the cluster.
- Obtaining the port number: On Redis nodes, the port number used by role **Redis\_1** is **22400**, and that used by role **Redis\_2** is **22401**. The others follow the same rule.
- **realm** indicates the cluster domain name. **HADOOP.COM** is for reference only. You can log in to FusionInsight Manager and choose **System > Permission > Domain** and **Mutual Trust** to view the actual domain name of the cluster.
- **Krb5.Krb5Auth**: The first two parameters indicate the location where the user authentication files decompressed from **user.keytab** and **krb5.conf** are uploaded to the Linux server.
- **setCCname** indicates the path of the cache file generated after you log in to Kerberos.
- **username**: The value is in the format of *Username@Domain name*.

## Running the Sample

**Step 1** Upload modified sample code **test.js** to the **/srv/kerberos-auth** directory on the Linux server and run the following command to install the dependencies:

**npm install**

**Step 2** Decompress the downloaded authentication credential to obtain the **krb5.conf** and **user.keytab** files and upload them to the **/srv/kerberos-auth** directory on the server.

**Step 3** Run the following command to run the sample:

**node test.js**

**Step 4** Check the command output, as shown in the following figure.

```
[testuser@192-168-64-77 kerberos-auth]$ node test.js
kinitd
auth ok
send info
-----result begin-----
maxmemory,1073741824
-----result end-----
[testuser@192-168-64-77 kerberos-auth]$
```

----End

### 1.18.3.4.4 Connection to Redis in Security Mode Using the Go Language

## Overview

This section describes how to use the Go language on Linux to connect to Redis in security mode. Currently, the development environment running Windows is not supported.

The Go language is used to invoke the binary dependency library to implement Kerberos authentication. This chapter describes how to log in to the Kerberos service using **kinit**, whose login duration is 24 hours. You can periodically update the login information of **kinit** based on the site requirements to prevent Redis access failures caused by login information expiration.

## Prerequisites

- SSL channel encryption has been disabled.  
Log in to FusionInsight Manager and choose **Cluster > Services > Redis**. Click **Configurations** then **All Configurations**, search for **REDIS\_SSL\_ON**, and set this parameter to **false**, and click **Save**. Restart the service for the configuration to take effect.
- A Redis role and user has been created on FusionInsight Manager, for example, create **redisuser**. For details, see [Preparing Operating Environment](#). The authentication file of the user has been downloaded.
- The system packages related to Kerberos authentication has been installed. This section uses CentOS 7.6 on an x86 server as an example. This section does not describe how to set up the basic environment of the Go language. For details about how to install the system package, see the following command:  
**yum install cyrus-sasl cyrus-sasl-devel cyrus-sasl-lib**

## Kerberos Authentication

The following code is used as an example to connect to the Redis instance in security mode using the Go language. Modify the parameters in the example based on the site requirements.

```

    }
}
```

#### NOTE

- Obtaining the instance service IP address: Log in to FusionInsight Manager, choose **Cluster** > **Services** > **Redis**, and click **Instance** to view the IP addresses of instances running in the cluster.
- Obtaining the port number: On Redis nodes, the port number used by role **Redis\_1** is **22400**, and that used by role **Redis\_2** is **22401**. The others follow the same rule.
- Format of **full\_server\_realm**: "*hadoop.Domain name*". You can log in to FusionInsight Manager and choose **System** > **Permission** > **Domain** and **Mutual Trust** to view the cluster domain name of the cluster.

## Debugging Program

**Step 1** Compile the code to obtain binary files. For details, see [Connection to Redis in Security Mode Using C and C++](#). The following is an example:

```
-rw----- 1 root root 17815 Dec 22 16:47 CMakeCache.txt
drwx----- 6 root root 4096 Dec 22 17:03 CMakeFiles
-rw----- 1 root root 1774 Dec 22 16:47 cmake_install.cmake
-rwx----- 1 root root 146784 Dec 22 17:03 kerberosTest
-rw----- 1 root root 4324 Dec 22 16:46 libckrb5.a
-rw----- 1 root root 17417 Dec 22 17:03 Makefile
drwx----- 3 root root 4096 Dec 22 16:47 src
```

**Step 2** Upload the Go language sample code to the **/srv/go-krb5** directory.

```
drwx----- 2 root root 4096 Oct 21 15:48 include  
-rw----- 1 root root 18058 Oct 24 17:28 krb.go
```

**Step 3** Create the **lib** folder in **/srv/go-krb5** and copy **libckrb5.a** obtained in **Step 1** to the **lib** folder.

```
-rw----- 1 root root 4180 Oct 24 19:02 libckrb5.a
```

**Step 4** Run the following commands to run the sample:

```
source Client path / bigdata_env  
kinit Redis user  
go run krb.go
```

**Step 5** Check the command output, as shown in the following figure.

```
[root@100-85-150-7 go-Krb5]# go run krb.go  
authRes= authok  
info= # Server

## 1.18.4 Application Commissioning

### 1.18.4.1 Commissioning an Application in Windows

#### 1.18.4.1.1 Compiling and Running an Application

##### Scenario

After the code development is complete, you can run the application in the Windows development environment.

If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

 NOTE

- If IBM JDK is used in the Windows development environment, the application cannot be run in the Windows environment.
- You need to set the mapping between the host names and IP addresses of the access nodes in the hosts file on the local host where the sample code is run. The host names and IP addresses must be mapped one by one.

## Procedure

**Step 1** Click **Reload All Maven Projects** in the Maven window on the right of the IDEA to reload the Maven project dependency.

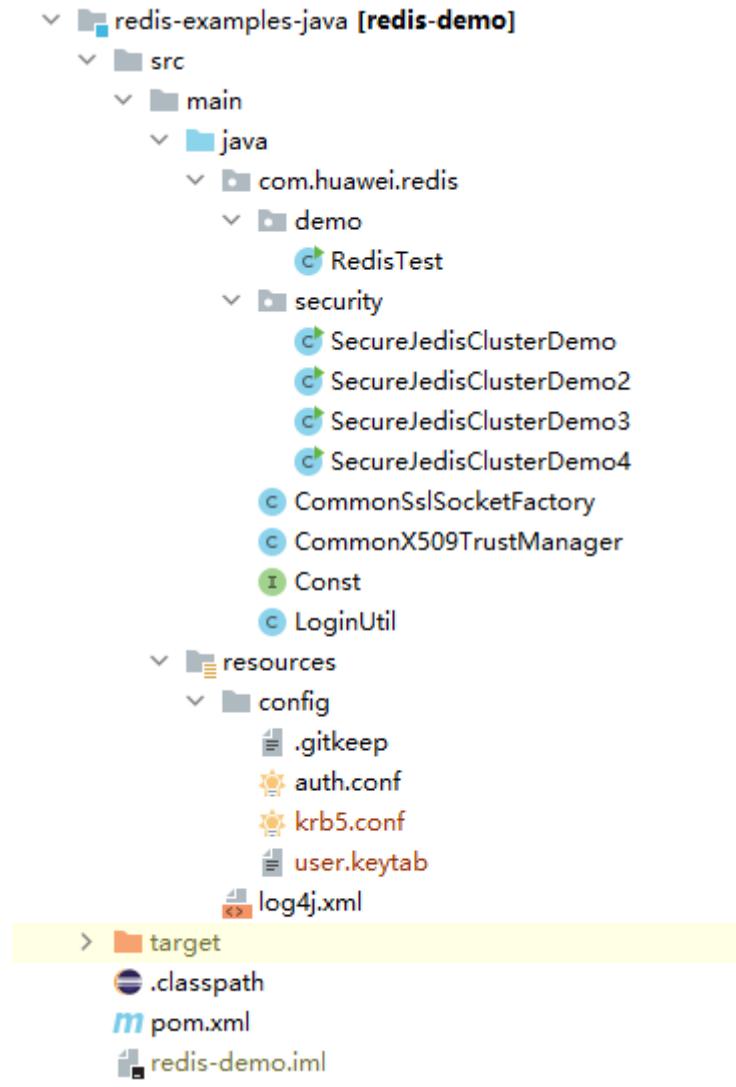

**Figure 1-223** reload projects

**Step 2** Compile and run an application.

Place the configuration file directory and modify the code to match the login user.  
See [Figure 1-224](#).

Figure 1-224 Directory list of **redis-demo** to be compiled

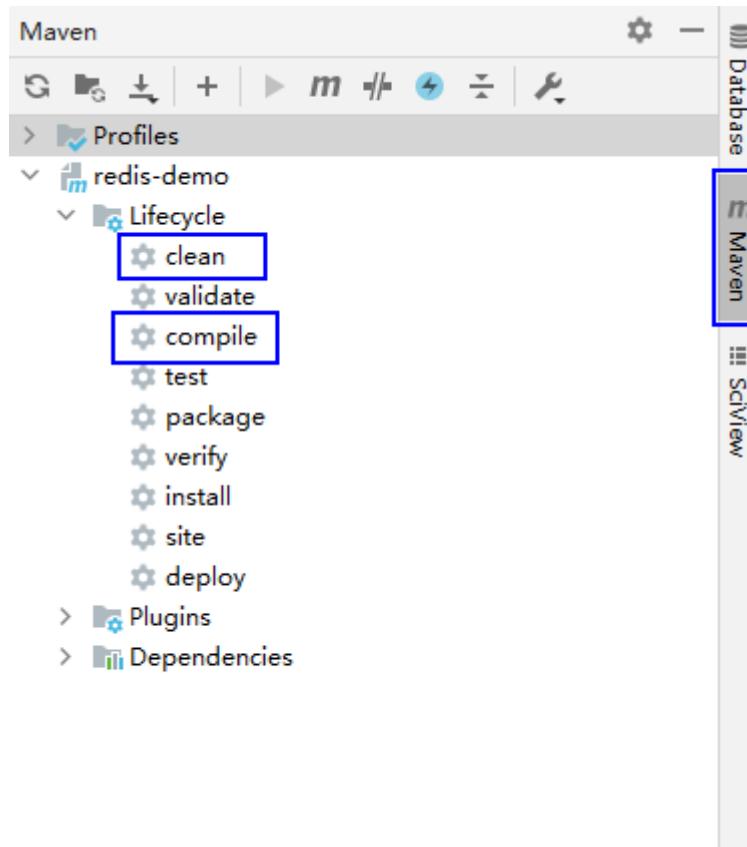

1. Compile an application.

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean** and double-click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **compile**, double click **compile** to run the **compile** command of Maven.

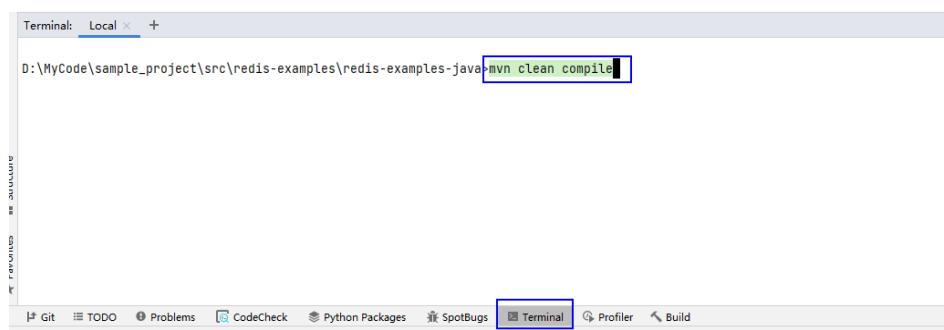

Figure 1-225 clean and compile tools of Maven

- Method 2:

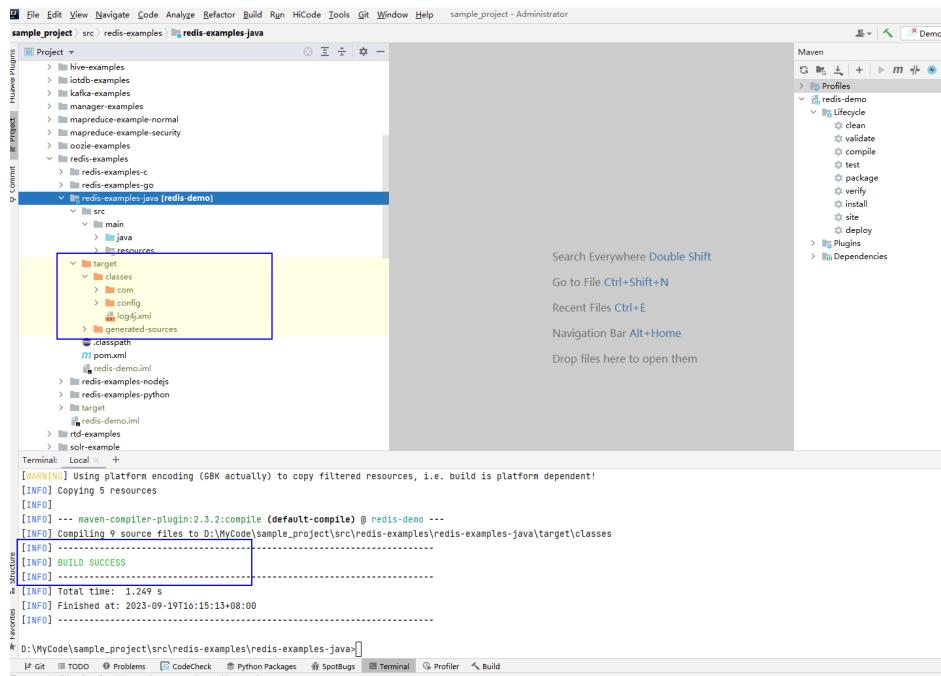

Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean compile** command to compile the **pom.xml** file.

Figure 1-226 Enter mvn clean compile in the IDEA Terminal text box

After the compilation is complete, the message "Build Success" is displayed and the **target** directory is generated.

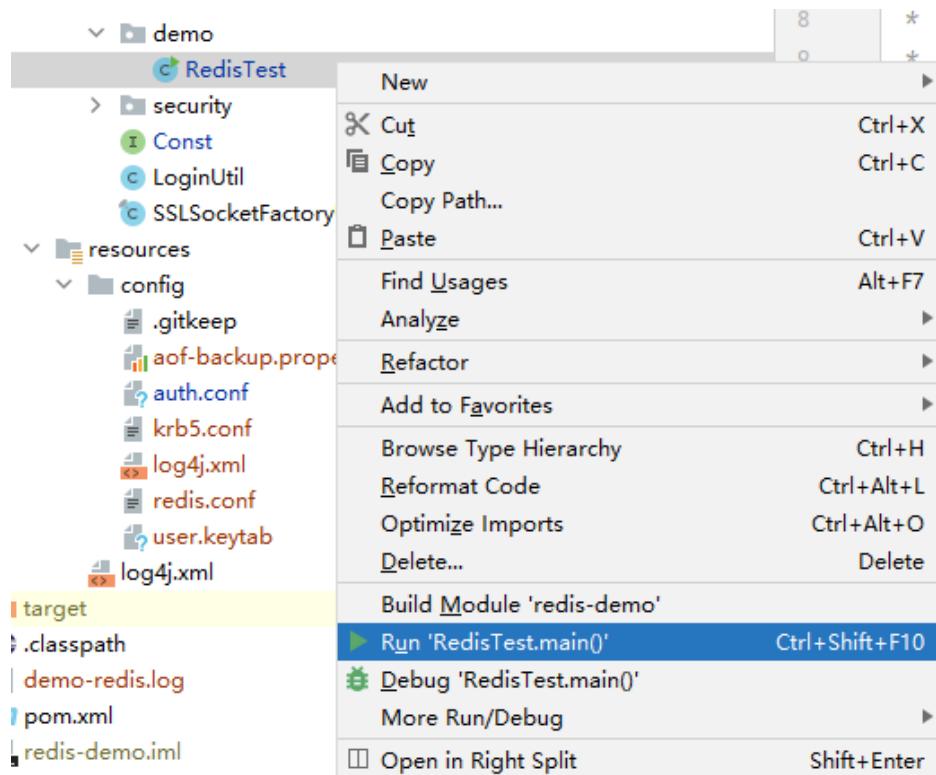

Figure 1-227 Compilation completed

## 2. Run the program.

Right-click **RedisTest.java**, and choose **Run 'RedisTest.main()'** from the shortcut menu to run the application project.

Figure 1-228 Run the application

----End

### 1.18.4.1.2 Viewing Commissioning Results

#### Scenario

After a Redis application is run, you can check the running result through one of the following methods:

- Viewing the IntelliJ IDEA running result.
- Logging in to the Redis Shell client to view the command output.

#### Procedure

- Viewing the IntelliJ IDEA running result

conversion can be done by dump and restore
```

- Logging in to the Redis Shell client to view the command output:

After the sample code is executed, keys are deleted. Therefore, you cannot directly use the shell command to view the application running result after the sample project is executed. The following uses sample code of **String Type Access** to explain how to use the shell command to view the application running result:

- Comment out **client.del(key);** in the last line of the **TestString()** method.

```
...
//client.del(key);
```

- Perform operations as instructed in **Compiling and Running an Application.**

- Install the Redis client and use the Redis user for authentication.

```
cd /opt/hadoopclient
```

```
source bigdata_env  
kinit redisuser
```

- d. Run the following command on the client node (<hostip> indicates any node in the Redis cluster):

```
cd /opt/client/Redis/bin  
redis-cli -c -p 22400 -h <hostip> get message
```

The value **A0BC9869FBC92933255A37A1D21167B2** set in the Java API is displayed:

```
"A0BC9869FBC92933255A37A1D21167B2"
```

#### NOTE

If channel encryption is enabled for Redis, run **redis-cli -c -p 22400 --tls -h <hostip> get message**.

To enable channel encryption for Redis, log in to Manager, choose **Cluster > Services > Redis > Configurations > All Configurations**, search for **REDIS\_SSL\_ON**, and change the parameter value to **true** to enable SSL channel encryption.

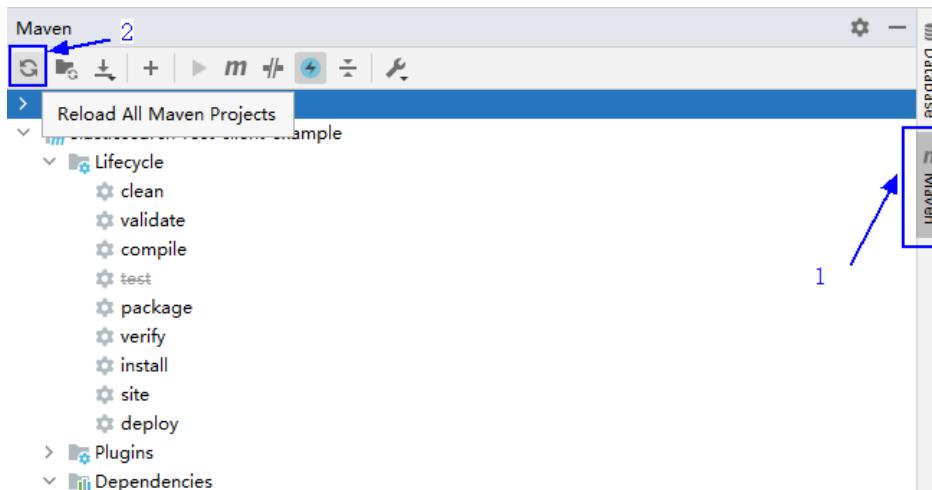

### 1.18.4.1.3 Commissioning a Spring Boot Program

You can run applications in the Windows environment after application code development is complete. If the local and cluster service planes can communicate with each other, you can perform the commissioning on the local host.

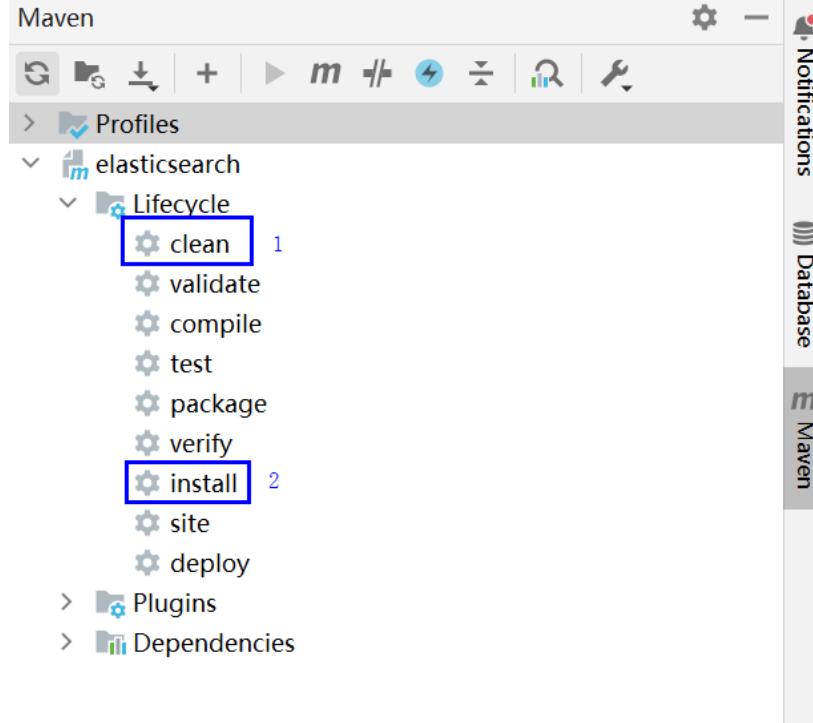

#### Step 1 Compile the Spring Boot sample to obtain **spring-boot-redis-1.0-SNAPSHOT.jar**.

1. Click **Reload All Maven Projects** in the Maven window on the right of IDEA to import Maven project dependency.

Figure 1-229 Importing dependencies

2. Double-click **clean** and **install** in sequence to run the **maven clean** and **maven install** commands. If "Build Success" is displayed, the compilation is successful.

## **Step 2** Read the configuration file.

1. Right-click **resource** in the sample code project and choose **Mark Directory as > Test Resource Root** from the shortcut menu.
  2. Decompress the user authentication file to obtain **krb5.conf** and **user.keytab**, and upload them to a local directory, for example, **D:\test**.
  3. Modify parameters in the **application.properties** file based on the site requirements.

### **Step 3** Run the applications.

Right-click **SpringDataRedisApplication** and choose **Run 'SpringDataRedisApplication...' from the shortcut menu** to start the Spring Boot service. If the Springboot service is started, the following information is displayed.

## Figure 1-230 Startup result

**Step 4** Open a browser, enter `http://localhost:9093/save` and save the data to Redis, as shown in the following figure.

Done

**Step 5** Open a browser, enter `http://localhost:9093/find?id=1` and save the data to Redis, as shown in the following figure.

a

----End

## 1.18.4.2 Commissioning an Application in Linux

### 1.18.4.2.1 Compiling and Running an Application

#### Scenario

In a Linux environment, you can upload the JAR package to the Linux and then run an application after the code development is complete.

#### Prerequisites

JDK has been installed.

#### Procedure

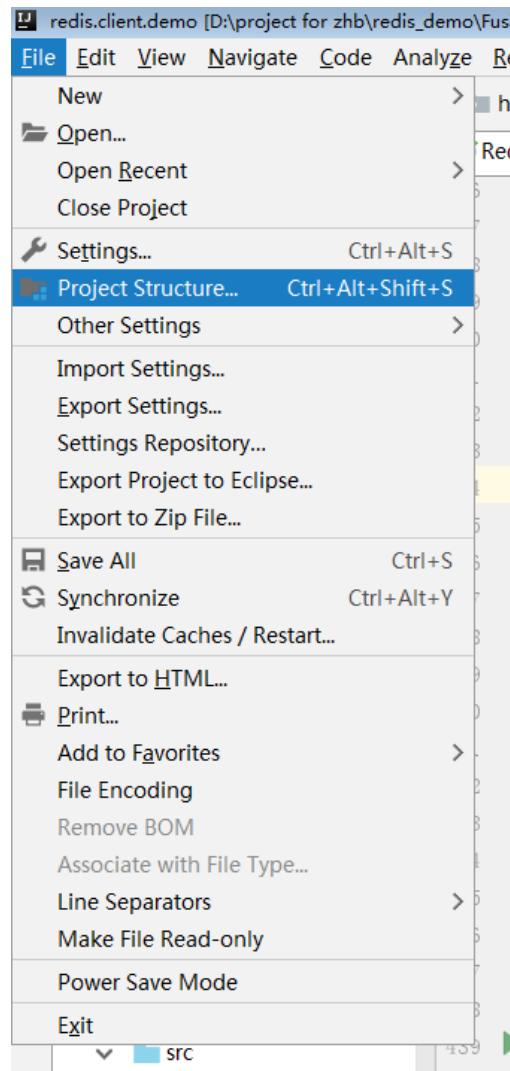

**Step 1** Export a JAR package.

1. On the IntelliJ IDEA redis-examples menu bar, choose **File > Project Structure....**

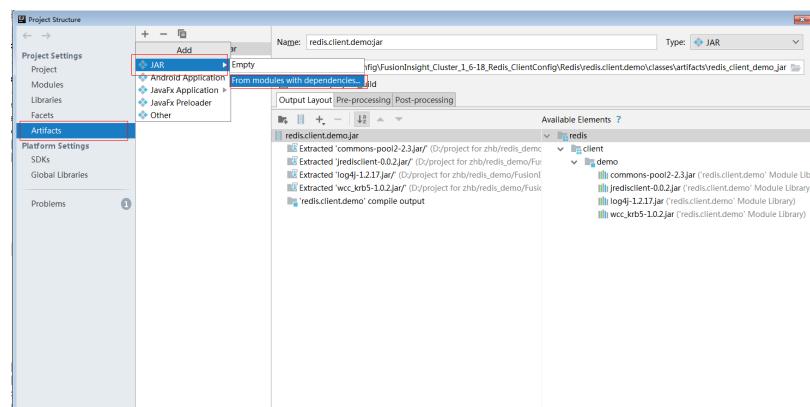

The preceding project name is for reference only. Use the actual project name in an actual scenario.

**Figure 1-231 "File > Project Structure..." shortcut menu**

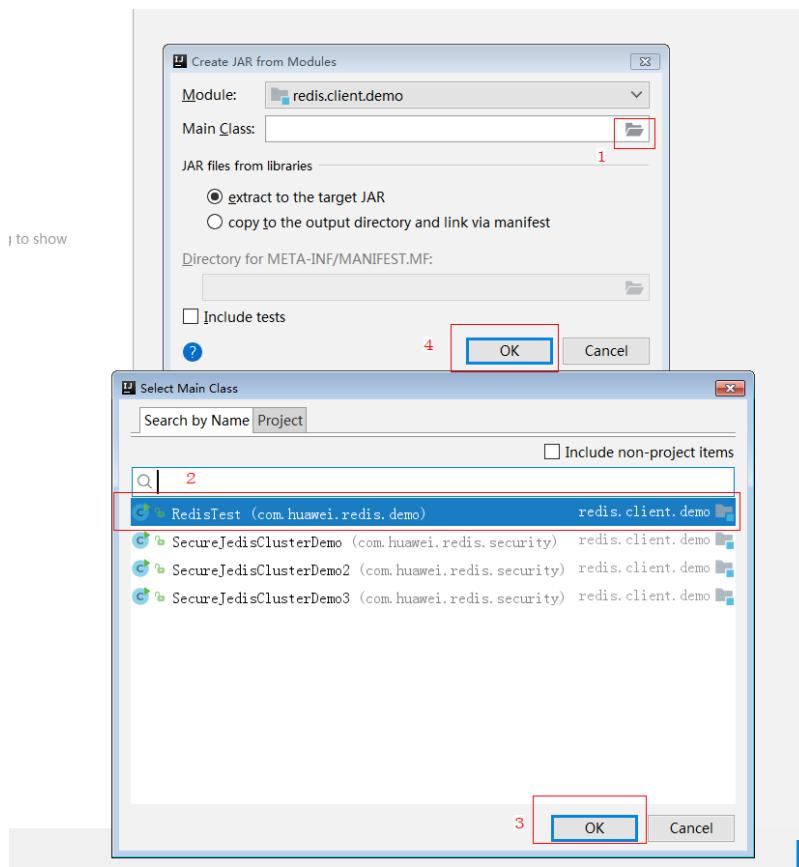

2. In the displayed **Project Structure** panel, select **Artifacts**. Then Click plus sign (+) and choose **JAR > From modules with dependencies**.

**Figure 1-232 Artifacts panel**

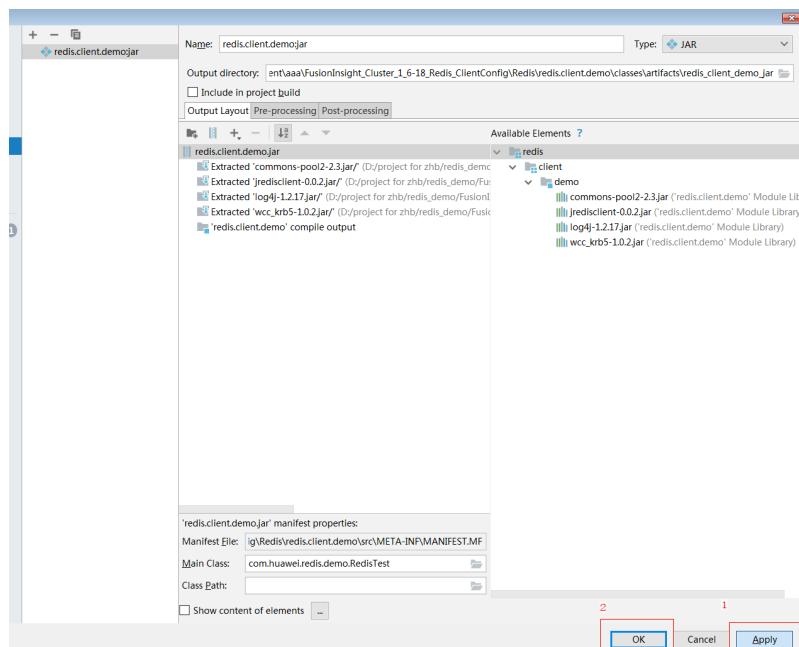

3. In the displayed **Create JAR from Modules** dialog box, click the folder icon, select **RedisTest** for **Main Class**, and click **OK**.

Figure 1-233 Specifying Main Class

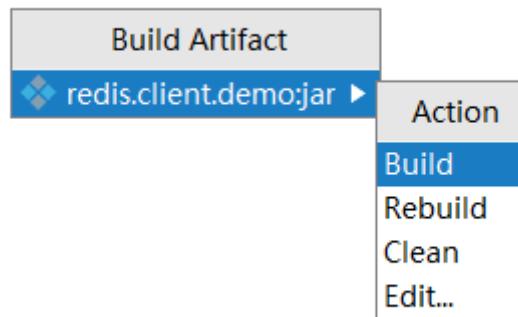

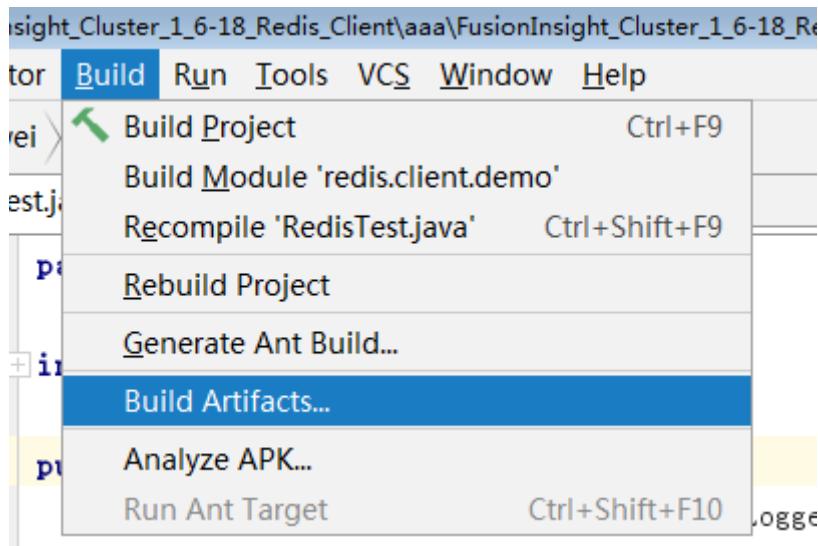

- Click the folder icon of **Output directory**, select the JAR package export path, and choose **Apply > OK**.

Figure 1-234 Selecting a JAR package export path

- Choose **Build > Build Artifacts**. In the displayed interface, choose **redis.client.demojar > Build** to export the JAR package.

Figure 1-235 export the JAR package

## Step 2 Prepare for the required JAR packages and configuration files.

In the Linux environment, create a directory, for example, `/opt/testone` and create subdirectories **config** and **lib**. Upload the JAR packages exported in **Step 1** to the **lib** directory in Linux. Upload the conf configuration files in the `/src/main/resources/config` of the sample project to the **config** directory in Linux.

## Step 3 Go to `/opt/testone`, Ensure that jdk has been installed, and java environment variables are set. Then, run the following commands to run the JAR packages:

```
java -cp .:lib/* com.huawei.redis.demo.RedisTest  
----End
```

### 1.18.4.2.2 Viewing Commissioning Results

#### Scenario

After a Redis application is run, you can check the running result through one of the following methods:<0>

- Viewing the Linux running result

- Logging in to the Redis Shell client to view the command output

## Procedure

- Viewing the Linux running result

The following success information will be displayed:

```
2019-06-22 16:23:27,519 [main] INFO com.huawei.redis.demo.RedisTest (RedisTest.java:93) - User sid-user01, session id: A0BC9869FBC92933255A37A1D21167B2

kinit redisuser
```

- Run the following command on the client node (<hostip> indicates any node in the Redis cluster):

```
cd /opt/client/Redis/bin  
redis-cli -c -p 22400 -h <hostip> get message
```

The value **A0BC9869FBC92933255A37A1D21167B2** set in the Java API is displayed:

"A0BC9869FBC92933255A37A1D21167B2"

 NOTE

If channel encryption is enabled for Redis, run `redis-cli -c -p 22400 --tls -h <hostip> get message`.

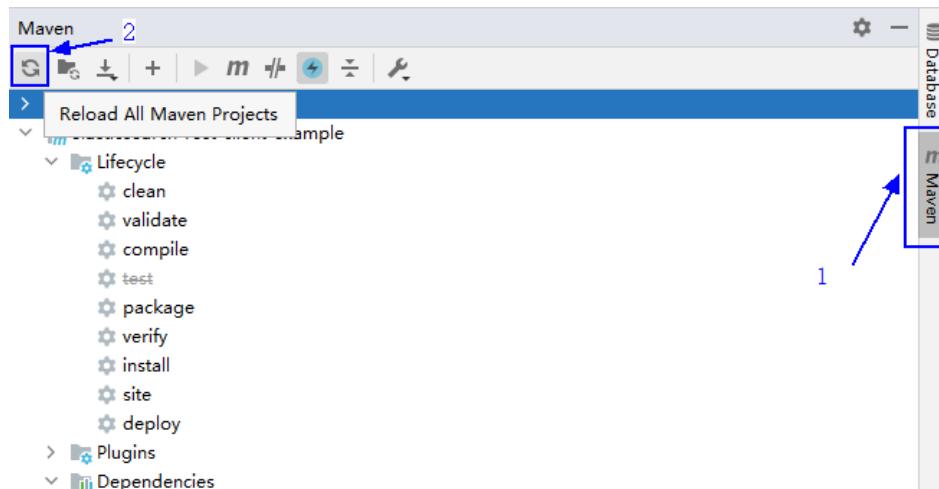

To enable channel encryption for Redis, log in to Manager, choose **Cluster > Services > Redis > Configurations > All Configurations**, search for **REDIS\_SSL\_ON**, and change the parameter value to **true** to enable SSL channel encryption.

#### 1.18.4.2.3 Commissioning the Spring Boot Program

**Step 1** Compile the Spring Boot sample to obtain **spring-boot-redis-1.0-SNAPSHOT.jar**.

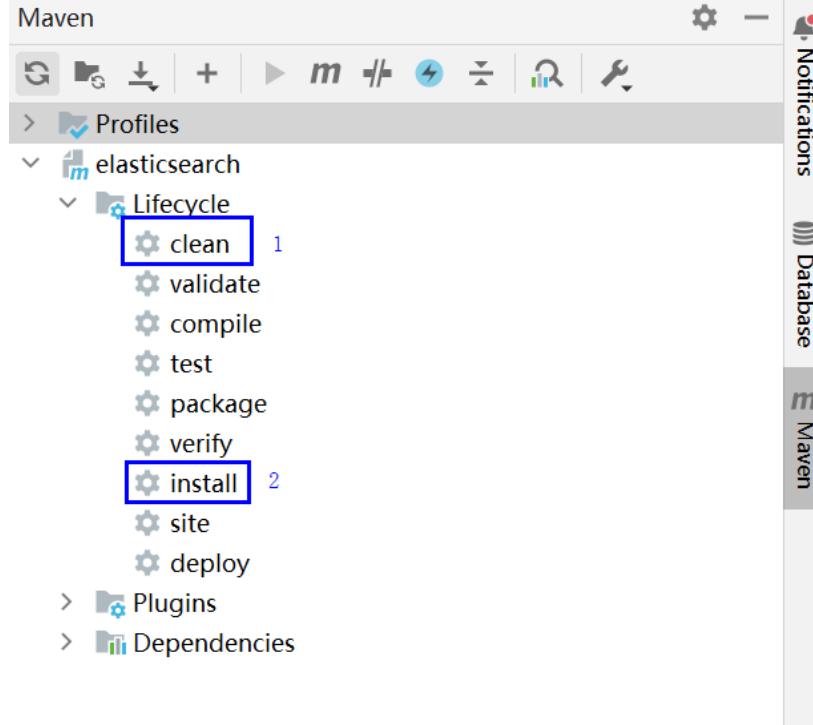

1. Click **Reload All Maven Projects** in the Maven window on the right of IDEA to import Maven project dependency.

**Figure 1-236** Importing dependencies

2. Double-click **clean** and **install** in sequence to run the **maven clean** and **maven install** commands. If "Build Success" is displayed, the compilation is successful.

A JAR file containing the **spring-boot-redis-** field is generated in the **target** directory of the sample project.

**Step 2** Create the `/opt/spring` directory on the Linux OS and upload the JAR packages whose names contain `spring-boot-redis-` in the target directory generated in **Step 1** to the directory.

**Step 3** Create the `/opt/spring/config` directory on Linux, modify the `application.properties` file based on the site requirements, and upload the file to the current directory.

**Step 4** Decompress the user authentication file to obtain **krb5.conf** and **user.keytab**, and upload them to the **/opt/spring/config** directory.

**Step 5** Run the following command in `/opt/spring/config` to start Spring Boot:

```
java -jar spring-boot-redis-1.0-SNAPSHOT.jar
```

The command output is as follows.

```
[root@宿主-192-168-64-138 ~]# spring -java -jar ./spring-boot-redis-1.0-SNAPSHOT.jar
```

Spring Boot (v2.4.2)

```

```

**Step 6** Open a browser, enter `http://IP address of the Linux server:9093/save` in the address box, and save the data to Redis, as shown in the following figure.

**Step 7** Open a browser, enter `http://IP address of the Linux server:9093/find?id=1`, and save the data to Redis, as shown in the following figure.

## 1.18.5 More Information

### 1.18.5.1 External Interfaces

#### 1.18.5.1.1 Shell

You can directly perform operations on Redis using Shell on the server. Versions of Shell interfaces of Redis need to be consistent with those in the open-source community. For details, see <http://redis.io/commands>.

Methods of running the Shell command:

**Step 1** After the client is installed, go to the Redis client installation directory and run the `source bigdata_env` command. For a cluster in security mode, run the `kinit login user name`.

**Step 2** run the following command:

`redis-cli -h IP -p port`

#### NOTE

If channel encryption is enabled for Redis, run `redis-cli -c -h IP -p port --tls`

To enable channel encryption for Redis, log in to Manager, choose **Cluster > Services > Redis > Configurations > All Configurations**, search for **REDIS\_SSL\_ON**, and change the parameter value to **true** to enable SSL channel encryption.

**Step 3** Go to the running mode of the Redis command (also called CLI client connection).  
192.168.0.11:22400>

**Step 4** Run the `help` command to obtain the help information of the Redis command parameters.

----End

### 1.18.5.1.2 Java API

Redis APIs are consistent with community Jedis APIs. For details, see <https://github.com/xetorthio/jedis>.

### 1.18.5.2 Performance Optimization

#### 1.18.5.2.1 Optimized Redis Write/Read Performance in Security Mode

##### Disabling channel encryption

Check whether channel encryption is enabled in the Redis. If services have high requirements and no sensitive information is stored in the Redis, disable channel encryption.

- Step 1** Log in to FusionInsight Manager.
  - Step 2** choose **Cluster > Services > Redis**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On this sub-tab page, search for **REDIS\_SSL\_ON**. If its value is **true**, SSL channel encryption has been enabled for Redis. To disable channel encryption, change the value of **REDIS\_SSL\_ON** to **false**.
  - Step 3** Click the **Dashboard** tab, choose **More > Restart Service** to restart the Redis service.
- End

##### The number of client connections is optimized.

When a service application accesses the Redis cluster in security mode, security authentication is required for each connection to the Redis server. If connections are frequently set up in service applications, read/write performance is affected, leading to long delay. In this case, you are advised to use the permanent connection pool to connect service applications to the server. The following is an example:

```
JedisPoolConfig poolConfig = new JedisPoolConfig();
//Maximum number of connections in the connection pool, which is 8 by default.
poolConfig.setMaxTotal(50);

//Maximum number of idle connections in the connection pool, which is 8 by default.
poolConfig.setMaxIdle(50);
poolConfig.setMinIdle(0);

//Minimum idle time of the connection. When the time is reached, the idle connection is removed. The
recommended value is -1, indicating that the connection is not removed.
poolConfig.setMinEvictableIdleTimeMillis(-1);
poolConfig.setSoftMinEvictableIdleTimeMillis(-1);

JedisCluster client = new JedisCluster(hosts, 15000, poolConfig);
```

The client does not invoke the `close()` method after each read/write operation. The `close()` method is invoked when the service application exits.

### Adding the Client Environment to a Domain

In security mode, when accessing the Redis, ensure that the node where the client resides and the Redis service are in the same domain. For details about how to

install the client, see section [Development and Operating Environment](#) to ensure that the client and server are in the same domain.

## 1.19 RTD Development Guide

### 1.19.1 Overview

#### 1.19.1.1 Application Development Overview

FusionInsight RTD is an enterprise-level distributed real-time decision-making platform that suits for mass data processing in high-concurrency and low latency scenarios. It supports user-defined rules and horizontal expansion. It bridges the "last mile" towards business decision-making, providing enterprises with precise risk control and marketing.

#### 1.19.1.2 Common Concepts

FusionInsight RTD is a component of MRS. It provides the following functions:

- RTDService
  - As the core component of RTD, RTDService functions as the unified web definition entry of RTD and allows users to define tenants, event sources, dimensions, variables, models, and rules. RTDService is deployed in active/standby mode to ensure availability.
- Containers
  - The Containers service provides physical environments for the running of Business Logic Unit (BLU) instances and controls the start and stop of the BLUs.
  - The Containers service provides Access Load Balance (ALB) to connect to load balancers. ALB implements socket access. Specifically, it distributes requests of different projects to service instances on the platform based on different processing policies and implements conversion between protocol interfaces. ALB is not provided as an independent service but integrated in Containers.
- MOTService
  - MOTService provides fast and large-throughput access capabilities and uses stored procedures to quickly process service logic at the database layer. It is deployed in active/standby mode.

#### 1.19.1.3 Development Process

This section describes how to use Java APIs to develop RTD applications.

[Figure 1-237](#) and [Table 1-168](#) describe the phases in the development process.

Figure 1-237 RTD development process

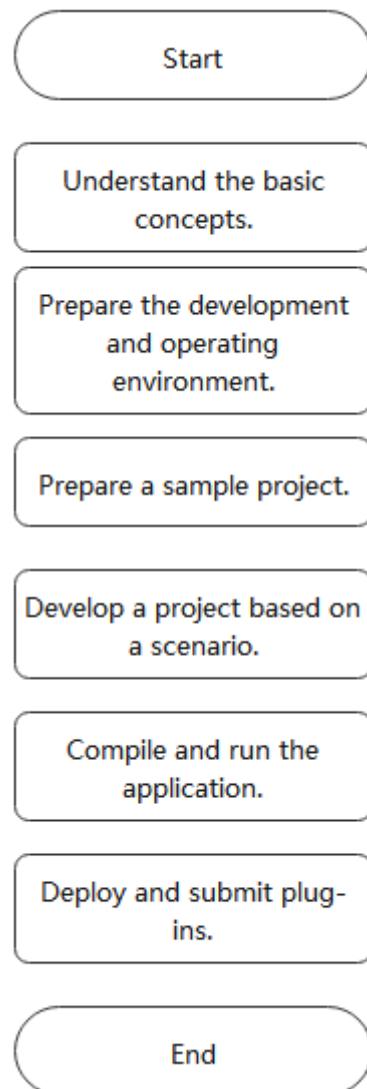

Table 1-168 Description of RTD development process

Step	Description	Reference
Understand the basic concepts.	Before developing an application, learn basic concepts of RTD and understand the scenario requirements and design tables.	<a href="#">Common Concepts</a>
Prepare the development and operating environment.	The Java language is recommended for RTD application development. You can use the IntelliJ IDEA tool.	<a href="#">Preparing the Development and Operating Environment</a>

Step	Description	Reference
Prepare a sample project.	RTD provides sample projects in various scenarios. Sample projects can be imported for studying.	<a href="#">Configuring and Importing Sample Projects</a>
Develop a project based on a scenario.	Decision engine and decision-making flow customization are supported, and dynamic variables can be extended.	<a href="#">Developing an Application</a>
Compile and run the application.	Users compile the developed application and deliver it for running based on the reference.	<a href="#">Compiling and Packaging</a>

## 1.19.2 Environment Preparation

### 1.19.2.1 Preparing the Development and Operating Environment

[Table 1-169](#) describes the environment required for application development.

**Table 1-169** Items needed for environment preparation

Item	Description
OS	Windows 7 or later is supported. Network environment: The local development environment must interconnect with the cluster service-plane network.
JDK installation	Basic configuration of the development and running environment. The version requirements are as follows: The JDK version must be the same as the version of FusionInsight Manager to be accessed. For details about the JDK version, see the corresponding version document or contact the system administrator.
IntelliJ IDEA installation and configuration	Basic configuration of the development environment. The version must be 2019.1 or other compatible versions.

## 1.19.2.2 Configuring and Importing Sample Projects

### Procedure

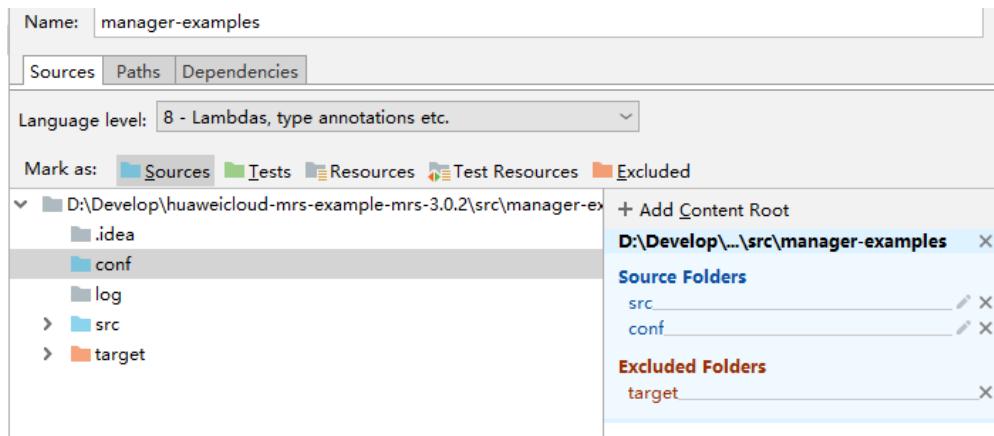

- Step 1** Obtain the sample project folder **rtd-examples** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.
1. Open IntelliJ IDEA and choose **File > New > Project from Existing Sources**. In the displayed **Select File or Directory to Import** window, select the sample code folder.
  2. Select the **pom.xml** file in the sample project folder, select **Import project from external model > Maven** as prompted, and click **Next** until **Finish** is displayed.

#### NOTE

The sample code is a Maven project. You can adjust the project configuration as required. The operations vary according to the IntelliJ IDEA version.

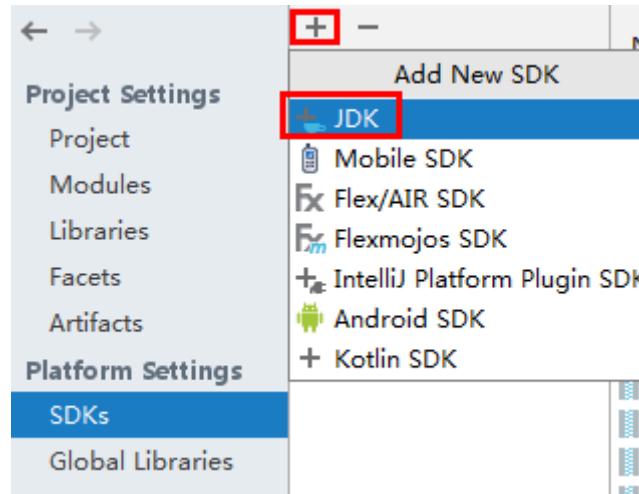

3. Add the **src** and **conf** directories in the project to the source file path. After the project is imported, choose **File > Project Structure** on the menu bar of IntelliJ IDEA. In the displayed window, choose **Project Settings > Modules**.

Select the current project, click the **src** folder, click **Sources** on the right of **Mark as**, click the **conf** folder, and click **Sources** on the right of **Mark as**. Click **Apply** and then **OK**.

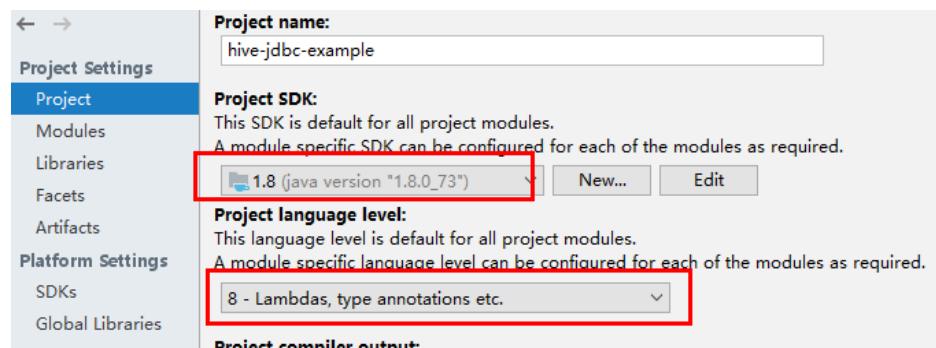

- Step 3** Set the JDK of the project.

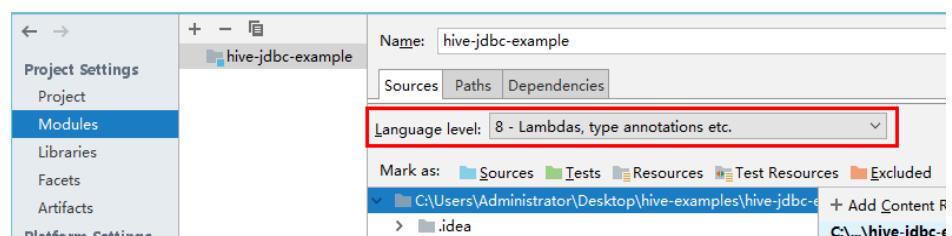

1. On the menu bar of IntelliJ IDEA, choose **File > Project Structure....** The **Project Structure** window is displayed.
2. Choose **SDKs**, click the plus sign (+), and select **JDK**.

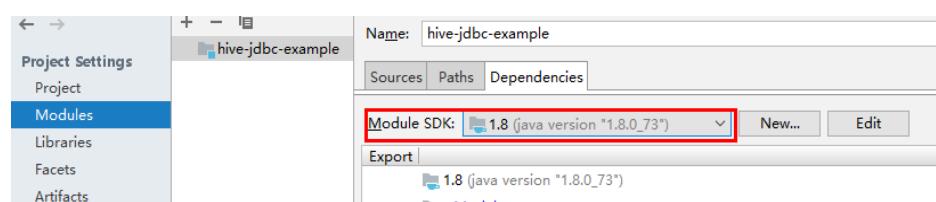

3. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.
4. Click **Apply**.
5. Select **Project**, select the JDK added in **SDKs** from the **Project SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Project language level** drop-down list box.

6. Click **Apply**.
7. Choose **Modules**. On the **Sources** tab page, change the value of **Language level** to **8 - Lambdas, type annotations etc.**

On the **Dependencies** tab page, change the value of **Module SDK** to the JDK added in **SDKs**.

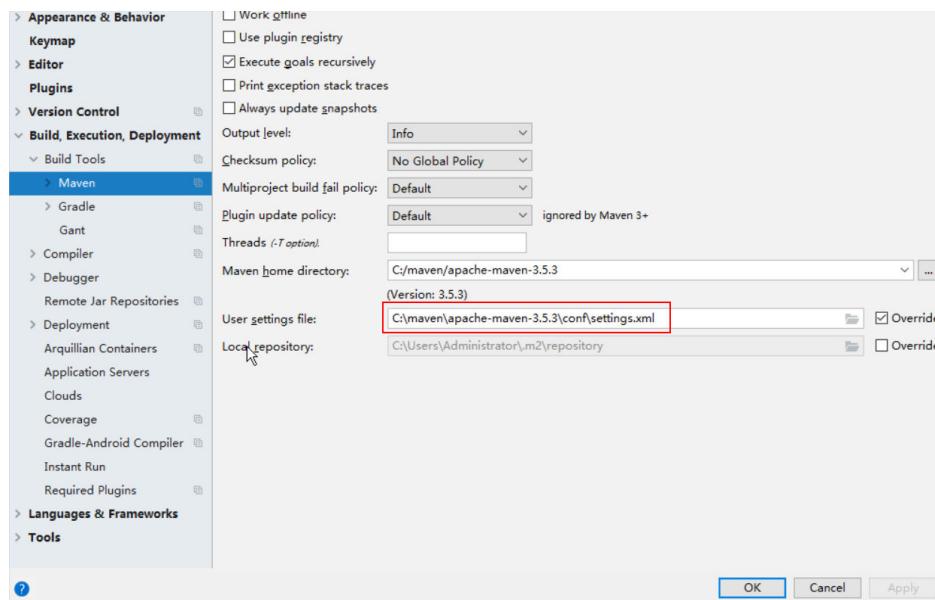

8. Click **Apply** and then **OK**.

**Step 4** Configure Maven.

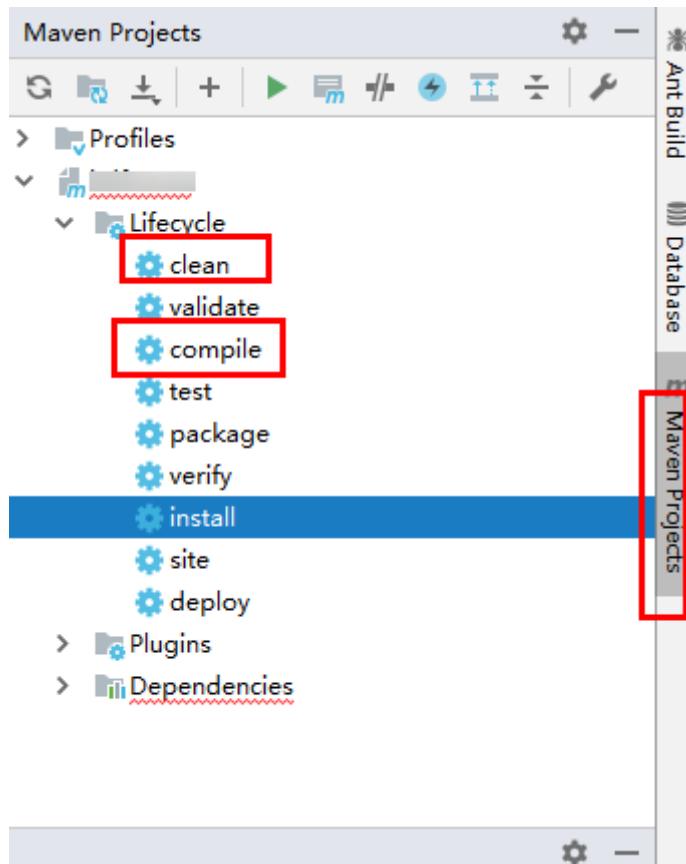

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, choose **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is *<Local Maven installation directory>\conf\settings.xml*.

**Figure 1-238** Directory for storing the **settings.xml** file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply** and then **OK**.
5. On the right of the IntelliJ IDEA home page, click **Maven Projects**. On the displayed page, choose **Project name > Lifecycle** and run the **clean** and **compile** scripts.

Figure 1-239 Maven Projects page

----End

## 1.19.3 Developing an Application

### 1.19.3.1 Event Source Custom Plug-in Program

#### 1.19.3.1.1 Scenario

Users can customize and orchestrate decision-making flows and extended variables based on actual service requirements to meet more complex service requirements.

#### Data Preparation

Use Maven to package the entire project. By default, the following two files are generated:

- rtdexecutor-plugins-bundle-\*-.zip
  - This file contains only the content related to the DecisionFlowPlugin module.
  - If the content related to the DecisionFlowPlugin module is modified, the associated BLU will be restarted (rolling restart) after the update is performed on the RTD web UI.

- **rtdexecutor-plugins-bundle-\*-update.zip**
  - This file contains the contents of all modules of the current project.
  - If the content related to the VarsExtensionPlugin module is modified and updated on the RTD web UI, the update is loaded in hot loading mode and the associated BLU is not restarted.

 NOTE

You can modify the **assembly** configuration file as required.

## File Modification

Modify the **pom.xml** and **plugin.properties** files for each submodule in the project.

- **pom.xml**

```
<properties>
<plugin.id>DecisionFlowPlugin</plugin.id>
<plugin.class>com.huawei.fi.plugins.ExampleDecisionFlowPlugin</plugin.class>
<plugin.version>0.1.0</plugin.version>
<plugin.provider>cmb</plugin.provider>
</properties>
```

- **plugin.properties**

```
plugin.id=DecisionFlowPlugin
plugin.class=com.huawei.fi.plugins.decisionflow.ExampleDecisionFlowPlugin
plugin.version=0.1.0
plugin.provider=cmb
```

 NOTE

Modify all parameters except **plugin.id** based on the site requirements.

### 1.19.3.1.2 Development Guidelines

#### Project Description

- Project name: **rtdexecutor-plugins**
- The following sub-modules are included:
  - DecisionFlowPlugin: used for custom orchestration of decision-making flows and can contain the **RTDEventHandler** class implemented by users.
  - VarsExtensionPlugin: used for packet extension and variable extension. You can implement the subclasses of **EventFieldsExtension** and **DynamicVarsExtension** to customize packets and variables.
- The names of sub-modules in a project are fixed and cannot be customized.
- The project must contain the **DecisionFlowPlugin** submodule. The **VarsExtensionPlugin** submodule is optional.

### 1.19.3.1.3 Sample Code

#### DecisionFlowPlugin

The following code snippets are stored in **com/huawei/fi/plugins/decisionflow**.

- **ExampleDecisionFlowPlugin.java**

The custom plug-in needs to inherit the plug-in class of **pf4j** and overwrite the default construction method, as well as **start** and **stop** methods. When

the BLU associated with the RTD event source is started or stopped, the **start** or **stop** method is invoked.

```
public class ExampleDecisionFlowPlugin extends Plugin
{
    private static final Logger LOG = Logger.getLogger(ExampleDecisionFlowPlugin.class);

    public ExampleDecisionFlowPlugin(PluginWrapper wrapper)
    {
        super(wrapper);
    }

    @Override
    public void start()
    {
        LOG.info("ExampleDecisionFlowPlugin.start()");
    }

    @Override
    public void stop()
    {
        LOG.info("ExampleDecisionFlowPlugin.stop()");
    }
}
```

- **ExampleScoreEventHandler.java**

Implement the **RTDEventHandler** subclass based on the site requirements.  
This is optional.

```
public class ExampleScoreEventHandler extends RTDEventHandler
{
}
```

- **ExampleDecisionFlowExtension.java**

- Inherit **DecisionFlowExtension** and add **pf4j** annotations to the subclass so that the subclass can be loaded by **pf4j**.

```
@Extension
public class ExampleDecisionFlowExtension extends DecisionFlowExtension
{
}
```

- Overwrite the **getPipelineDecisionServiceMode** method of **DecisionFlowExtension** to set the decision-making type (real-time or quasi-real-time mode) based on the service scenario.

```
/**
 * Obtain the decision-making type and customize it based on the business scenario
 * requirements.
 * Real-time mode: Constants.DECISION_SERVICE_MODE_RT
 * Quasi-real-time mode: Constants.DECISION_SERVICE_MODE_NRT
 * @return int decision mode
 */
@Override
public int getPipelineDecisionServiceMode()
{
    return Constants.DECISION_SERVICE_MODE_RT;
}
```

- Override the **orchestrateDecisionFlow** method of **DecisionFlowExtension** to orchestrate the **handler** process of a custom decision-making flow based on service requirements.

```
@Override
public void orchestrateDecisionFlow(RTDPipeline pipeline)
{
    String runtimeModel = RTDEnvironment.getProperty("plugin.RuntimeMode");
    LOG.info("RuntimeMode: " + runtimeModel + ".");
    // for testing the development mode
    if (RuntimeMode.DEVELOPMENT.toString().equalsIgnoreCase(runtimeModel))
    {
```

```
        pipeline.setInboundEventHandler(new EventInboundEventHandler());
        pipeline.setOutboundEventHandler(new EventOutboundEventHandler());

        pipeline.addEventHandler(new DataPreEventHandler());
    }
else
{
    pipeline.setInboundEventHandler(new EventInboundEventHandler());
    pipeline.setOutboundEventHandler(new EventOutboundEventHandler());
    // Instructions:
    // 1. If the custom DataPreEventHandler is used to extend event variables,
    // pay attention to the package path of the DataPreEventHandler class.
    // Note: This mode does not support online dynamic update.
    // 2. If VarsExtensionPlugin is used to extend event variables,
    // DataPreEventHandler must be placed at the beginning of the entire pipeline,
    // DataPreEventHandler is a Huawei JAR built-in class.
    // The customer logic is in Extension of the VarsExtensionPlugin plug-in.
    // Note: This mode supports online dynamic update.
    pipeline.addEventHandler(new DataPreEventHandler());
    pipeline.addEventHandler(new InsertDataEventHandler());
    pipeline.addEventHandler(new CallFilterRulesEventHandler());
    pipeline.addEventHandler(new ComputeVarsEventHandler());
    // 1. If VarsExtensionPlugin is used to dynamically extend variables,
    // Add DynamicVarsEventHandler to the pipeline.
    // 2. If there is no dynamic extended variable, delete the handler from the pipeline.
    // 3. DynamicVarsEventHandler must be placed after ComputeVarsEventHandler.
    pipeline.addEventHandler(new DynamicVarsEventHandler());
    // Add the scoring model capability to the pipeline.
    pipeline.addEventHandler(new ScoreModelEventHandler());
    pipeline.addEventHandler(new CallProcRulesEventHandler());
    // The logic for adding custom decision-making is the same as the existing method.
    pipeline.addEventHandler(new ExampleScoreEventHandler());
}
}
```

- d. If you need to use the built-in packet extension and variable extension functions, import the class path of the handler when orchestrating the handler in the pipeline in 3.

```
import com.huawei.fi.rtdexecutor.RTDEnvironment;
import com.huawei.fi.rtdexecutor.common.Constants;
import com.huawei.fi.rtdexecutor.plugin.DecisionFlowExtension;
import com.huawei.fi.rtdexecutor.rtdeventhandlers. DataPreEventHandler;
import com.huawei.fi.rtdexecutor.rtdeventhandlers. DynamicVarsEventHandler;
import com.huawei.fi.rtdexecutor.rtdpipeline.RTDPipeline;
```

## VarsExtensionPlugin

The following code snippets are in the **com.huawei.fi.plugins.varsextension** package.

- **ExampleVarsExtensionPlugin.java**

The custom plug-in needs to inherit the plug-in class of **pf4j** and overwrite the default construction method, as well as **start** and **stop** methods. When the BLU associated with the RTD event source is started or stopped, the **start** or **stop** method is invoked.

In the current version, only one implementation of **EventFieldExtension** and **DynamicVarsExtension** is loaded for **ExampleVarsExtensionPlugin**. Even if the plug-in contains multiple implementations of **EventFieldExtension** and **DynamicVarsExtension**, only one implementation is loaded.

```
public class ExampleVarsExtensionPlugin extends Plugin
{
    private static final Logger LOG = Logger.getLogger(ExampleVarsExtensionPlugin.class);

    public ExampleVarsExtensionPlugin(PluginWrapper wrapper)
    {
```

```

        super(wrapper);
    }

    @Override
    public void start() { LOG.info("ExampleVarsExtensionPlugin.start()"); }

    @Override
    public void stop()
    {
        LOG.info("ExampleVarsExtensionPlugin.stop()");
    }
}

```

- **ExampleEventFieldsExtension.java**

- In this example, packet field extension is implemented, and the BLU does not need to be restarted when **VarsExtensionPlugin** is updated. Inherit the **EventFieldsExtension** class, add the **pf4j** extension point annotation **@Extension**, and rewrite the parent class method. In the **init/destroy** method, initialize or destroy basic resources related to packet extension. **init/destroy** is invoked when the BLU associated with the event source is restarted or the plug-in is updated.

```

@Extension
public class ExampleEventFieldsExtension extends EventFieldsExtension
{
    @Override
    public void init()
    {
        LOG.info("{} init start ...", this.getClass().getName());
        super.init();
        // add your init code at here
        this.timeoutMS = 20L;
        LOG.info("{} init end ...", this.getClass().getName());
    }

    @Override
    public void destroy()
    {
        LOG.info("{} destroy start ...", this.getClass().getName());
        super.destroy();
        // add your destroy code at here
        LOG.info("{} destroy end ...", this.getClass().getName());
    }
}

```

- Implement the **compute** method in **EventFieldsExtension**. The definition and calculation of extended packets are implemented in this method. In the following example code, the **BANK\_CUSTOMER\_ID**, **BANK\_CUSTOMER\_AGE** and **BANK\_CUSTOMER\_SALARY** fields are extended.

```

@Override
public void compute(PipelineContext ctx, EventData eventData) throws EventHandlerException
{
    ExtendEventField<String> bankCustomerID = new
    ExtendEventField.String("BANK_CUSTOMER_ID");
    ExtendEventField<Integer> bankCustomerAge = new
    ExtendEventField.Integer("BANK_CUSTOMER_AGE");
    ExtendEventField<Double> bankCustomerSalary = new
    ExtendEventField.Double("BANK_CUSTOMER_SALARY");

    bankCustomerAge.setValue(32);
    bankCustomerID.setValue("0000001");

    String city = (String) eventData.getData().get("LBS_CITY");
    if("Boston".equals(city)) {
        bankCustomerSalary.setValue(7830.25);
    } else if("New York".equals(city)) {

```

```

        bankCustomerSalary.setValue(9765.40);
    } else {
        bankCustomerSalary.setValue(6300.62);
    }

    putComputeResult(ctx, bankCustomerID.getName(), bankCustomerID);
    putComputeResult(ctx, bankCustomerAge.getName(), bankCustomerAge);
    putComputeResult(ctx, bankCustomerSalary.getName(), bankCustomerSalary);
}

```

- After the plug-in code is developed, use the packet field definition function of event source management on the RTDService web UI to map the plug-in code to event variables for subsequent calculation. In addition, the default value is defined for this function. If the packet extension calculation in the plug-in fails, the default value defined here will be used in subsequent calculation steps.

## DynamicVarsExtension

- In the ExampleDynamicVarsExtension.java example, variables are dynamically extended. When **VarsExtensionPlugin** is updated, the BLU does not need to be restarted. Inherit the **DynamicVarsExtension** class, add the **pf4j** extension point annotation **@Extension**, and rewrite the parent class method. In the **init/destroy** method, initialize or destroy basic resources related to dynamic extended variables. **init/destroy** is invoked when the BLU associated with the event source is restarted or the plug-in is updated.

```

@Extension
@SuppressWarnings({"rawtypes", "unchecked"})
public class ExampleDynamicVarsExtension extends DynamicVarsExtension
{
    /**
     * init your public resource at here,
     * plugins create or update, this method will be invoked
     *
     */
    @Override
    public void init()
    {
        LOG.info("{} init start ...", this.getClass().getName());
        super.init();
        // add your init code at here
        this.timeoutMS = 20L;
        LOG.info("{} init end ...", this.getClass().getName());
    }

    /**
     * recycle your resource at here,
     * plugins destroy or update, this method will be invoked
     *
     */
    @Override
    public void destroy()
    {
        LOG.info("{} destroy start ...", this.getClass().getName());
        super.destroy();
        // add your destroy code at here
        LOG.info("{} destroy end ...", this.getClass().getName());
    }
}

```

- When implementing the **DynamicVarsExtension** subclass, you can override the **verify** method to add some custom checks. This method is invoked when the plug-in is uploaded. If **false** is returned, the update fails.

```

public abstract class DynamicVarsExtension implements ExtensionPoint
{

```

```
public boolean verify()
{
    return true;
}
```

- To dynamically extend variables, implement the **addRequiredInputVars** method to define the event variables, real-time query variables, and batch variables that these variables depend on during calculation. When the update plug-in is uploaded, the system verifies the existence and online status of the variables defined in the method. If the verification fails, the system displays an update error. The definition of the dependent variable is very important. If the dependent variable is not defined or omitted, the calculation of the dynamic extended variable may be abnormal or incorrect, affecting the decision-making result of the request. In the following example, the plug-in depends on event variable **ev\_client\_ip**, real-time query variable **rv\_online\_pay**, and batch variable **bv\_history\_pay**.

```
@Override
public List<String> addRequiredInputVars()
{
    // define input vars which required in your code and built-in RTD platform,
    // include event vars, batch vars, runtime query vars
    List<String> inputVars = new ArrayList<>();
    inputVars.add("ev_client_ip");
    inputVars.add("rv_online_pay");
    inputVars.add("bv_history_pay");

    return inputVars;
}
```

- To dynamically extend variables, implement the **defineDynamicEventVars** method to define the dynamic extended variables contained in the **DynamicVarsExtension** implementation class. The dynamic extended variable must start with **ev\_d\_**, and the type and default value must be specified. In the following example, two dynamic extended variables are defined. The names are **ev\_d\_local\_city** and **ev\_d\_total\_pay**, the types are **String** and **Long**, and the default values are **Boston** and **11**. Currently, dynamic extended variables support five types: Integer, Long, String, Double, and Timestamp.

To dynamically extend variables, you need to implement the **compute** method and calculate the variables based on the variable values in the current pipeline request. The obtained variable values must be defined in **addRequiredInputVars** of the current implementation class.

```
@Override
public Map<String, DynamicEventVar<?>> defineDynamicEventVars()
{
    DynamicEventVar<String> localCity = new DynamicEventVar.String("ev_d_local_city", "Boston");
    DynamicEventVar<Long> totalPay = new DynamicEventVar.Long("ev_d_total_pay", 11L);

    Map<String, DynamicEventVar<?>> dynamicEventVarMap = new HashMap<>();
    dynamicEventVarMap.put(localCity.getName(), localCity);
    dynamicEventVarMap.put(totalPay.getName(), totalPay);

    return dynamicEventVarMap;
}
```

- During the calculation, when obtaining the dependent variable value from the pipeline, check whether the value is null and matches the type. Otherwise, null pointers and type conversion exceptions may occur.

```
@Override
public void compute(PipelineContext ctx, EventData eventData) throws EventHandlerException
{
    DynamicEventVar<?> definedTotalPay = getDefineDynamicEventVars().get("ev_d_total_pay");
    DynamicEventVar<Long> totalPay = computeTotalPay(ctx, eventData, definedTotalPay);
```

```
putComputeResult(ctx, totalPay.getName(), totalPay);

DynamicEventVar<?> definedLocalCity = getDefineDynamicEventVars().get("ev_d_local_city");
DynamicEventVar<String> localCity = computeLocalCity(ctx, eventData, definedLocalCity);
putComputeResult(ctx, localCity.getName(), localCity);
}
```

## End-to-End Timeout Control

Unified timeout control is supported for the pipeline. The timing starts when a request enters the BLU. If the threshold is exceeded, the request is returned quickly.

## Internal Dotting Timeout Control for Plug-ins

The timeout control is based on the timing dotting code. It determines whether the plug-in calculation exceeds the threshold from the time when the **compute** method is executed to the time when the dotting code is executed. The timeout threshold can be initialized in the **init** method or customized for a single timing point.

- In the following DynamicVarsExtensions sample code, `checkTimeoutMS(ctx, timeoutMS, true)` is the specific format of the timing dotting code. The first parameter indicates that the current dotting threshold is the value of the **timeoutMS** attribute. The second parameter indicates the exception handling mode after the timeout. If the value is **true**, the request is interrupted and the subsequent calculation is not performed. If the value is **false**, the subsequent variable calculation logic is skipped. The variables that are not calculated are calculated based on the default values, and the remaining steps are calculated normally.

```
private DynamicEventVar<Long> computeTotalPay(PipelineContext ctx, EventData eventData,
DynamicEventVar totalPayVar) throws EventHandlerException
{
    // get batch vars from eventData to compute dynamicEventVar
    Long historyPay = (Long) eventData.getBatchVars().get("bv_history_pay");
    historyPay = Objects.isNull(historyPay) ? 0L : historyPay;

    // get real time vars from eventData to compute dynamicEventVar
    Long onlinePay = (Long) eventData.getRtqVars().get("rv_online_pay");
    onlinePay = Objects.isNull(onlinePay) ? 0L : onlinePay;

    Long totalPay = historyPay + onlinePay;
    if(totalPay != 0L) {
        totalPayVar.setValue(totalPay);
    } else {
        totalPayVar.setException("required input vars maybe not exists or offline.");
    }

    checkTimeoutMS(ctx, timeoutMS, true);

    return totalPayVar;
}
```

- To ensure that original packet data can be properly imported to the database, **EventFieldExtension** provides only the `checkTimeoutMS(ctx, timeoutMS)` API. The subsequent variable calculation logic is skipped, and the variables that are not calculated are calculated based on the default values in the subsequent steps, and the remaining steps are calculated normally.

## Runtime Exception

If a runtime exception is thrown during variable calculation, the current request is quickly returned and all subsequent calculation steps are skipped.

## Checked Exception

If a checked exception is thrown during variable calculation, the remaining calculation of dynamic extended variables is skipped. However, the subsequent calculation steps defined in the pipeline continue to be processed.

- If an expected exception occurs during the calculation and you want to output the information to the result, you can invoke **DynamicEventVar**. The **setException()** method is used to set exception information. The exception information is displayed in the **EventVarsException** field in the calculation result.
- If the value of a defined dynamic extended variable fails to be set during request calculation, the default value will be used in subsequent calculation and will be displayed in the **EventVarsException** field in the calculation result.
- The following is an example of the **RTDExecutor\_result.log** file.

### 1.19.3.2 Decision Engine Custom Program

#### 1.19.3.2.1 Scenario

Users can customize decision engine configurations to control the output of scoring results of multiple rule engines, meeting more complex service requirements.

#### 1.19.3.2.2 Development Guidelines

- Check whether the current event source plug-in is an extended decision-making flow and whether the plug-in code contains a rating decision-making flow. For details, see [Event Source Custom Plug-in Program](#).
- Determine whether to make decisions on the stored procedure rules of the current event source.

### 1.19.3.2.3 Sample Code

#### RtdDroolsFileGeneratorTest

The following code snippets are in the **RtdDroolsFileGeneratorTest** class in the **com/huawei/fi/rtd/drools/generator** package in the **test** directory.

```
package com.huawei.fi.rtd.drools.generator;
import com.huawei.fi.rtd.drools.generator.common.AlgorithmType;
import com.huawei.fi.rtd.drools.generator.common.ZipFileUtil;
import org.apache.commons.lang3.StringUtils;
import org.junit.*;
import org.junit.rules.TemporaryFolder;
import org.kie.api.runtime.KieContainer;
import java.io.*;
import java.util.zip.ZipEntry;
import java.util.zip.ZipInputStream;
public class RtdDroolsFileGeneratorTest {

    private static final String RTD_DROOLS_K_MODULE_XML = "kmodule.xml";
    private static final String RTD_META_DATA_PROPERTIES = "rtd_meta_data.properties";
    private static final String RTD_DROOLS_DECISION_JSON = "drools_contract.json";
    private static final String RTD_DROOLS_FILE_PREFIX = "rtd_drools_decision_";
    private static final int BUFFER = 10 * 1024;
    private KieContainer kieContainer;
    private RtdDroolsDecision droolsDecision;
    @Rule
    public TemporaryFolder temporaryFolder = new TemporaryFolder();
    @Before
    public void setUp() {

        droolsDecision = new RtdDroolsDecision(AlgorithmType.AVERAGE.name());
        RtdDroolsElementsGroup weightGroupOne = new RtdDroolsElementsGroup("drools_group_01",
AlgorithmType.WEIGHTING.name());
        weightGroupOne.setSalience(99);
        weightGroupOne.addElement(new RtdDroolsElement("pr_rule_01", 0.5));
        weightGroupOne.addElement(new RtdDroolsElement("pr_rule_02", 0.3));
        RtdDroolsElementsGroup weightGroupTwo = new RtdDroolsElementsGroup("drools_group_02",
AlgorithmType.WEIGHTING.name());
        weightGroupTwo.setSalience(99);

    //     compareZipFileContentOneByOne(zipIn);  
    // } catch (Exception e) {  
    //     Assert.fail("Unzip file fail ....");  
    // } finally {  
    //     ZipFileUtil.closeIOResource(zipIn);  
    // }  
    //  
    // boolean deleteSuccess = result.delete();  
    // Assert.assertTrue(deleteSuccess);  
}  
  
@Test  
public void input_invalid_contract_json_and_out_put_zip_stream_then_compare_content_success() {  
  
    RtdDroolsFileGenerator generator = RtdDroolsFileGenerator.INSTANCE;  
    String jsonContract = JSONObject.toJSONString(droolsDecision);  
    ByteArrayOutputStream outputBaos = generator.outputZipStream(jsonContract);  
    ByteArrayInputStream bais = new ByteArrayInputStream(outputBaos.toByteArray());  
    ZipInputStream zipIn = null;  
    try {  
        zipIn = new ZipInputStream(new BufferedInputStream(bais));  
        compareZipFileContentOneByOne(zipIn);  
    } catch (Exception e) {  
        Assert.fail("Unzip file fail ....");  
    } finally {  
        ZipFileUtil.closeIOResource(zipIn);  
    }  
}  
  
private void compareZipFileContentOneByOne(ZipInputStream zipIn) throws IOException {  
    for (ZipEntry zipEntry; (zipEntry = zipIn.getNextEntry()) != null; ) {  
        ByteArrayOutputStream baos = new ByteArrayOutputStream();  
        byte data[] = new byte[BUFFER];  
        for (int count; (count = zipIn.read(data, 0, BUFFER)) != -1; ) {  
            baos.write(data, 0, count);  
        }  
    }  
}
```

```

        String fileContent = new String(baos.toByteArray());
        ZipFileUtil.closeIOResource(baos);
        if (zipEntry.getName().equals(RTD_DROOLS_K_MODULE_XML)) {
            Assert.assertTrue(fileContent.contains("rtdDecisionStateless"));
        } else if (zipEntry.getName().equals(RTD_META_DATA_PROPERTIES)) {
            Assert.assertTrue(fileContent.contains("drools_group_01"));
        } else if (zipEntry.getName().startsWith(RTD_DROOLS_FILE_PREFIX)) {
            Assert.assertTrue(fileContent.contains("package com.huawei.fi.rtd.drools.common"));
        } else if (zipEntry.getName().equals(RTD_DROOLS_DECISION_JSON)) {
            Assert.assertTrue(StringUtils.isNotBlank(fileContent));
        } else {
            Assert.fail("Invalid file name ....");
        }
    }
}

```

## Sample Description

- Obtain all rule names of the current event source and specify the algorithm to be decided in the `setup()` method. For example, obtain the minimum score of rules `pr_rule_01`, `pr_rule_02` and `pr_rule_03`.

```

RtdDroolsElementsGroup minimumGroup = new RtdDroolsElementsGroup("drools_group_05",
AlgorithmType.MINIMUM.name());
minimumGroup.setSalience(99);
minimumGroup.addElement(new RtdDroolsElement("pr_rule_01"));
minimumGroup.addElement(new RtdDroolsElement("pr_rule_02"));
minimumGroup.addElement(new RtdDroolsElement("pr_rule_03"));

```

- Run the `input_invalid_contract_json_and_out_put_zip_file_then_compare_content_success()` command to download the file to the local host after compiling the custom decision-making code. Specify the download directory and comment out the following code for deleting the compressed package when you download the file.

```

/**
 * Run the following commands to generate a decision engine file on the local host:
 */
@Test
public void input_invalid_contract_json_and_out_put_zip_file_then_compare_content_success() {

    RtdDroolsFileGenerator generator = RtdDroolsFileGenerator.INSTANCE;
    String jsonContract = JSONObject.toJSONString(droolsDecision);
    File result = null;
    try {
        // Specify the directory to be downloaded.
        File tempDirectory = new File("d:/");
        result = generator.outputZipFile(jsonContract, tempDirectory.getPath(), "rtd-drools-
example.zip");
    } catch (Exception e) {
        e.printStackTrace();
        Assert.fail("Create zip file fail ....");
    }

    // ZipInputStream zipIn = null;
    // try {
    //     zipIn = new ZipInputStream(new BufferedInputStream(new FileInputStream(result)));
    //     compareZipFileContentOneByOne(zipIn);
    // } catch (Exception e) {
    //     Assert.fail("Unzip file fail ....");
    // } finally {
    //     ZipFileUtil.closeIOResource(zipIn);
    // }
    // boolean deleteSuccess = result.delete();
}

```

```
//     Assert.assertTrue(deleteSuccess);
}
```

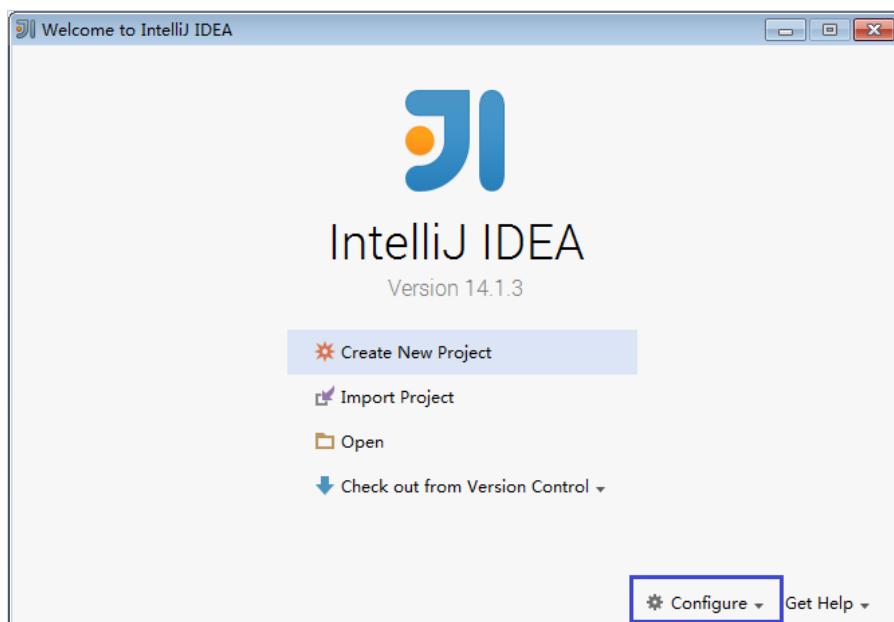

## 1.19.4 Commissioning the Application

### 1.19.4.1 Compiling and Packaging

**Step 1** Before importing the sample project, configure JDK for IntelliJ IDEA.

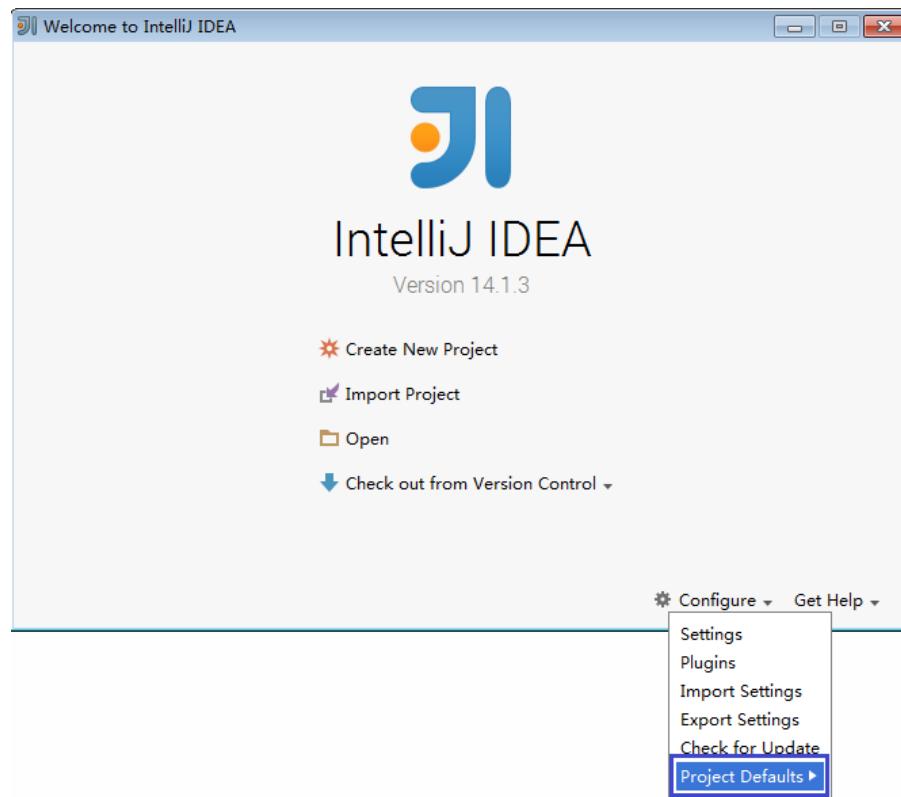

1. Start IntelliJ IDEA and click **Configure**.

**Figure 1-240** Choosing Configure

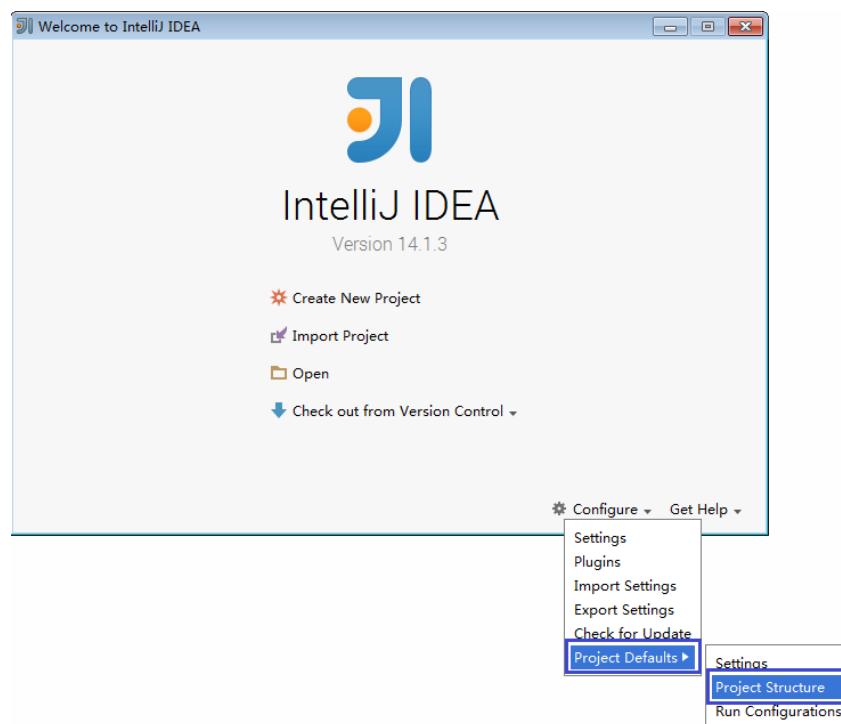

2. Choose **Project Defaults** from the **Configure** drop-down list.

Figure 1-241 Choosing Project Defaults

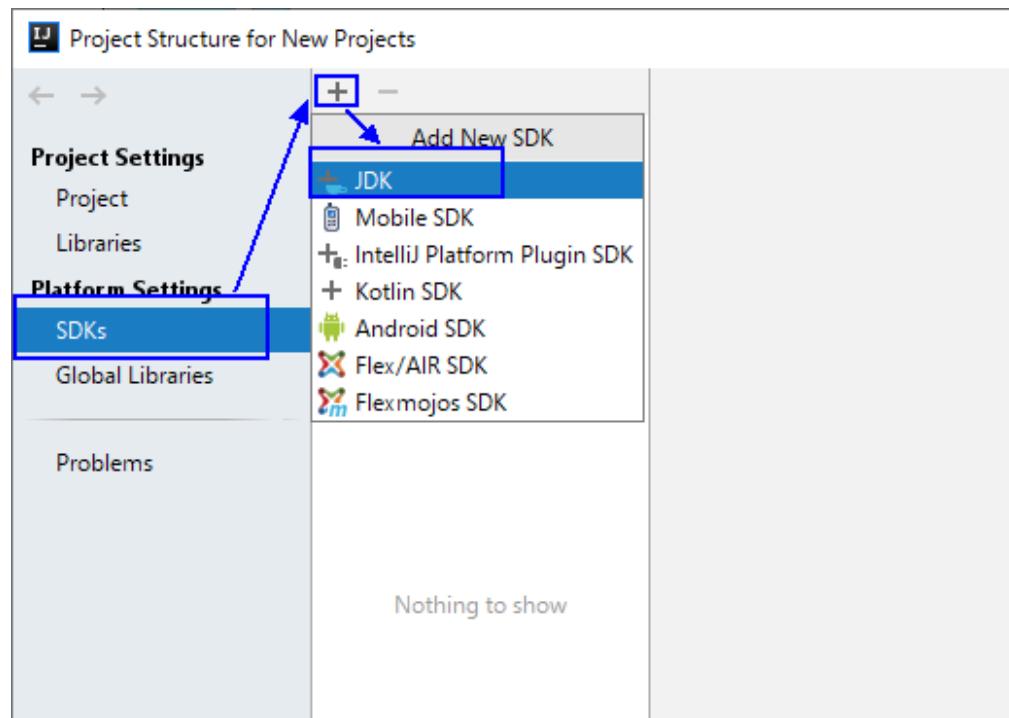

3. Select **Project Structure** from **Project Defaults**.

Figure 1-242 Project Defaults

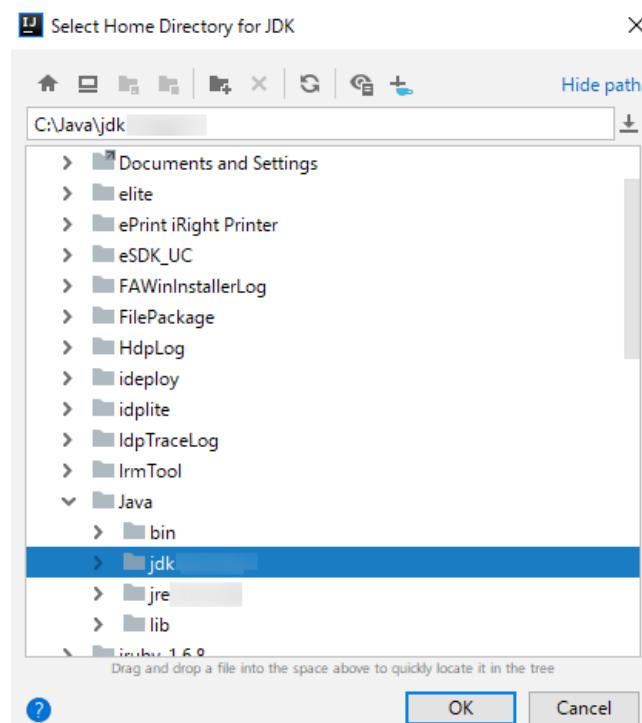

4. On the **Project Structure** page, select **SDKs** and click the plus sign to add the JDK.

Figure 1-243 Adding the JDK

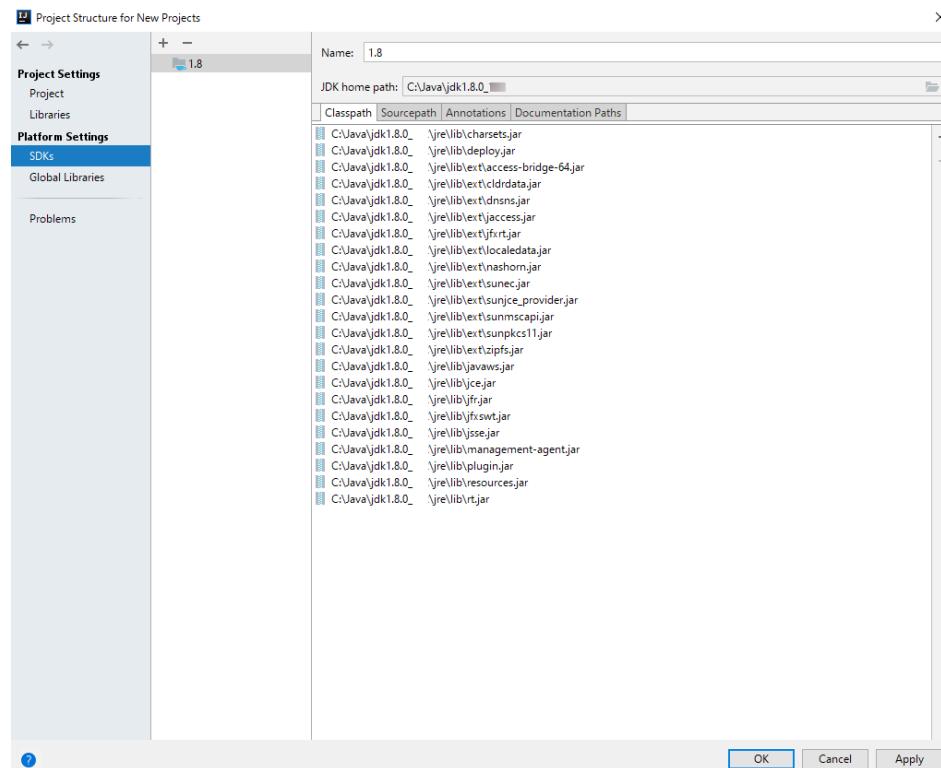

5. On the displayed **Select Home Directory for JDK** page, select the JDK directory and click **OK**.

Figure 1-244 Selecting the JDK directory

6. After selecting the JDK, click **OK** to complete the configuration.

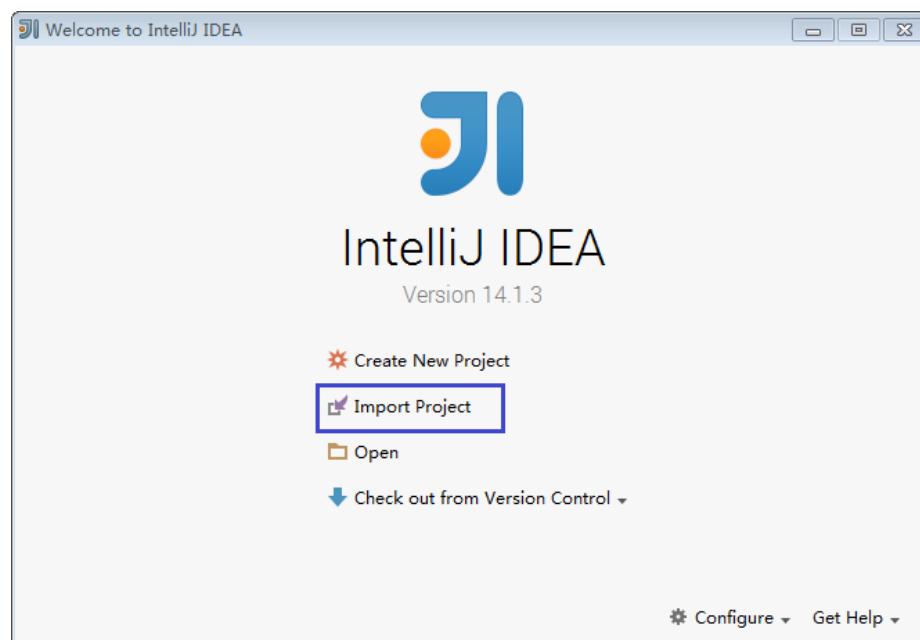

Figure 1-245 Completing the configuration

**Step 2** Import the Java sample projects to the IDEA.

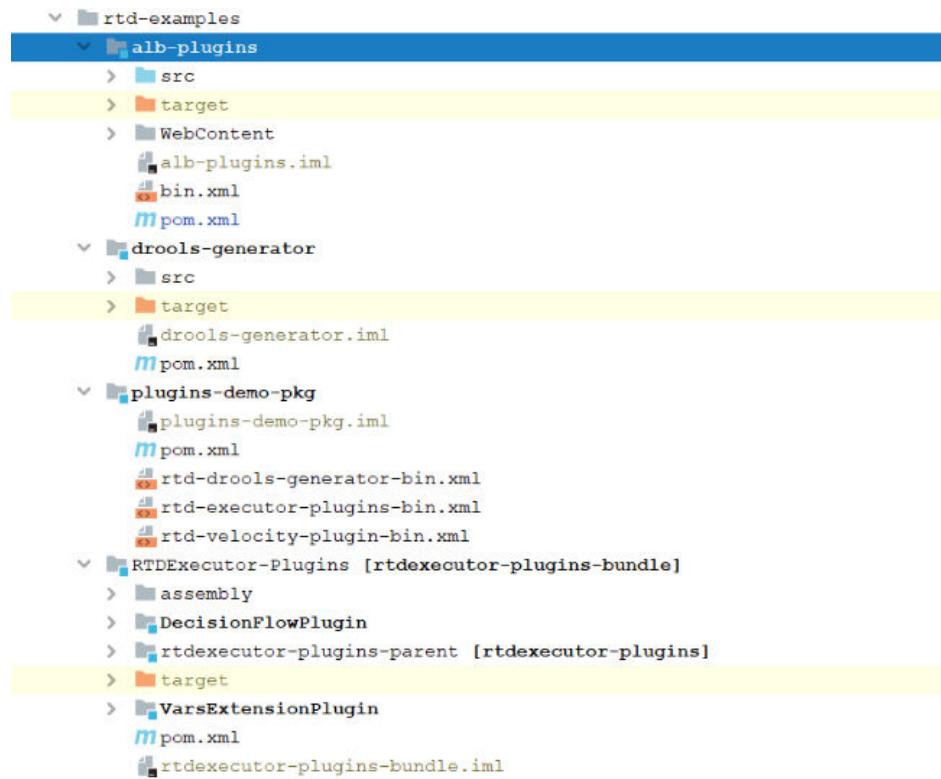

1. Start the IntelliJ IDEA. On the **Quick Start** page, select **Import Project**.  
Alternatively, for the used IDEA tool, add the project directly from the IDEA home page. Select **File > Import project...** to import projects.

Figure 1-246 Importing a project (on the Quick Start page)

2. Select the directory for storing the imported projects and click **OK**.

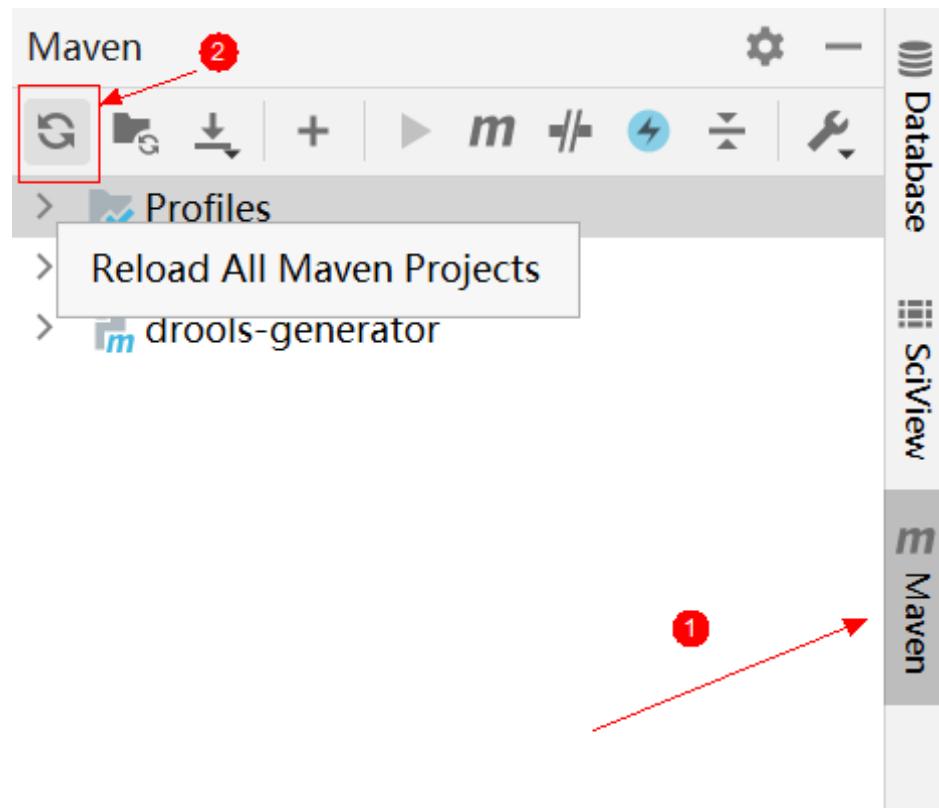

Figure 1-247 Select File or Directory to Import

3. Retain the default dependency library that is automatically recognized by IDEA and the suggested module structure, and click **Next**.

**Step 3** In IntelliJ IDEA, click **Reload All Maven Projects** in the Maven window on the right to import Maven project dependencies.

Figure 1-248 Reload projects

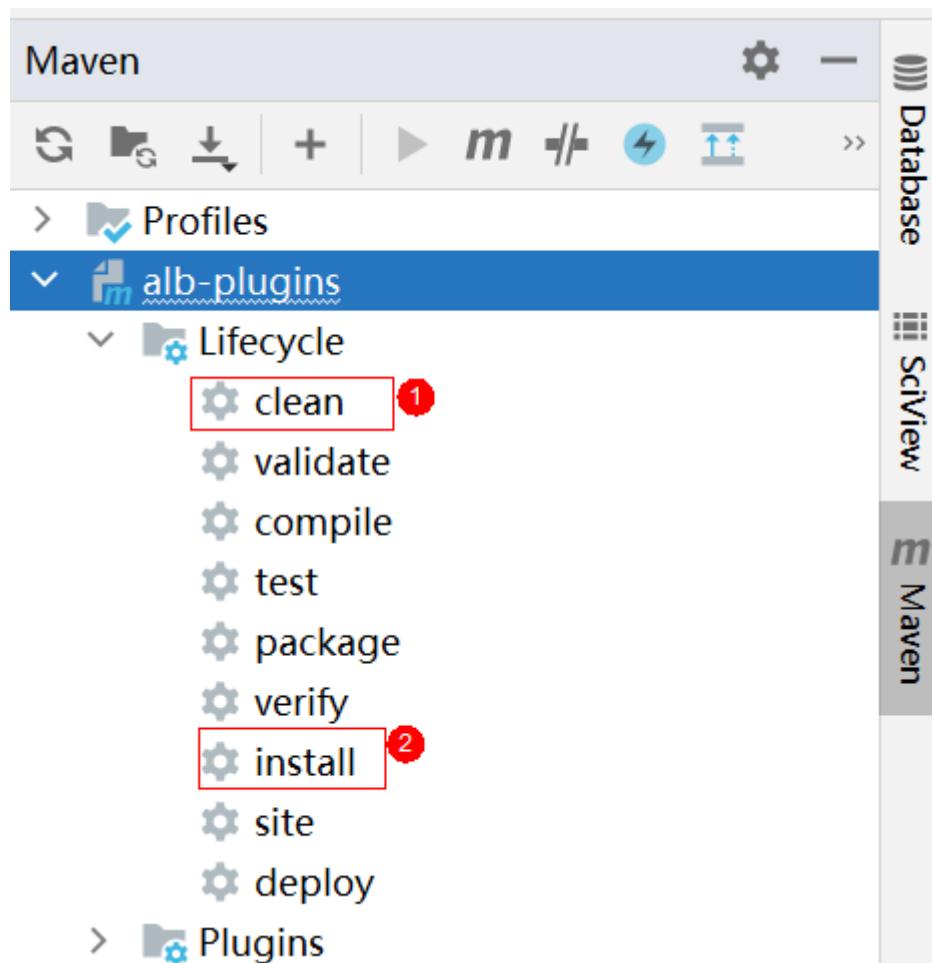

**Step 4** Compile the application.

There are two compilation methods:

- Method 1
  - a. Choose **Maven**, locate the target project name, and double-click **clean** under **Lifecycle** to run the **clean** command of Maven.
  - b. Choose **Maven**, locate the target project name, and double-click **install** under **Lifecycle** to run the **install** command of Maven.

Figure 1-249 Maven clean and install commands

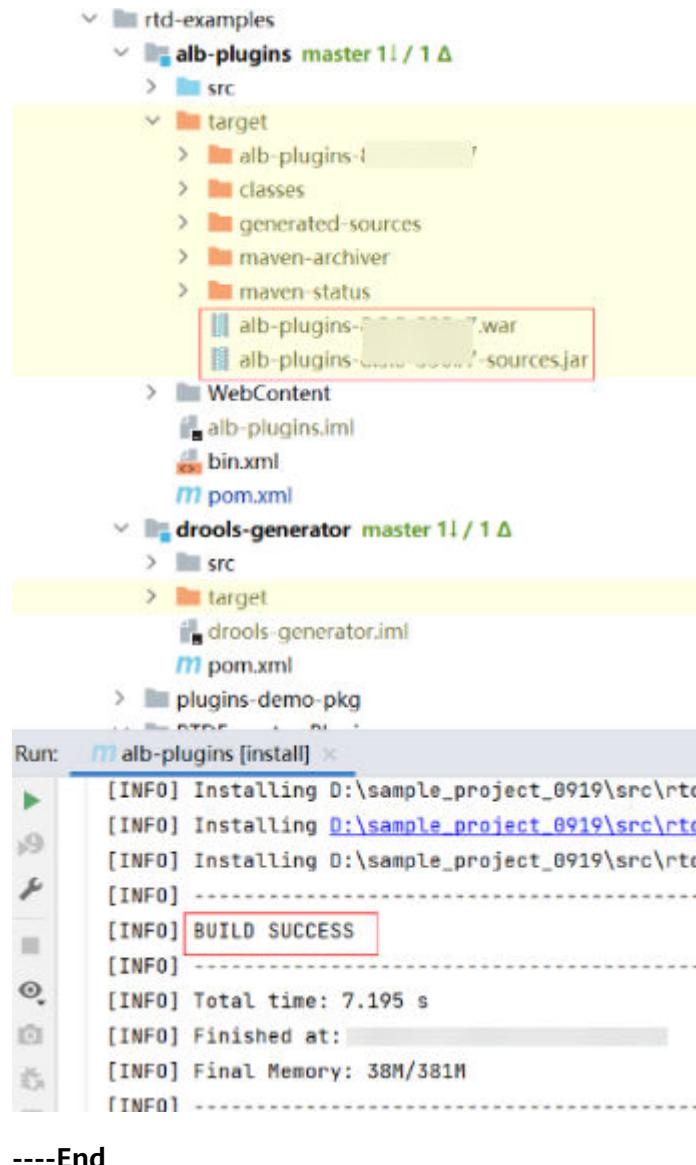

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window of IDEA, and run the **mvn clean install** command to build the file.

Figure 1-250 Entering "mvn clean install" to Idea Terminal

The screenshot shows the IntelliJ IDEA terminal window. The command 'mvn clean install' is typed into the terminal, with the 'install' part highlighted in a red box. The terminal tab is selected at the bottom of the interface.

**Step 5** Obtain the JAR or WAR package from the **target** directory which is generated after "BUILD SUCCESS" is displayed.

Figure 1-251 Compilation completed

----End

## 1.20 Solr Development Guide

### 1.20.1 Overview

#### 1.20.1.1 Application Development Overview

##### Solr Introduction

Solr is an independent enterprise search server based on Apache Lucene. It provides Representational State Transfer (REST)-similar Hypertext Transfer Protocol (HTTP)/Extensible Markup Language (XML) and JavaScript object notation (JSON) application programming interfaces (APIs). Main functions of Solr include full-text search, hit highlighting, faceted search, near real-time indexing,

dynamic clustering, database integration, rich document (for example, Word and PDF) handling, and geographic information search.

As an outstanding enterprise search server, Solr supports the following features:

- Advanced full-text search function
- Optimized large-capacity network traffic
- Standard open APIs, including XML, JSON, and HTTP
- Comprehensive HTML management interface
- Java management extensions (JMX) for monitoring servers
- Linear scalability, automatic index replication, and automatic failover and restoration
- Near real-time indexing
- XML configuration enabling flexibility and adaptability
- Extensible plug-in architecture

### 1.20.1.2 Common Concepts

Solr can be deployed in multiple modes, such as single-node mode, master-slave mode, and cloud mode. This document describes the SolrCloud deployment mode. SolrCloud is a distributed search solution in Solr based on Solr and ZooKeeper.

- **Collection**

Collection is a complete logical index in a SolrCloud cluster. A Collection can be divided into multiple Shards that use the same Config Set.

- **Config Set**

Config Set is a group of configuration files required by Solr Cores to provide services. A Config Set includes solrconfig.xml (SolrConfigXml) and schema.xml (SchemaXml).

- **Core**

Core refers to Solr Core. A Solr includes one or multiple Solr Cores. Each Solr Core independently provides indexing and query functions. Each Solr Core corresponds to an index or a Collection Shard. In SolrCloud, Solr configurations are stored in ZooKeeper.

- **Replica**

Replica is a copy of a Shard. Each Replica is in a Solr Core.

- **Shard**

Shard is a logical section of a Collection. Each Shard has one or multiple replicas, among which a leader is elected.

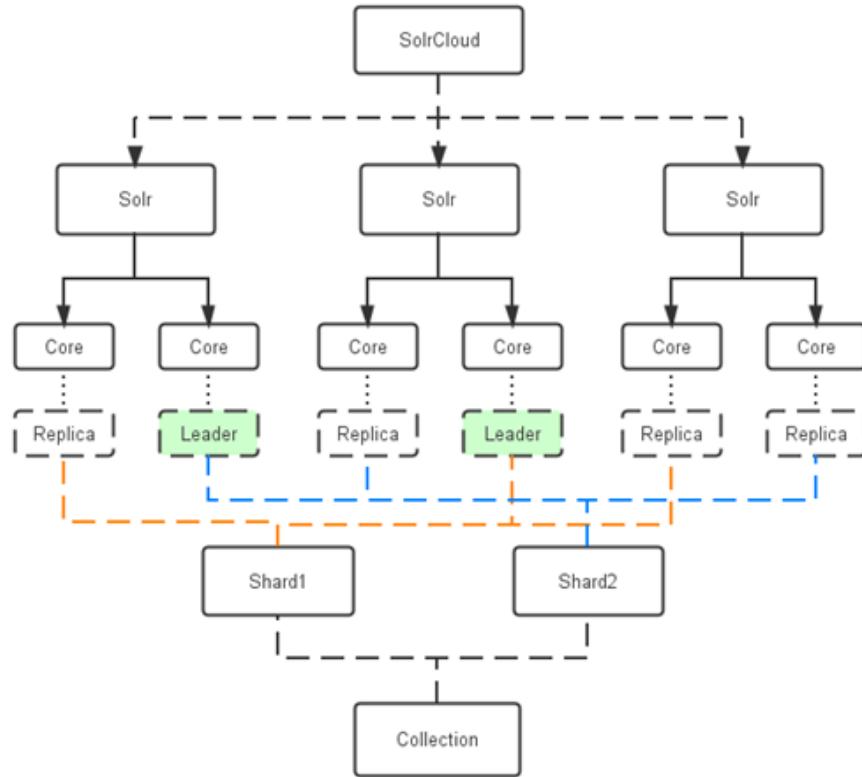

- **Leader**

Leader is a Shard replica elected from multiple replicas. When documents are indexed, SolrCloud transfers them to the leader, and the leader distributes them to replicas of all Shards.

- **Zookeeper**

ZooKeeper is mandatory in SolrCloud. It provides distributed lock and leader election functions.

Figure 1-252 Collection and Solr entities

### 1.20.1.3 Development Process

This document describes HBase application development based on the Java API.

For information about each phase in the development process, see [Figure 1-253](#) and [Table 1-170](#).

Figure 1-253 Solr application development process

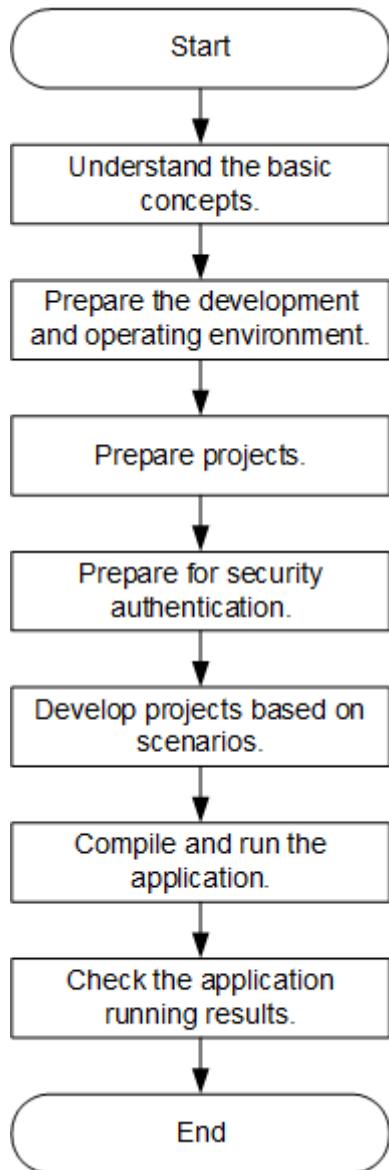

Table 1-170 Solr application development process description

Phase	Description	Reference Document
Understand the basic concepts.	Before developing an application, learn basic concepts of Solr and understand the scenario requirements and design tables.	<a href="#">Common Concepts</a>

Phase	Description	Reference Document
Prepare the development and operating environment.	The Java language is recommended for the development of Solr applications. The IntelliJ IDEA tool can be used. The Solr running environment is the Solr client. Install and configure the client according to the guide.	<a href="#">Preparing for Development and Operating Environment</a>
Prepare projects.	Import an example project according to the guide.	<a href="#">Configuring and Importing Sample Projects</a>
Preparing for security authentication.	The security authentication is mandatory if security clusters are used.	<a href="#">Preparing for Security Authentication</a>
Develop projects based on scenarios.	Provide an example project using Java language, covering an entire process for example project from query index to delete index.	<a href="#">Developing an Application</a>
Compile and run the application.	Compile the developed application and submit it for running.	<a href="#">Application Commissioning</a>

## 1.20.2 Environment Preparation

### 1.20.2.1 Preparing for Development and Operating Environment

#### Preparing Development Environment

[Table 1-171](#) describes the environment required for secondary development.

**Table 1-171** Development environment

Item	Description
OS	<ul style="list-style-type: none"><li>Development environment: Windows OS. Windows 7 or later is supported.</li><li>Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul>
Installing JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>Oracle JDK 1.8</li><li>IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>For security purposes, the server supports only TLS V1.2 or later.</li><li>By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>Tool used for developing HBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>

Item	Description
JUnit plug-in installation	Basic configuration for the development environment.
Installation of Maven	Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development.
Developer account preparation	See <a href="#">Preparing a Developer Account</a> for configuration.
7-zip	Used to decompress .zip and .rar packages. The 7-Zip 16.04 is supported.

## Preparing an Operating Environment

During application development, you need to prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#). In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.

    - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Solr\config** and manually import the configuration file to the configuration file directory (usually the **conf** folder) of the Solr sample project.

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory.

      - c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**
- When configuring IPv6 hosts on the local PC running Windows, add % and InterfaceIndex of the network interface card (NIC) to the end of the IPv6 address. The InterfaceIndex can be obtained by running the **ipconfig** command.

Example:

fec1:0:0:e505:8:99:5:1%10

- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.

- a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.

Ensure that the difference between the client time and the cluster time is less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).

- b. **Accessing FusionInsight Manager of an MRS Cluster**. Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Solr\config** directory to the **conf** directory where the compiled JAR package is stored for subsequent commissioning, for example, **/opt/hadoopclient/conf**.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Solr/config/* root@/IP address of the client node:/opt/hadoopclient/conf
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory.

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

## 1.20.2.2 Configuring and Importing Sample Projects

### Background

Obtain the Solr development example project. Import the project to IntelliJ IDEA for learning.

### Prerequisites

Ensure that the difference between the local PC time and the cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the cluster time in the lower-right corner on FusionInsight Manager.

### Procedure

- Step 1** Obtain the sample project folder **solr-examples** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Copy the **user.keytab** and **krb5.conf** files obtained in [Preparing a Developer Account](#) section to the **conf** directory of the sample project, and change the **principal** value in the **solr-example.properties** to the **principal=developuser**.
- Step 3** Change the **zkHost** value in the **solr-example.properties** to the **-DzkHost** value queried on the Dashboard on the **Solr Admin** page.  
Log in to FusionInsight Manager as a user who has the Solr page access permission, choose **Cluster > Services > Solr**, and click the link next to **Solr WebUI**. The Solr Admin page is displayed.
- Step 4** Change the **zkSslEnable** value in the **solr-example.properties** to the value of **ssl.enabled** of ZooKeeper.  
Log in to FusionInsight Manager, choose **Cluster > Services > ZooKeeper > Configurations > All Configurations**, search for and record the value of **ssl.enabled** of the ZooKeeper service.
- Step 5** Change the **createNodeSet** value in the **solr-example.properties** to the IP address and port number of the Solr instance. Use commas (,) to separate multiple values.  
Log in to FusionInsight Manager, choose **Cluster > Services > Solr > Instance**, and view the service IP address of the SolrServer instance. The default port number is **21101**.

The configuration example of the **solr-example.properties** file is as follows:

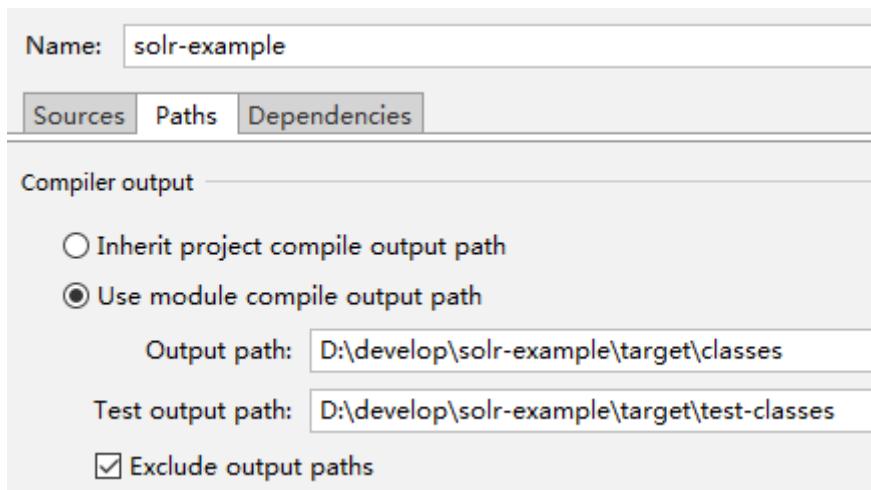

```
zkHost=192.168.1.189:24002,192.168.1.228:24002,192.168.1.150:24002/solr
zkSslEnable=false
ZOOKEEPER_DEFAULT_SERVER_PRINCIPAL=zookeeper/hadoop.hadoop.com
principal=developuser
zkClientTimeout=20000
zkConnectTimeout=30000
SOLR_KBS_ENABLED=true
COLLECTION_NAME=col_test
DEFAULT_CONFIG_NAME=confWithSchema
shardNum=3
replicaNum=1
```

```
maxShardsPerNode=1  
autoAddReplicas=false  
assignToSpecifiedNodeSet=false  
createNodeSet=192.168.1.136:21101_solr,192.168.1.228:21101_solr  
isNeedZkClientConfig=true
```

**Step 6** Import the example project to the IntelliJ IDEA development environment.

1. Choose **File > Open... > Open File or Project**.
2. Enter the path of the solr-example sample project.
3. Select the solr-example example project folder, and click **OK**.
4. Before running the **solr-example** sample project, configure **Compiler output** for the project. Otherwise, the error message "the output path is not specified" may be displayed.

Specifically, choose **File > Project Structure > Modules** and configure the compilation output path of the **solr-example** sample project, as shown in the following figure.

**NOTE**

You can customize **Compiler output**. Ensure that the path exists. To change the output path during the project running, create the required path, and then configure the path by following the instruction in the preceding figure. The modification takes effect after the compilation.

----End

### 1.20.2.3 Preparing for Security Authentication

#### Scenario

In a secure cluster environment, components must perform mutual authentication before communicating with each other to ensure communication security.

Solr application development requires ZooKeeper and Kerberos security authentication. The **jaas.conf** file is used for ZooKeeper authentication. Spnego authentication is a security protocol expending Kerberos and using GSS-API authentication mechanism.

Security authentication uses the code authentication mode. Only **jaas.conf** and **krb5.conf** files need to be configured. This example project applies to the Oracle

Java platform and the IBM Java platform. **jaas.conf** is generated and configured using the code, such as **LoginUtil.setJaasFile(principal, path + "user.keytab")** in the following initial configuration example.

- Code authentication

```
if (testSample.SOLR_KBS_ENABLED.equals("true")) {  
    testSample.setSecConfig();  
}
```

- Initial configuration

```
private void setSecConfig() throws SolrException {  
    String path = System.getProperty("user.dir") +  
        File.separator + "conf" + File.separator;  
    path = path.replace("\\", "\\\\"");  
    try {  
        LoginUtil.setJaasFile(principal, path + "user.keytab");  
        LoginUtil.setKrb5Config(path + "krb5.conf");  
        LoginUtil.setZookeeperServerPrincipal(  
            ZOOKEEPER_DEFAULT_SERVER_PRINCIPAL);  
  
    } catch (IOException e) {  
        LOG.error("Failed to set security conf", e);  
        throw new SolrException("Failed to set security conf");  
    }  
}
```

## 1.20.3 Developing an Application

### 1.20.3.1 Typical Scenario Description

Based on typical scenarios, users can quickly learn and master the Solr development process and know important interface functions.

#### Scenario

Provided that a user needs an application to manage employees and search employee personal information. Solr can provide the searching service. The search process is as follows:

- Check whether the index to be created exists. If the index exists, delete it.
- Create an index for personal information data of employees.
- Insert the personal information data of employees into the index.
- Query personal information of employees based on the search criteria.
- Delete personal information of employees based on the search criteria.

#### NOTE

The schema information about the column corresponding to the data table of employees needs to be planned in Solr index configurations.

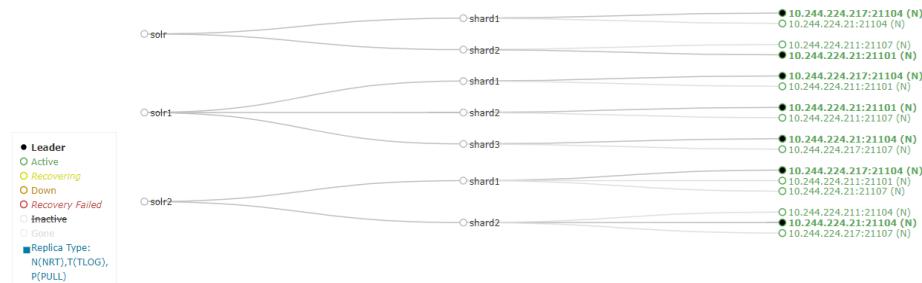

### 1.20.3.2 Development Idea

The core function of Solr is search. You need to create a Collection before searching.

This topic uses the SolrCloud deployment mode as an example. In the following figure, two collections are created, in which three instances of collection 1 are

distributed over three nodes and each shard in collection 2 has two replicas, as shown in [Figure 1-254](#).

**Figure 1-254** Collection relationships

Operations involved in example codes include establishing a connection with the Solr server, querying a Collection, deleting a Collection, creating a Collection, adding one document, adding multiple documents, simple search, and deleting a document. You can learn advanced Solr operations based on basic example codes.

Example codes are described in the following sequence:

1. Establish a connection between the client and the CloudSolr server.
2. Querying Collation.
3. Deleting a Collection.
4. Creating a Collection.
5. Add one or multiple documents.
6. Query documents.
7. Delete documents.
8. Release the CloudSolr connection.

**NOTE**

In this development guide, the used Solr configuration files are all built-in. If users want to customize the configuration set, see [Component Operation Guide > Solr > Common Service Operations > Shell Client Operation Commands](#) to create and upload the configuration set.

### 1.20.3.3 Example Code Description

#### 1.20.3.3.1 Initializing Solr

##### Function

Solr initialization is a prerequisite for using application programming interfaces (APIs) provided by Solr. Solr initialization aims to connect to SolrCloud.

**NOTE**

Call `cloudSolrClient.close ()` to close requested resources after the Solr operation is complete.

## Example Code

The following code snippet belongs to the **getCloudSolrClient** method in the **TestSample** class of the **com.huawei.fusioninsight.solr.example** package.

```
/*
 *Initialize CloudSolrClient instance, and collect SolrCloud
 */
private CloudSolrClient getCloudSolrClient(String zkHost) throws SolrException {
    Builder builder = new CloudSolrClient.Builder();
    builder.withZkHost(zkHost);
    CloudSolrClient cloudSolrClient = builder.build();
    cloudSolrClient.setZkClientTimeout(zkClientTimeout);
    cloudSolrClient.setZkConnectTimeout(zkConnectTimeout);
    cloudSolrClient.connect();
    LOG.info("The cloud Server has been connected !!!!");
    ZkStateReader zkStateReader = cloudSolrClient.getZkStateReader();
    ClusterState cloudState = zkStateReader.getClusterState();
    LOG.info("The zookeeper state is : {}", cloudState);
    return cloudSolrClient;
}
```

## Precautions

The three values **zkHost**, **zkClientTimeout**, and **zkConnectTimeout** can be configured in the **solr-example.properties** file under the **conf** directory. Change the **zkHost** value in the **solr-example.properties** to the **-DzkHost** value queried on the Dashboard of the Solr Admin page.

### 1.20.3.3.2 Querying a Collection

#### Function

By calling **process (cloudSolrClient)** in **CollectionAdminRequest.List** and the returned responses, users can obtain the names of all collections.

## Example Code

The following code snippet belongs to the **queryAllCollections** method in the **TestSample** class of the **com.huawei.fusioninsight.solr.example** package.

```
private List<String> queryAllCollections(CloudSolrClient
    cloudSolrClient) throws SolrException {
    CollectionAdminRequest.List list = new CollectionAdminRequest.List();

    CollectionAdminResponse listRes = null;
    try {
        listRes = list.process(cloudSolrClient);
    } catch (SolrServerException | IOException e) {
        LOG.error("Failed to list collection", e);
        throw new SolrException("Failed to list collection");
    } catch (Exception e) {
        LOG.error("Failed to list collection", e);
        throw new SolrException("unknown exception");
    }

    List<String> collectionNames = (List<String>)
    listRes.getResponse().get("collections");
    LOG.info("All existed collections : {}", collectionNames);
    return collectionNames;
}
```

### 1.20.3.3.3 Deleting a Collection

#### Function

By calling **process (cloudSolrClient)** in **CollectionAdminRequest.Deleted** and the returned responses, users can check whether the deleting collection operation is successfully executed.

#### Example Code

The following code snippet belongs to the **deleteCollection** method in the **TestSample** class of the **com.huawei.fusioninsight.solr.example** package.

```
private void deleteCollection(CloudSolrClient cloudSolrClient)
    throws SolrException {
    CollectionAdminRequest.Delete delete =
        new CollectionAdminRequest.Delete();
    delete.setCollectionName(collectionName);
    CollectionAdminResponse response = null;
    try {
        response = delete.process(cloudSolrClient);
    } catch (SolrServerException | IOException e) {
        LOG.error("Failed to delete collection", e);
        throw new SolrException("Failed to create collection");
    } catch (Exception e) {
        LOG.error("Failed to delete collection", e);
        throw new SolrException("unknown exception");
    }
    if (response.isSuccess()) {
        LOG.info("Success to delete collection[{}]", collectionName);
    } else {
        LOG.error("Failed to delete collection[{}], cause : {}", collectionName, response.getErrorMessages());
        throw new SolrException("Failed to delete collection");
    }
}
```

### 1.20.3.3.4 Creating a Collection

#### Function

By calling process **cloudSolrClient** in the **CollectionAdminRequest.Create** and **responses**, users can check whether the creating collection operation is successfully executed.

#### Example Code

The following code snippet belongs to the **createCollection** method in the **TestSample** class of the **com.huawei.fusioninsight.solr.example** package.

```
private void createCollection(CloudSolrClient cloudSolrClient) throws SolrException {
    CollectionAdminRequest.Create create = CollectionAdminRequest.createCollection(collectionName,
        defaultConfigName, shardNum, replicaNum);
    CollectionAdminResponse response = null;
    try {
        response = create.process(cloudSolrClient);
    } catch (SolrServerException e) {
        LOG.error("Failed to create collection", e);
        throw new SolrException("Failed to create collection");
    } catch (IOException e) {
        LOG.error("Failed to create collection", e);
        throw new SolrException("Failed to create collection");
    }
```

```
        } catch (Exception e) {
            LOG.error("Failed to create collection", e);
            throw new SolrException("unknown exception");
        }
        if (response.isSuccess()) {
            LOG.info("Success to create collection[{}]", collectionName);
        } else {
            LOG.error("Failed to create collection[{}], cause : {}", collectionName, response.getErrorMessages());
            throw new SolrException("Failed to create collection");
        }
    }
```

## Precautions

1. **collectionName** is the name of the index to be created. **defaultConfigName** is the configuration set used by the index. The configuration set is the default Solr confWithSchema. Users can run the client script to download the configuration client information or view the information on the web page of the Solr Admin. **shardNum** indicates the number of fragments. **replicaNum** indicates the number of copies. All of these items can be configured in the **solr-example.properties** file under the **conf** directory and the configuration sets can be changed based on practical application.
2. It is suggested to limit the alias name and collection name **collectionName** at 255 characters while creating a collection, otherwise it might affect the performance of ZooKeeper and Solr. For more information please refer to Solr service configuration **SOLR\_COLLECTION\_CORE\_MAX\_LENGTH**.

### 1.20.3.3.5 Adding a Document

## Function

The index data is added by calling the adding method of cloudSolrClient or by constructing UpdateRequest to call request method of cloudSolrClient.

## Example Code 1

The following code snippet belongs to the **addDocs** method in the **TestSample** class of the **com.huawei.fusioninsight.solr.example** package.

```
private void addDocs(CloudSolrClient cloudSolrClient) throws SolrException {
    Collection<SolrInputDocument> documents = new ArrayList<SolrInputDocument>();
    for (Integer i = 0; i < 5; i++) {
        SolrInputDocument doc = new SolrInputDocument();
        doc.addField("id", i.toString());
        doc.addField("name", "Luna_" + i);
        doc.addField("features", "test" + i);
        doc.addField("price", (float) i * 1.01);
        documents.add(doc);
    }
    try {
        cloudSolrClient.add(documents);
        LOG.info("success to add index");
    } catch (SolrServerException e) {
        LOG.error("Failed to add document to collection", e);
        throw new SolrException("Failed to add document to collection");
    } catch (IOException e) {
        LOG.error("Failed to add document to collection", e);
        throw new SolrException("Failed to add document to collection");
    } catch (Exception e) {
        LOG.error("Failed to add document to collection", e);
        throw new SolrException("unknown exception");
    }
}
```

```
}
```

## Example Code 2

The following code snippet belongs to the **addDocs2** method in the **TestSample** class of the **com.huawei.fusioninsight.solr.example** package.

```
private void addDocs2(CloudSolrClient cloudSolrClient) throws  
SolrException{  
    UpdateRequest request = new UpdateRequest();  
    Collection<SolrInputDocument> documents = new ArrayList<>();  
    for (Integer i = 5; i < 10; i++) {  
        SolrInputDocument doc = new SolrInputDocument();  
        doc.addField("id", i.toString());  
        doc.addField("name", "Tom" + i);  
        doc.addField("features", "test" + i);  
        doc.addField("price", (float) i * 1.01);  
        documents.add(doc);  
    }  
    request.add(documents);  
    try {  
        cloudSolrClient.request(request);  
        cloudSolrClient.commit();  
    } catch (SolrServerException | IOException e) {  
        LOG.error("Failed to add document to collection", e);  
        throw new SolrException("Failed to add document to  
collection");  
    }  
}
```

### 1.20.3.3.6 Querying a Document

#### Function

The index data can be queried by constructing a **SolrQuery** instance and calling the **cloudSolrClient.query** API.

## Example Code

The following code snippet belongs to the **queryIndex** method in the **TestSample** class of the **com.huawei.fusioninsight.solr.example** package.

```
private void queryIndex(CloudSolrClient cloudSolrClient) throws SolrException {  
    SolrQuery query = new SolrQuery();  
    query.setQuery("name:Luna*");  
  
    try {  
        QueryResponse response = cloudSolrClient.query(query);  
        SolrDocumentList docs = response.getResults();  
        LOG.info("Query wasted time : {}ms", response.getQTime());  
  
        LOG.info("Total doc num : {}", docs.getNumFound());  
        for (SolrDocument doc : docs) {  
            LOG.info("doc detail : " + doc.getFieldValueMap());  
        }  
    } catch (SolrServerException e) {  
        LOG.error("Failed to query document", e);  
        throw new SolrException("Failed to query document");  
    } catch (IOException e) {  
        LOG.error("Failed to query document", e);  
        throw new SolrException("Failed to query document");  
    } catch (Exception e) {  
        LOG.error("Failed to query document", e);  
        throw new SolrException("unknown exception");  
    }  
}
```

```
}
```

### 1.20.3.3.7 Deleting a Document

#### Function

The data of a specified index can be deleted by calling **cloudSolrClient.deleteByQuery**.

#### Example Code

The following code snippet belongs to the **removeIndex** method in the **TestSample** class of the **com.huawei.fusioninsight.solr.example** package.

```
private void removeIndex(CloudSolrClient cloudSolrClient) throws  
SolrException {  
    try {  
        cloudSolrClient.deleteByQuery("*:*");  
        cloudSolrClient.commit();  
        LOG.info("Success to delete index");  
    } catch (SolrServerException | IOException e){  
        LOG.error("Failed to remove document", e);  
        throw new SolrException("Failed to remove document");  
    }  
}
```

## 1.20.4 Application Commissioning

### 1.20.4.1 Commissioning an Application in Windows

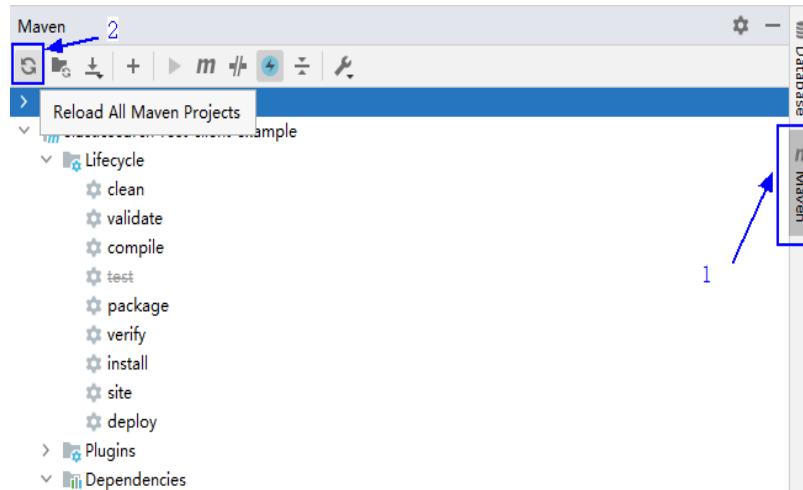

#### 1.20.4.1.1 Compiling and Running an Application

##### Scenario

After the code development is complete, you can run the application in the Windows development environment. If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

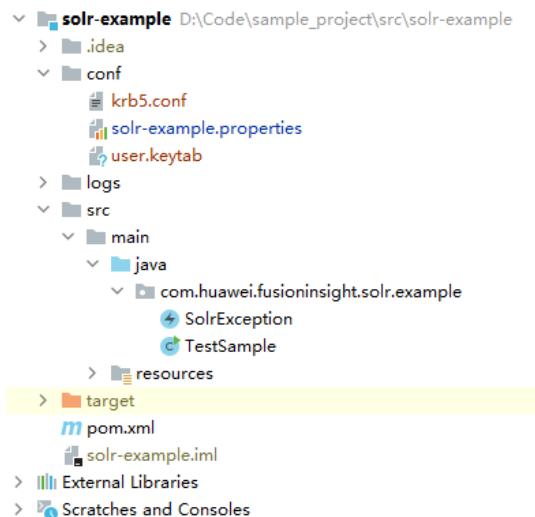

##### Procedure

- Step 1 Click **Reimport All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

## Step 2 Compile and run an application.

1. The following figure shows the file list after the configuration file has been placed and the code has been modified to match the login user.

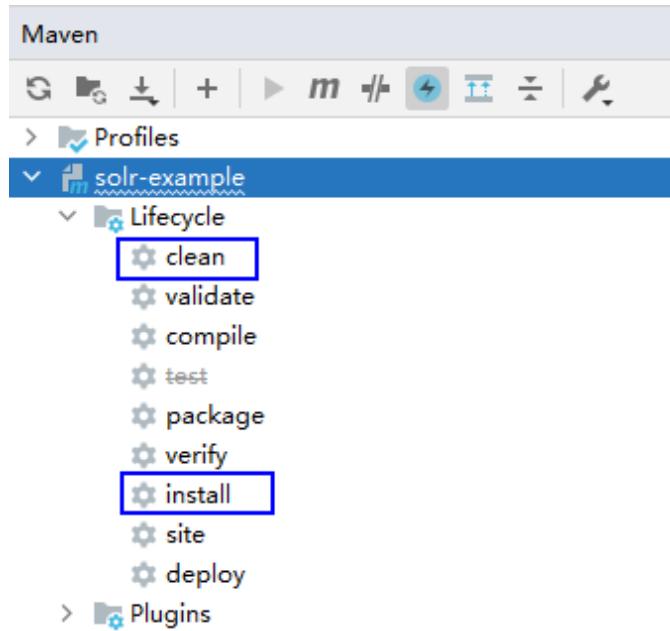

2. Compile an application.

There are two compilation modes.

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean** and double-click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **compile**, double click **compile** to run the **compile** command of Maven.

- Method 2:

Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean compile** command to compile the **pom.xml** file.

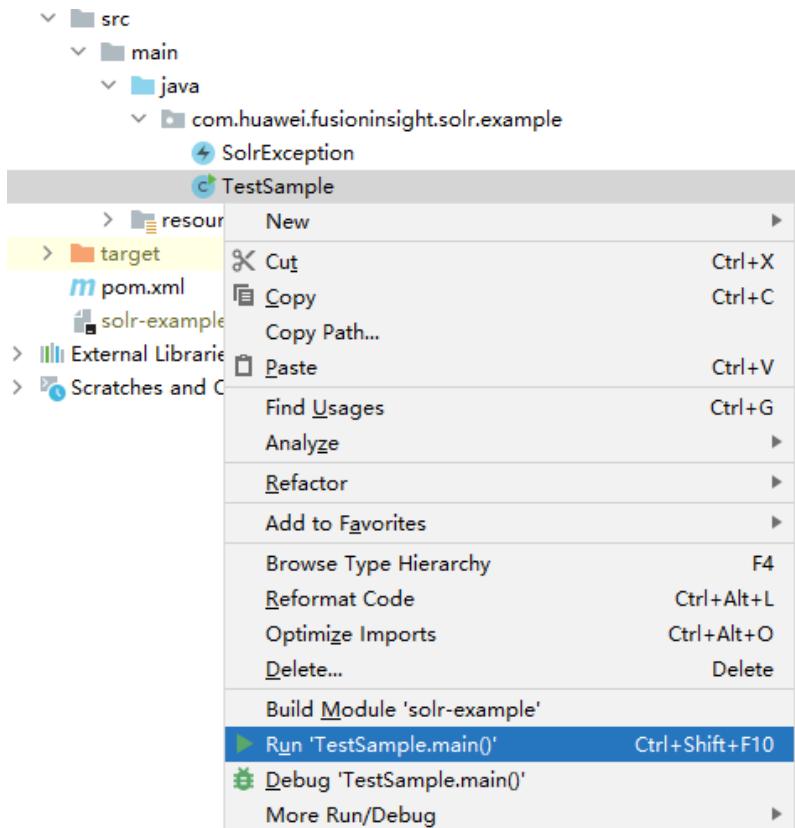

```
Terminal: Local +  
Microsoft Windows  
(c) Microsoft Corporation.  
  
D:\code\sample_project>cd src\solr-example  
  
D:\code\sample_project\src\solr-example>mvn clean compile
```

- After the compilation is complete, the message "Build Success" is displayed and the **target** directory is generated.

```
[INFO] Copying 1 resource  
[INFO]  
[INFO] --- maven-compiler-plugin:3.1:compile (default-compile) @ solr-example ---  
[INFO] Changes detected - recompiling the module!  
[INFO] Compiling 2 source files to D:\code\sample_project\src\solr-example\target\c  
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 1.621 s  
[INFO] Finished at: 2023-09-19T17:18:06+08:00  
[INFO] -----
```

- Run the program.

Right-click the **TestSample** file and choose **Run 'TestSample.main()'** from the shortcut menu to run samples.

----End

#### 1.20.4.1.2 Viewing Commissioning Results

##### Scenario

After an Solr application is run, you can use one of the following methods to view the running result:

- Viewing the IntelliJ IDEA running result
- Viewing Solr logs
- Logging in to the Solr WebUI. For details, see [Component Operation Guide > Solr > Common Service Operations > Operations on Solr Admin UI](#).

##### Procedure

The following information is displayed in the running results:

```
...
2021-07-05 14:27:26,604 | INFO | main | Client is connected to ZooKeeper |
org.apache.solr.common.cloud.ConnectionManager.waitForConnected(ConnectionManager.java:251)

## NOTE

In the Windows environment, the following exception occurs but does not affect services.  
java.io.IOException: Could not locate executable null\bin\winutils.exe in the Hadoop binaries.

## Log description

The log level is **INFO** by default and more detailed information can be viewed by changing the log level (**DEBUG**, **INFO**, **WARN**, **ERROR**, and **FATAL**).

You can modify the **log4j.properties** file to change log levels, for example:

```
# Set root category priority to info and its only appender to console.  
log4j.rootCategory=info,console,R  
#log4j.debug=true  
  
# console is set to be a ConsoleAppender using a PatternLayout.  
log4j.appender.console=org.apache.log4j.ConsoleAppender  
log4j.appender.console.Threshold=DEBUG  
log4j.appender.console.layout=org.apache.log4j.PatternLayout  
log4j.appender.console.layout.ConversionPattern=%d{yyyy-MM-dd HH:mm:ss,SSS} | %-5p | %t | %m | %l%n  
  
# R is set to be a File appender using a PatternLayout.  
log4j.appender.R=org.apache.log4j.RollingFileAppender  
log4j.appender.R.Append=true  
log4j.appender.R.Threshold=debug  
log4j.appender.R.MaxFileSize=1024KB  
log4j.appender.R.MaxBackupIndex=10  
log4j.appender.R.File=logs/solrclient.log  
log4j.appender.R.layout=org.apache.log4j.PatternLayout  
log4j.appender.R.layout.ConversionPattern=%d{yyyy-MM-dd HH:mm:ss,SSS} | %-5p | %t | %m | %l%n
```

## 1.20.4.2 Commissioning an Application in Linux

### 1.20.4.2.1 Compiling and Running an Application When a Client Is Installed

#### Scenario

In a Linux environment where an Solr client is installed, you can upload the JAR package to the Linux and then run an application after the code development is complete.

#### Prerequisites

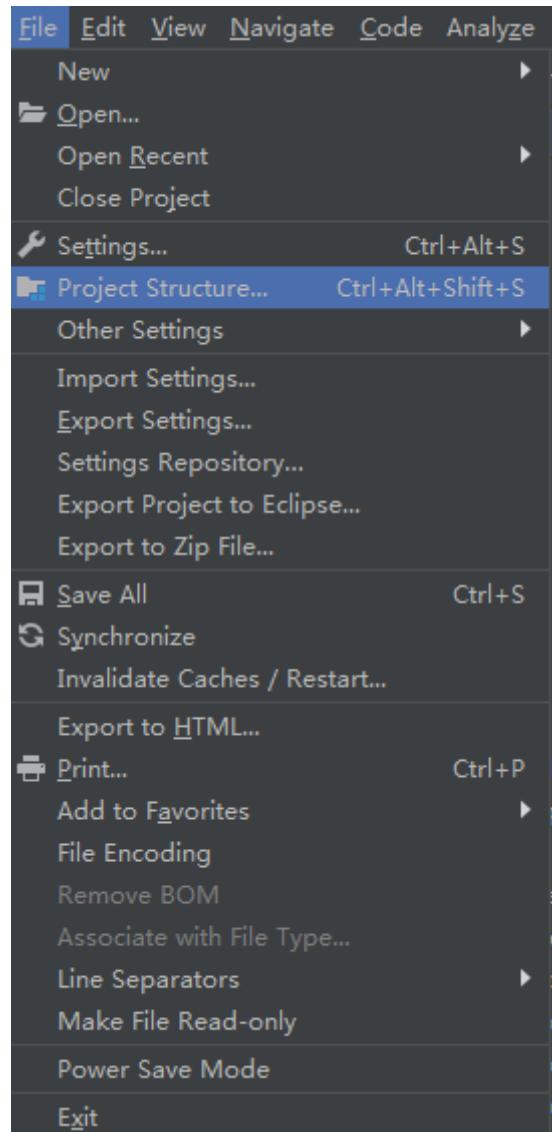

You have installed the Solr client.

#### Procedure

##### Step 1 Export the jar package.

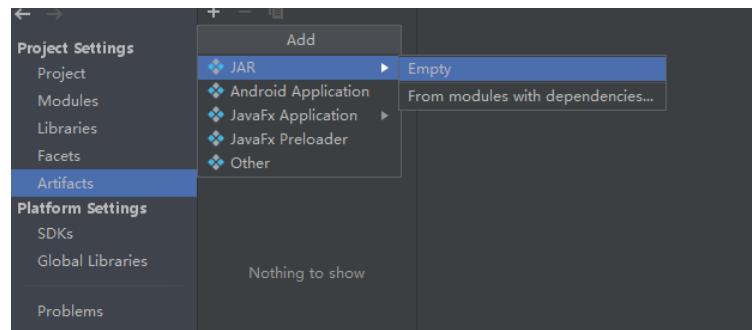

1. Log in to IntelliJ IDEA and choose **File > Project Structure**.

Figure 1-255 Project Structure

2. Select **Artifacts**, click +, and choose **JAR > Empty**.

Figure 1-256 Adding artifacts

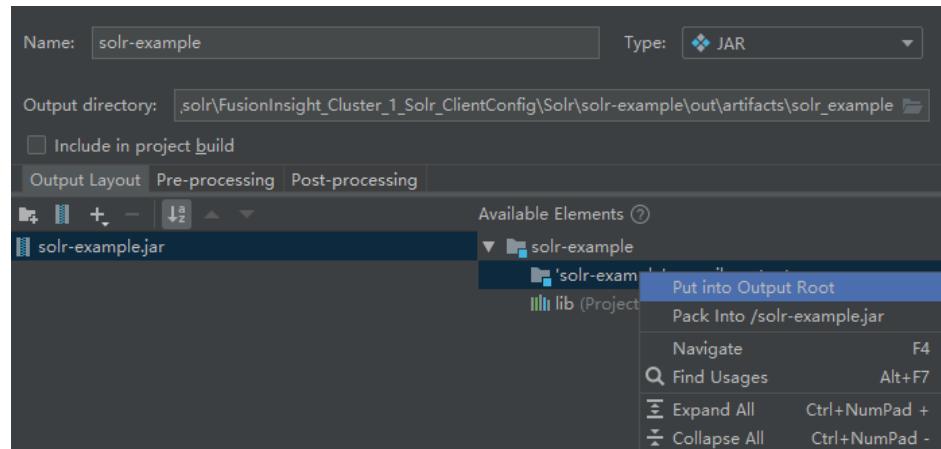

3. Change the value of **Name** to a user-defined name, for example, **solr-example**.

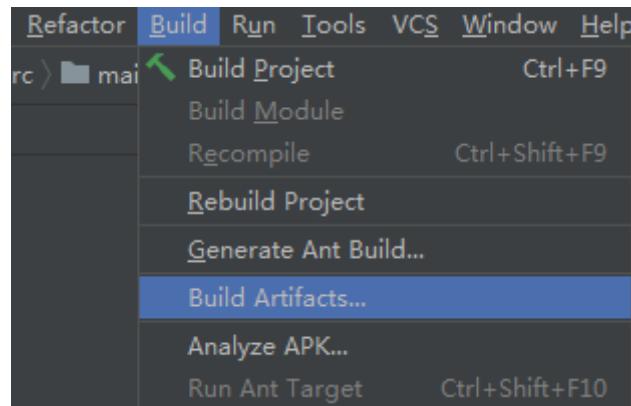

4. Select **Output Layout**, right-click 'solr-example' compile output in **Available Elements** on the right, and choose **Put Into Output Root**.

**Figure 1-257 Adding output**

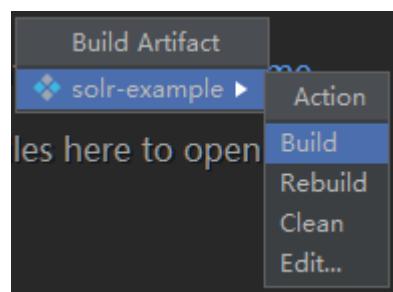

5. Click **Apply** to save the modification, and then click **OK** to exit.
6. Choose **Build > Build Artifacts....**

**Figure 1-258 Preparing for compilation**

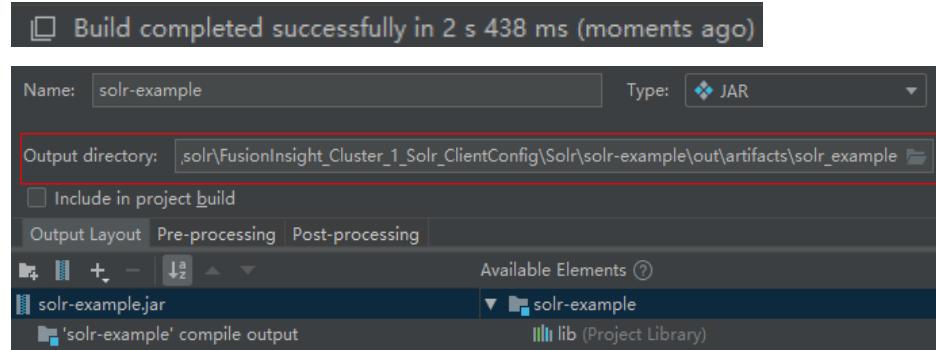

7. In the dialog box that is displayed, choose **solr-example > Build** to compile the artifact.

**Figure 1-259 Compiling an artifact**

8. If information similar to the following is displayed in the event log, the JAR file has been successfully generated. Obtain the JAR file from the **Output directory** configured in **Artifacts**.

#### Step 2 Run the jar package.

1. Assume that the client installation directory is **/opt/hadoopclient**. Copy the exported jar package **solr-example.jar** to **/opt/hadoopclient/Solr/tools/solr-example** in the client installation directory and copy the **conf** directory files of the project to **/opt/hadoopclient/Solr/tools/solr-example/conf**.
2. Run **source /opt/hadoopclient/bigdata\_env**, and then switch to the code function directory **cd /opt/hadoopclient/Solr/tools/solr-example**.
3. Run the java command:  
**java -cp /opt/hadoopclient/Solr/tools/lib/\*:solr-example.jar:/opt/hadoopclient/Solr/tools/solr-example/conf/com.huawei.fusioninsight.solr.example.TestSample**

----End

### 1.20.4.2.2 Compiling and Running an Application When No Client Is Installed

#### Scenario

In a Linux environment where no Solr client is installed, you can upload the JAR package to the Linux and then run an application after the code development is complete.

#### Prerequisites

JDK has been installed on Linux. The version must be the same as JDK version of the jar package exported from IntelliJ IDEA. Java environment variables have been set.

#### Procedure

- Step 1** Export the jar package. For details, see [Compiling and Running an Application When a Client Is Installed](#).
- Step 2** Access the directory where the **pom.xml** file is stored in the **Terminal** window of the IDEA or other command line tools. Run the following command to generate the **lib** folder in the directory where **pom.xml** is located. The folder contains the JAR package on which the sample project depends.

**mvn dependency:copy-dependencies -DoutputDirectory=lib**

- Step 3** Copy the **lib** directory which the application development environment requires and conf directory to any directory in the client operating environment, for example, **/opt/solr-example**, and then copy the jar package generated in the application environment to **/opt/solr-example/lib/**.
- Step 4** On the client, run the **cd/opt/solr-example** command to switch to the copy directory.
- Step 5** Run the jar commands:

```
java -cp /opt/solr-example/lib/*:/opt/solr-example/conf/  
com.huawei.fusioninsight.solr.example.TestSample
```

----End

#### 1.20.4.2.3 Viewing Commissioning Results

##### Scenario

After an Solr application is run, you can use one of the following methods to view the running result:

- Viewing the command output.
- Viewing Solr logs.
- Logging in to the Solr WebUI. For details, see **Component Operation Guide > Solr > Common Service Operations > Operations on Solr Admin UI**.

##### Procedure

The following information is displayed in the running results:

```

## 1.20.5 More Information

### 1.20.5.1 External Interfaces

#### 1.20.5.1.1 Shell

You can directly perform operations on Solr by running Shell client scripts.

Methods of running the Shell command (assuming that the client installation directory is: **/opt/hadoopclient**):

```
source /opt/hadoopclient/bigdata_env
```

```
kinit solr service user
```

Run **/opt/hadoopclient/Solr/solr-client/bin/solrctl --help** to obtain the help information for specific Solr parameters.

```
usage: solrctl [options] command [command-arg] [command [command-arg]] ...
```

```
Options:  
--help  
--quiet  
  
Commands:  
confset [--generate path [-schemaless | -confWithHBase]]  
[--create name path -force]  
[--update name path -force]  
[--get name path]  
[--putfile path localpath]

### 1.20.5.1.2 Java API

Common Solr Java classes are as follows:

- CloudSolrClient: core class of client applications. It encapsulates HttpClient and communicates with SolrCloud.
- CollectionAdminRequest: various request APIs. It is displayed in the internal form, such as CollectionAdminRequest.Create, CollectionAdminRequest.List, and CollectionAdminRequest.Delete.

- SolrInputDocument: index record.
- SolrQuery: index query class.

For details about the API of each class, see: <https://lucene.apache.org/solr/8.4.0/solr-solrj/index.html?overview-summary.html>

### 1.20.5.1.3 Web UI

#### Scenario

The Web UI displays the Solr cluster status, including summary of a cluster and information about SolrServer, SolrServerAdmin, snapshots, and running processes. You can better understand the Solr cluster status based on information displayed on the Web UI.

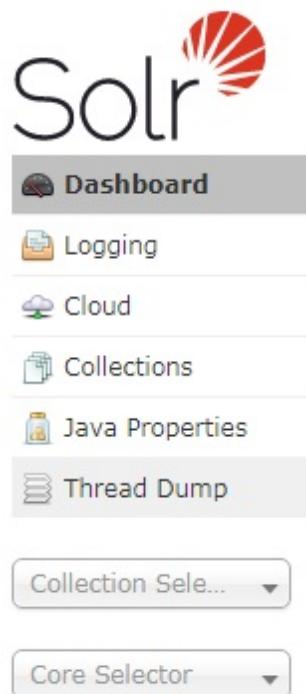

##### NOTE

Contact the administrator to obtain a service account that has the right to access the WebUI and obtain its password.

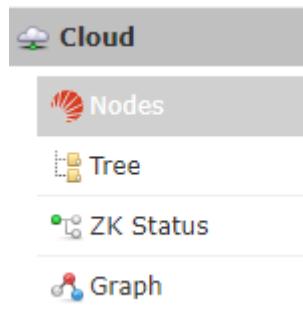

#### Procedure

- Step 1** Accessing FusionInsight Manager of an MRS Cluster. Choose **Cluster > Name of the desired cluster > Services > Solr > SolrServerAdmin** and open the Web UI in Solr.
- Step 2** The Solr web UI page includes several parts several parts, as shown in [Figure 1-260](#).

**Figure 1-260** Solr Web UI control menu

- DashBoard: displays some system parameters, such as JVM startup parameters and JVM memory usage.
- Logging: displays logs at the warn and upper levels on the page, and provides the function of dynamically adjusting the level of logs.
- Cloud: displays each structure of the Collection.

- Tree displays the tree-like structure for the directory files of index in Zookeeper.
- Graph displays the relationship among each Collection, shard, and replica.
- Graph (Radial) displays the relationship among Collection, shard, and replica in radial shape.
- Dump enables a user to download ZooKeeper configuration files of a Collection.
- Collections: Management UI of collections. It provides functions such as Add, Delete, Reload, Create Alias and Delete Alias.
- Java Properties: lists all environment variables used by Solr.
- Thread Dump: thread stack, lists information about all thread stacks running in the background.
- Core Selector: is used to choose a core as well as create data indexes for and search data in the core.

----End

## 1.21 Spark Development Guide

### 1.21.1 Overview

#### 1.21.1.1 Application Development Overview

##### Spark Introduction

Spark is a distributed batch processing system as well as an analysis and mining engine. It provides an iterative memory computation framework and supports the development in multiple programming languages, including Scala, Java, and Python. The application scenarios of Spark include:

- Data processing: Spark can process data quickly and has fault tolerance and scalability.

- Iterative computation: Spark supports iterative computation to meet the requirements of multi-step data processing logic.
- Data mining: Based on massive data, Spark can handle complex data mining and analysis and support multiple data mining and machine learning algorithms.
- Streaming processing: Spark supports stream processing at a seconds-level delay and supports multiple external data sources.
- Query analysis: Spark supports standard SQL query analysis, provides the DSL (DataFrame), and supports multiple external inputs.

This section focuses on the application development guides of Spark, Spark SQL and Spark Streaming.

## Spark Development API Introduction

Spark supports the development in multiple programming languages, including Scala, Java, and Python. Since Spark is developed in Scala and Scala is easy to read, users are advised to develop Spark application in Scala.

Divided by different languages, the APIs of Spark are listed in [Table 1-172](#).

**Table 1-172** Spark APIs

Function	Description
Scala API	Indicates the API in Scala. For common APIs of Spark Core, Spark SQL and Spark Streaming, see <a href="#">Scala</a> . Since Scala is easy to read, users are advised to use Scala APIs in the program development.
Java API	Indicates the API in Java. For common APIs of Spark Core, Spark SQL and Spark Streaming, see <a href="#">Java</a> .
Python API	Indicates the API in Python. For common APIs of Spark Core, Spark SQL and Spark Streaming, see <a href="#">Python</a> .

Divided by different modes, APIs listed in the preceding table are used in the development of Spark Core and Spark Streaming. Spark SQL supports CLI and JDBCServer for accessing. There are two ways to access the JDBCServer: Beeline and the JDBC client code. For details, see [JDBCServer Interface](#).

### NOTE

For spark-sql, spark-shell and spark-submit (which application contains SQL operations), do not use the **proxy user** parameter to submit a task. This is partly because the spark-sql script with the **proxy user** parameter does not support task submission and partly because the sample program mentioned in this document already contains security authentication.

### 1.21.1.2 Basic Concepts

#### Basic Concepts

- **RDD**

Resilient Distributed Dataset (RDD) is a core concept of Spark. It indicates a read-only and partitioned distributed dataset. Partial or all data of this dataset can be cached in the memory and reused between computations.

##### RDD Generation

- An RDD can be generated from the Hadoop file system or other storage systems that are compatible with Hadoop, such as Hadoop Distributed File System (HDFS).
- A new RDD can be transferred from a parent RDD.
- An RDD can be converted from a collection.

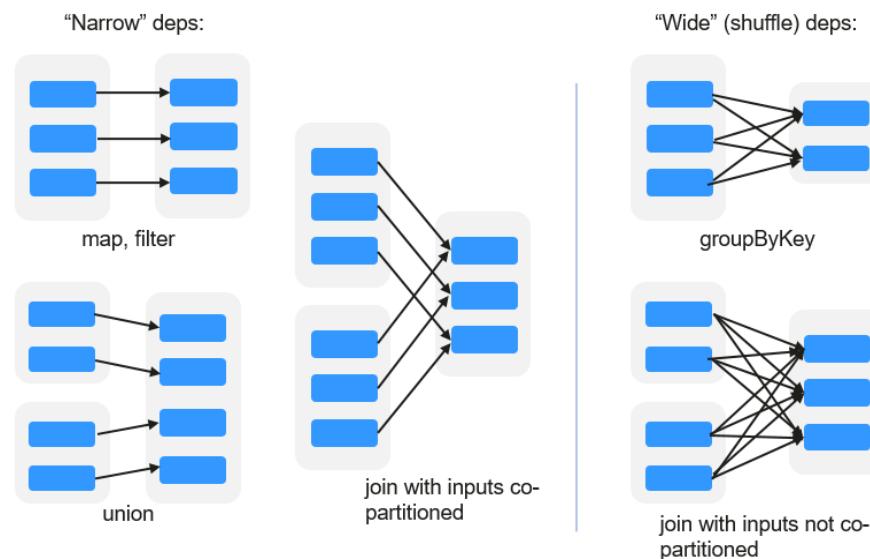

##### RDD Storage

- Users can select different storage levels to store an RDD for reuse. (There are 11 storage levels to store an RDD.)
- The current RDD is stored in the memory by default. When the memory is insufficient, the RDD overflows to the disk.

- **RDD Dependency**

The RDD dependency includes the narrow dependency and wide dependency.

**Figure 1-261** RDD dependency

- **Narrow dependency:** Each partition of the parent RDD is used by at most one partition of the child RDD partition.
- **Wide dependency:** Partitions of the child RDD depend on all partitions of the parent RDD due to shuffle operations.

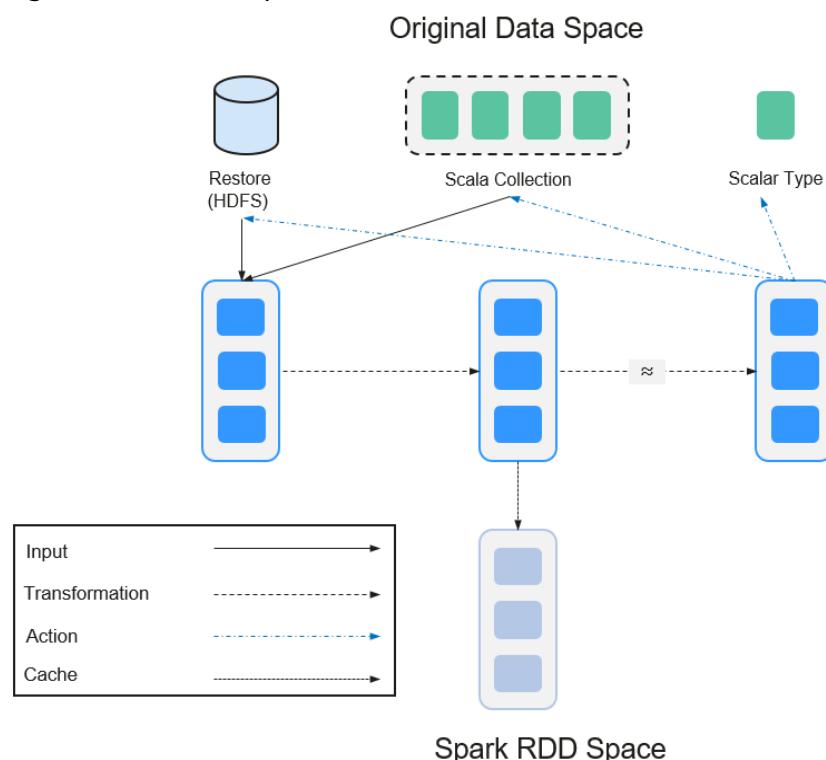

The narrow dependency facilitates the optimization. Logically, each RDD operator is a fork/join process. Fork the RDD to each partition, and then perform the computation. After the computation, join the results, and then

perform the fork/join operation on next operator. It takes a long period of time to directly translate the RDD to physical implementation. There are two reasons: Each RDD (even the intermediate results) must be physicalized to the memory or storage, which takes time and space; the partitions can be joined only when the computation of all partitions is complete (if the computation of a partition is slow, the entire join process is slowed down). If the partitions of the child RDD narrowly depend on the partitions of the parent RDD, the two fork/join processes can be combined to optimize the entire process. If the relationship in the continuous operator sequence is narrow dependency, multiple fork/join processes can be combined to reduce the time for waiting and improve the performance. This is called pipeline optimization in Spark.

- **Transformation and Action (RDD Operations)**

Operations on RDD include transformation (the returned value is an RDD) and action (the returned value is not an RDD). [Figure 1-262](#) shows the process. The transformation is lazy, which indicates that the transformation from one RDD to another RDD is not immediately executed. Spark only records the transformation but does not execute it immediately. The real computation is started only when the action is started. The action returns results or writes the RDD data into the storage system. The action is the driving force for Spark to start the computation.

**Figure 1-262** RDD operation

The data and operation model of RDD are quite different from those of Scala.

```
val file = sc.textFile("hdfs://...")  
val errors = file.filter(_.contains("ERROR"))  
errors.cache()  
errors.count()
```

- a. The **textFile** operator reads log files from HDFS and returns **file** (as an RDD).

- b. The filter operator filters rows with ERROR and assigns them to errors (a new RDD). The filter operator is a transformation.
- c. The cache operator caches errors for future use.
- d. The count operator returns the number of rows of errors. The count operator is an action.

**Transformation includes the following types:**

- The RDD elements are regarded as simple elements:

The input and output have the one-to-one relationship, and the partition structure of the result RDD remains unchanged, for example, map.

The input and output have the one-to-many relationship, and the partition structure of the result RDD remains unchanged, for example, flatMap (one element becomes a sequence containing multiple elements and then flattens to multiple elements).

The input and output have the one-to-one relationship, but the partition structure of the result RDD changes, for example, union (two RDDs integrates to one RDD, and the number of partitions becomes the sum of the number of partitions of two RDDs) and coalesce (partitions are reduced).

Operators of some elements are selected from the input, such as filter, distinct (duplicate elements are deleted), subtract (elements only exist in this RDD are retained), and sample (samples are taken).

- The RDD elements are regarded as Key-Value pairs.

Perform the one-to-one calculation on the single RDD, such as mapValues (the partition mode of the source RDD is retained, which is different from map).

Sort the single RDD, such as sort and partitionBy (partitioning with consistency, which is important to the local optimization).

Restructure and reduce the single RDD based on key, such as groupByKey and reduceByKey.

Join and restructure two RDDs based on key, such as join and cogroup.

 **NOTE**

The later three operations involve sorting and are called shuffle operations.

**Action is classified into the following types:**

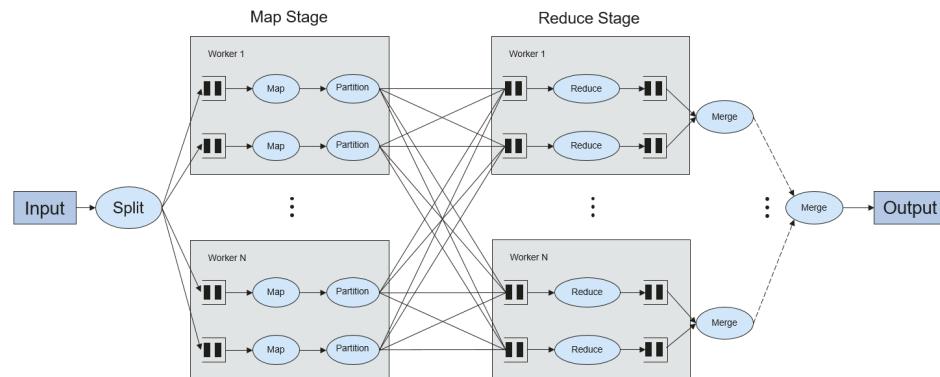

- Generate scalar configuration items, such as count (the number of elements in the returned RDD), reduce, fold/aggregate (the number of scalar configuration items that are returned), and take (the number of elements before the return).
- Generate the Scala collection, such as collect (import all elements in the RDD to the Scala collection) and lookup (look up all values corresponds to the key).
- Write data to the storage, such as saveAsTextFile (which corresponds to the preceding textFile).
- Check points, such as checkpoint. When Lineage is long (which occurs frequently in graphics computation), it takes a long period of time to execute the whole sequence again when a fault occurs. In this case, checkpoint is used as the check point to write the current data to stable storage.

- **Shuffle**

Shuffle is a specific phase in the MapReduce framework, which is located between the Map phase and the Reduce phase. If the output results of Map are to be used by Reduce, each output result must be hashed based on the key and distributed to the corresponding Reducer. This process is called Shuffle. Shuffle involves the read and write of the disk and the transmission of the network, so that the performance of Shuffle directly affects the operation efficiency of the entire program.

The following figure describes the entire process of the MapReduce algorithm.

**Figure 1-263** Algorithm process

Shuffle is a bridge connecting data. The following describes the implementation of shuffle in Spark.

Shuffle divides the Job of a Spark into multiple stages. The former stages contain one or multiple ShuffleMapTasks, and the last stage contains one or multiple ResultTasks.

- **Spark Application Structure**

The Spark application structure includes the initial `SparkContext` and the main program.

- Initial `SparkContext`: constructs the operation environment of the Spark application.

Constructs the `SparkContext` object. For example:

```
new SparkContext(master, appName, [SparkHome], [jars])
```

Parameter description

**master**: indicates the link string. The link modes include local, YARN-cluster, and YARN-client.

**appName**: indicates the application name.

**SparkHome**: indicates the directory where Spark is installed in the cluster.

**jars**: indicates the code and dependency package of the application.

- Main program: processes data.

For submitting applications details, see <https://spark.apache.org/docs/3.3.1/submitting-applications.html>.

- **Spark Shell Command**

The basic Spark shell command supports the submitting of the Spark application. The Spark shell command is

```
./bin/spark-submit \  
  --class <main-class> \  
  --master <master-url> \  
  ... # other options  
  <application-jar> \  
  [application-arguments]
```

Parameter description:

--class: indicates the name of the class of the Spark application.

--master: indicates the master that the Spark application links, such as YARN-client and YARN-cluster.

application-jar: indicates the path of the jar package of the Spark application.

application-arguments: indicates the parameter required to submit the Spark application. (This parameter can be empty.)

- **Spark JobHistory Server**

The Spark web UI is used to monitor the details in each phase of the Spark framework of a running or historical Spark job and provide the log display, which helps users to develop, configure, and optimize the job in more fine-grained units.

## Spark SQL Basic Concepts

### DataSet

A DataSet is a strongly typed collection of domain-specific objects that can be transformed in parallel using functional or relational operations. Each Dataset also has an untyped view called a DataFrame, which is a Dataset of Row.

DataFrame is a structured distributed data set composed of several columns, which is similar to a table in the relationship database or the data frame in R/Python. DataFrame is a basic concept in Spark SQL, and can be created by using multiple methods, such as structured data set, Hive table, external database, or RDD.

## Spark Streaming Basic Concepts

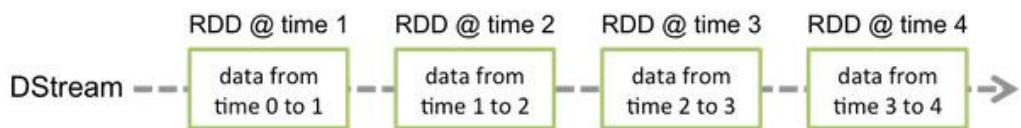

### DStream

DStream (Discretized Stream) is an abstract concept provided by the Spark Streaming.

DStream is a continuous data stream which is obtained from the data source or transformed and generated by the inflow. In essence, a DStream is a series of continuous RDDs. The RDD is a distributed dataset which can be read only and divided into partitions.

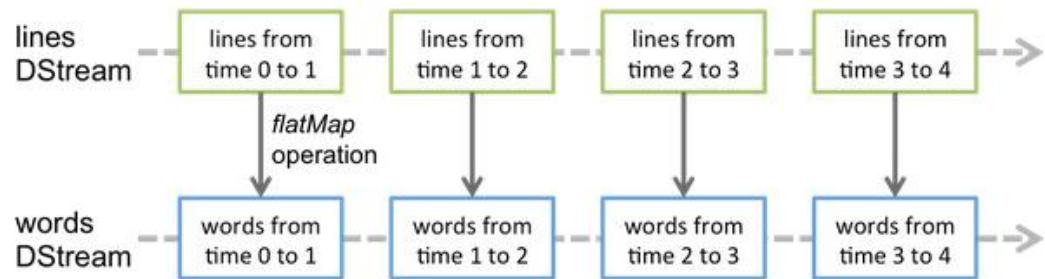

Each RDD in DStream contains the data of a partition as shown in [Figure 1-264](#).

**Figure 1-264** Relationship between DStream and RDD

All operators applied in the DStream are translated to the operations in the lower RDD, as shown in [Figure 1-265](#). The transformation of the lower RDDs is calculated by using the Spark engine. Most operation details are concealed in DStream operators and High-level APIs are provided for developers.

**Figure 1-265** DStream operator transfer

## Structured Streaming Basic Concepts

- **Input Source**

Input data sources. Data sources must support data replay based on the offset. Different data sources have different fault tolerance capabilities.

- **Sink**

Data output. Sink must support idempotence write operations. Different Sinks have different fault tolerance capabilities.

- **outputMode**

Result output mode, which can be:

- Complete Mode: The entire updated result table will be written to the external storage. It is up to the storage connector to decide how to handle writing of the entire table.
- Append Mode: If an interval is triggered, only the new rows appended in the Result Table will be written into an external system. This mode is applicable only to a result set that has already existed and will not be updated.
- Update Mode: If an interval is triggered, only updated data in the result table will be written into an external system, which is the difference between the Complete Mode and Update Mode.

- **Trigger**

Output trigger. Currently, the following trigger types are supported:

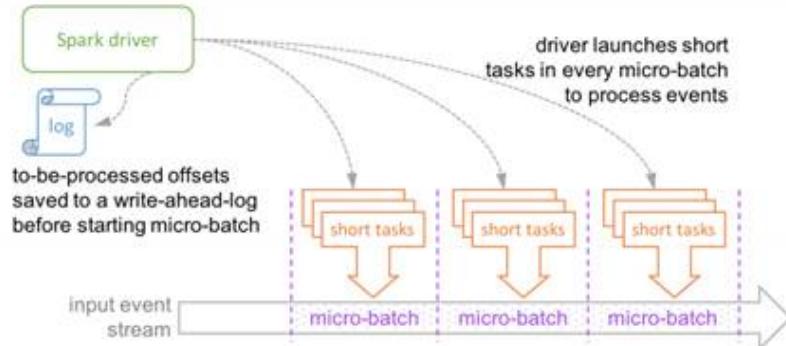

- Default: Micro-batch mode. After a batch is complete, the next batch is automatically executed.
- Specific interval: Processing is performed at a specific interval.
- One-time execution: Query is performed only once.
- Continuous mode: This is an experimental feature. In this mode, the stream processing delay can be decreased to 1 ms.

Structured Streaming supports the micro-batch mode and continuous mode. The micro-batch mode cannot ensure low-delay but has a larger throughput within the same time. The continuous mode is suitable for data processing requiring millisecond-level delay, which is an experimental feature.

 NOTE

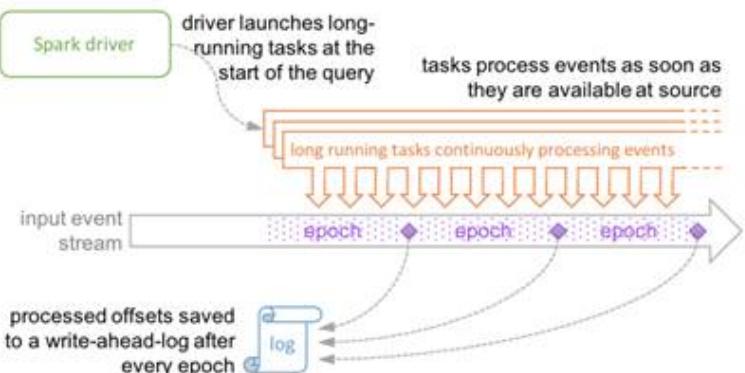

In the current version, if the stream-to-batch joins function is required, **outputMode** must be set to **Append Mode**.

**Figure 1-266** Running process in micro-batch mode

Micro-batch Processing uses periodic tasks to process events

**Figure 1-267** Running process in continuous mode

Continuous Processing uses long-running tasks to continuously process events

### 1.21.1.3 Development Process

#### Development Process of a Spark Application

Spark includes Spark Core, Spark SQL and Spark Streaming, whose development processes are the same.

[Figure 1-268](#) and [Table 1-173](#) describe the stages in the development process.

Figure 1-268 Spark development process

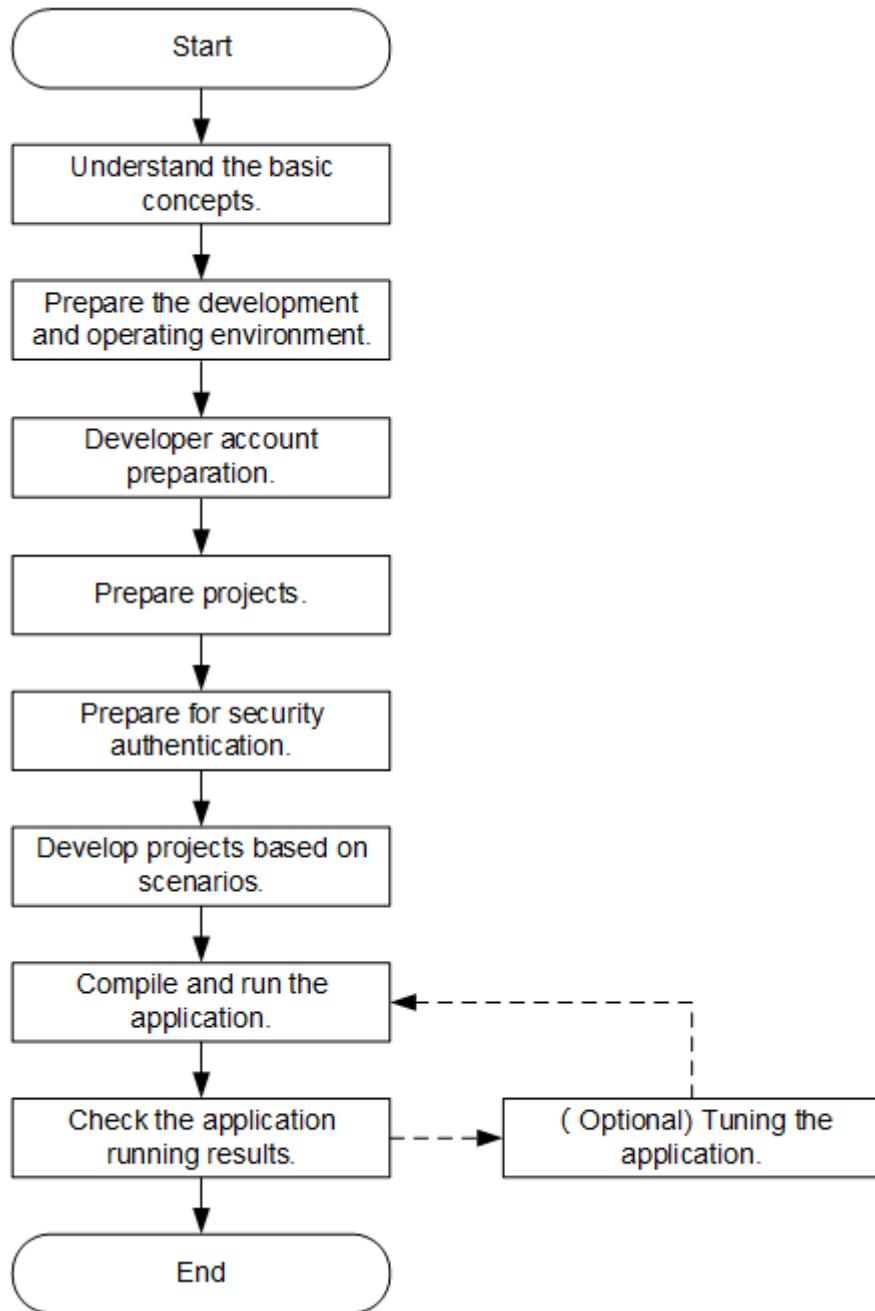

Table 1-173 Description of Spark development process

Stage	Description	Reference
Understand the basic concepts.	Before the application development, the basic concepts of Spark are required to be understood. Choose the concepts required to be understood based on the actual scenario. The basic concepts include the basic concept of Spark Core, basic concept of Spark SQL and basic concept of Spark Streaming.	<a href="#">Basic Concepts</a>

Stage	Description	Reference
Prepare the development and operating environment.	The Spark application is developed in Scala, Java, and Python. The IDEA tool is recommended to prepare development environments in different languages based on the reference. The running environment of Spark is the Spark client. Install and configure the client based on the reference.	<a href="#">Preparing for Development and Operating Environment</a>
Prepare a developer account.	The development account is used to run the sample project. Only the developer user with permission to access HDFS, YARN, Kafka, and Hive is allowed to run Spark sample projects.	<a href="#">Preparing a Developer Account</a>
Prepare projects.	Spark provides sample projects in various scenarios. Sample projects can be imported for studying. Or you can create a new Spark project based on the reference.	<a href="#">Configuring and Importing Sample Projects</a> <a href="#">Creating a New Project (Optional)</a>
Prepare for safety authentication.	If a safe cluster is used, the safety authentication must be performed.	<a href="#">Preparing for Security Authentication</a>
Develop projects based on scenarios	Sample projects in different languages including Scala, Java, and Python are provided. Sample projects in different scenarios including Streaming, SQL, JDBC client program, and Spark on HBase are also provided.  This helps users to better understand the programming interfaces of all Spark components quickly.	<a href="#">Developing the Project</a>
Compile and run the application.	Users compile the developed application and deliver it for running based on the reference.	<a href="#">Compiling and Running the Application</a>
Check the application running results.	Application running results are stored in the directory specified by users. Users can also check the running results through the UI.	<a href="#">Checking the Commissioning Result</a>

Stage	Description	Reference
Tune the application.	<p>Based on the application running results, tune the application to meet the requirements of the service scenario.</p> <p>After application tuning, compile and run the application again.</p>	"Component Operation Guide" > "Using Spark" > "Spark Performance Tuning" in <i>MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)</i> in the <i>MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)</i> .

## 1.21.2 Preparing for the Environment

### 1.21.2.1 Preparing for Development and Operating Environment

- Spark applications can be developed in Scala, Java, and Python. [Table 1-174](#) describes the development and operating environment to be prepared.

**Table 1-174** Development environment

Preparation Item	Description
OS	<ul style="list-style-type: none"><li>Development environment: Windows OS. Windows 7 or later is supported.</li><li>Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the runtime environment must be able to communicate with the cluster service plane network.</li></ul>

Preparation Item	Description
JDK installation	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>Oracle JDK 1.8</li><li>IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>For security purposes, the server supports only TLS V1.2 or later.</li><li>By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls</a>.</li><li>For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>It is a tool used to develop Spark applications. Version 2019.1 or other compatible versions are recommended.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>
Installation of Maven	Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development.
Scala installation	It is the basic configuration for the Scala development environment. The required version is 2.12.14.

Preparation Item	Description
Scala plug-in installation	It is the basic configuration for the Scala development environment. The required version is 2018.2.11 or other compatible versions.
Editra installation	Editra is an editor in the Python development environment and is used to compile Python programs. You can also use other IDEs for Python programming.
Developer account preparation	See <a href="#">Preparing a Developer Account</a> for configuration.
7-zip	Used to decompress .zip and .rar packages. The 7-Zip 16.04 is supported.
Python installation	Its version must be 3.7 or later.

## Preparing a Runtime Environment

During application development, you need to prepare the environment for code running and commissioning to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. **Accessing FusionInsight Manager of an MRS Cluster** In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Configuration Files Only**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain the **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** file, and then decompress it to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles** directory on the local PC. The directory name cannot contain spaces.

  - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles\Spark\config** and manually import the configuration file to the configuration file directory (usually the **resources** folder) of the Spark sample project.

The keytab file obtained during the operation of [Preparing a Developer Account](#) is also stored in this directory. **Table 1-175** describes the main configuration files.

**Table 1-175 Configuration files**

File	Function
carbon.properties	CarbonData configuration file
core-site.xml	Configures HDFS parameters.
hdfs-site.xml	Configures HDFS parameters.
hbase-site.xml	Configures HBase parameters.
hive-site.xml	Configures Hive parameters.
jaas-zk.conf	Java authentication configuration file
log4j-executor.properties	executor log configuration file
mapred-site.xml	Hadoop mapreduce configuration file
ranger-spark-audit.xml	Ranger audit log configuration file
ranger-spark-security.xml	Ranger permission management configuration file
yarn-site.xml	Configures Yarn parameters.
spark-defaults.conf	Configures Spark parameters.
spark-env.sh	Spark environment variable configuration file
user.keytab	Provides HDFS user information for Kerberos security authentication.
krb5.conf	Provides Kerberos server configuration information.

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 **NOTE**

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
  - The local **hosts** file in a Windows environment is stored in, for example, C:\WINDOWS\system32\drivers\etc\hosts.
- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
    - a. Install the client in a directory, for example, /opt/hadoopclient, on the node.

Ensure that the difference between the client time and the cluster time is less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).

- b. **Accessing FusionInsight Manager of an MRS Cluster.** Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the

**FusionInsight\_Cluster\_1\_Services\_ClientConfig/Spark/config** directory to the **conf** directory where the compiled JAR package is stored for subsequent commissioning, for example, **/opt/hadoopclient/conf**.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Spark/config/* root@/IP address of the client node:/opt/  
hadoopclient/conf
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. [Table 1-176](#) describes the main configuration files.

**Table 1-176** Configuration files

File	Function
carbon.properties	CarbonData configuration file
core-site.xml	Configures HDFS parameters.
hdfs-site.xml	Configures HDFS parameters.
hbase-site.xml	Configures HBase parameters.
hive-site.xml	Configures Hive parameters.
jaas-zk.conf	Java authentication configuration file
log4j-executor.properties	executor log configuration file
mapred-site.xml	Hadoop mapreduce configuration file
ranger-spark-audit.xml	Ranger audit log configuration file
ranger-spark-security.xml	Ranger permission management configuration file
yarn-site.xml	Configures Yarn parameters.
spark-defaults.conf	Configures Spark parameters.

File	Function
spark-env.sh	Spark environment variable configuration file
user.keytab	Provides HDFS user information for Kerberos security authentication.
krb5.conf	Provides Kerberos server configuration information.

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

### 1.21.2.2 Configuring and Importing Sample Projects

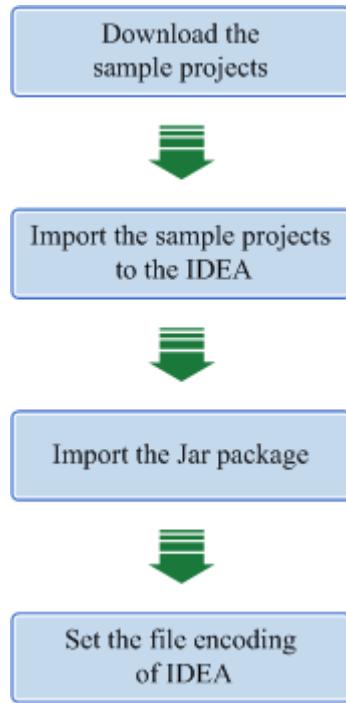

#### Scenario

Spark provides sample projects for multiple scenarios, including Java projects and Scala projects. This helps users to learn Spark projects quickly.

Import methods of Java and Scala projects are the same. Sample projects developed by using the Python do not need to be imported, and you only need to open the Python file (\*.py).

The import of Java sample codes is used as a sample in the following procedure. [Figure 1-269](#) shows the procedure if importing sample projects.

Figure 1-269 Procedure of importing sample projects

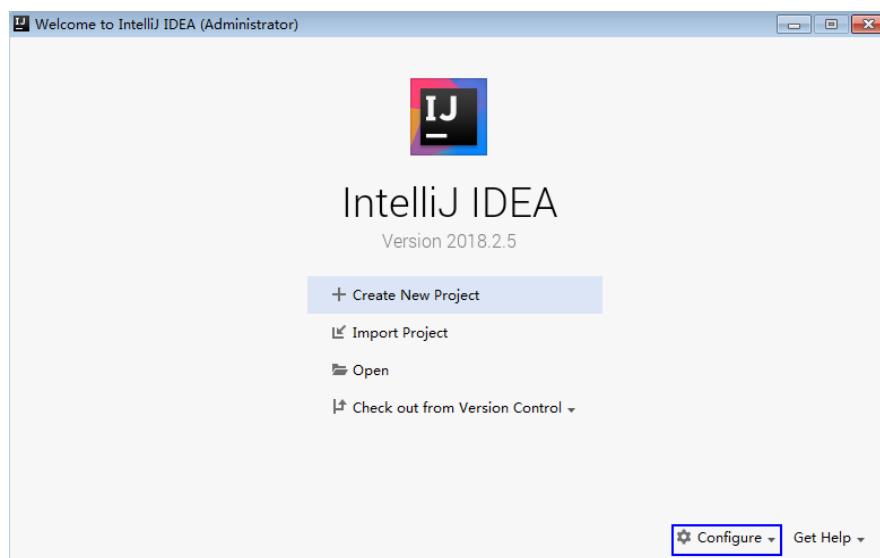

## Procedure

**Step 1** Obtain multiple sample projects such as Scala and Spark Streaming in the **sparksecurity-examples** folder in the **spark-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** After the IntelliJ IDEA and JDK are installed, configure the JDK in IntelliJ IDEA.

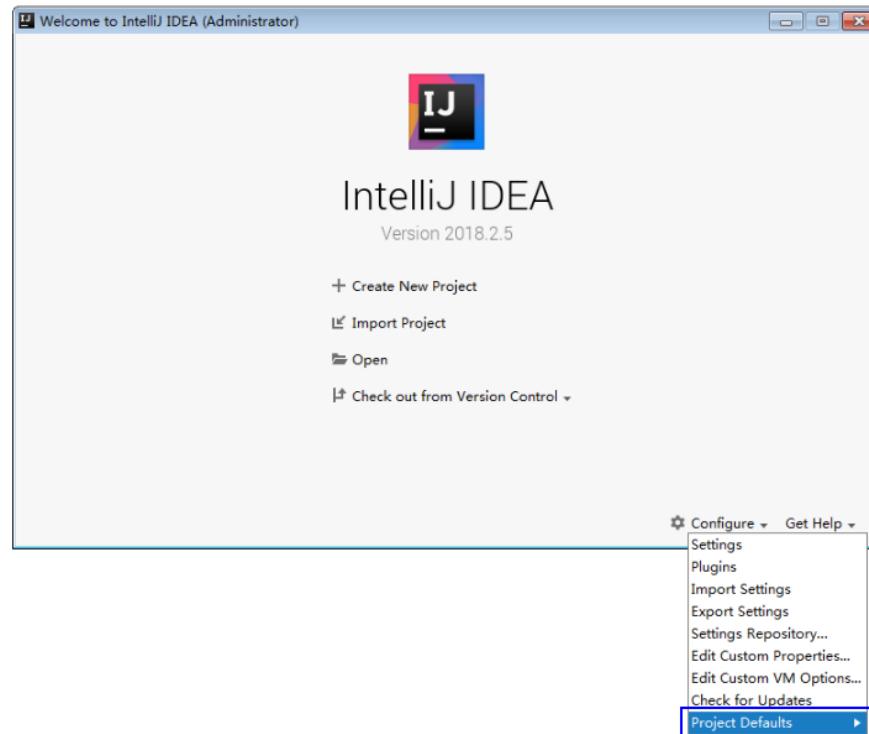

1. Start the IntelliJ IDEA and select **Configure**.

Figure 1-270 Quick Start

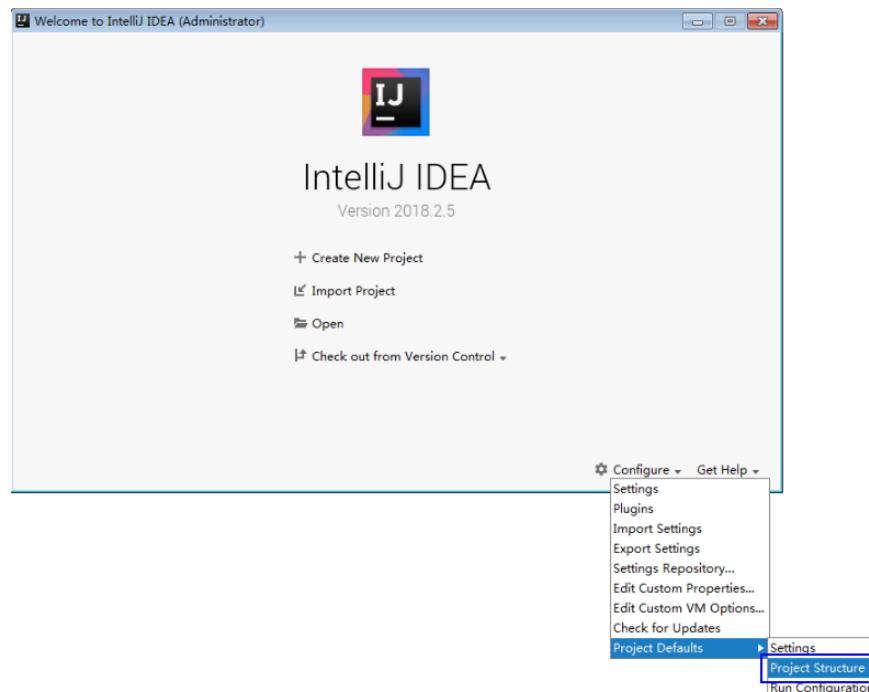

2. Select **Project Defaults** from the **Configure** drop-down list.

Figure 1-271 Configure

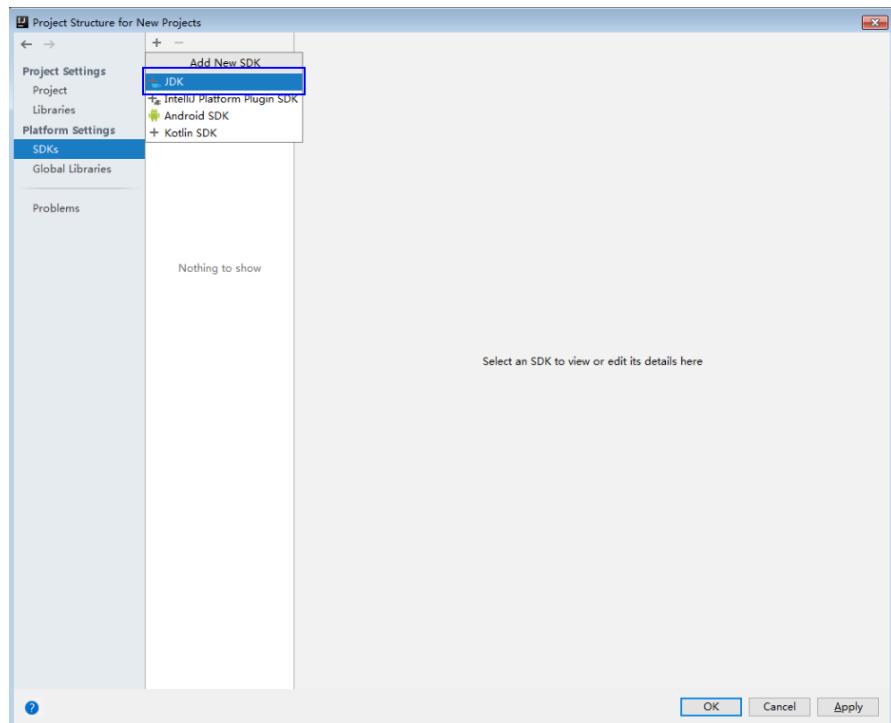

3. Select **Project Structure** from **Project Defaults**.

Figure 1-272 Project Defaults

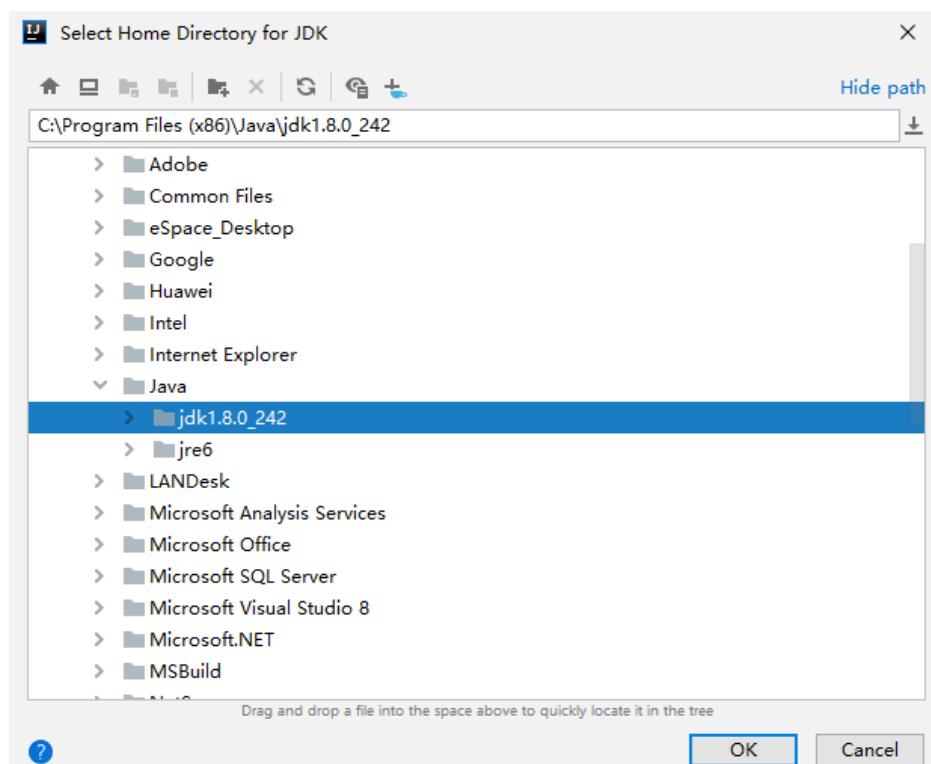

4. On the displayed **Project Structure** page, select **SDKs** and click the plus sign to add the JDK.

Figure 1-273 Adding the JDK

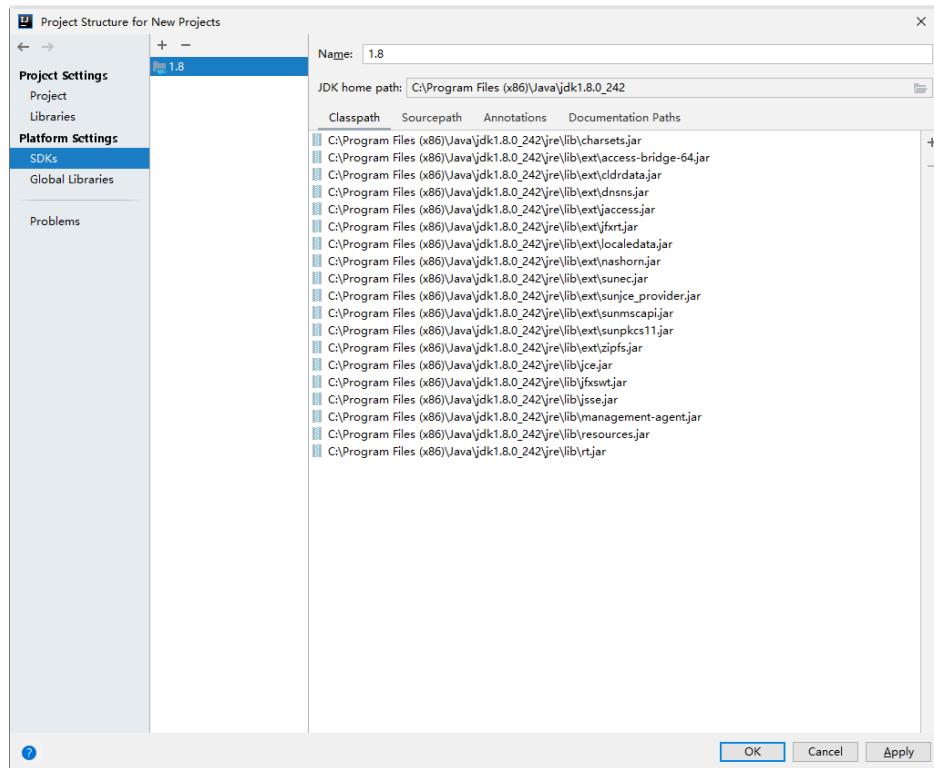

5. In the displayed **Select Home Directory for JDK** window, select a home directory for JDK and click **OK**.

Figure 1-274 Selecting a home directory for the JDK

6. After selecting the JDK, click **OK** to complete the configuration.

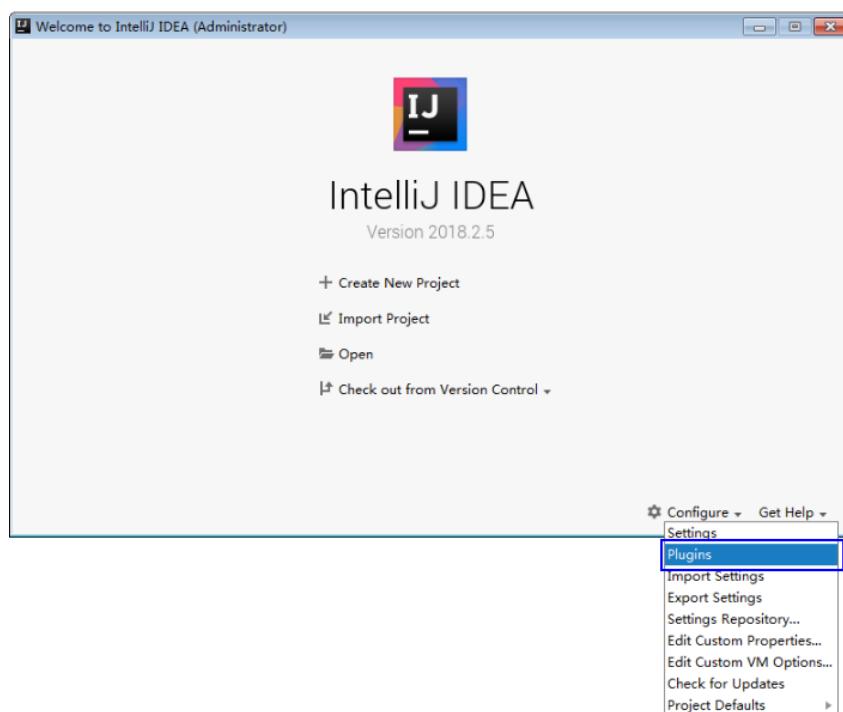

Figure 1-275 Completing the configuration

**Step 3** (Optional) If the Scala development environment is used, install the Scala plug-in in IntelliJ IDEA.

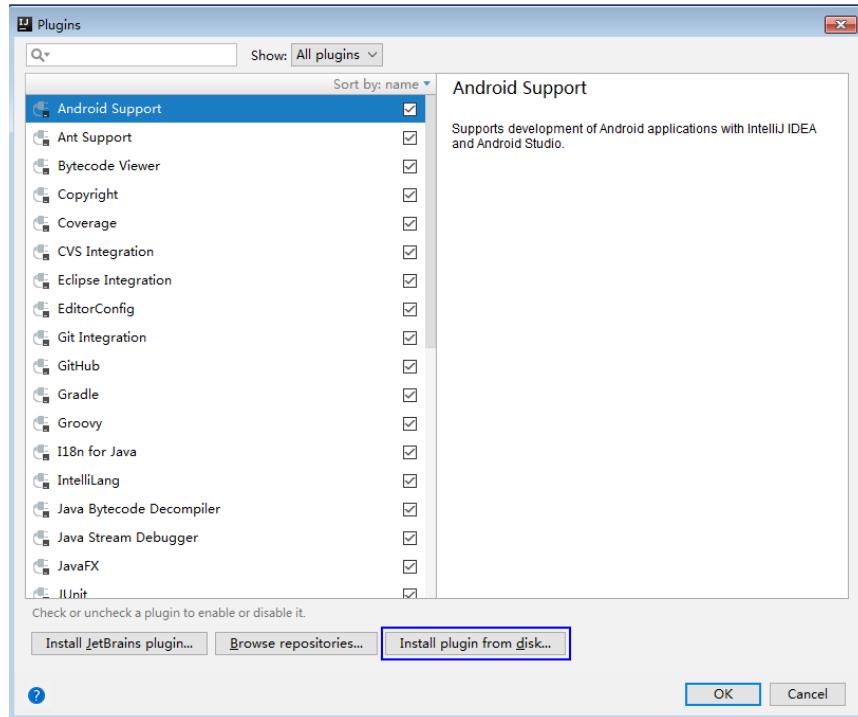

1. Select **Plugins** from the **Configure** drop-down list.

Figure 1-276 Plugins

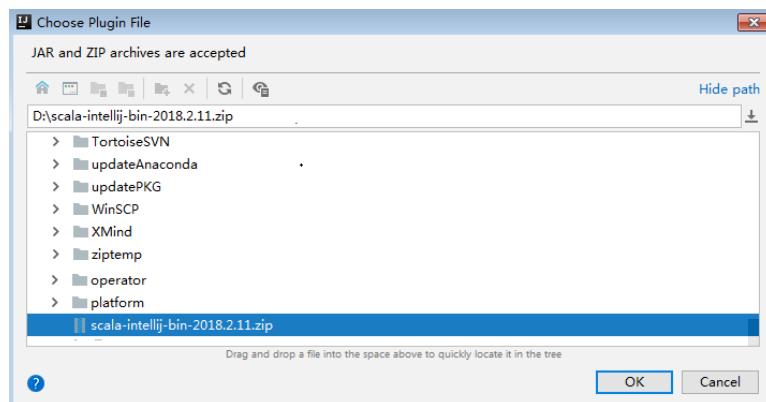

2. On the **Plugins** page, select **Install plugin from disk**.

**Figure 1-277** Install plugin from disk

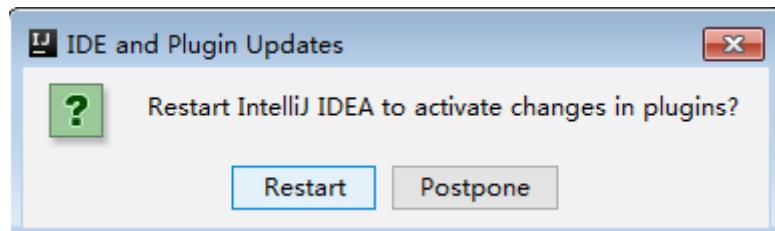

3. On the **Choose Plugin File** page, select the Scala plugin file of the corresponding version and click **OK**.

4. On the **Plugins** page, click **Apply** to install the Scala plugin.
5. On the displayed **Plugins Changed** page, click **Restart** for the configuration to take effect.

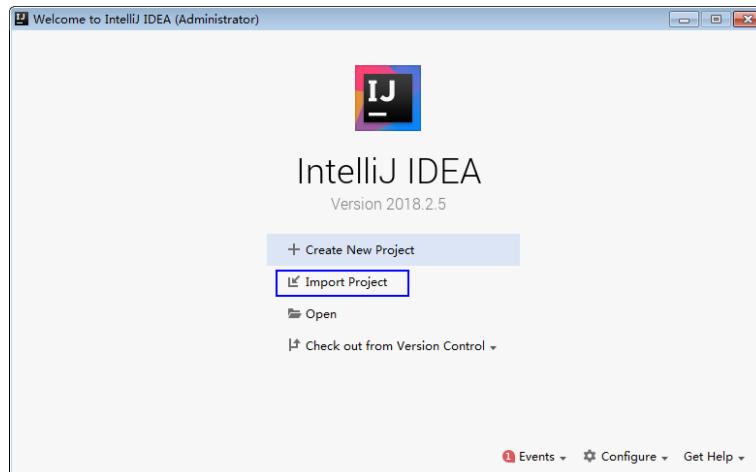

**Figure 1-278** Plugins Changed

**Step 4** Import the Java sample projects to the IDEA.

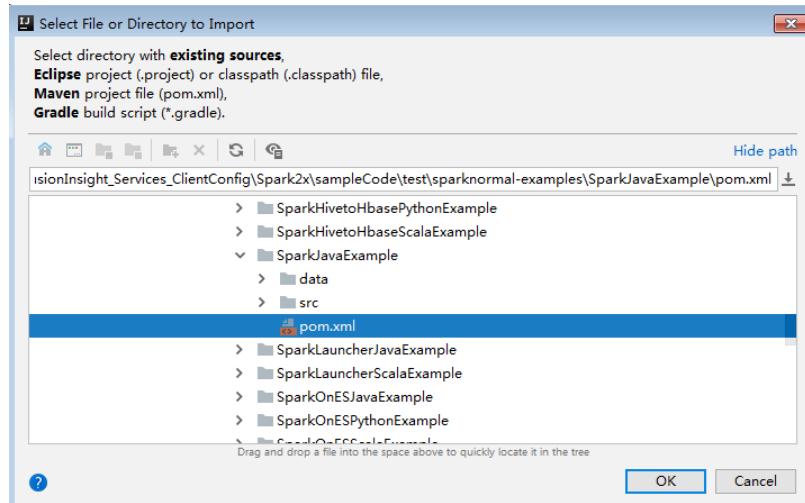

1. Start the IntelliJ IDEA. On the **Quick Start** page, select **Import Project**.  
Or, for the used IDEA tool, add projects directly from the IDEA homepage.  
Select **File > Import project...** to import projects.

**Figure 1-279** Import Project (on the Quick Start page)

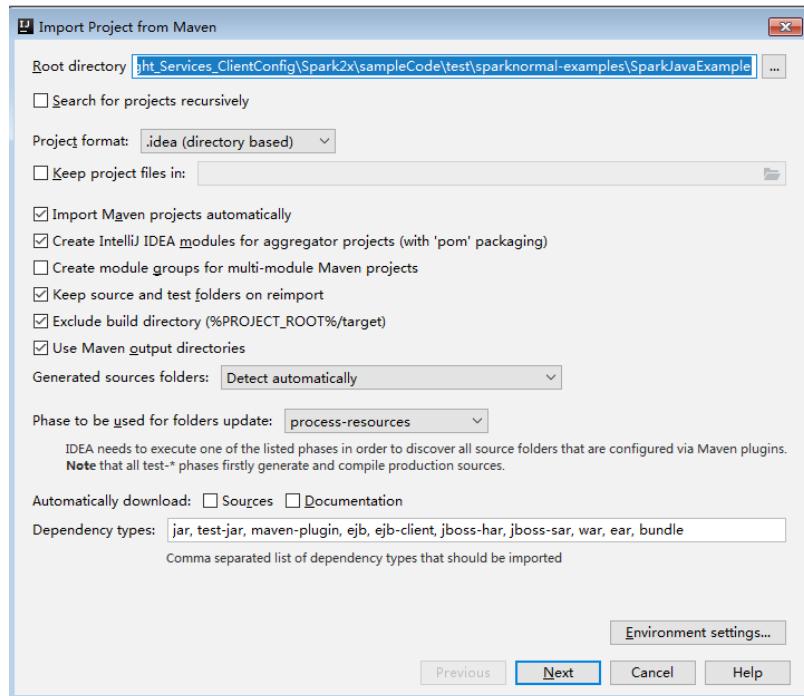

2. Select the directory to store the imported projects and the pom file, and click **OK**.

**Figure 1-280** Select File or Directory to Import

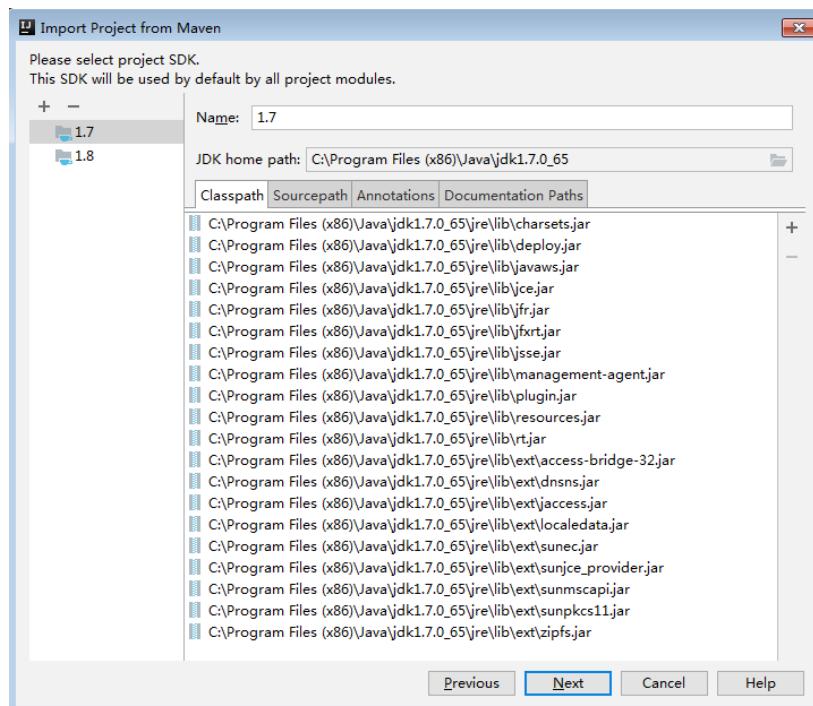

3. Confirm the import directory and project name, and click **Next**.

Figure 1-281 Import Project from Maven

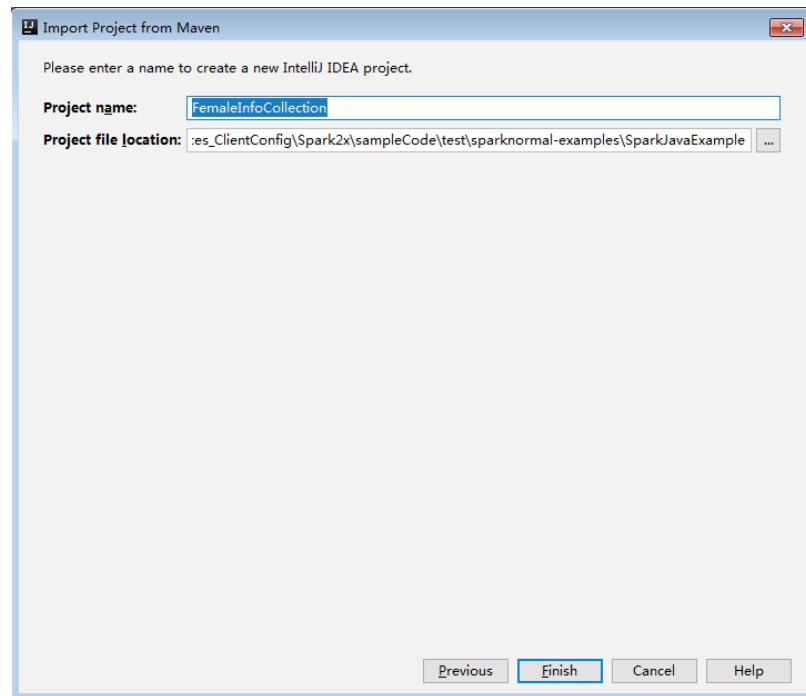

4. Select the projects to import and click **Next**.
5. Confirm the project JDK and click **Next**.

Figure 1-282 Select project SDK

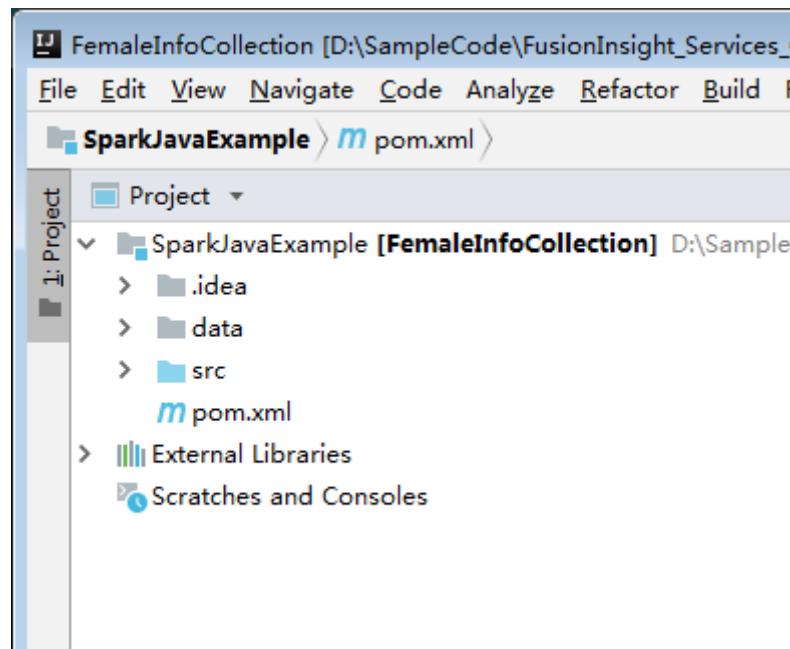

6. Confirm the project name and project file location, and click **Finish** to complete the import.

Figure 1-283 Confirm the project name and file location

- After the import, the imported projects are displayed on the IDEA homepage.

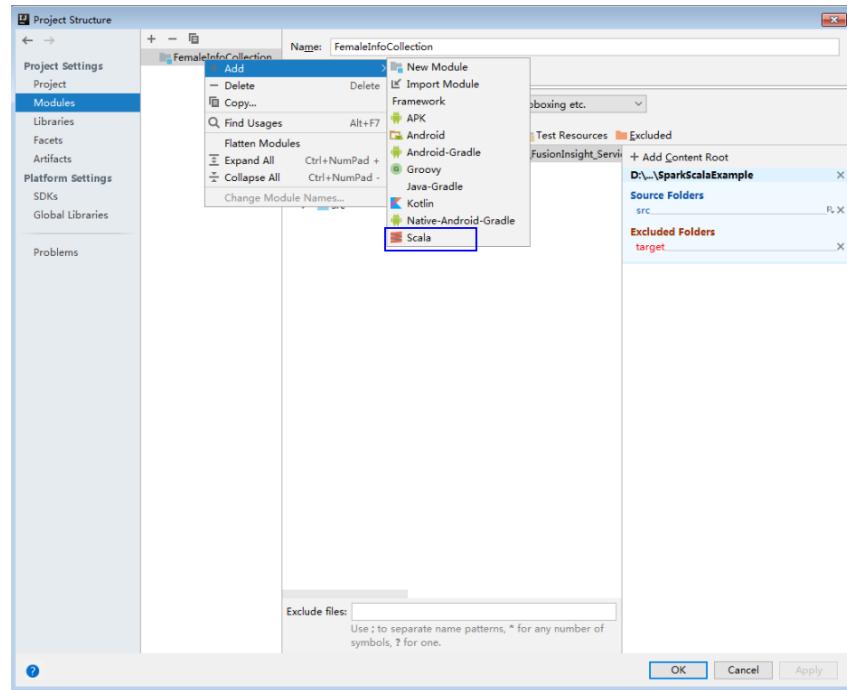

Figure 1-284 Imported projects

**Step 5** (Optional) If a sample application developed in Scala is imported, configure the language for the project.

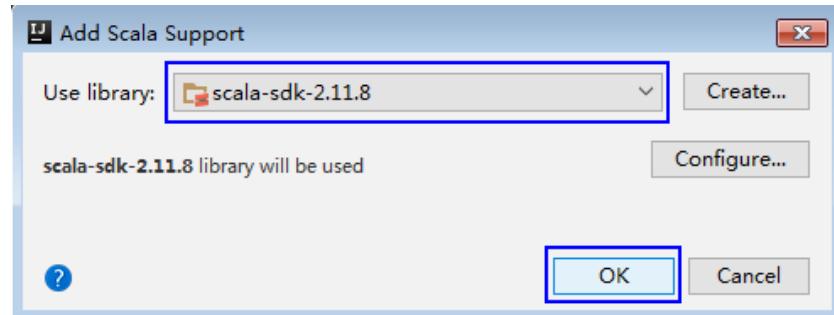

- On the main page of the IDEA, choose **File > Project Structures...** to access the **Project Structure** page.
- Choose **Modules**, right-click the project name, and choose **Add > Scala**.

Figure 1-285 Selecting the Scala language

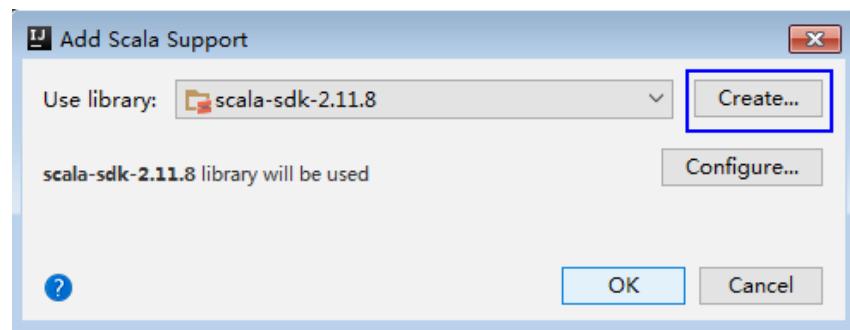

3. Wait until IDEA identifies Scala SDK, select the dependency JAR packages in the **Add Scala Support** dialog box, and then click **OK**

Figure 1-286 Add Scala Support

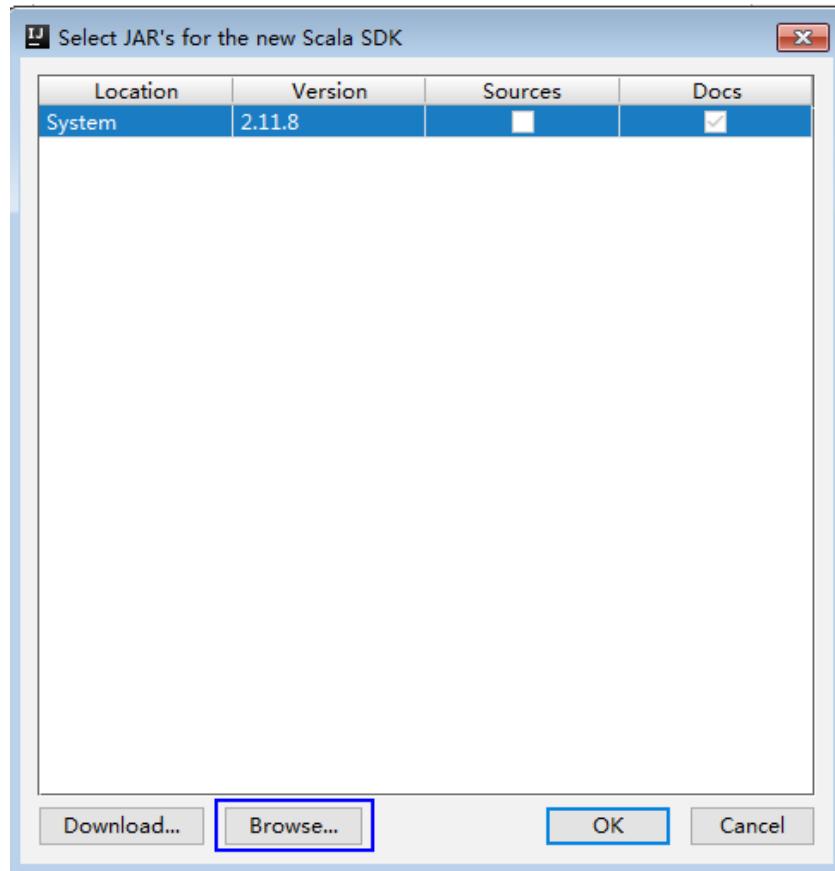

4. If IDEA fails to identify Scala SDK, you are required to create a Scala SDK.
  - a. Click **Create...**

Figure 1-287 Create...

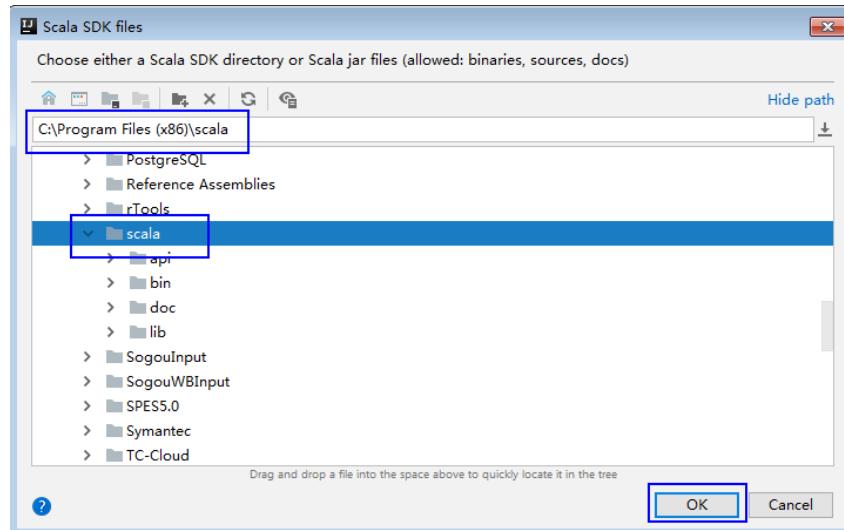

- b. On the **Select JAR's for the new Scala SDK** page, click **Browse...**

Figure 1-288 Select JAR's for the new Scala SDK

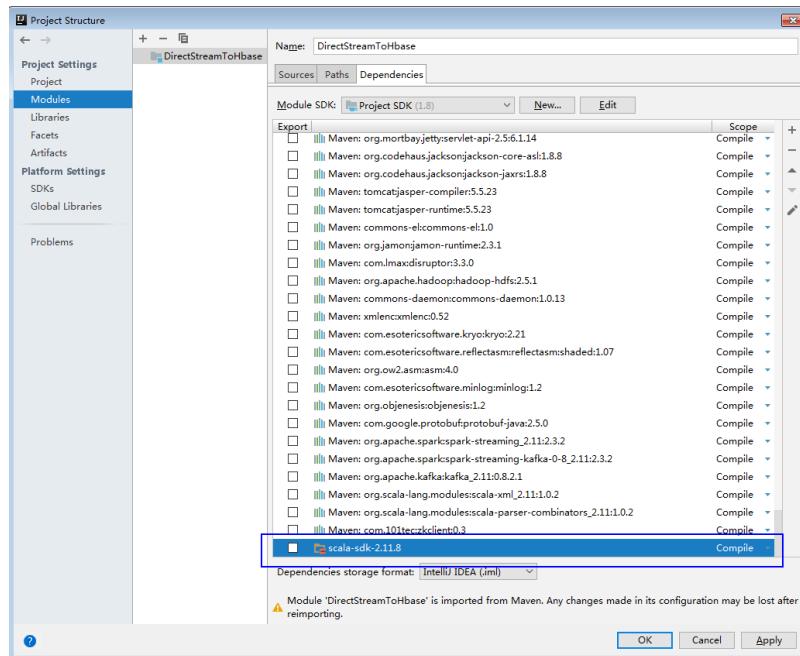

- c. On the **Scala SDK files** page, select the **scala sdk** directory, and then click **OK**.

Figure 1-289 Scala SDK files

5. Click **OK**.

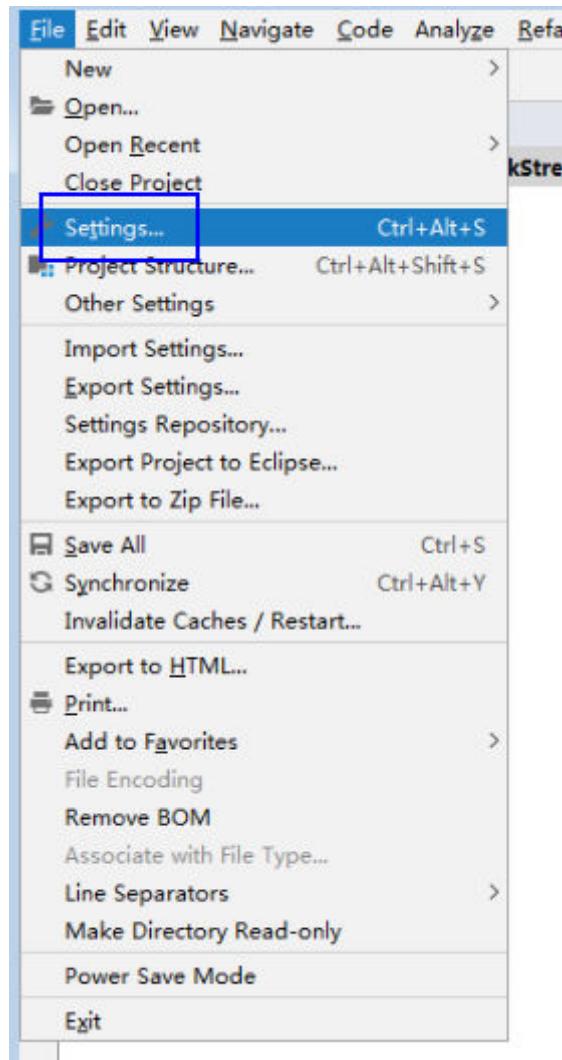

Figure 1-290 Successful configuration

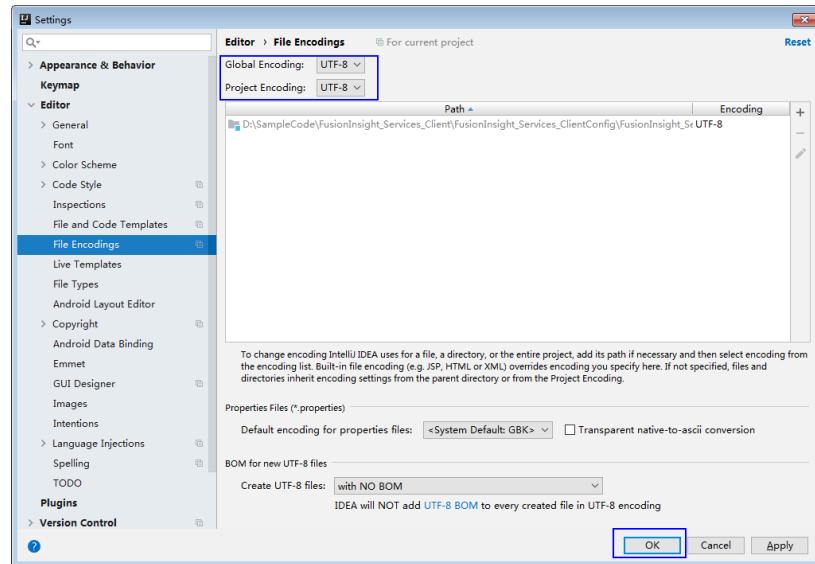

**Step 6** Set the file encoding of IDEA and solve the display of garble characters.

1. On the IDEA homepage, choose **File > Settings....**

Figure 1-291 Choosing Settings

2. Configure the encoding.
  - a. On the **Settings** page, choose **Editor > File Encodings**.
  - b. In the **Global Encoding** and **Project Encoding** drop-down lists, select **UTF-8**, respectively.
  - c. Click **Apply**.
  - d. Click **OK** to complete the encoding configuration.

----End

### 1.21.2.3 Creating a New Project (Optional)

#### Scenario

Besides importing Spark sample projects, the IDEA can be used to create a new Spark project. A Scala project is used as an example in the following steps.

#### Procedure

**Step 1** Start the IDEA and select **Create New Project**.

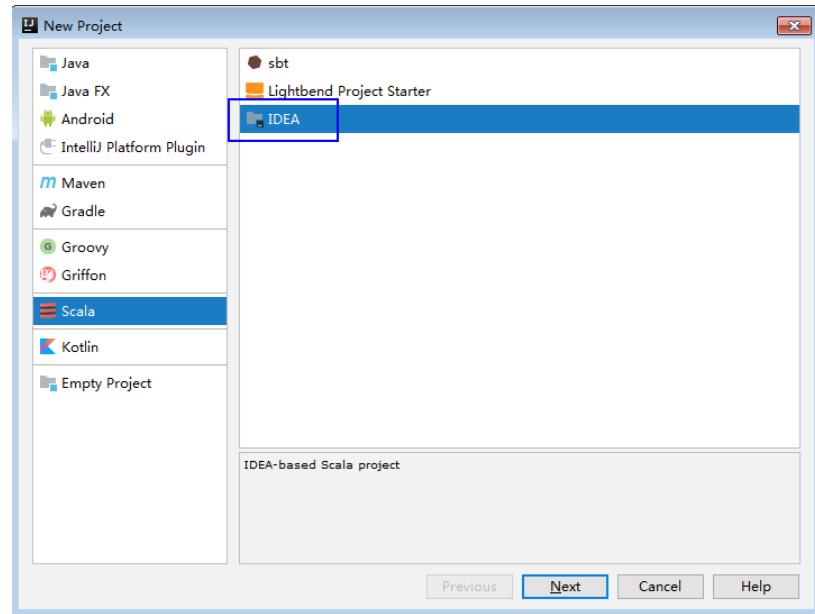

**Figure 1-292** Create a project

**Step 2** On the **New Project** page, select **Scala** as the development environment, select **IDEA**, and click **Next**.

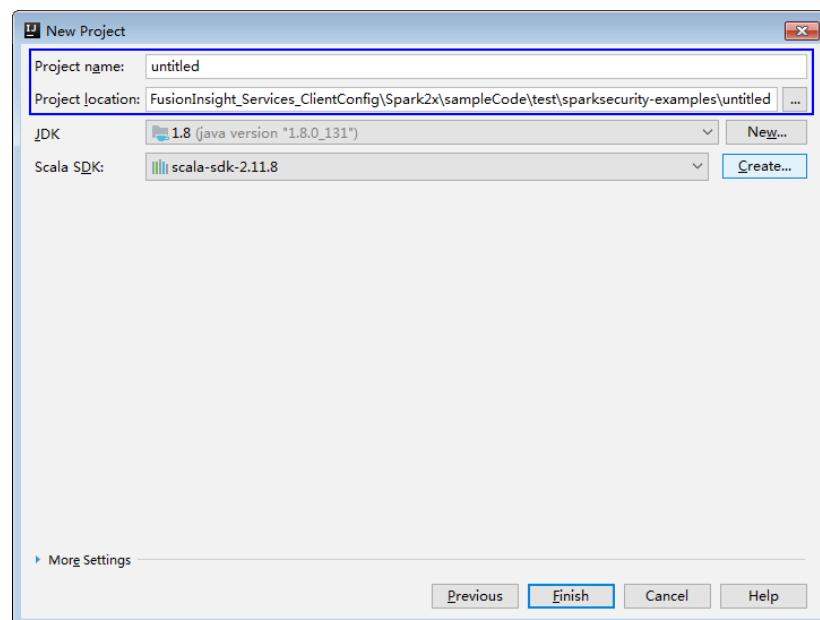

If a new project in Java is required, choose corresponding parameters.

**Figure 1-293** Select the development language

**Step 3** On the project information page, specify **Project name**, **Project location**, **Project JDK**, and **Scala SDK**, and click **Finish** to complete the project creation.

**Figure 1-294** Add the project information

----End

### 1.21.2.4 Preparing for Security Authentication

#### Scenario

In a safe cluster environment, the communication among components cannot be a simple communication. Components must be authorized by each other before the communication to ensure the security of the communication.

When users are developing the Spark application, the Spark is required to interwork with Hadoop and HBase in certain scenarios. Therefore, security authentication codes must be written into the Spark application to ensure that the Spark application can run properly.

Three security authentication modes are available:

- Authentication by running command lines:

Before submitting the Spark application for running or using the CLI to log in to the Spark SQL, run the following command in the Spark client to obtain authentication:

**kinit component service user**

- Authentication by configuring parameters

You can use any of the following methods to specify the security authentication information.

- Configure the **spark.kerberos.keytab** and **spark.kerberos.principal** parameters in the spark-defaults.conf file on the client.
- Add the following parameters to the **bin/spark-submit** command:  
**--conf spark.kerberos.keytab=<keytab file path> --conf spark.kerberos.principal=<Principal account>**
- Add the following parameter to the **bin/spark-submit** command:  
**--keytab <keytab file path> --principal <Principal account>**

- Authentication by adding codes:

Authenticate in the application by obtaining principal and keytab files of the client.

**Table 1-178** lists the authentication method for the sample code in security cluster environment.

**Table 1-178** Authentication methods

Sample Code	Mode	Authentication Method
sparknormal-examples	yarn-client	Command authentication, configuration authentication, or code authentication
	yarn-cluster	By running command lines or configuring parameters.
sparksecurity-examples (containing authentication code)	yarn-client	By adding code.
	yarn-cluster	Not supported.

 NOTE

- In the yarn cluster mode, the security authentication is not supported in the Spark projects. The security authentication needs to be completed before the application is started.
- For the safety authentication codes of the Python sample project that are not provided, configure the safety authentication parameter in the command that runs the application.

## Safety Security Code (Java)

The safety authentication of the sample codes is completed by invoking the LoginUtil class. For the secure login process, see the chapter Security Authentication Interfaces.

In the Spark sample project code, different sample projects use different authentication codes which are basic safety authentication and the basic safety authentication with the ZooKeeper authentication. The example authentication parameters used in the sample project are displayed as [Table 1-179](#). Modify the parameter value as required.

**Table 1-179** Parameter Description

Parameter	Example Parameter Value	Description
userPrincipal	sparkuser	User <b>Principal</b> for authentication. Use the account prepared in <a href="#">Preparing a Developer Account</a> .
userKeytabPath	/opt/FIclient/user.keytab	Users use the authenticated Keytab file, Copy the <b>user.keytab</b> file of the prepared developer account to the directory indicated by the example parameter value.
ZKServerPrincipal	zookeeper/hadoop.<system domain name>	The principal of the server in ZooKeeper. Contact the administrator to obtain the account.

The following code snippet belongs to the main method of the **FemaleInfoCollection** class in the **com.huawei.bigdata.spark.examples** package.

- Basic safety authentication:

Spark Core and Spark SQL programs needs only the basic safety authentication codes because both of them do not need to access the HBase or ZooKeeper. Add the following codes in the program, and configure the safety authentication parameter as required.

```
String userPrincipal = "sparkuser";
String userKeytabPath = "/opt/FIclient/user.keytab";
String krb5ConfPath = "/opt/FIclient/KrbClient/kerberos/var/krb5kdc/krb5.conf";
```

```
Configuration hadoopConf = new Configuration();
LoginUtil.login(userPrincipal, userKeytabPath, krb5ConfPath, hadoopConf);
```

- Basic safety authentication with ZooKeeper Authentication:

Because the sample programs "Spark Streaming", "access Spark SQL with JDBC", and "Spark on HBase" require not only the basic safety authentication, but also the Principal of the ZooKeeper server to complete the safety authentication. Add the following codes in the program, and configure the safety authentication parameter as required.

```
String userPrincipal = "sparkuser";
String userKeytabPath = "/opt/FIclient/user.keytab";
String krb5ConfPath = "/opt/FIclient/KrbClient/kerberos/var/krb5kdc/krb5.conf";
String ZKServerPrincipal = "zookeeper/hadoop.<System domain name >";

String ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME = "Client";
String ZOOKEEPER_SERVER_PRINCIPAL_KEY = "zookeeper.server.principal";

Configuration hadoopConf = new Configuration();
LoginUtil.setJaasConf(ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME, userPrincipal, userKeytabPath);
LoginUtil.setZookeeperServerPrincipal(ZOOKEEPER_SERVER_PRINCIPAL_KEY, ZKServerPrincipal);
LoginUtil.login(userPrincipal, userKeytabPath, krb5ConfPath, hadoopConf);
```

## Safety Authentication Codes for the Communication of Spark and Zookeeper (Scala)

Currently the safety authentication of the sample codes is completed by invoking the LoginUtil class. For the secure login process, see the chapter about the unified authentication.

In the Spark sample project code, different sample projects use different authentication codes, which are basic safety authentication and basic safety authentication with ZooKeeper authentication. The example authentication parameters used in the sample project are displayed as [Table 1-180](#). Modify the parameter value as required.

**Table 1-180** Parameter Description

Parameter	Example Parameter Value	Description
userPrincipal	sparkuser	User <b>Principal</b> for authentication. Use the account prepared in <a href="#">Preparing a Developer Account</a> .
userKeytabPath	/opt/FIclient/user.keytab	Users use the authenticated Keytab file, Copy the <b>user.keytab</b> file of the prepared developer account to the directory indicated by the example parameter value.
ZKServerPrincipal	zookeeper/hadoop.<System domain name>	The principal of the server in ZooKeeper. Contact the administrator to obtain the account.

- Basic safety authentication:

Spark Core and Spark SQL programs needs only the basic safety authentication codes because both of them do not need to access the HBase or ZooKeeper. Add the following codes in the program, and configure the safety authentication parameter as required.

```
val userPrincipal = "sparkuser"  
val userKeytabPath = "/opt/FIclient/user.keytab"  
val krb5ConfPath = "/opt/FIclient/KrbClient/kerberos/var/krb5kdc/krb5.conf"  
val hadoopConf: Configuration = new Configuration()  
LoginUtil.login(userPrincipal, userKeytabPath, krb5ConfPath, hadoopConf);
```

- Basic safety authentication with ZooKeeper Authentication:

Because the sample programs "Spark Streaming", "access Spark SQL with JDBC", and "Spark on HBase" require not only the basic safety authentication, but also the Principal of the ZooKeeper server to complete the safety authentication. Add the following codes in the program, and configure the safety authentication parameter as required.

```
val userPrincipal = "sparkuser"  
val userKeytabPath = "/opt/FIclient/user.keytab"  
val krb5ConfPath = "/opt/FIclient/KrbClient/kerberos/var/krb5kdc/krb5.conf"  
val ZKServerPrincipal = "zookeeper/hadoop.<system domain name>"  
  
val ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME: String = "Client"  
val ZOOKEEPER_SERVER_PRINCIPAL_KEY: String = "zookeeper.server.principal"  
val hadoopConf: Configuration = new Configuration();  
LoginUtil.setJaasConf(ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME, userPrincipal, userKeytabPath)  
LoginUtil.setZookeeperServerPrincipal(ZOOKEEPER_SERVER_PRINCIPAL_KEY, ZKServerPrincipal)  
LoginUtil.login(userPrincipal, userKeytabPath, krb5ConfPath, hadoopConf);
```

## 1.21.2.5 Configuring the Python3 Sample Project

### Scenario

To run the Python3 interface sample code of the Spark component of MRS, perform the following operations.

### Procedure

- Step 1** Install Python3 of 3.7 or a higher version on the client.

The Python version can be viewed by running the **python3** command on the CLI of the client. The following information indicates that the Python version is 3.8.2.

```
Python 3.8.2 (default, Jun 23 2020, 10:26:03)  
[GCC 4.8.5 20150623 (Red Hat 4.8.5-36)] on linux  
Type "help", "copyright", "credits" or "license" for more information.
```

- Step 2** Setuptools 47.3.1 must be installed on the client.

To obtain the software, visit the official websites.

<https://pypi.org/project/setuptools/#files>

Copy the downloaded setuptools package to the client, decompress the package, go to the decompressed directory, and run the **python3 setup.py install** command in the CLI of the client.

The following information indicates that setuptools 47.3.1 is installed successfully.

```
Finished processing dependencies for setuptools==47.3.1
```

- Step 3** Install Python on the client.

1. Obtain the sample project folder **python3-examples** in the **src\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
2. Go to the **python3-examples** folder.
3. Go to the **dependency\_python3.6**, **dependency\_python3.7**, or **dependency\_python3.8** folder based on the Python3 version.
4. Run the **whereis easy\_install** command to find the path of the **easy\_install** program. If there are multiple paths, run the **easy\_install --version** command to select the **easy\_install** path corresponding to the **setuptools** version, for example, **/usr/local/bin/easy\_install**.
5. Run the **easy\_install** command to install the EGG files in the **dependency\_python3.x** folder in sequence. Example:  
`/usr/local/bin/easy_install future-0.18.2-py3.8.egg`  
If the following information is displayed, the EGG file is successfully installed.  
`Finished processing dependencies for future==0.18.2`

----End

## 1.21.3 Developing the Project

### 1.21.3.1 Spark Core Project

#### 1.21.3.1.1 Overview

##### Scenarios

Develop a Spark application to perform the following operations on logs about dwell durations of netizens for shopping online:

- Collect statistics on female netizens who dwell on online shopping for more than 2 hours at a weekend.
- The first column in the log file records names, the second column records gender, and the third column records the dwell duration in the unit of minute. Three attributes are separated by commas (,).

log1.txt: logs collected on Saturday

```
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,5
CaiXuyu,female,50
Liyuan,male,20
FangBo,female,50
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,50
CaiXuyu,female,50
FangBo,female,60
```

log2.txt: logs collected on Sunday

```
LiuYang,female,20
YuanJing,male,10
CaiXuyu,female,50
FangBo,female,50
GuoYijun,male,5
```

```
CaiXuyu,female,50  
Liyuan,male,20  
CaiXuyu,female,50  
FangBo,female,50  
LiuYang,female,20  
YuanJing,male,10  
FangBo,female,50  
GuoYijun,male,50  
CaiXuyu,female,50  
FangBo,female,60
```

## Data Preparation

Save log files in the Hadoop distributed file system (HDFS).

1. Create text files **input\_data1.txt** and **input\_data2.txt** on a local computer, and copy **log1.txt** to **input\_data1.txt** and **log2.txt** to **input\_data2.txt**.
2. Create **/tmp/input** on HDFS client path, and run the following commands to upload **input\_data1.txt** and **input\_data2.txt** to **/tmp/input**:
  - a. On the HDFS client, run the following commands to obtain the safety authentication:  
**cd /opt/hadoopclient**  
**source bigdata\_env**  
**kinit <Service user for authentication>**
  - b. On the Linux HDFS client, run the **hadoop fs -mkdir /tmp/input** command (a hdfs dfs command provides the same function.) to create a directory.
  - c. Go to the **/tmp/input** directory on the HDFS client, on the Linux HDFS client, run the **hadoop fs -put input\_data1.txt /tmp/input** and **hadoop fs -put input\_data2.txt /tmp/input** commands to upload data files.

## Development Idea

Collects the information of female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

The process includes:

- Read the source file data.
- Filter the data information of the time that female netizens spend online.
- Aggregate the total time that each female netizen spends online.
- Filter the information of female netizens who spend more than 2 hours online.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

## Packaging the Project

1. Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed.
2. Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).

### NOTE

- Before compilation and packaging, change the paths of the user.keytab and krb5.conf files in the sample code to the actual paths on the client server where the files are located. Example: **/opt/female/user.keytab** and **/opt/female/krb5.conf**.
  - To run the Python sample code, you do not need to use Maven for packaging. You only need to upload the **user.keytab** and **krb5.conf** files to the server where the client is located.
3. Upload the JAR file to any directory (for example, **/opt/female/**) on the server where the Spark client is located.

## Running Tasks

Go to the Spark client directory and run the following commands to invoke the **bin/spark-submit** script to run the code (the class name and file name must be the same as those in the actual code. The following is only an example):

- Run the Scala and Java sample programs.  
**bin/spark-submit --class com.huawei.bigdata.spark.examples.FemaleInfoCollection --master yarn --deploy-mode client /opt/female/FemaleInfoCollection-1.0.jar <inputPath>**  
*<inputPath>* indicates the input path in HDFS.
- Run the Python sample program.

### NOTE

- The Python sample code does not provide authentication information. Configure **--keytab** and **--principal** to specify authentication information.  
**bin/spark-submit --master yarn --deploy-mode client --keytab /opt/Flclient/user.keytab --principal sparkuser /opt/female/SparkPythonExample/collectFemaleInfo.py <inputPath>**  
*<inputPath>* indicates the input path in HDFS.

### 1.21.3.1.2 Java Sample Code

## Function

Collects the information of female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

## Sample Code

The following code segment is only an example. For details, see the `com.huawei.bigdata.spark.examples.FemaleInfoCollection` class.

```
// Create a configuration class SparkConf, and then create a SparkContext.  
SparkSession spark = SparkSession
```

```
.builder()
.appName("CollectFemaleInfo")
.config("spark.some.config.option", "some-value")
.getOrCreate();

// Read the source file data, and transfer each row of records to an element of the RDD.
JavaRDD<String> data = spark.read()
.textFile(args[0])
.javaRDD();

// Split each column of each record, and generate a Tuple.
JavaRDD<Tuple3<String, String, Integer>> person = data.map(new
Function<String, Tuple3<String, String, Integer>>()
{
    private static final long serialVersionUID = -2381522520231963249L;
    public Tuple3<String, String, Integer> call(String s) throws Exception
    {
        // Split a row of data by commas (,).
        String[] tokens = s.split(",");

        // Integrate the three split elements to a ternary Tuple.
        Tuple3<String, String, Integer> person = new Tuple3<String, String, Integer>(tokens[0], tokens[1],
Integer.parseInt(tokens[2]));
        return person;
    }
});

// Use the filter function to filter the data information about the time that female netizens spend online.
JavaRDD<Tuple3<String, String, Integer>> female = person.filter(new
Function<Tuple3<String, String, Integer>, Boolean>()
{
    private static final long serialVersionUID = -4210609503909770492L;

    public Boolean call(Tuple3<String, String, Integer> person) throws Exception
    {
        // Filter the records of which the gender in the second column is female.
        Boolean isFemale = person._2().equals("female");
        return isFemale;
    }
});

// Aggregate the total time that each female netizen spends online.
JavaPairRDD<String, Integer> females = female.mapToPair(new PairFunction<Tuple3<String, String,
Integer>, String, Integer>()
{
    private static final long serialVersionUID = 8313245377656164868L;

    public Tuple2<String, Integer> call(Tuple3<String, String, Integer> female) throws Exception
    {
        // Extract the two columns representing the name and online time for the sum of online time by
name during further operations.
        Tuple2<String, Integer> femaleAndTime = new Tuple2<String, Integer>(female._1(), female._3());
        return femaleAndTime;
    }
});
JavaPairRDD<String, Integer> femaleTime = females.reduceByKey(new Function2<Integer, Integer,
Integer>()
{
    private static final long serialVersionUID = -3271456048413349559L;

    public Integer call(Integer integer, Integer integer2) throws Exception
    {
        // Sum two online time durations of the same female netizen.
        return (integer + integer2);
    }
});

// Filter the information about female netizens who spend more than 2 hours online.
JavaPairRDD<String, Integer> rightFemales = females.filter(new Function<Tuple2<String, Integer>,
```

```
Boolean>()
{
    private static final long serialVersionUID = -3178168214712105171L;

    public Boolean call(Tuple2<String, Integer> s) throws Exception
    {
        // Extract the total time that female netizens spend online, and determine whether the time is
        more than 2 hours.
        if(s._2() > (2 * 60))
        {
            return true;
        }
        return false;
    }
});

// Print the information about female netizens who meet the requirements.
for(Tuple2<String, Integer> d: rightFemales.collect())
{
    System.out.println(d._1() + "," + d._2());
}
```

### 1.21.3.1.3 Scala Sample Code

#### Function

Collects the information of female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

#### Sample Code

The following code segment is only an example. For details, see the com.huawei.bigdata.spark.examples.FemaleInfoCollection class.

Example: CollectMapper class

```
val spark = SparkSession
    .builder()
    .appName("CollectFemaleInfo")
    .config("spark.some.config.option", "some-value")
    .getOrCreate()

// Read data. This code indicates the data path that the input parameter args(0) specifies.
val text = spark.sparkContext.textFile(args(0))
// Filter the data information about the time that female netizens spend online.
val data = text.filter(_.contains("female"))
// Aggregate the time that each female netizen spends online.
val femaleData:RDD[(String,Int)] = data.map{line =>
    val t= line.split(',')
    (t(0),t(2).toInt)
}.reduceByKey(_ + _)

// Filter the information about female netizens who spend more than 2 hours online, and export the results.
val result = femaleData.filter(line => line._2 > 120)
result.collect().map(x => x._1 + ',' + x._2).foreach(println)
spark.stop()
```

### 1.21.3.1.4 Python Sample Code

#### Function

Collects the information of female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

## Sample Code

The following code segment is only an example. For details, see [collectFemaleInfo.py](#).

```
def contains(str, substr):
    if substr in str:
        return True
    return False

if __name__ == "__main__":
    if len(sys.argv) < 2:
        print "Usage: CollectFemaleInfo <file>"
        exit(-1)

    spark = SparkSession \
        .builder \
        .appName("CollectFemaleInfo") \
        .getOrCreate()

    """
    The following programs are used to implement the following functions:
    1. Read data. This code indicates the data path that the input parameter argv[1] specifies. - text
    2. Filter data about the time that female netizens spend online. - filter
    3. Aggregate the total time that each female netizen spends online. - map/map/reduceByKey
    4. Filter information about female netizens who spend more than 2 hours online. - filter
    """

    inputPath = sys.argv[1]
    result = spark.read.text(inputPath).rdd.map(lambda r: r[0])\
        .filter(lambda line: contains(line, "female")) \
        .map(lambda line: line.split(',')) \
        .map(lambda dataArr: (dataArr[0], int(dataArr[2]))) \
        .reduceByKey(lambda v1, v2: v1 + v2) \
        .filter(lambda tupleVal: tupleVal[1] > 120) \
        .collect()
    for (k, v) in result:
        print k + "," + str(v)

    # Stop SparkContext.
    spark.stop()
```

### 1.21.3.2 Spark SQL Project

#### 1.21.3.2.1 Overview

##### Scenario

Develop a Spark application to perform the following operations on logs about dwell durations of netizens for shopping online:

- Collect statistics on female netizens who dwell on online shopping for more than 2 hours at a weekend.
- The first column in the log file records names, the second column records gender, and the third column records the dwell duration in the unit of minute. Three attributes are separated by commas (,).

log1.txt: logs collected on Saturday

```
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,5
CaiXuyu,female,50
Liyuan,male,20
FangBo,female,50
```

```
LiuYang,female,20  
YuanJing,male,10  
GuoYijun,male,50  
CaiXuyu,female,50  
FangBo,female,60
```

log2.txt: logs collected on Sunday

```
LiuYang,female,20  
YuanJing,male,10  
CaiXuyu,female,50  
FangBo,female,50  
GuoYijun,male,5  
CaiXuyu,female,50  
Liyuan,male,20  
CaiXuyu,female,50  
FangBo,female,50  
LiuYang,female,20  
YuanJing,male,10  
FangBo,female,50  
GuoYijun,male,50  
CaiXuyu,female,50  
FangBo,female,60
```

## Data Preparation

Save log files in the Hadoop distributed file system (HDFS).

1. Create text files **input\_data1.txt** and **input\_data2.txt** on a local computer, and copy **log1.txt** to **input\_data1.txt** and **log2.txt** to **input\_data2.txt**.
2. Create **/tmp/input** on the HDFS client path, and run the following commands to upload **input\_data1.txt** and **input\_data2.txt** to **/tmp/input**:
  - a. On the HDFS client, run the following commands to obtain the safety authentication:  
**cd /opt/hadoopclient**  
**source bigdata\_env**  
**kinit <component service user>**
  - b. On the Linux HDFS client, run the **hadoop fs -mkdir /tmp/input** command (a hdfs dfs command provides the same function.) to create a directory.
  - c. Go to the **/tmp/input** directory on the HDFS client, on the Linux HDFS client, run the **hadoop fs -put input\_data1.txt /tmp/input** and **hadoop fs -put input\_data2.txt /tmp/input** commands to upload data files.

## Development Idea

Collects the information of female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

The process includes:

- Create a table and import the log files into the table.
- Filter the data information of the time that female netizens spend online.
- Aggregate the total time that each female netizen spends online.
- Filter the information of female netizens who spend more than 2 hours online.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

## Packaging the Project

1. Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed.
2. Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).

### NOTE

- Before compilation and packaging, change the paths of the **user.keytab** and **krb5.conf** files in the sample code to the actual paths on the client server where the files are located. Example: **/opt/female/user.keytab** and **/opt/female/krb5.conf**.
  - To run the Python sample code, you do not need to use Maven for packaging. You only need to upload the **user.keytab** and **krb5.conf** files to the server where the client is located.
3. Upload the JAR file to any directory (for example, **/opt/female/**) on the server where the Spark client is located.

## Running Tasks

Go to the Spark client directory and run the following commands to invoke the **bin/spark-submit** script to run the code (the class name and file name must be the same as those in the actual code. The following is only an example):

- Run the Scala and Java sample programs.

### **bin/spark-submit --class**

```
com.huawei.bigdata.spark.examples.FemaleInfoCollection --master yarn --  
deploy-mode client /opt/female/SparkSqlScalaExample-1.0.jar <inputPath>  
<inputPath> indicates the input path in HDFS.
```

- Run the Python sample program

### NOTE

- The Python sample code does not provide authentication information. Configure **--keytab** and **--principal** to specify authentication information.

```
bin/spark-submit --master yarn --deploy-mode client --keytab /opt/  
FIclient/user.keytab --principal sparkuser /opt/female/  
SparkPythonExample/SparkSQLPythonExample.py <inputPath>  
<inputPath> indicates the input path in HDFS.
```

### 1.21.3.2.2 Java Sample Code

#### Function

Collects the information of female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

#### Sample Code

The following code segment is only an example. For details, see com.huawei.bigdata.spark.examples.FemaleInfoCollection.

```
public static void main(String[] args) throws Exception {
    SparkSession spark = SparkSession
        .builder()
        .appName("CollectFemaleInfo")
        .config("spark.some.config.option", "some-value")
        .getOrCreate();

    // Convert RDD to DataFrame through the implicit conversion.
    JavaRDD<FemaleInfo> femaleInfoJavaRDD = spark.read().textFile(args[0]).javaRDD().map(
        new Function<String, FemaleInfo>() {
            @Override
            public FemaleInfo call(String line) throws Exception {
                String[] parts = line.split(",");
                FemaleInfo femaleInfo = new FemaleInfo();
                femaleInfo.setName(parts[0]);
                femaleInfo.setGender(parts[1]);
                femaleInfo.setStayTime(Integer.parseInt(parts[2].trim()));
                return femaleInfo;
            }
        });

    // Register table.
    Dataset<ROW> schemaFemaleInfo = spark.createDataFrame(femaleInfoJavaRDD,FemaleInfo.class);
    schemaFemaleInfo.registerTempTable("FemaleInfoTable");

    // Run SQL query
    Dataset<ROW> femaleTimeInfo = spark.sql("select * from " +
        "(select name,sum(stayTime) as totalStayTime from FemaleInfoTable " +
        "where gender = 'female' group by name )" +
        " tmp where totalStayTime >120");

    // Collect the columns of a row in the result.
    List<String> result = femaleTimeInfo.javaRDD().map(new Function<Row, String>() {
        public String call(Row row) {
            return row.getString(0) + "," + row.getLong(1);
        }
    }).collect();
    System.out.println(result);
    spark.stop();
}
```

In the preceding code example, data processing logic is implemented by SQL statements. It can also be implemented by invoking the SparkSQL interface in Scala/Java/Python code. For details, see <http://spark.apache.org/docs/3.3.1/sql-programming-guide.html#running-sql-queries-programmatically>.

### 1.21.3.2.3 Scala Sample Code

#### Function

Collects the information of female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

## Sample Code

The following code segment is only an example. For details, see com.huawei.bigdata.spark.examples.FemaleInfoCollection.

```
object FemaleInfoCollection
{
    //Table structure, used for mapping the text data to df
    case class FemaleInfo(name: String, gender: String, stayTime: Int)
    def main(args: Array[String]) {
        //Configure Spark application name
        val spark = SparkSession
            .builder()
            .appName("FemaleInfo")
            .config("spark.some.config.option", "some-value")
            .getOrCreate()
        import spark.implicits._

        //Convert RDD to DataFrame through the implicit conversion, then register table.
        spark.sparkContext.textFile(args(0)).map(_.split(","))
            .map(p => FemaleInfo(p(0), p(1), p(2).trim.toInt))
            .toDF.registerTempTable("FemaleInfoTable")

        //Via SQL statements to screen out the time information of female stay on the Internet , and aggregated
        //the same names.
        val femaleTimeInfo = spark.sql("select name,sum(stayTime) as stayTime from FemaleInfoTable where
        gender = 'female' group by name")
        //Filter information about female netizens who spend more than 2 hours online.
        val c = femaleTimeInfo.filter("stayTime >= 120").collect().foreach(println)
        spark.stop()
    }
}
```

In the preceding code example, data processing logic is implemented by SQL statements. It can also be implemented by invoking the SparkSQL interface in Scala/Java/Python code. For details, see <http://spark.apache.org/docs/3.3.1/sql-programming-guide.html#running-sql-queries-programmatically>.

### 1.21.3.2.4 Python Sample Code

#### Function

Collect information about female netizens who have spent more than 2 hours in online shopping on the weekend.

## Sample Code

The following code segment is only an example. For details, see SparkSQLPythonExample.

```
# -*- coding:utf-8 -*-
import sys
from pyspark.sql import SparkSession
from pyspark.sql import SQLContext

def contains(str1, substr1):
    if substr1 in str1:
        return True
    return False

if __name__ == "__main__":
    if len(sys.argv) < 2:
        print "Usage: SparkSQLPythonExample.py <file>"
```

```
exit(-1)

# Initialize the SparkSession and SQLContext.
sc = SparkSession.builder.appName("CollectFemaleInfo").getOrCreate()
sqlCtx = SQLContext(sc)

#Convert RDD to DataFrame.
inputPath = sys.argv[1]
inputRDD = sc.read.text(inputPath).rdd.map(lambda r: r[0])\
    .map(lambda line: line.split(","))\
    .map(lambda dataArr: (dataArr[0], dataArr[1], int(dataArr[2])))\
    .collect()
df = sqlCtx.createDataFrame(inputRDD)

# Register a table.
df.registerTempTable("FemaleInfoTable")

# Run SQL query statements and display the result.
FemaleTimeInfo = sqlCtx.sql("SELECT * FROM " +
    "(SELECT _1 AS Name,SUM(_3) AS totalStayTime FROM FemaleInfoTable " +
    "WHERE _2 = 'female' GROUP BY _1 )" +
    " WHERE totalStayTime >120").show()

sc.stop()
```

### 1.21.3.3 Accessing the Spark SQL Through JDBC

### **1.21.3.3.1 Overview**

## Scenarios

Users customize JDBCServer clients and use JDBC connections to create, load data to, query, and delete data tables.

Spark allows you to add extension identifiers to JDBC connection strings. These extension identifiers are printed in JDBCServer audit logs to distinguish SQL sources. To add extension identifiers, add the following content to the end of the connection strings in the **`$SPARK_HOME/bin/spark-beeline`** script in the client directory:

**auditAddition=xxx**

```
#!/bin/bash
# Set the current directory as the working directory
# CURRENT_PATH=$PWD
CURRENT_PATH=$(pwd)
echo "It's running the $1 spark-script, it calls $CURRENT_PATH/mainline
and helps to connect to the $2(hadoop namenode)!"
```

*xxx* is the custom identifier. The identifier can contain a maximum of 256 bytes and only letters, digits, underscores (\_), commas (,), and colons (:) are allowed.

After the SQL statement is executed, the configured extension identifier is printed in the HiveServer audit log `/var/log/Bigdata/audit/spark/jdbcserver/jdbcserver-audit.log`. The following is an example.

## Data Preparation

**Step 1** Ensure that the JDBCServer service has been started in multi-active instance HA mode and at least one instance provides connections for client. Create the **/home/data** file on every available instance node of the JDBCServer.

Miranda,32  
Karlie,23  
Candice,27

**Step 2** Ensure that the user whose starts the JDBCServer has the read and write permission on the file.

**Step 3** Ensure that the **hive-site.xml** file exists in **classpath**, and set parameters required for the client connection. For details about parameters required for the JDBCServer, see [JDBCServer Interface](#).

----End

## Development Idea

1. Create a child table in the default database.
2. Add data in **/home/data** to the child table.
3. Query data in the child table.
4. Delete the child table.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on FusionInsight Manager. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

## Packaging the Project

- Upload the **krb5.conf** and **user.keytab** files to the node where the client is located.
- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).

### NOTE

Before compilation and packaging, change the paths of the **user.keytab** and **krb5.conf** files in the sample code to the actual paths on the client server where the files are located. Example: **/opt/female/user.keytab** and **/opt/female/krb5.conf**.

- Upload the JAR file to any directory (for example, **/opt/female/**) on the server where the Spark client is located.

## Running Tasks

Go to the Spark client directory and run the **java -cp** command to run the code (the class name and file name must be the same as those in the actual code. The following is only an example).

- Run the Java sample code:

```
java -cp $SPARK_HOME/jars/*:$SPARK_HOME/jars/hive/*:$SPARK_HOME/
conf:/opt/female/SparkThriftServerJavaExample-1.0.jar
com.huawei.bigdata.spark.examples.ThriftServerQueriesTest $SPARK_HOME/
conf/hive-site.xml $SPARK_HOME/conf/spark-defaults.conf
```

- Run the Scala sample code:

```
java -cp $SPARK_HOME/jars/*:$SPARK_HOME/jars/hive/*:$SPARK_HOME/
conf:/opt/female/SparkThriftServerExample-1.0.jar
com.huawei.bigdata.spark.examples.ThriftServerQueriesTest $SPARK_HOME/
conf/hive-site.xml $SPARK_HOME/conf/spark-defaults.conf
```

#### NOTE

After the SSL feature of ZooKeeper is enabled for the cluster (check the `ssl.enabled` parameter of the ZooKeeper service), add the `-Dzookeeper.client.secure=true -Dzookeeper.clientCnxnSocket=org.apache.zookeeper.ClientCnxnSocketNetty` parameter to the command:

```
java -Dzookeeper.client.secure=true -
Dzookeeper.clientCnxnSocket=org.apache.zookeeper.ClientCnxnSocketNetty -cp
$SPARK_HOME/jars/*:$SPARK_HOME/jars/hive/*:$SPARK_HOME/conf:/opt/female/
SparkThriftServerJavaExample-1.0.jar
com.huawei.bigdata.spark.examples.ThriftServerQueriesTest $SPARK_HOME/conf/hive-
site.xml $SPARK_HOME/conf/spark-defaults.conf
```

### 1.21.3.3.2 Java Sample Code

## Function

The JDBC interface of the user-defined client is used to submit the data analysis task and return the results.

## Sample Code

**Step 1** Define an SQL statement. The SQL statement must be a single statement that cannot contain the semicolon (;). For example,

```
ArrayList<String> sqlList = new ArrayList<String>();
sqlList.add("CREATE TABLE CHILD (NAME STRING, AGE INT) ROW FORMAT DELIMITED FIELDS
TERMINATED BY ',';");
sqlList.add("LOAD DATA LOCAL INPATH '/home/data' INTO TABLE CHILD");
sqlList.add("SELECT * FROM child");
sqlList.add("DROP TABLE child");
executeSql(url, sqlList);
```

#### NOTE

The data file in the sample project must be placed into the Home directory of the host where the JDBCServer is located.

**Step 2** Assemble the JDBC URL.

```
String securityConfig = ";saslQop=auth-conf;auth=KERBEROS;principal=spark2x/hadoop.<system domain
name>@<system domain name>;user.principal=sparkuser;user.keytab=/opt/FIclient/user.keytab;";
Configuration config = new Configuration();
config.addResource(new Path(args[0]));
String zkUrl = config.get("spark.deploy.zookeeper.url");
String auditAddition = "auditAddition=sparktest1111test";
```

```
String zkNamespace = null;
zkNamespace = fileInfo.getProperty("spark.thriftserver.zookeeper.namespace");
if (zkNamespace != null) {
```

```
//Remove redundant characters from configuration items
zkNamespace = zkNamespace.substring(1);
}

StringBuilder sb = new StringBuilder("jdbc:hive2://" +
+ zkUrl +
+ ";serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=" +
+ zkNamespace +
+ securityConfig +
+ auditAddition);
String url = sb.toString();
```

#### NOTE

The default validity period of KERBEROS authentication is one day. After the validity period, the authentication needs to be performed again if you want to connect the client and JDBCServer. You can add the user.principal and user.keytab authentication information to **url** to ensure that the authentication is performed each time the connection is established. For example, add **user.principal=sparkuser;user.keytab=/opt/hadoopclient/user.keytab** to **url**.

**Step 3** Load the Hive JDBC driver.

```
Class.forName("org.apache.hive.jdbc.HiveDriver").newInstance();
```

**Step 4** Obtain the JDBC connection, execute the HQL, export the obtained column name and results to the console, and close the JDBC connection.

The **zk.quorum** in the connection string can be replaced by **spark.deploy.zookeeper.url** in the configuration file.

In network congestion, configure the timeout of the connection between the client and JDBCServer to avoid the suspending of the client due to timeless wait of the return from the server. The method is as follows:

Before executing the DriverManager.getConnection script to obtain the JDBC connection, add the DriverManager.setLoginTimeout(n) script to configure the timeout. n indicates the timeout length of waiting for the return from the server. The unit is second, the type is Int, and the default value is 0 (indicating never timing out).

```
static void executeSql(String url, ArrayList<String> sqls) throws ClassNotFoundException, SQLException {
    try {
        Class.forName("org.apache.hive.jdbc.HiveDriver").newInstance();
    } catch (Exception e) {
        e.printStackTrace();
    }
    Connection connection = null;
    PreparedStatement statement = null;

    try {
        connection = DriverManager.getConnection(url);
        for (int i = 0; i < sqls.size(); i++) {
            String sql = sqls.get(i);
            System.out.println("---- Begin executing sql: " + sql + " ----");
            statement = connection.prepareStatement(sql);
            ResultSet result = statement.executeQuery();
            ResultSetMetaData metaData = result.getMetaData();
            Integer colNum = metaData.getColumnCount();
            for (int j = 1; j <= colNum; j++) {
                System.out.println(metaData.getColumnName(j) + "\t");
            }
            System.out.println();

            while (result.next()) {
                for (int j = 1; j <= colNum; j++) {
                    System.out.println(result.getString(j) + "\t");
                }
            }
        }
    } catch (SQLException e) {
        e.printStackTrace();
    } finally {
        if (connection != null) {
            try {
                connection.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
        if (statement != null) {
            try {
                statement.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
    }
}
```

```
        }
        System.out.println();
    }
    System.out.println("---- Done executing sql: " + sql + " ----");
}

} catch (Exception e) {
    e.printStackTrace();
} finally {
    if (null != statement) {
        statement.close();
    }
    if (null != connection) {
        connection.close();
    }
}
}
```

----End

### 1.21.3.3.3 Scala Sample Code

#### Function

The JDBC interface of the user-defined client is used to submit the data analysis task and return the results.

#### Sample Code

- Step 1** Define an SQL statement. The SQL statement must be a single statement that cannot contain the semicolon (;). For example,

```
val sqlList = new ArrayBuffer[String]
sqlList += "CREATE TABLE CHILD (NAME STRING, AGE INT) " +
"ROW FORMAT DELIMITED FIELDS TERMINATED BY ','"
sqlList += "LOAD DATA LOCAL INPATH '/home/data' INTO TABLE CHILD"
sqlList += "SELECT * FROM child"
sqlList += "DROP TABLE child"
```

The data file in the sample project must be placed into the Home directory of the host where the JDBCServer is located.

- Step 2** Assemble the JDBC URL.

```
val securityConfig = ";saslQop=auth-conf;auth=KERBEROS;principal=spark2x/hadoop.<system domain name>@<system domain name>" + ";"
val config: Configuration = new Configuration()
config.addResource(new Path(args(0)))
val zkUrl = config.get("spark.deploy.zookeeper.url")
val auditAddtion = "auditAddtion=sparktest1111test;"

var zkNamespace: String = null
zkNamespace = fileInfo.getProperty("spark.thriftserver.zookeeper.namespace")
//Remove redundant characters from configuration items
if (zkNamespace != null) zkNamespace = zkNamespace.substring(1)
val sb = new StringBuilder("jdbc:hive2://"
+ zkUrl
+ ";serviceDiscoveryMode=zooKeeper;zooKeeperNamespace="
+ zkNamespace
+ securityConfig
+ auditAddtion)
val url = sb.toString()
```

 NOTE

The default validity period of KERBEROS authentication is one day. After the validity period, the authentication needs to be performed again if you want to connect the client and JDBCServer. You can add the user.principal and user.keytab authentication information to **url** to ensure that the authentication is performed each time the connection is established. For example, add **user.principal=sparkuser;user.keytab=/opt/hadoopclient/user.keytab** to **url**.

- Step 3** Load the Hive JDBC driver. Obtain the JDBC connection, execute the HQL, export the obtained column name and results to the console, and close the JDBC connection.

The **zk.quorum** in the connection string can be replaced by **spark.deploy.zookeeper.url** in the configuration file.

In network congestion, configure the timeout of the connection between the client and JDBCServer to avoid the suspending of the client due to timeless wait of the return from the server. The method is as follows:

Before executing the DriverManager.getConnection script to obtain the JDBC connection, add the DriverManager.setLoginTimeout(n) script to configure the timeout. n indicates the timeout length of waiting for the return from the server. The unit is second, the type is Int, and the default value is 0 (indicating never timing out).

```
def executeSql(url: String, sqls: Array[String]): Unit = {
    //Load the Hive JDBC driver.
    Class.forName("org.apache.hive.jdbc.HiveDriver").newInstance()

    var connection: Connection = null
    var statement: PreparedStatement = null
    try {
        connection = DriverManager.getConnection(url)
        for (sql <- sqls) {
            println(s"---- Begin executing sql: $sql ----")
            statement = connection.prepareStatement(sql)

            val result = statement.executeQuery()

            val resultMetaData = result.getMetaData
            val colNum = resultMetaData.getColumnCount
            for (i <- 1 to colNum) {
                print(resultMetaData.getColumnName(i) + "\t")
            }
            println()

            while (result.next()) {
                for (i <- 1 to colNum) {
                    print(result.getString(i) + "\t")
                }
                println()
            }
            println(s"---- Done executing sql: $sql ----")
        }
    } finally {
        if (null != statement) {
            statement.close()
        }
        if (null != connection) {
            connection.close()
        }
    }
}
```

```
}
```

----End

### 1.21.3.4 Spark on HBase

#### 1.21.3.4.1 Performing Operations on Data in Avro Format

##### Scenario

Users can use HBase as data sources in Spark applications. In this example, data is stored in HBase in Avro format. Data is read from the HBase, and the read data is filtered.

##### Data Planning

On the client, run the **hbase shell** command to go to the HBase command line and run the following commands to create HBase tables to be used in the sample code:

```
create 'ExampleAvrotable','rowkey','cf1'  
create 'ExampleAvrotableInsert','rowkey','cf1'
```

##### Development Guideline

1. Create an RDD.
2. Perform operations on HBase to treat it as the data source and write the generated RDD into HBase tables.
3. Read data from HBase tables and performs simple operations on the data.

##### Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **super**, change the value to the prepared development user name.

##### Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.
- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

 NOTE

To run the Spark on HBase example program, set `spark.yarn.security.credentials.hbase.enabled` (`false` by default) in the `spark-defaults.conf` file on the Spark client to `true`. Changing the `spark.yarn.security.credentials.hbase.enabled` value does not affect existing services. (To uninstall the HBase service, you need to change the value of this parameter back to `false`.) Set the value of the configuration item `spark.inputFormat.cache.enabled` to `false`.

## Submitting Commands

Assume that the JAR package name of the case code is `spark-hbaseContext-test-1.0.jar` that is stored in the `$SPARK_HOME` directory on the client. Run the following commands in the `$SPARK_HOME` directory.

- yarn-client mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode client --jars /opt/female/protobuf-java-2.5.0.jar --conf spark.yarn.user.classpath.first=true --class com.huawei.bigdata.spark.examples.datasources.AvroSource SparkOnHbaseJavaExample.jar
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is `SparkOnHbaseJavaExample.jar` and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode client --conf spark.yarn.user.classpath.first=true --jars SparkOnHbaseJavaExample.jar,/opt/female/protobuf-java-2.5.0.jar AvroSource.py
```

- yarn-cluster mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode cluster --jars /opt/female/protobuf-java-2.5.0.jar --conf spark.yarn.user.classpath.first=true --class com.huawei.bigdata.spark.examples.datasources.AvroSource --files /opt/user.keytab,/opt/krb5.conf SparkOnHbaseJavaExample.jar
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is `SparkOnHbaseJavaExample.jar` and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode cluster --files /opt/user.keytab,/opt/krb5.conf --conf spark.yarn.user.classpath.first=true --jars SparkOnHbaseJavaExample.jar,/opt/female/protobuf-java-2.5.0.jar AvroSource.py
```

## Java Sample Code

The following code snippet is only for demonstration. For details about the code, see the `AvroSource` file in `SparkOnHbaseJavaExample`.

```

public static void main(JavaSparkContext jsc) throws IOException {
    LoginUtil.loginWithUserKeytab();
    SQLContext sqlContext = new SQLContext(jsc);
    Configuration hbaseconf = new HBaseConfiguration().create();
    JavaHBaseContext hBaseContext = new JavaHBaseContext(jsc, hbaseconf);
    List list = new ArrayList<AvroHBaseRecord>();
    for(int i=0; i<=255 ; ++i){
        list.add(AvroHBaseRecord.apply(i));
    }
    try{
        Map<String, String> map = new HashMap<String, String>();
        map.put(HBaseTableCatalog.tableCatalog(), catalog);
        map.put(HBaseTableCatalog.newTable(), "5");
        sqlContext.createDataFrame(list,
        AvroHBaseRecord.class).write().options(map).format("org.apache.hadoop.hbase.spark").save();
        Dataset<Row> ds = withCatalog(sqlContext,catalog);
        ds.show();
        ds.printSchema();
        ds.registerTempTable("ExampleAvrotable");
        Dataset<Row> c= sqlContext.sql("select count(1) from ExampleAvrotable");
        c.show();
        Dataset<Row> filtered = ds.select("col0", "col1.favorite_array").where("col0 = 'name1'");
        filtered.show();
        java.util.List<Row> collected = filtered.collectAsList();
        if (collected.get(0).get(1).toString().equals("number1")) {
            throw new UserCustomizedSampleException("value invalid", new Throwable());
        }
        if (collected.get(0).get(1).toString().equals("number2")) {
            throw new UserCustomizedSampleException("value invalid", new Throwable());
        }
        Map avroCatalogInsertMap = new HashMap<String, String>();
        avroCatalogInsertMap.put("avroSchema" , AvroHBaseRecord.schemaString);
        avroCatalogInsertMap.put(HBaseTableCatalog.tableCatalog(), avroCatalogInsert);
        ds.write().options(avroCatalogInsertMap).format("org.apache.hadoop.hbase.spark").save();
        Dataset<Row> newDS = withCatalog(sqlContext,avroCatalogInsert);
        newDS.show();
        newDS.printSchema();
        if (newDS.count() != 256) {
            throw new UserCustomizedSampleException("value invalid", new Throwable());
        }
        ds.filter("col1.name = 'name5' || col1.name <= 'name5'").select("col0","col1.favorite_color",
        "col1.favorite_number").show();
    } finally{
        jsc.stop();
    }
}

```

## Scala Sample Code

The following code snippet is only for demonstration. For details about the code, see the [AvroSource file in SparkOnHbaseScalaExample](#).

```

def main(args: Array[String]) {
    LoginUtil.loginWithUserKeytab()
    val sparkConf = new SparkConf().setAppName("AvroSourceExample")
    val sc = new SparkContext(sparkConf)
    val sqlContext = new SQLContext(sc)
    val hbaseConf = HBaseConfiguration.create()
    val hBaseContext = new HBaseContext(sc, hbaseConf)
    import sqlContext.implicits_
    def withCatalog(cat: String): DataFrame = {
        sqlContext
            .read
            .options(Map("avroSchema" -> AvroHBaseRecord.schemaString, HBaseTableCatalog.tableCatalog ->
        avroCatalog))
            .format("org.apache.hadoop.hbase.spark")
            .load()
    }
    val data = (0 to 255).map { i =>

```

```
    AvroHBaseRecord(i)
}
try {
    sc.parallelize(data).toDF.write.options(
        Map(HBaseTableCatalog.tableCatalog -> catalog, HBaseTableCatalog.newTable -> "5"))
        .format("org.apache.hadoop.hbase.spark")
        .save()

    val df = withCatalog(catalog)
    df.show()
    df.printSchema()
    df.registerTempTable("ExampleAvrotable")

        Map("avroSchema" -> AvroHBaseRecord.schemaString, HBaseTableCatalog.tableCatalog ->
avroCatalogInsert,
        HBaseTableCatalog.newTable -> "5"))
        .format("org.apache.hadoop.hbase.spark")
        .save()
    val newDF = withCatalog(avroCatalogInsert)
    newDF.show()
    newDF.printSchema()
    if (newDF.count() != 256) {
        throw new UserCustomizedSampleException("value invalid")
    }
    df.filter($"col1.name" === "name005" || $"col1.name" <= "name005")
        .select("col0", "col1.favorite_color", "col1.favorite_number")
        .show()
} finally {
    sc.stop()
}
```

## Python Sample Code

The following code snippet is only for demonstration. For details about the code, see the `AvroSource` file in `SparkOnHbasePythonExample`.

```
# -*- coding:utf-8 -*-
"""
[Note]
(1) PySpark does not provide Hbase-related APIs. In this example, Python is used to invoke Java code to
implement required operations.
(2) If yarn-client is used, ensure that the spark.yarn.security.credentials.hbase.enabled parameter in the
spark-defaults.conf file under Spark/spark/conf/ is set to true on the Spark client.
    Set spark.yarn.security.credentials.hbase.enabled to true.
"""

from py4j.java_gateway import java_import
from pyspark.sql import SparkSession
# Create a SparkSession instance.
spark = SparkSession\
    .builder\
    .appName("AvroSourceExample")\
    .getOrCreate()
# Import the required class to sc._jvm.
java_import(spark._jvm, 'com.huawei.bigdata.spark.examples.datasources.AvroSource')
# Create a class instance and invoke the method. Transfer the sc._jsc parameter.
```

```
spark._jvm.AvroSource().execute(spark._jsc)
# Stop the SparkSession instance.
spark.stop()
```

### 1.21.3.4.2 Performing Operations on the HBase Data Source

#### Scenario

Users can use HBase as data sources in Spark applications, write DataFrame to HBase, read data from HBase, and filter the read data.

#### Data Planning

On the client, run the **hbase shell** command to go to the HBase command line and run the following commands to create HBase tables to be used in the sample code:

```
create 'HBaseSourceExampleTable','rowkey','cf1','cf2','cf3','cf4','cf5','cf6','cf7', 'cf8'
```

#### Development Guideline

1. Create an RDD.
2. Perform operations on HBase to treat it as the data source and write the generated RDD into HBase tables.
3. Read data from HBase tables and performs simple operations on the data.

#### Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **super**, change the value to the prepared development user name.

#### Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.
- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

##### NOTE

To run the Spark on HBase example program, set **spark.yarn.security.credentials.hbase.enabled** (**false** by default) in the **spark-defaults.conf** file on the Spark client to **true**. Changing the **spark.yarn.security.credentials.hbase.enabled** value does not affect existing services. (To uninstall the HBase service, you need to change the value of this parameter back to **false**.) Set the value of the configuration item **spark.inputFormat.cache.enabled** to **false**.

## Submitting Commands

Assume that the JAR package name of the case code is **spark-hbaseContext-test-1.0.jar** that is stored in the **\$SPARK\_HOME** directory on the client. Run the following commands in the **\$SPARK\_HOME** directory.

- yarn-client mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode client --jars /opt/female/protobuf-java-2.5.0.jar --conf spark.yarn.user.classpath.first=true --class com.huawei.bigdata.spark.examples.datasources.HBaseSource SparkOnHbaseJavaExample.jar
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode client --conf spark.yarn.user.classpath.first=true --jars SparkOnHbaseJavaExample.jar,/opt/female/protobuf-java-2.5.0.jar HBaseSource.py
```

- yarn-cluster mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode cluster --jars /opt/female/protobuf-java-2.5.0.jar --conf spark.yarn.user.classpath.first=true --class com.huawei.bigdata.spark.examples.datasources.HBaseSource --files /opt/user.keytab,/opt/krb5.conf SparkOnHbaseJavaExample.jar
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --files /opt/user.keytab,/opt/krb5.conf --conf spark.yarn.user.classpath.first=true --jars SparkOnHbaseJavaExample.jar,/opt/female/protobuf-java-2.5.0.jar HBaseSource.py
```

## Java Sample Code

The following code snippet is only for demonstration. For details about the code, see the **HBaseSource** file in **SparkOnHbaseJavaExample**.

```
public static void main(String args[]) throws IOException{
    LoginUtil.loginWithUserKeytab();
    SparkConf sparkConf = new SparkConf().setAppName("HBaseSourceExample");
    JavaSparkContext jsc = new JavaSparkContext(sparkConf);
    SQLContext sqlContext = new SQLContext(jsc);

    Configuration conf = HBaseConfiguration.create();
    JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc,conf);
    try{
        List<HBaseRecord> list = new ArrayList<HBaseRecord>();
        for(int i=0 ; i<256; i++){
            list.add(new HBaseRecord());
        }
        hbaseContext.write(list);
    } catch (Exception e) {
        e.printStackTrace();
    }
}
```

```
        list.add(new HBaseRecord(i));
    }
    Map map = new HashMap<String, String>();
    map.put(HBaseTableCatalog.tableCatalog(), cat);
    map.put(HBaseTableCatalog.newTable(), "5");
    System.out.println("Before insert data into hbase table");
    sqlContext.createDataFrame(list,
HBaseRecord.class).write().options(map).format("org.apache.hadoop.hbase.spark").save();
    Dataset<Row> ds = withCatalog(sqlContext, cat);
    System.out.println("After insert data into hbase table");
    ds.printSchema();
    ds.show();
    ds.filter("key <= 'row5'").select("key", "col1").show();
    ds.registerTempTable("table1");
    Dataset<Row> tempDS = sqlContext.sql("select count(col1) from table1 where key < 'row5'");
    tempDS.show();
} finally {
    jsc.stop();
}
}
```

## Scala Sample Code

The following code snippet is only for demonstration. For details about the code, see the HBaseSource file in SparkOnHbaseScalaExample.

```
def main(args: Array[String]) {
    LoginUtil.loginWithUserKeytab()
    val sparkConf = new SparkConf().setAppName("HBaseSourceExample")
    val sc = new SparkContext(sparkConf)
    val sqlContext = new SQLContext(sc)
    val conf = HBaseConfiguration.create()
    val hbaseContext = new HBaseContext(sc, conf)
    import sqlContext.implicits._

    def withCatalog(cat: String): DataFrame = {
        sqlContext
            .read
            .options(Map(HBaseTableCatalog.tableCatalog -> cat))
            .format("org.apache.hadoop.hbase.spark")
            .load()
    }

    val data = (0 to 255).map { i =>
        HBaseRecord(i)
    }

    try {
        sc.parallelize(data).toDF.write.options(
            Map(HBaseTableCatalog.tableCatalog -> cat, HBaseTableCatalog.newTable -> "5"))
            .format("org.apache.hadoop.hbase.spark")
            .save()

        val df = withCatalog(cat)
        df.show()
        df.filter($"col0" <= "row005")
            .select($"col0", $"col1").show()
        df.registerTempTable("table1")
        val c = sqlContext.sql("select count(col1) from table1 where col0 < 'row050'")
        c.show()
    } finally {
        sc.stop()
    }
}
```

## Python Sample Code

The following code snippet is only for demonstration. For details about the code, see the HBaseSource file in SparkOnHbasePythonExample.

```
# -*- coding:utf-8 -*-
"""

```

[Note]

(1) PySpark does not provide HBase-related APIs. In this example, Python is used to invoke Java code to implement the required operations.

(2) If yarn-client is used, ensure that the **spark.yarn.security.credentials.hbase.enabled** parameter in the **spark-defaults.conf** file under **Spark/spark/conf/** is set to **true** on the Spark client.

Set **spark.yarn.security.credentials.hbase.enabled** to **true**.

.....

```
from py4j.java_gateway import java_import
from pyspark.sql import SparkSession
# Create a SparkSession instance.
spark = SparkSession\
    .builder\
    .appName("HBaseSourceExample")\
    .getOrCreate()
# Import the required class to sc._jvm.
java_import(spark._jvm, 'com.huawei.bigdata.spark.examples.datasources.HBaseSource')
# Create a class instance and invoke the method. Transfer the sc._jsc parameter.
spark._jvm.HBaseSource().execute(spark._jsc)
# Stop the SparkSession instance.
spark.stop()
```

#### 1.21.3.4.3 Using the BulkPut Interface

##### Scenario

Users can use the HBaseContext method to use HBase in Spark applications and write the constructed RDD into HBase.

##### Data Planning

On the client, run the **hbase shell** command to go to the HBase command line and run the following commands to create HBase tables to be used in the sample code:

```
create 'bulktable','cf1'
```

##### Development Guideline

1. Create an RDD.
2. Perform operations on HBase in HBaseContext mode and write the generated RDD into the HBase table.

##### Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on FusionInsight Manager. The user in the sample code is **super**, change the value to the prepared development user name.

##### Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.

- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

 NOTE

To run the Spark on HBase example program, set **spark.yarn.security.credentials.hbase.enabled** (**false** by default) in the **spark-defaults.conf** file on the Spark client to **true**. Changing the **spark.yarn.security.credentials.hbase.enabled** value does not affect existing services. (To uninstall the HBase service, you need to change the value of this parameter back to **false**.) Set configuration item **spark.inputFormat.cache.enabled** to **false**.

## Submitting Commands

Assume that the JAR package name is **spark-hBaseContext-test-1.0.jar** that is stored in the **\$SPARK\_HOME** directory on the client. The following commands are executed in the **\$SPARK\_HOME** directory. Java is displayed before the class name of the Java API. For details, see the sample code.

- yarn-client mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode client --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkPutExa  
mple SparkOnHbaseJavaExample.jar bulktable cf1
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode client --jars  
SparkOnHbaseJavaExample.jar HBaseBulkPutExample.py bulktable cf1
```

- yarn-cluster mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode cluster --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkPutExa  
mple --files /opt/user.keytab,/opt/krb5.conf  
SparkOnHbaseJavaExample.jar bulktable cf1
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode cluster --files /opt/  
user.keytab,/opt/krb5.conf --jars SparkOnHbaseJavaExample.jar  
HBaseBulkPutExample.py bulktable cf1
```

## Java Sample Code

The following code snippet is only for demonstration. For details about the code, see the **JavaHBaseBulkPutExample** file in **SparkOnHbaseJavaExample**.

```
public static void main(String[] args) throws Exception{  
    if (args.length < 2) {
```

```
System.out.println("JavaHBaseBulkPutExample " +
    "{tableName} {columnFamily}");
return;
}
LoginUtil.loginWithUserKeytab();
String tableName = args[0];
String columnFamily = args[1];
SparkConf sparkConf = new SparkConf().setAppName("JavaHBaseBulkPutExample " + tableName);
JavaSparkContext jsc = new JavaSparkContext(sparkConf);
try {
    List<String> list = new ArrayList<String>(5);
    list.add("1," + columnFamily + ",1,1");
    list.add("2," + columnFamily + ",1,2");
    list.add("3," + columnFamily + ",1,3");
    list.add("4," + columnFamily + ",1,4");
    list.add("5," + columnFamily + ",1,5");
    list.add("6," + columnFamily + ",1,6");
    list.add("7," + columnFamily + ",1,7");
    list.add("8," + columnFamily + ",1,8");
    list.add("9," + columnFamily + ",1,9");
    list.add("10," + columnFamily + ",1,10");
    JavaRDD<String> rdd = jsc.parallelize(list);
    Configuration conf = HBaseConfiguration.create();
    JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);
    hbaseContext.bulkPut(rdd,
        TableName.valueOf(tableName),
        new PutFunction());
    System.out.println("Bulk put into Hbase successfully!");
} finally {
    jsc.stop();
}
}
```

## Scala Sample Code

The following code snippet is only for demonstration. For details about the code, see the HBaseBulkPutExample file in SparkOnHbaseScalaExample.

```
def main(args: Array[String]) {

```

### 1.21.3.4.4 Using the BulkGet Interface

#### Scenario

Users can use the `HBaseContext` method to use HBase in Spark applications, construct the rowkey of the data to be obtained into RDDs, and obtain the data corresponding to the rowkey in the HBase tables through the BulkGet interface of `HBaseContext`.

#### Data Planning

Perform operations based on the HBase tables and data in the tables that are created in [Using the BulkPut Interface](#).

## Development Guideline

- Creates RDDs containing the rowkey to be obtained.
- Perform operations on HBase in HBaseContext mode and obtain data corresponding to rowkey in HBase tables through the BulkGet interface of HBaseContext.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on FusionInsight Manager. The user in the sample code is **super**, change the value to the prepared development user name.

## Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.
- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

### NOTE

To run the Spark on HBase example program, set **spark.yarn.security.credentials.hbase.enabled** (**false** by default) in the **spark-defaults.conf** file on the Spark client to **true**. Changing the **spark.yarn.security.credentials.hbase.enabled** value does not affect existing services. (To uninstall the HBase service, you need to change the value of this parameter back to **false**.) Set configuration item **spark.inputFormat.cache.enabled** to **false**.

## Submitting Commands

Assume that the JAR package name is **spark-hbaseContext-test-1.0.jar** that is stored in the **\$SPARK\_HOME** directory on the client. The following commands are executed in the **\$SPARK\_HOME** directory, and Java is displayed before the class name of the Java interface. For details, see the sample code.

- yarn-client mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode client --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkGetExa  
mple SparkOnHbaseJavaExample.jar bulktable
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode client --jars  
SparkOnHbaseJavaExample.jar HBaseBulkGetExample.py bulktable
```

- yarn-cluster mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode cluster --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkGetExa  
mple --files /opt/user.keytab,/opt/krb5.conf  
SparkOnHbaseJavaExample.jar bulktable
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode cluster --files /opt/  
user.keytab,/opt/krb5.conf --jars SparkOnHbaseJavaExample.jar  
HBaseBulkGetExample.py bulktable
```

## Java Sample Code

The following code snippet is only for demonstration. For details about the code, see the **HBaseBulkGetExample** file in **SparkOnHbaseJavaExample**.

```
public static void main(String[] args) throws IOException{  
    if (args.length < 1) {  
        System.out.println("JavaHBaseBulkGetExample {tableName}");  
        return;  
    }  
    LoginUtil.loginWithUserKeytab();  
    String tableName = args[0];  
    SparkConf sparkConf = new SparkConf().setAppName("JavaHBaseBulkGetExample " + tableName);  
    JavaSparkContext jsc = new JavaSparkContext(sparkConf);  
    try {  
        List<byte[]> list = new ArrayList<byte[]>(5);  
        list.add(Bytes.toBytes("1"));  
        list.add(Bytes.toBytes("2"));  
        list.add(Bytes.toBytes("3"));  
        list.add(Bytes.toBytes("4"));  
        list.add(Bytes.toBytes("5"));  
        JavaRDD<byte[]> rdd = jsc.parallelize(list);  
        Configuration conf = HBaseConfiguration.create();  
        JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);  
        List resultList = hbaseContext.bulkGet(TableName.valueOf(tableName), 2, rdd, new GetFunction(),  
            new ResultFunction()).collect();  
        for(int i=0 ;<resultList.size();i++){  
            System.out.println(resultList.get(i));  
        }  
    } finally {  
        jsc.stop();  
    }  
}
```

## Scala Sample Code

The following code snippet is only for demonstration. For details about the code, see the **HBaseBulkGetExample** file in **SparkOnHbaseScalaExample**.

```
def main(args: Array[String]) {  
    if (args.length < 1) {  
        println("HBaseBulkGetExample {tableName} missing an argument")  
        return  
    }  
    LoginUtil.loginWithUserKeytab()  
    val tableName = args(0)
```

```
val sparkConf = new SparkConf().setAppName("HBaseBulkGetExample " + tableName)
val sc = new SparkContext(sparkConf)
try {
    //[(Array[Byte])]
    val rdd = sc.parallelize(Array(
        Bytes.toBytes("1"),
        Bytes.toBytes("2"),
        Bytes.toBytes("3"),
        Bytes.toBytes("4"),
        Bytes.toBytes("5"),
        Bytes.toBytes("6"),
        Bytes.toBytes("7")))
    val conf = HBaseConfiguration.create()
    val hbaseContext = new HBaseContext(sc, conf)
    val getRdd = hbaseContext.bulkGet[Array[Byte], String](
        TableName.valueOf(tableName),
        2,
        rdd,
        record => {
            System.out.println("making Get")
            new Get(record)
        },
        (result: Result) => {
            val it = result.listCells().iterator()
            val b = new StringBuilder
            b.append(Bytes.toString(result.getRow) + ":")
            while (it.hasNext) {
                val cell = it.next()
                val q = Bytes.toString(CellUtil.cloneQualifier(cell))
                if (q.equals("counter")) {
                    b.append("(" + q + "," + Bytes.toLong(CellUtil.cloneValue(cell)) + ")")
                } else {
                    b.append("(" + q + "," + Bytes.toString(CellUtil.cloneValue(cell)) + ")")
                }
            }
            b.toString()
        })
        getRdd.collect().foreach(v => println(v))
    } finally {
        sc.stop()
    }
}
```

## Python Sample Code

The following code snippet is only for demonstration. For details about the code, see the `HBaseBulkGetExample` file in `SparkOnHbasePythonExample`.

```
# -*- coding:utf-8 -*-
"""
[Note]
(1) PySpark does not provide HBase-related APIs. In this example, Python is used to invoke Java code to implement required operations.
(2) If yarn-client is used, ensure that the spark.yarn.security.credentials.hbase.enabled parameter in the spark-defaults.conf file under Spark/spark/conf/ is set to true on the Spark client.
    Set spark.yarn.security.credentials.hbase.enabled to true.
"""

from py4j.java_gateway import java_import
from pyspark.sql import SparkSession
# Create a SparkSession instance.
spark = SparkSession\
    .builder\
    .appName("JavaHBaseBulkGetExample")\
    .getOrCreate()
# Import required class to sc._jvm.
java_import(spark._jvm, 'com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkGetExample')
# Create a class instance and invoke the method. Transfer the sc._jsc parameter.
spark._jvm.JavaHBaseBulkGetExample().execute(spark._jsc, sys.argv)
```

```
# Stop the SparkSession instance.  
spark.stop()
```

#### 1.21.3.4.5 Using the BulkDelete Interface

##### Scenario

Users can use the HBaseContext method to use HBase in Spark applications, construct rowkey of the data to be deleted into RDDs, and delete the data corresponding to the rowkey in HBase tables through the BulkDelete interface of HBaseContext.

##### Data Planning

Perform operations based on the HBase tables and data in the tables that are created in [Using the BulkPut Interface](#).

##### Development Guideline

1. Create RDDs containing the rowkey to be deleted.
2. Perform operations on the HBase in HBaseContext mode and delete the data corresponding to the rowkey in HBase tables through the BulkDelete interface of HBaseContext.

##### Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on FusionInsight Manager. The user in the sample code is **super**, change the value to the prepared development user name.

##### Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.
- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

###### NOTE

To run the Spark on HBase example program, set **spark.yarn.security.credentials.hbase.enabled** (**false** by default) in the **spark-defaults.conf** file on the Spark client to **true**. Changing the **spark.yarn.security.credentials.hbase.enabled** value does not affect existing services. (To uninstall the HBase service, you need to change the value of this parameter back to **false**.) Set configuration item **spark.inputFormat.cache.enabled** to **false**.

##### Submitting Commands

Assume that the JAR package name is **spark-hbaseContext-test-1.0.jar** that is stored in the **\$SPARK\_HOME** directory on the client. The following commands are

executed in the **\$SPARK\_HOME** directory, and Java is displayed before the class name of the Java interface. For details, see the sample code.

- yarn-client mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode client --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkDeleteE  
xample SparkOnHbaseJavaExample.jar bulktable
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode client --jars  
SparkOnHbaseJavaExample.jar HBaseBulkDeleteExample.py bulktable
```

- yarn-cluster mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode cluster --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkDeleteE  
xample --files /opt/user.keytab,/opt/krb5.conf  
SparkOnHbaseJavaExample.jar bulktable
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode cluster --files /opt/  
user.keytab,/opt/krb5.conf --jars SparkOnHbaseJavaExample.jar  
HBaseBulkDeleteExample.py bulktable
```

## Java Sample Code

The following code snippet is only for demonstration. For details about the code, see the **HBaseBulkDeleteExample** file in **SparkOnHbaseJavaExample**.

```
public static void main(String[] args) throws IOException {  
    if (args.length < 1) {  
        System.out.println("JavaHBaseBulkDeleteExample {tableName}");  
        return;  
    }  
    LoginUtil.loginWithUserKeytab();  
    String tableName = args[0];  
    SparkConf sparkConf = new SparkConf().setAppName("JavaHBaseBulkDeleteExample " + tableName);  
    JavaSparkContext jsc = new JavaSparkContext(sparkConf);  
    try {  
        List<byte[]> list = new ArrayList<byte[]>(5);  
        list.add(Bytes.toBytes("1"));  
        list.add(Bytes.toBytes("2"));  
        list.add(Bytes.toBytes("3"));  
        list.add(Bytes.toBytes("4"));  
        list.add(Bytes.toBytes("5"));  
        JavaRDD<byte[]> rdd = jsc.parallelize(list);  
        Configuration conf = HBaseConfiguration.create();  
        JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);  
        hbaseContext.bulkDelete(rdd,  
                               TableName.valueOf(tableName), new DeleteFunction(), 4);  
    } catch (Exception e) {  
        e.printStackTrace();  
    } finally {  
        jsc.stop();  
    }  
}
```

```
        System.out.println("Bulk Delete successfully!");
    } finally {
        jsc.stop();
    }
}
```

## Scala Sample Code

The following code snippet is only for demonstration. For details about the code, see the `HBaseBulkDeleteExample` file in `SparkOnHbaseScalaExample`.

```
def main(args: Array[String]) {
    if (args.length < 1) {
        println("HBaseBulkDeleteExample {tableName} missing an argument")
        return
    }
    LoginUtil.loginWithUserKeytab()
    val tableName = args(0)
    val sparkConf = new SparkConf().setAppName("HBaseBulkDeleteExample " + tableName)
    val sc = new SparkContext(sparkConf)
    try {
        //[[Array[Byte]]]
        val rdd = sc.parallelize(Array(
            Bytes.toBytes("1"),
            Bytes.toBytes("2"),
            Bytes.toBytes("3"),
            Bytes.toBytes("4"),
            Bytes.toBytes("5")
        ))
        val conf = HBaseConfiguration.create()
        val hbaseContext = new HBaseContext(sc, conf)
        hbaseContext.bulkDelete[Array[Byte]](rdd,
            TableName.valueOf(tableName),
            putRecord => new Delete(putRecord),
            4)
    } finally {
        sc.stop()
    }
}
```

## Python Sample Code

The following code snippet is only for demonstration. For details about the code, see the `HBaseBulkDeleteExample` file in `SparkOnHbasePythonExample`.

```
def main(args: Array[String]) {
# -*- coding:utf-8 -*-
"""
[Note]
(1) PySpark does not provide HBase-related APIs. This example uses Python to invoke Java code to
implement required operations.
(2) If yarn-client is used, ensure that the spark.yarn.security.credentials.hbase.enabled parameter in the
spark-defaults.conf file under Spark/spark/conf/ is set to true on the Spark client.
    Set spark.yarn.security.credentials.hbase.enabled to true.
"""

from py4j.java_gateway import java_import
from pyspark.sql import SparkSession
# Create a SparkSession instance.
spark = SparkSession\
    .builder\
    .appName("JavaHBaseBulkDeleteExample")\
    .getOrCreate()
# Import the required class to sc._jvm.
java_import(spark._jvm, 'com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkDeleteExample')
# Create a class instance and invoke the method, Transfer the sc._jsc parameter.
spark._jvm.JavaHBaseBulkDeleteExample().execute(spark._jsc, sys.argv)
# Stop the SparkSession instance.
spark.stop()
```

### 1.21.3.4.6 Using the BulkLoad Interface

#### Scenario

Users can use HBaseContext to use HBase in Spark applications, construct rowkey of the data to be inserted into RDDs, write RDDs into HFiles through the BulkLoad interface of HBaseContext. The following command is used to import the generated HFiles to the HBase table and will not be described in this section.

```
hbase org.apache.hadoop.hbase.mapreduce.LoadIncrementalHFiles {hfilePath}  
{tableName}
```

#### Data Planning

1. Run the **hbase shell** command on the client to go to the HBase command line.
2. Run the following command to create HBase tables:  
`create 'bulkload-table-test','f1','f2'`

#### Development Guideline

1. Construct the data to be imported into RDDs
2. Perform operations on HBase in HBaseContext mode and write RDDs into HFiles through the BulkLoad interface of HBaseContext.

### Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on FusionInsight Manager. The user in the sample code is **super**, change the value to the prepared development user name.

#### Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.
- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

#### Submitting Commands

Assume that the JAR package name is **spark-hbaseContext-test-1.0.jar** that is stored in the **\$SPARK\_HOME** directory on the client. The following commands are executed in the **\$SPARK\_HOME** directory, and Java is displayed before the class name of the Java interface. For details, see the sample code.

- yarn-client mode:  
Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode client --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkLoadExa  
mple SparkOnHbaseJavaExample.jar /tmp/hfile bulkload-table-test
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode client --jars  
SparkOnHbaseJavaExample.jar HBaseBulkLoadExample.py /tmp/hfile  
bulkload-table-test
```

- yarn-cluster mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode cluster --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseBulkLoadExa  
mple --files /opt/user.keytab,/opt/krb5.conf  
SparkOnHbaseJavaExample.jar /tmp/hfile bulkload-table-test
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode cluster --files /opt/  
user.keytab,/opt/krb5.conf --jars SparkOnHbaseJavaExample.jar  
HBaseBulkLoadExample.py /tmp/hfile bulkload-table-test
```

## Java Sample Code

The following code snippet is only for demonstration. For details about the code, see the JavaHBaseBulkLoadExample file in SparkOnHbaseJavaExample.

```
public static void main(String[] args) throws IOException{  
    if (args.length < 2) {  
        System.out.println("JavaHBaseBulkLoadExample {outputPath} {tableName}");  
        return;  
    }  
    LoginUtil.loginWithUserKeytab();  
    String outputPath = args[0];  
    String tableName = args[1];  
    String columnFamily1 = "f1";  
    String columnFamily2 = "f2";  
    SparkConf sparkConf = new SparkConf().setAppName("JavaHBaseBulkLoadExample " + tableName);  
    JavaSparkContext jsc = new JavaSparkContext(sparkConf);  
    try {  
        List<String> list= new ArrayList<String>();  
        // row1  
        list.add("1," + columnFamily1 + ",b,1");  
        // row3  
        list.add("3," + columnFamily1 + ",a,2");  
        list.add("3," + columnFamily1 + ",b,1");  
        list.add("3," + columnFamily2 + ",a,1");  
        /* row2 */  
        list.add("2," + columnFamily2 + ",a,3");  
        list.add("2," + columnFamily2 + ",b,3");  
        JavaRDD<String> rdd = jsc.parallelize(list);  
        Configuration conf = HBaseConfiguration.create();  
        JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);  
        hbaseContext.bulkLoad(rdd, TableName.valueOf(tableName),new BulkLoadFunction(), outputPath,  
        new HashMap<byte[], FamilyHFileWriteOptions>(), false, HConstants.DEFAULT_MAX_FILE_SIZE);  
    } catch (Exception e) {  
        e.printStackTrace();  
    } finally {  
        jsc.stop();  
    }  
}
```

```
    } finally {
        jsc.stop();
    }
}
```

## Scala Sample Code

The following code snippet is only for demonstration. For details about the code, see the HBaseBulkLoadExample file in SparkOnHbaseScalaExample.

```
def main(args: Array[String]) {
    if(args.length < 2) {
        println("HBaseBulkLoadExample {outputPath} {tableName}")
        return
    }
    LoginUtil.loginWithUserKeytab()
    val Array(outputPath, tableName) = args
    val columnFamily1 = "f1"
    val columnFamily2 = "f2"
    val sparkConf = new SparkConf().setAppName("JavaHBaseBulkLoadExample " + tableName)
    val sc = new SparkContext(sparkConf)
    try {
        val arr = Array("1," + columnFamily1 + ",b,1",
                      "2," + columnFamily1 + ",a,2",
                      "3," + columnFamily1 + ",b,1",
                      "3," + columnFamily2 + ",a,1",
                      "4," + columnFamily2 + ",a,3",
                      "5," + columnFamily2 + ",b,3")

        val rdd = sc.parallelize(arr)
        val config = HBaseConfiguration.create
        val hbaseContext = new HBaseContext(sc, config)
        hbaseContext.bulkLoad[String](rdd,
                                      TableName.valueOf(tableName),
                                      (putRecord) => {
            if(putRecord.length > 0) {
                val strArray = putRecord.split(",")

                                                Bytes.toBytes(strArray(2)))
                val ite = (kfq, Bytes.toBytes(strArray(3)))
                val itea = List(ite).iterator
                itea
            } else {
                null
            },
            outputPath)
        } finally {
            sc.stop()
        }
    }
}
```

## Python Sample Code

The following code snippet is only for demonstration. For details about the code, see the HBaseBulkLoadPythonExample file in SparkOnHbasePythonExample.

```
# -*- coding:utf-8 -*-
"""
[Note]
(1) PySpark does not provide HBase-related APIs. In this example, Python is used to invoke Java code to
implement required operations.
(2) If yarn-client is used, ensure that the spark.yarn.security.credentials.hbase.enabled parameter in the
spark-defaults.conf file under Spark/spark/conf/ is set to true on the Spark client.
Set spark.yarn.security.credentials.hbase.enabled to true.
```

```
"""
from py4j.java_gateway import java_import
from pyspark.sql import SparkSession
# Create a SparkSession instance.
spark = SparkSession\
    .builder\
    .appName("JavaHBaseBulkLoadExample")\
    .getOrCreate()
# Import required class to sc._jvm.
java_import(spark._jvm, 'com.huawei.bigdata.spark.examples.HBaseBulkLoadPythonExample')
# Create a class instance and invoke the method. Transfer the sc._jsc parameter.
spark._jvm.HBaseBulkLoadPythonExample().hbaseBulkLoad(spark._jsc, sys.argv[1], sys.argv[2])
# Stop the SparkSession instance.
spark.stop()
```

#### 1.21.3.4.7 Using the foreachPartition Interface

##### Scenario

Users can use HBaseContext to perform operations on HBase in the Spark application, construct rowkey of the data to be inserted into RDDs, and write RDDs to HBase tables through the mapPartition interface of HBaseContext.

##### Data Planning

1. Run the **hbase shell** command on the client to go to the HBase command line.
2. Run the following command to create an HBase table:  
**create 'table2','cf1'**

##### Development Guideline

1. Construct the data to be imported into RDDs
2. Perform operations on HBase in HBaseContext mode and concurrently write data to HBase through the foreachPartition interface of HBaseContext.

##### Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **super**, change the value to the prepared development user name.

##### Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.
- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

### NOTE

To run the Spark on HBase example program, set `spark.yarn.security.credentials.hbase.enabled` (`false` by default) in the `spark-defaults.conf` file on the Spark client to `true`. Changing the `spark.yarn.security.credentials.hbase.enabled` value does not affect existing services. (To uninstall the HBase service, you need to change the value of this parameter back to `false`.) Set configuration item `spark.inputFormat.cache.enabled` to `false`.

## Submitting Commands

Assume that the JAR package name is **spark-hbaseContext-test-1.0.jar** that is stored in the `$SPARK_HOME` directory on the client. The following commands are executed in the `$SPARK_HOME` directory, and Java is displayed before the class name of the Java interface. For details, see the sample code.

- yarn-client mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```

tionExample --files /opt/user.keytab,/opt/krb5.conf  
SparkOnHbaseJavaExample.jar table2 cf1
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode cluster --files /opt/  
user.keytab,/opt/krb5.conf --jars SparkOnHbaseJavaExample.jar  
HBaseForEachPartitionExample.py table2 cf1
```

## Java Sample Code

The following code snippet is only for demonstration. For details about the code, see the `JavaHBaseForEachPartitionExample` file in `SparkOnHbaseJavaExample`.

```
public static void main(String[] args) throws IOException {  
    if (args.length < 1) {  
        System.out.println("JavaHBaseForEachPartitionExample {tableName} {columnFamily}");  
        return;  
    }
```

```

    }
    LoginUtil.loginWithUserKeytab();
    final String tableName = args[0];
    final String columnFamily = args[1];
    SparkConf sparkConf = new SparkConf().setAppName("JavaHBaseBulkGetExample " + tableName);
    JavaSparkContext jsc = new JavaSparkContext(sparkConf);
    try {
        List<byte[]> list = new ArrayList<byte[]>(5);
        list.add(Bytes.toBytes("1"));
        list.add(Bytes.toBytes("2"));
        list.add(Bytes.toBytes("3"));
        list.add(Bytes.toBytes("4"));
        list.add(Bytes.toBytes("5"));
        JavaRDD<byte[]> rdd = jsc.parallelize(list);
        Configuration conf = HBaseConfiguration.create();
        JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);
        hbaseContext.foreachPartition(rdd,
            new VoidFunction<Tuple2<Iterator<byte[]>, Connection>>() {
                public void call(Tuple2<Iterator<byte[]>, Connection> t)
                    throws Exception {
                    Connection con = t._2();
                    Iterator<byte[]> it = t._1();
                    BufferedMutator buf = con.getBufferedMutator(tableName.valueOf(tableName));
                    while (it.hasNext()) {
                        byte[] b = it.next();
                        Put put = new Put(b);
                        put.add(Bytes.toBytes(columnFamily), Bytes.toBytes("cid"), b);
                        buf.mutate(put);
                    }
                    buf.flush();
                    buf.close();
                }
            });
        } finally {
            jsc.stop();
        }
    }
}

```

## Scala Sample Code

The following code snippet is only for demonstration. For details about the code, see the `HBaseForEachPartitionExample` file in `SparkOnHbaseScalaExample`.

```

def main(args: Array[String]) {
    if (args.length < 2) {
        println("HBaseForEachPartitionExample {tableName} {columnFamily} are missing an arguments")
        return
    }
    LoginUtil.loginWithUserKeytab()
    val tableName = args(0)
    val columnFamily = args(1)
    val sparkConf = new SparkConf().setAppName("HBaseForEachPartitionExample " +
        tableName + " " + columnFamily)
    val sc = new SparkContext(sparkConf)
    try {
        //[(Array[Byte], Array[(Array[Byte], Array[Byte], Array[Byte])])]
        val rdd = sc.parallelize(Array(
            (Bytes.toBytes("1"),
                Array((Bytes.toBytes(columnFamily), Bytes.toBytes("1"), Bytes.toBytes("1")))),
            (Bytes.toBytes("2"),
                Array((Bytes.toBytes(columnFamily), Bytes.toBytes("1"), Bytes.toBytes("2")))),
            (Bytes.toBytes("3"),
                Array((Bytes.toBytes(columnFamily), Bytes.toBytes("1"), Bytes.toBytes("3")))),
            (Bytes.toBytes("4"),
                Array((Bytes.toBytes(columnFamily), Bytes.toBytes("1"), Bytes.toBytes("4")))),
            (Bytes.toBytes("5"),
                Array((Bytes.toBytes(columnFamily), Bytes.toBytes("1"), Bytes.toBytes("5"))))
        ))
    }
}

```

```
val conf = HBaseConfiguration.create()
val hbaseContext = new HBaseContext(sc, conf)
rdd.hbaseForEachPartition(hbaseContext,
  (it, connection) => {
  val m = connection.getBufferedMutator(TableName.valueOf(tableName))
  it.foreach(r => {
    val put = new Put(r._1)
    r._2.foreach((putValue) =>
      put.addColumn(putValue._1, putValue._2, putValue._3))
    m.mutate(put)
  })
  m.flush()
  m.close()
})
} finally {
  sc.stop()
}
}
```

## Python Sample Code

The following code snippet is only for demonstration. For details about the code, see the `HBaseForEachPartitionExample` file in `SparkOnHbasePythonExample`.

```
# -*- coding:utf-8 -*-
"""
[Note]

spark.stop()
```

### 1.21.3.4.8 Distributedly Scanning HBase Tables

#### Scenario

Users can use `HBaseContext` to perform operations on HBase in Spark applications and use HBase RDDs to scan HBase tables based on specific rules.

#### Data Planning

Use HBase tables created in [Performing Operations on Data in Avro Format](#)

#### Development Guideline

1. Set the scanning rule. For example: `setCaching`.
2. Use specific rules to scan the HBase table.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **super**, change the value to the prepared development user name.

## Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.
- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

### NOTE

To run the Spark on HBase example program, set **spark.yarn.security.credentials.hbase.enabled** (**false** by default) in the **spark-defaults.conf** file on the Spark client to **true**. Changing the **spark.yarn.security.credentials.hbase.enabled** value does not affect existing services. (To uninstall the HBase service, you need to change the value of this parameter back to **false**.) Set configuration item **spark.inputFormat.cache.enabled** to **false**.

## Submitting Commands

Assume that the JAR package name is **spark-hBaseContext-test-1.0.jar** that is stored in the **\$SPARK\_HOME** directory on the client. The following commands are executed in the **\$SPARK\_HOME** directory, and Java is displayed before the class name of the Java interface. For details, see the sample code.

- yarn-client mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode client --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseDistributedS  
canExample SparkOnHbaseJavaExample.jar ExampleAvrotable
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode client --jars  
SparkOnHbaseJavaExample.jar HBaseDistributedScanExample.py  
ExampleAvrotable
```

- yarn-cluster mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```
bin/spark-submit --master yarn --deploy-mode cluster --class  
com.huawei.bigdata.spark.examples.hbasecontext.JavaHBaseDistributedS
```

```
canExample --files /opt/user.keytab,/opt/krb5.conf  
SparkOnHbaseJavaExample.jar ExampleAvrotable
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode cluster --files /opt/  
user.keytab,/opt/krb5.conf --jars SparkOnHbaseJavaExample.jar  
HBaseDistributedScanExample.py ExampleAvrotable
```

## Java Sample Code

The following code snippet is only for demonstration. For details about the code, see the JavaHBaseDistributedScanExample file in SparkOnHbaseJavaExample.

```
public static void main(String[] args) throws IOException{  
    if (args.length < 1) {  
        System.out.println("JavaHBaseDistributedScan {tableName}");  
        return;  
    }  
    LoginUtil.loginWithUserKeytab();  
    String tableName = args[0];  
    SparkConf sparkConf = new SparkConf().setAppName("JavaHBaseDistributedScan " + tableName);  
    JavaSparkContext jsc = new JavaSparkContext(sparkConf);  
    try {  
        Configuration conf = HBaseConfiguration.create();  
        JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);  
        Scan scan = new Scan();  
        scan.setCaching(100);  
        JavaRDD<Tuple2<ImmutableBytesWritable, Result>> javaRdd =  
            hbaseContext.hbaseRDD(tableName.valueOf(tableName), scan);  
        List<String> results = javaRdd.map(new ScanConvertFunction()).collect();  
        System.out.println("Result Size: " + results.size());  
    } finally {  
        jsc.stop();  
    }  
}
```

## Scala Sample Code

The following code snippet is only for demonstration. For details about the code, see the HBaseDistributedScanExample file in SparkOnHbaseScalaExample.

```
def main(args: Array[String]) {  
    if (args.length < 1) {  
        println("HBaseDistributedScanExample {tableName} missing an argument")  
        return  
    }  
    LoginUtil.loginWithUserKeytab()  
    val tableName = args(0)  
    val sparkConf = new SparkConf().setAppName("HBaseDistributedScanExample " + tableName )  
    val sc = new SparkContext(sparkConf)  
    try {  
        val conf = HBaseConfiguration.create()  
        val hbaseContext = new HBaseContext(sc, conf)  
        val scan = new Scan()  
        scan.setCaching(100)  
        val getRdd = hbaseContext.hbaseRDD(tableName.valueOf(tableName), scan)  
        getRdd.foreach(v => println(Bytes.toString(v._1.get())))  
        println("Length: " + getRdd.map(r => r._1.copyBytes()).collect().length);  
    } finally {  
        sc.stop()  
    }  
}
```

## Python Sample Code

The following code snippet is only for demonstration. For details about the code, see the HBaseDistributedScanExample file in SparkOnHbasePythonExample.

```
# -*- coding:utf-8 -*-
# -*- coding:utf-8 -*-
"""
[Note]
(1) PySpark does not provide HBase-related APIs. In this example, Python is used to invoke Java code to implement required operations.
(2) If yarn-client is used, ensure that the spark.yarn.security.credentials.hbase.enabled parameter in the spark-defaults.conf file under Spark/spark/conf/ is set to true on the Spark client.
    Set spark.yarn.security.credentials.hbase.enabled to true.
"""

# Stop the SparkSession instance.
spark.stop()
```

### 1.21.3.4.9 Using the mapPartition Interface

#### Scenario

Users can use the HBaseContext method to perform operations on HBase in Spark applications and use the mapPartition interface to traverse HBase tables in parallel.

#### Data Planning

Use HBase tables created in [Using the foreachPartition Interface](#).

#### Development Guideline

1. Construct RDDs corresponding to rowkey in HBase tables to be traversed.
2. Use the mapPartition interface to traverse the data corresponding to rowkey and perform simple operations.

#### Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **super**, change the value to the prepared development user name.

#### Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).

- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.
- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

 NOTE

To run the Spark on HBase example program, set **spark.yarn.security.credentials.hbase.enabled** (**false** by default) in the **spark-defaults.conf** file on the Spark client to **true**. Changing the **spark.yarn.security.credentials.hbase.enabled** value does not affect existing services. (To uninstall the HBase service, you need to change the value of this parameter back to **false**.) Set configuration item **spark.inputFormat.cache.enabled** to **false**.

## Submitting Commands

Assume that the JAR package name is **spark-hBaseContext-test-1.0.jar** that is stored in the **\$SPARK\_HOME** directory on the client. The following commands are executed in the **\$SPARK\_HOME** directory, and Java is displayed before the class name of the Java interface. For details, see the sample code.

- yarn-client mode:

Java/Scala version (The class name must be the same as the actual code. The following is only an example.)

```

### 1.21.3.4.10 Writing Data to HBase Tables In Batches Using SparkStreaming

#### Scenario

Users can use HBaseContext to perform operations on HBase in Spark applications and write streaming data to HBase tables using the streamBulkPut interface.

#### Data Planning

1. Create a session connected to the client and run the **hbase shell** command in the session to go to the HBase command line.
2. Run the following command in the HBase command line to create an HBase table:  
**create 'streamingTable','cf1'**
3. In another session of the client, run the Linux command to construct a port for receiving data. (The command may be different for servers running different operating systems. For the SUSE operating system, the following command is used: **netcat -lk 9999**.)  
**nc -lk 9999**

After the command for submitting a task is executed, enter the data to be submitted in this command and receive the data through the HBase table.

 NOTE

To construct a port for receiving data, you need to install netcat on the server where the client is located.

#### Development Guideline

1. Use SparkStreaming to continuously read data from a specific port.
2. Write the read DStream to HBase tables through the streamBulkPut interface.

#### Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **super**, change the value to the prepared development user name.

#### Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, **\$SPARK\_HOME**) on the server where the Spark client is located.

- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed (The file upload path must be the same as the path of the generated JAR file).

 NOTE

To run the Spark on HBase example program, set **spark.yarn.security.credentials.hbase.enabled** (**false** by default) in the **spark-defaults.conf** file on the Spark client to **true**. Changing the **spark.yarn.security.credentials.hbase.enabled** value does not affect existing services. (To uninstall the HBase service, you need to change the value of this parameter back to **false**.) Set the value of the configuration item **spark.inputFormat.cache.enabled** to **false**.

## Submitting Commands

Assume that the JAR package name is **spark-hBaseContext-test-1.0.jar** that is stored in the **\$SPARK\_HOME** directory on the client. The following commands are executed in the **\$SPARK\_HOME** directory, and Java is displayed before the class name of the Java interface. For details, see the sample code.

- yarn-client mode:

Java/Scala version. (The class name must be the same as the actual code. The following is only an example.) **\${ip}** must be the IP address of the host where the **nc -lk 9999** command is executed.

```
bin/spark-submit --master yarn --deploy-mode client --class  
com.huawei.bigdata.spark.examples.streaming.JavaHBaseStreamingBulkP  
utExample SparkOnHbaseJavaExample.jar ${ip} 9999 streamingTable cf1
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode client --jars  
SparkOnHbaseJavaExample.jar HBaseStreamingBulkPutExample.py ${ip}  
9999 streamingTable cf1
```

- yarn-cluster mode:

Java/Scala version. (The class name must be the same as the actual code. The following is only an example.) **\${ip}** must be the IP address of the host where the **nc -lk 9999** command is executed.

```
bin/spark-submit --master yarn --deploy-mode cluster --class  
com.huawei.bigdata.spark.examples.streaming.JavaHBaseStreamingBulkP  
utExample --files /opt/user.keytab,/opt/krb5.conf  
SparkOnHbaseJavaExample.jar ${ip} 9999 streamingTable cf1
```

Python version. (The file name must be the same as the actual one. The following is only an example.) Assume that the package name of the corresponding Java code is **SparkOnHbaseJavaExample.jar** and the package is saved to the current directory.

```
bin/spark-submit --master yarn --deploy-mode cluster --files /opt/  
user.keytab,/opt/krb5.conf --jars SparkOnHbaseJavaExample.jar  
HBaseStreamingBulkPutExample.py ${ip} 9999 streamingTable cf1
```

## Java Sample Code

The following code snippet is only for demonstration. For details about the code, see the JavaHBaseStreamingBulkPutExample file in SparkOnHbaseJavaExample.

### NOTE

The **awaitTerminationOrTimeout()** method is used to set the task timeout interval (in milliseconds). You are advised to set this parameter based on the expected task execution time.

```
public static void main(String[] args) throws IOException {
    if (args.length < 4) {
        System.out.println("JavaHBaseBulkPutExample " +
            "{host} {port} {tableName}");
        return;
    }
    LoginUtil.loginWithUserKeytab();
    String host = args[0];
    String port = args[1];
    String tableName = args[2];
    String columnFamily = args[3];
    SparkConf sparkConf =
        new SparkConf().setAppName("JavaHBaseStreamingBulkPutExample " +
            tableName + ":" + port + ":" + tableName);
    JavaSparkContext jsc = new JavaSparkContext(sparkConf);
    try {
        JavaStreamingContext jssc =
            new JavaStreamingContext(jsc, new Duration(1000));
        JavaReceiverInputDStream<String> javaDstream =
            jssc.socketTextStream(host, Integer.parseInt(port));
        Configuration conf = HBaseConfiguration.create();
        JavaHBaseContext hbaseContext = new JavaHBaseContext(jsc, conf);
        hbaseContext.streamBulkPut(javaDstream,
            TableName.valueOf(tableName),
            new PutFunction(columnFamily));
        jssc.start();
        jssc.awaitTerminationOrTimeout(60000);
        jssc.stop(false,true);
    }catch(InterruptedException e){
        e.printStackTrace();
    } finally {
        jsc.stop();
    }
}
```

## Scala Sample Code

The following code snippet is only for demonstration. For details about the code, see the HBaseStreamingBulkPutExample file in SparkOnHbaseScalaExample.

### NOTE

The **awaitTerminationOrTimeout()** method is used to set the task timeout interval (in milliseconds). You are advised to set this parameter based on the expected task execution time.

```
def main(args: Array[String]): Unit = {
    loginUtil.loginWithUserKeytab()
    val host = args(0)
    val port = args(1)
    val tableName = args(2)
    val columnFamily = args(3)
    val conf = new SparkConf()
    conf.setAppName("HBase Streaming Bulk Put Example")
    val sc = new SparkContext(conf)
    try {
```

```
val config = HBaseConfiguration.create()
val hbaseContext = new HBaseContext(sc, config)
val ssc = new StreamingContext(sc, Seconds(1))
val lines = ssc.socketTextStream(host, port.toInt)
hbaseContext.streamBulkPut[String](lines,
    TableName.valueOf(tableName),
    (putRecord) => {
    if (putRecord.length() > 0) {
        val put = new Put(Bytes.toBytes(putRecord))
        put.addColumn(Bytes.toBytes(columnFamily), Bytes.toBytes("foo"), Bytes.toBytes("bar"))
        put
    } else {
        null
    }
})
ssc.start()
ssc.awaitTerminationOrTimeout(60000)
ssc.stop(stopSparkContext = false)
} finally {
    sc.stop()
}
}
```

## Python Sample Code

The following code snippet is only for demonstration. For details about the code, see the `HBaseStreamingBulkPutExample` file in `SparkOnHbasePythonExample`.

```
# -*- coding:utf-8 -*-
"""
[Note]
(1) PySpark does not provide HBase-related APIs. In this example, Python is used to invoke Java code to
implement required operations.
(2) If yarn-client is used, ensure that the spark.yarn.security.credentials.hbase.enabled parameter in the
spark-defaults.conf file under Spark/spark/conf/ is set to true on the Spark client.
    Set spark.yarn.security.credentials.hbase.enabled to true.
"""

from py4j.java_gateway import java_import
from pyspark.sql import SparkSession
# Create a SparkSession instance.
spark = SparkSession\
    .builder\
    .appName("JavaHBaseStreamingBulkPutExample")\
    .getOrCreate()
# Import required class to sc._jvm.
java_import(spark._jvm,
'com.huawei.bigdata.spark.examples.streaming.JavaHBaseStreamingBulkPutExample')
# Create class instance and invoke the method. Transfer the sc._jsc parameter.
spark._jvm.JavaHBaseStreamingBulkPutExample().execute(spark._jsc, sys.argv)
# Stop the SparkSession instance.
spark.stop()
```

### 1.21.3.5 Reading Data from HBase and Write It Back to HBase

#### 1.21.3.5.1 Overview

##### Scenarios

Assume `table1` of HBase stores the user consumption amount of the current day and `table2` stores the history consumption data.

In `table1`, `key=1` and `cf:cid=100` indicate that the consumption amount of user 1 in the current day is 100 CNY.

In table2, key=1 and cf:cid=1000 indicate that the history consumption amount of user 1 is 1000 CNY.

The Spark application shall achieve the following function:

Add the current consumption amount (100) to the history consumption amount (1000).

The running result is that the total consumption amount of user 1 (key=1) in table2 is 1100 CNY (cf:cid=1100).

## Data Preparation

Use the Spark-Beeline tool to create table1 and table2 (Spark table and HBase table, respectively), and insert data by HBase.

**Step 1** Ensure that JDBCServer is started. On the Spark client, perform the following operations using the Spark-Beeline command tool:

**Step 2** Use the Spark-Beeline tool to create Spark table1:

```
create table table1
(
    key string,
    cid string
)
using org.apache.spark.sql.hbase.HBaseSource
options(
    hbaseTableName "table1",
    keyCols "key",
    colsMapping "cid=cf.cid");
```

**Step 3** Run the following command on HBase to insert data to table1:

```
put 'table1', '1', 'cf:cid', '100'
```

**Step 4** Use the Spark-Beeline tool to create Spark table2:

```
create table table2
(
    key string,
    cid string
)
using org.apache.spark.sql.hbase.HBaseSource
options(
    hbaseTableName "table2",
```

```
keyCols "key",
colsMapping "cid=cf.cid");
```

**Step 5** Run the following command on HBase to insert data to table 2:

```
put 'table2', '1', 'cf:cid', '1000'
```

**Step 6** Run the following command to update **table1**:

```
flush 'table1'
```

```
----End
```

## Development Idea

1. Query the data in table1.
2. Query the data in table2 using the key value of table1.
3. Add up the queried data.
4. Write the results of the preceding step to table2.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

## Packaging the Project

1. Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed.
2. Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).

### NOTE

- Before compilation and packaging, change the paths of the **user.keytab** and **krb5.conf** files in the sample code to the actual paths on the client server where the files are located. Example: **/opt/female/user.keytab** and **/opt/female/krb5.conf**.
  - Before running the sample program, set the **spark.yarn.security.credentials.hbase.enabled** configuration item to **true** in the **spark-defaults.conf** configuration file of Spark client. (The default value is **false**. Changing the value to **true** does not affect existing services.) If you want to uninstall the HBase service, change the value back to **false** first.
3. Upload the JAR file to any directory (for example, **/opt/female/**) on the server where the Spark client is located.

## Running Tasks

Go to the Spark client directory and run the following commands to invoke the **bin/spark-submit** script to run the code (the class name and file name must be the same as those in the actual code. The following is only an example):

- Run Java or Scala sample code.

```
bin/spark-submit --conf spark.yarn.user.classpath.first=true --class com.huawei.bigdata.spark.examples.SparkHbasetoHbase --master yarn --deploy-mode client /opt/female/SparkHbasetoHbase-1.0.jar
```

- Run the Python sample program.

 NOTE

- PySpark does not provide HBase-related APIs. Therefore, Python is used to invoke Java code in this sample. Use Maven to pack the provided Java code into a JAR package and place it in the same driver class directory. When running the Python program, configure **--jars** to load the JAR package to the directory where the Python file resides.
- The Python sample code does not provide authentication information. Configure **--keytab** and **--principal** to specify authentication information

```
bin/spark-submit --master yarn --deploy-mode client --keytab /opt/FIclient/user.keytab --principal sparkuser --conf spark.yarn.user.classpath.first=true --jars /opt/female/SparkHbasetoHbasePythonExample/SparkHbasetoHbase-1.0.jar,/opt/female/protobuf-java-2.5.0.jar /opt/female/SparkHbasetoHbasePythonExample/SparkHbasetoHbasePythonExample.py
```

### 1.21.3.5.2 Java Example Code

#### Function

Call HBase API using Spark to operate HBase table1, analyze the data, and then write the analyzed data to HBase table2.

#### Example Code

For details about the code, see the class  
com.huawei.bigdata.spark.examples.SparkHbasetoHbase.

Example code:

```
/**  
 * calculate data from hbase1/hbase2,then update to hbase2  
 */  
public class SparkHbasetoHbase {  
  
    public static void main(String[] args) throws Exception {  
  
        SparkConf conf = new SparkConf().setAppName("SparkHbasetoHbase");  
        conf.set("spark.serializer", "org.apache.spark.serializer.KryoSerializer");  
        conf.set("spark.kryo.registrator", "com.huawei.bigdata.spark.examples.MyRegistrar");  
        JavaSparkContext jsc = new JavaSparkContext(conf);  
        // Create the configuration parameter to connect the HBase. The hbase-site.xml must be included in the  
        //classpath.  
        Configuration hbConf = HBaseConfiguration.create(jsc.hadoopConfiguration());  
  
        // Declare the information of the table to be queried.  
        Scan scan = new org.apache.hadoop.hbase.client.Scan();  
        scan.addFamily(Bytes.toBytes("cf")); //column family  
        org.apache.hadoop.hbase.protobuf.generated.ClientProtos.Scan proto = ProtobufUtil.toScan(scan);  
        String scanToString = Base64.encodeBytes(proto.toByteArray());  
        hbConf.set(TableInputFormat.INPUT_TABLE, "table1"); //table name  
        hbConf.set(TableInputFormat.SCAN, scanToString);  
  
        // Obtain the data in the table through the Spark interface.
```

```
JavaPairRDD rdd = jsc.newAPIHadoopRDD(hbConf, TableInputFormat.class,
ImmutableBytesWritable.class, Result.class);

// Traverse every Partition in the HBase table1 and update the HBase table2
//If less data, you can use rdd.foreach()

rdd.foreachPartition(
    new VoidFunction<Iterator<Tuple2<ImmutableBytesWritable, Result>>() {
        public void call(Iterator<Tuple2<ImmutableBytesWritable, Result>> iterator) throws Exception {
            hBaseWriter(iterator);
        }
    }
);

jsc.stop();
}

/**
 * write to table2 in exetutor
 *
 * @param iterator partition data from table1
 */
private static void hBaseWriter(Iterator<Tuple2<ImmutableBytesWritable, Result>> iterator) throws
IOException {
    //read hbase
    String tableName = "table2";
    String columnFamily = "cf";
    String qualifier = "cid";
    Configuration conf = HBaseConfiguration.create();

    Connection connection = null;
    Table table = null;

    try {
        connection =ConnectionFactory.createConnection(conf);
        table = connection.getTable(Table.Name.valueOf(tableName));

        List<Get> rowList = new ArrayList<Get>();
        List<Tuple2<ImmutableBytesWritable, Result>> table1List = new
ArrayList<Tuple2<ImmutableBytesWritable, Result>>();
        while (iterator.hasNext()) {
            Tuple2<ImmutableBytesWritable, Result> item = iterator.next();
            Get get = new Get(item._2().getRow());
            table1List.add(item);
            rowList.add(get);
        }

        //get data from hbase table2
        Result[] resultDataBuffer = table.get(rowList);

        //set data for hbase
        List<Put> putList = new ArrayList<Put>();
        for (int i = 0; i < resultDataBuffer.length; i++) {
            Result resultData = resultDataBuffer[i];//hbase2 row
            if (!resultData.isEmpty()) {
                //query hbase1Value
                String hbase1Value = "";
                Iterator<Cell> it = table1List.get(i)._2().listCells().iterator();
                while (it.hasNext()) {
                    Cell c = it.next();
                    // query table1 value by colomn family and colomn qualifier
                    if (columnFamily.equals(Bytes.toString(CellUtil.cloneFamily(c)))
                        && qualifier.equals(Bytes.toString(CellUtil.cloneQualifier(c)))) {
                        hbase1Value = Bytes.toString(CellUtil.cloneValue(c));
                    }
                }
            }

            String hbase2Value = Bytes.toString(resultData.getValue(columnFamily.getBytes(),
                qualifier.getBytes()));
            Put put = new Put(item.getRow());
            put.addColumn(columnFamily, qualifier, Bytes.toBytes(hbase2Value));
            putList.add(put);
        }
    } catch (Exception e) {
        e.printStackTrace();
    } finally {
        if (connection != null) {
            try {
                connection.close();
            } catch (IOException e) {
                e.printStackTrace();
            }
        }
    }
}
```

```
Put put = new Put(table1List.get(i)._2().getRow());

//calculate result value
int resultValue = Integer.parseInt(hbase1Value) + Integer.parseInt(hbase2Value);
//set data to put
put.addColumn(Bytes.toBytes(columnFamily), Bytes.toBytes(qualifier),
Bytes.toBytes(String.valueOf(resultValue)));
putList.add(put);
}

if (putList.size() > 0) {
    table.put(putList);
}
} catch (IOException e) {
    e.printStackTrace();
} finally {
    if (table != null) {
        try {
            table.close();
        } catch (IOException e) {
            e.printStackTrace();
        }
    }
    if (connection != null) {
        try {
            // Close the HBase connection
            connection.close();
        } catch (IOException e) {
            e.printStackTrace();
        }
    }
}
}

}
```

### 1.21.3.5.3 Scala Example Code

#### Function

Call HBase API using Spark to operate HBase table1, analyze the data, and then write the analyzed data to HBase table2.

#### Example Code

For details about code, see  
[com.huawei.bigdata.spark.examples.SparkHbasetoHbase](#).

Example code:

```
/*
 * calculate data from hbase1/hbase2,then update to hbase2
 */
object SparkHbasetoHbase {

    case class FemaleInfo(name: String, gender: String, stayTime: Int)

    def main(args: Array[String]) {

        val conf = new SparkConf().setAppName("SparkHbasetoHbase")
        conf.set("spark.serializer", "org.apache.spark.serializer.KryoSerializer")
        conf.set("spark.kryo.registrator", "com.huawei.bigdata.spark.examples.MyRegistrar")
        val sc = new SparkContext(conf)
        // Create the configuration parameter to connect the HBase. The hbase-site.xml must be included in the
        //classpath.
```

```
val hbConf = HBaseConfiguration.create(sc.hadoopConfiguration)

// Declare the information of the table to be queried.
val scan = new Scan()
scan.addFamily(Bytes.toBytes("cf")) //column family
val proto = ProtobufUtil.toScan(scan)
val scanToString = Base64.encodeBytes(proto.toByteArray)
hbConf.set(TableInputFormat.INPUT_TABLE, "table1") //table name
hbConf.set(TableInputFormat.SCAN, scanToString)

// Obtain the data in the table through the Spark interface.
val rdd = sc.newAPIHadoopRDD(hbConf, classOf[TableInputFormat], classOf[ImmutableBytesWritable],
classOf[Result])

// Traverse every Partition in the HBase table1 and update the HBase table2
//If less data, you can use rdd.foreach()
rdd.foreachPartition(x => hBaseWriter(x))

sc.stop()
}

/**
 * write to table2 in exetutor
 *
 * @param iterator partition data from table1
 */
def hBaseWriter(iterator: Iterator[(ImmutableBytesWritable, Result)]): Unit = {
//read hbase
val tableName = "table2"
val columnFamily = "cf"
val qualifier = "cid"
val conf = HBaseConfiguration.create()

var table: Table = null
var connection: Connection = null

try {
connection =ConnectionFactory.createConnection(conf)
table = connection.getTable(TableNames.valueOf(tableName))

val iteratorArray = iterator.toArray
val rowList = new util.ArrayList[Get]()
for (row <- iteratorArray) {
val get = new Get(row._2.getRow)
rowList.add(get)
}

//get data from hbase table2
val resultDataBuffer = table.get(rowList)

//set data for hbase
val putList = new util.ArrayList[Put]()
for (i < 0 until iteratorArray.size) {
val resultData = resultDataBuffer(i) //hbase2 row
if (!resultData.isEmpty) {
//query hbase1Value
var hbase1Value = ""
val it = iteratorArray(i)._2.listCells().iterator()
while (it.hasNext) {
val c = it.next()
// query table1 value by column family and column qualifier
if (columnFamily.equals(Bytes.toString(CellUtil.cloneFamily(c)))
&& qualifier.equals(Bytes.toString(CellUtil.cloneQualifier(c)))) {
hbase1Value = Bytes.toString(CellUtil.cloneValue(c))
}
}

val hbase2Value = Bytes.toString(resultData.getValue(columnFamily.getBytes, qualifier.getBytes))
val put = new Put(iteratorArray(i)._2.getRow)
putList.add(put)
}
}
}
```

```
//calculate result value
val resultValue = hbase1Value.toInt + hbase2Value.toInt
//set data to put
put.addColumn(Bytes.toBytes(columnFamily), Bytes.toBytes(qualifier),
Bytes.toBytes(resultValue.toString))
putList.add(put)
}
}

if (putList.size() > 0) {
    table.put(putList)
}
} catch {
    case e: IOException =>
        e.printStackTrace();
} finally {
    if (table != null) {
        try {
            table.close()
        } catch {
            case e: IOException =>
                e.printStackTrace();
        }
    }
    if (connection != null) {
        try {
            //Close the HBase connection.
            connection.close()
        } catch {
            case e: IOException =>
                e.printStackTrace()
        }
    }
}
}

/**
 * Define serializer class.
 */
class MyRegistrar extends KryoRegistrar {
    override def registerClasses(kryo: Kryo) {
        kryo.register(classOf[org.apache.hadoop.hbase.io.ImmutableBytesWritable])
        kryo.register(classOf[org.apache.hadoop.hbase.client.Result])
        kryo.register(classOf[Array[(Any, Any)]])
        kryo.register(classOf[Array[org.apache.hadoop.hbase.Cell]])
        kryo.register(classOf[org.apache.hadoop.hbase.NoTagsKeyValue])
        kryo.register(classOf[org.apache.hadoop.hbase.protobuf.generated.ClientProtos.RegionLoadStats])
    }
}
```

#### 1.21.3.5.4 Python Example Code

### Function

Use Spark to call an HBase API to operate HBase table1 and write the data analysis result of table1 to HBase table2.

### Example Code

PySpark does not provide HBase related APIs. In this example, Python with the Java programming language invoked is used.

The following code snippets are used as an example. For complete codes, see [SparkHbaseToHbasePythonExample](#).

```
# -*- coding:utf-8 -*-

from py4j.java_gateway import java_import
from pyspark.sql import SparkSession

# Create the SparkContext and set kryo serialization.
spark = SparkSession\
    .builder\
    .appName("SparkHbasetoHbase") \
    .config("spark.serializer", "org.apache.spark.serializer.KryoSerializer") \
    .config("spark.kryo.registrator", "com.huawei.bigdata.spark.examples.MyRegistrator") \
    .getOrCreate()

# Import the class that will run into sc._jvm.
java_import(spark._jvm, 'com.huawei.bigdata.spark.examples.SparkHbasetoHbase')

# Create a class instance and invoke the method.
spark._jvm.SparkHbasetoHbase().hbasetohbase(spark._jsc)

# Stop the SparkSession
spark.stop()
```

### 1.21.3.6 Reading Data from Hive and Write It to HBase

#### 1.21.3.6.1 Overview

##### Scenarios

Assume that table **person** of Hive stores the user consumption amount of the current day and table2 of HBase stores the history consumption data.

In table person, name=1 and account=100 indicates that the consumption amount of user 1 in the current day is 100 CNY.

In table2, key=1 and cf:cid=1000 indicate that the history consumption amount of user 1 is 1000 CNY.

The Spark application shall achieve the following function:

Add the current consumption amount (100) to the history consumption amount (1000).

The running result is that the total consumption amount of user 1 (key=1) in table2 is 1100 CNY (cf:cid=1100).

#### Data Preparation

Before develop the application, create the Hive table **person** and insert data to it. Create HBase table2.

##### Step 1 Place the source log file to HDFS.

1. Create a blank file **log1.txt** in the local and write the following content to the file:  
1,100
2. Create a directory **/tmp/input** in HDFS and copy the **log1.txt** file to the directory.
  - a. On the HDFS client, run the following commands to obtain the security authentication:

- ```
cd /opt/hadoopclient
kinit <Service user for authentication>
b. On the Linux HDFS client, run the hadoop fs -mkdir /tmp/input
   command (a hdfs dfs command provides the same function.) to create a
   directory.
c. On the Linux HDFS client, run the hadoop fs -put log1.txt /tmp/input
   command to upload the data file.
```

**Step 2** Store the imported data to the Hive table.

Ensure that JDBCServer is started. Use the Beeline tool to create a Hive table and insert data to it.

1. Run the following commands to create the Hive table person:

```
create table person
(
  name STRING,
  account INT
)
ROW FORMAT DELIMITED FIELDS TERMINATED BY ',' ESCAPED BY '\\'
STORED AS TEXTFILE;
```

2. Run the following command to insert data to the table:

```
load data inpath '/tmp/input/log1.txt' into table person;
```

**Step 3** Create a HBase table:

Ensure that JDBCServer is started. Use the Spark-Beeline tool to create a HBase table and insert data to it.

1. Run the following commands to create the HBase table table2:

```
create table table2
(
  key string,
  cid string
)
using org.apache.spark.sql.hbase.HBaseSource
options(
  hbaseTableName "table2",
  keyCols "key",
  colsMapping "cid=cf.cid"
);
```

2. Run the following command on HBase to insert data to the table:

```
put 'table2', '1', 'cf:cid', '1000'
```

----End

## Development Idea

1. Query the data in Hive table person.
2. Query the data in table2 using the key value of table person.
3. Add the queried data.
4. Write the results of the preceding step to table2.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

## Packaging the Project

1. Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed.
2. Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).

### NOTE

- Before compilation and packaging, change the paths of the **user.keytab** and **krb5.conf** files in the sample code to the actual paths on the client server where the files are located. Example: **/opt/female/user.keytab** and **/opt/female/krb5.conf**.
  - Before running the sample program, set the **spark.yarn.security.credentials.hbase.enabled** configuration item to **true** in the **spark-defaults.conf** configuration file of Spark client. (The default value is **false**. Changing the value to **true** does not affect existing services.) If you want to uninstall the HBase service, change the value back to **false** first.
3. Upload the JAR file to any directory (for example, **/opt/female/**) on the server where the Spark client is located.

## Running Tasks

Go to the Spark client directory and run the following commands to invoke the **bin/spark-submit** script to run the code (the class name and file name must be the same as those in the actual code. The following is only an example):

- Run Java or Scala sample code.  
**bin/spark-submit --class com.huawei.bigdata.spark.examples.SparkHivetoHbase --master yarn --deploy-mode client /opt/female/SparkHivetoHbase-1.0.jar**
- Run the Python sample program.

#### NOTE

- PySpark does not provide HBase-related APIs. Therefore, Python is used to invoke Java code in this sample. Use Maven to pack the provided Java code into a JAR file and place it in the same directory. When running the Python program, use **--jars** to load the JAR file to **classpath**.
- The Python sample code does not provide authentication information. Configure **--keytab** and **--principal** to specify authentication information.

```
bin/spark-submit --master yarn --deploy-mode client --keytab /opt/
Flclient/user.keytab --principal sparkuser --jars /opt/female/
SparkHivetoHbasePythonExample/SparkHivetoHbase-1.0.jar /opt/female/
SparkHivetoHbasePythonExample/SparkHivetoHbasePythonExample.py
```

### 1.21.3.6.2 Java Sample Code

#### Function

In a Spark application, users can use Spark to call a Hive API to operate a Hive table, and write the data analysis result of the Hive table to an HBase table.

#### Sample Code

The following code snippets are used as an example. For complete codes, see [com.huawei.bigdata.spark.examples.SparkHivetoHbase](#).

```
/*
 * Read data from the Hive table, and obtain the corresponding record from the HBase table based on the
 * key value. Sum the obtained two data records and update the sum result to the HBase table.
 */
public class SparkHivetoHbase {

    public static void main(String[] args) throws Exception {

        String userPrincipal = "sparkuser";
        String userKeytabPath = "/opt/Flclient/user.keytab";
        String krb5ConfPath = "/opt/Flclient/KrbClient/kerberos/var/krb5kdc/krb5.conf";
        Configuration hadoopConf = new Configuration();
        LoginUtil.login(userPrincipal, userKeytabPath, krb5ConfPath, hadoopConf);
        // Use the Spark API to obtain table data.
        SparkConf conf = new SparkConf().setAppName("SparkHivetoHbase");
        JavaSparkContext jsc = new JavaSparkContext(conf);
        HiveContext sqlContext = new org.apache.spark.sql.hive.HiveContext(jsc);

        Dataset<Row> dataFrame = sqlContext.sql("select name, account from person");

        // Traverse every partition in the Hive table and update data to the HBase table.
        // If the number of data records is small, you can use the foreach() method.
        dataFrame.toJavaRDD().foreachPartition(
            new VoidFunction<Iterator<Row>>() {
                public void call(Iterator<Row> iterator) throws Exception {
                    hBaseWriter(iterator);
                }
            });
        spark.stop();
    }

    /**
     * Update records in the HBase table on the executor.
     *
     * @param iterator Partition data in the Hive table.
     */
}
```

```
private static void hBaseWriter(Iterator<Row> iterator) throws IOException {
    // Read the HBase table.
    String tableName = "table2";
    String columnFamily = "cf";
    Configuration conf = HBaseConfiguration.create();
    Connection connection = null;
    Table table = null;
    try {
        connection = ConnectionFactory.createConnection(conf);
        table = connection.getTable(Table.Name.valueOf(tableName));
        List<Row> table1List = new ArrayList<Row>();
        List<Get> rowList = new ArrayList<Get>();
        while (iterator.hasNext()) {
            Row item = iterator.next();
            Get get = new Get(item.getString(0).getBytes());
            table1List.add(item);
            rowList.add(get);
        }
        // Obtain the records in the HBase table.
        Result[] resultDataBuffer = table.get(rowList);
        // Modify records in the HBase table.
        List<Put> putList = new ArrayList<Put>();
        for (int i = 0; i < resultDataBuffer.length; i++) {
            // Hive table value
            Result resultData = resultDataBuffer[i];
            if (!resultData.isEmpty()) {
                // get hiveValue
                int hiveValue = table1List.get(i).getInt(1);
                // Obtain the HBase table value based on the column family and column.
                String hbaseValue = Bytes.toString(resultData.getValue(columnFamily.getBytes(), "cid".getBytes()));
                Put put = new Put(table1List.get(i).getString(0).getBytes());
                // Calculate the result.
                int resultValue = hiveValue + Integer.valueOf(hbaseValue);
                // Set the result to the Put object.
                put.addColumn(Bytes.toBytes(columnFamily), Bytes.toBytes("cid"),
                    Bytes.toBytes(String.valueOf(resultValue)));
                putList.add(put);
            }
        }
        if (putList.size() > 0) {
            table.put(putList);
        }
    } catch (IOException e) {
        e.printStackTrace();
    } finally {
        if (table != null) {
            try {
                table.close();
            } catch (IOException e) {
                e.printStackTrace();
            }
        }
        if (connection != null) {
            try {
                // Close the HBase connection.
                connection.close();
            } catch (IOException e) {
                e.printStackTrace();
            }
        }
    }
}
```

### 1.21.3.6.3 Scala Example Code

#### Function

In Spark application, call Hive API using Spark to operate Hive table, analyze the data, and then write the analyzed data to the HBase table.

#### Example Code

For details about code, see  
[com.huawei.bigdata.spark.examples.SparkHbasetoHbase](#).

Example code

```
/*
 * calculate data from hive/hbase,then update to hbase
 */
object SparkHivetoHbase {

  case class FemaleInfo(name: String, gender: String, stayTime: Int)

  def main(args: Array[String]) {

    String userPrincipal = "sparkuser";
    String userKeytabPath = "/opt/FIclient/user.keytab";
    String krb5ConfPath = "/opt/FIclient/KrbClient/kerberos/var/krb5kdc/krb5.conf";
    Configuration hadoopConf = new Configuration();
    LoginUtil.login(userPrincipal, userKeytabPath, krb5ConfPath, hadoopConf);
    // Obtain the data in the table through the Spark interface.

    val spark = SparkSession
      .builder()
      .appName("SparkHiveHbase")
      .config("spark.sql.warehouse.dir", "spaek-warehouse")
      .enableHiveSupport()
      .getOrCreate()

    import spark.implicits._
    val dataFrame = spark.sql("select name, account from person")

    // Traverse every Partition in the hive table and update the hbase table
    // If less data, you can use rdd.foreach()
    dataFrame.rdd.foreachPartition(x => hBaseWriter(x))

    spark.stop()
  }

  /**
   * write to hbase table in exetutor
   *
   * @param iterator partition data from hive table
   */
  def hBaseWriter(iterator: Iterator[Row]): Unit = {
    // read hbase
    val tableName = "table2"
    val columnFamily = "cf"
    val conf = HBaseConfiguration.create()

    var table: Table = null
    var connection: Connection = null

    try {
      connection = ConnectionFactory.createConnection(conf)
      table = connection.getTable(TableName.valueOf(tableName))

      val iteratorArray = iterator.toArray
      for (row<- iteratorArray) {
        val family = row.get(0).asInstanceOf[Cell].getFamily()
        val value = row.get(0).asInstanceOf[Cell].getQualifier()
        val timestamp = row.get(0).asInstanceOf[Cell].getTimestamp()
        val cell = new Cell(family, value, timestamp)
        table.put(row.get(1), cell)
      }
    } catch {
      case e: Exception =>
        e.printStackTrace()
    } finally {
      if (connection != null) {
        connection.close()
      }
    }
  }
}
```

```
val rowList = new util.ArrayList[Get]()
for (row <- iteratorArray) {
    val get = new Get(row.getString(0).getBytes)
    rowList.add(get)
}

// get data from hbase table
val resultDataBuffer = table.get(rowList)

// set data for hbase
val putList = new util.ArrayList[Put]()
for (i <- 0 until iteratorArray.size) {
    // hbase row
    val resultData = resultDataBuffer(i)
    if (!resultData.isEmpty) {
        // get hiveValue
        var hiveValue = iteratorArray(i).getInt(1)

        // get hbaseValue by column Family and column qualifier
        val hbaseValue = Bytes.toString(resultData.getValue(columnFamily.getBytes, "cid".getBytes))
        val put = new Put(iteratorArray(i).getString(0).getBytes)

        // calculate result value
        val resultValue = hiveValue + hbaseValue.toInt

        // set data to put
        put.addColumn(Bytes.toBytes(columnFamily), Bytes.toBytes("cid"),
        Bytes.toBytes(resultValue.toString))
        putList.add(put)
    }
}

if (putList.size() > 0) {
    table.put(putList)
}
} catch {
    case e: IOException =>
    e.printStackTrace();
} finally {
    if (table != null) {
        try {
            table.close()
        } catch {
            case e: IOException =>
            e.printStackTrace();
        }
    }
    if (connection != null) {
        try {
            //Close the HBase connection.
            connection.close()
        } catch {
            case e: IOException =>
            e.printStackTrace()
        }
    }
}
}
```

#### 1.21.3.6.4 Python Example Code

### Function

In a Spark application, use Spark to call a Hive API to operate a Hive table, and write the data analysis result of the Hive table to an HBase table.

## Example Code

PySpark does not provide HBase related APIs. In this example, Python with the Java programming language invoked is used.

The following code snippets are used as an example. For complete codes, see [SparkHivetoHbasePythonExample](#).

```
# -*- coding:utf-8 -*-

from py4j.java_gateway import java_import
from pyspark.sql import SparkSession

# Create the SparkSession
spark = SparkSession\
    .builder\
    .appName("SparkHivetoHbase") \
    .getOrCreate()

# Import the class that will run into sc._jvm.
java_import(spark._jvm, 'com.huawei.bigdata.spark.examples.SparkHivetoHbase')

# Create a class instance and invoke the method.
spark._jvm.SparkHivetoHbase().hivetohbase(spark._jsc)

# Stop the SparkSession
spark.stop()
```

### 1.21.3.7 Streaming Connecting to Kafka0-10

#### 1.21.3.7.1 Overview

##### Scenarios

Assume that the Kafka component receives one word record every 1 second.

The developed Spark application needs to achieve the following function:

Calculate the sum of records for each word in real time.

**log1.txt** example file:

```
LiuYang
YuanJing
GuoYijun
CaiXuyu
Liyuan
FangBo
LiuYang
YuanJing
GuoYijun
CaiXuyu
FangBo
```

##### Data Planning

Spark Streaming sample project data is stored in the Kafka component. A user with Kafka permission sends data to Kafka component.

1. Ensure that the cluster, including HDFS, Yarn, Spark, and Kafka is successfully installed.
2. Create the **input\_data1.txt** file in the local and copy the content of the **log1.txt** file to the **input\_data1.txt** file.

On the client installation node, create the **/home/data** directory and upload the **input\_data1.txt** file to the **/home/data** directory.

3. Change the value of **allow.everyone.if.no.acl.found**, the Broker configuration value of Kafka, to **true**.
4. Create a topic.

{*IP address of the Kafka cluster*} indicates the service IP address of the Broker service.

```
$KAFKA_HOME/bin/kafka-topics.sh --create --bootstrap-server <IP address of the Kafka cluster:21007> --command-config $KAFKA_HOME/config/client.properties --replication-factor 1 --partitions 3 --topic {Topic}
```

5. Start the Producer of Kafka and send data to Kafka.

```
java -cp {ClassPath}
com.huawei.bigdata.spark.examples.StreamingExampleProducer
{BrokerList} {Topic}
```

In this command, **ClassPath** must contain the absolute path of the Kafka JAR package on the Spark client in addition to the path of the sample JAR package, for example: /opt/hadoopclient/Spark/spark/jars/\*:/opt/hadoopclient/Spark/spark/jars/streamingClient010/\*:{ClassPath}.

## Development Approach

1. Receive data from Kafka and generate DStream.
2. Collect the statistics of word records by category.
3. Calculate and print the result.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

## Packaging the Project

- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed.
- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).

### NOTE

Before compilation and packaging, change the paths of the **user.keytab** and **krb5.conf** files in the sample code to the actual paths on the client server where the files are located. Example: /opt/female/user.keytab and /opt/female/krb5.conf.

- Upload the JAR package to any directory (for example, /opt) on the server where the Spark client is located.
- Prepare dependency packages and upload the following JAR packages to the **\$SPARK\_HOME/jars/streamingClient010** directory on the server where the Spark client is located.

- spark-streaming-kafkaWriter-xxx.cbu.mrs.jar
- kafka-clients-xxx.jar
- spark-sql-kafka-xxx.cbu.mrs.xxx.jar
- spark-streaming-kafka-xxx.cbu.mrs.xxx.jar
- spark-token-provider-kafka-xxx.cbu.mrs.xxx.jar

 NOTE

- For the dependency package whose version number contains "cbu.mrs", download from the Huawei open-source image site.
- For the dependency package whose version number does not contain "cbu.mrs", obtain them from the Maven central repository.

## Running Tasks

When running the sample program, you need to specify **<checkpointDir>**, **<brokers>**, **<topic>**, and **<batchTime>**. **<checkPointDir>** indicates the path for storing the program result backup in HDFS. **<brokers>** indicates the Kafka address for obtaining metadata. **<topic>** indicates the topic name read from Kafka. **<batchTime>** indicates the interval for Streaming processing in batches.

 NOTE

The location of Spark Streaming Kafka dependency package on the client is different from the location of other dependency packages. For example, the path to the Spark Streaming Kafka dependency package is **\$SPARK\_HOME/jars/streamingClient010**, whereas the path to other dependency packages is **\$SPARK\_HOME/jars**. Therefore, when running an application, you need to add a configuration item to the **spark-submit** command to specify the path of the dependency package of Spark Streaming Kafka, for example, **--jars \$ (files=(\$SPARK\_HOME/jars/streamingClient010/\*.jar); IFS=,; echo "\${files[\*]}")**

Because the cluster is security mode, you need to add configuration items and modify the command parameters.

1. Add configuration items to **\$SPARK\_HOME/conf/jaas.conf**:

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=false  
    useTicketCache=true  
    debug=false;  
};
```

2. Add configuration items to **\$SPARK\_HOME/conf/jaas-zk.conf**:

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=true  
    keyTab=".user.keytab"  
    principal="sparkuser@<system domain name>"  
    useTicketCache=false  
    storeKey=true  
    debug=true;  
};
```

3. Use **--files** and relative path to submit the **keytab** file to ensure that the **keytab** file is loaded to the container of the executor.

4. For the port number in **<brokers>**, use **SASL\_PLAINTEXT** for the **Kafka 0-10 Write To Print** example, use **PLAINTEXT** for the **Write To Kafka 0-10** example.

Go to the Spark client directory and run the following commands to invoke the **bin/spark-submit** script to run the code (the class name and file name must be the same as those in the actual code. The following is only an example):

- Sample code (**Spark Streaming** read **Kafka 0-10 Write To Print**)  
**bin/spark-submit --master yarn --deploy-mode client --files ./jaas.conf,./user.keytab --jars \$(files=(\${SPARK\_HOME}/jars/streamingClient010/\*.jar);IFS=;; echo "\${files[\*]}") --class com.huawei.bigdata.spark.examples.SecurityKafkaWordCount /opt/SparkStreamingKafka010JavaExample-1.0.jar <checkpointDir> <brokers> <topic> <batchTime>**  
The configuration example is as follows:  
--files ./jaas.conf,./user.keytab //Use --files to specify the jaas.conf and keytab files.
- Sample code (**Spark Streaming Write To Kafka 0-10**)  
**bin/spark-submit --master yarn --deploy-mode client --jars \${files=(\${SPARK\_HOME}/jars/streamingClient010/\*.jar);IFS=;; echo "\${files[\*]}") --class com.huawei.bigdata.spark.examples.JavaDstreamKafkaWriter /opt/SparkStreamingKafka010JavaExample-1.0.jar <groupId> <brokers> <topics>**

### 1.21.3.7.2 Java Example Code

#### Function

In Spark applications, use Streaming to invoke Kafka interface to obtain word records. Collect the statistics of records for each word, and write the data to Kafka 0-10.

#### Example Code (**Streaming Read Data from Kafka 0-10**)

The following code is an example. For details, see `com.huawei.bigdata.spark.examples.SecurityKafkaWordCount`.

```
**  
* Consumes messages from one or more topics in Kafka.  
* <checkPointDir> is the Spark Streaming checkpoint directory.  
* <brokers> is for bootstrapping and the producer will only use it for getting metadata  
* <topics> is a list of one or more kafka topics to consume from  
* <batchTime> is the Spark Streaming batch duration in seconds.  
*/  
public class SecurityKafkaWordCount  
{  
    public static void main(String[] args) throws Exception {  
        JavaStreamingContext ssc = createContext(args);  
  
        //The Streaming system starts.  
        ssc.start();  
        try {  
            ssc.awaitTermination();  
        } catch (InterruptedException e) {  
        }  
    }  
  
    private static JavaStreamingContext createContext(String[] args) throws Exception {  
        String checkPointDir = args[0];  
        String brokers = args[1];  
        String topics = args[2];  
        String batchTime = args[3];  
  
        // Create a Streaming startup environment.  
        SparkConf sparkConf = new SparkConf().setAppName("KafkaWordCount");  
        JavaStreamingContext ssc = new JavaStreamingContext(sparkConf, new  
Duration(Long.parseLong(batchTime) * 1000));  
    }  
}
```

```
//Configure the CheckPoint directory for the Streaming.  
//This parameter is mandatory because of existence of the window concept.  
ssc.checkpoint(checkPointDir);  
  
// Get the list of topic used by kafka  
String[] topicArr = topics.split(",");  
Set<String> topicSet = new HashSet<String>(Arrays.asList(topicArr));  
Map<String, Object> kafkaParams = new HashMap();  
kafkaParams.put("bootstrap.servers", brokers);  
kafkaParams.put("value.deserializer", "org.apache.kafka.common.serialization.StringDeserializer");  
kafkaParams.put("key.deserializer", "org.apache.kafka.common.serialization.StringDeserializer");  
kafkaParams.put("group.id", "DemoConsumer");  
kafkaParams.put("security.protocol", "SASL_PLAINTEXT");  
kafkaParams.put("sasl.kerberos.service.name", "kafka");  
kafkaParams.put("kerberos.domain.name", "hadoop.<system domain name>");  
  
LocationStrategy locationStrategy = LocationStrategies.PreferConsistent();  
ConsumerStrategy consumerStrategy = ConsumerStrategies.Subscribe(topicSet, kafkaParams);  
  
// Create direct kafka stream with brokers and topics  
// Receive data from the Kafka and generate the corresponding DStream  
JavaInputDStream<ConsumerRecord<String, String>> messages = KafkaUtils.createDirectStream(ssc,  
locationStrategy, consumerStrategy);  
  
// Obtain field properties in each row.  
JavaDStream<String> lines = messages.map(new Function<ConsumerRecord<String, String>, String>() {  
    @Override  
    public String call(ConsumerRecord<String, String> tuple2) throws Exception {  
        return tuple2.value();  
    }  
});  
  
// Aggregate the total time that calculate word count  
JavaPairDStream<String, Integer> wordCounts = lines.mapToPair(  
    new PairFunction<String, String, Integer>() {  
        @Override  
        public Tuple2<String, Integer> call(String s) {  
            return new Tuple2<String, Integer>(s, 1);  
        }  
    }).reduceByKey(new Function2<Integer, Integer, Integer>() {  
    @Override  
    public Integer call(Integer i1, Integer i2) {  
        return i1 + i2;  
    }  
}).updateStateByKey(  
    new Function2<List<Integer>, Optional<Integer>, Optional<Integer>>() {  
        @Override  
        public Optional<Integer> call(List<Integer> values, Optional<Integer> state) {  
            int out = 0;  
            if (state.isPresent()) {  
                out += state.get();  
            }  
            for (Integer v : values) {  
                out += v;  
            }  
            return Optional.of(out);  
        }  
});  
  
// print the results  
wordCounts.print();  
return ssc;  
}  
}
```

## Example Code (Streaming Write To Kafka 0-10)

The following code segment is only an example. For details, see com.huawei.bigdata.spark.examples.DstreamKafkaWriter.

### NOTE

It is advisable to use the new API createDirectStream instead of the old API createStream for application development. The old API continues to exist, but its performance and stability are worse than the new API.

```
/*
 * Parameter description:
 * <groupId> is the group ID for the consumer.
 * <brokers> is for bootstrapping and the producer will only use
 * <topic> is a kafka topic to consume from.
 */
public class JavaDstreamKafkaWriter {

    public static void main(String[] args) throws InterruptedException {
        if (args.length != 3) {
            System.err.println("Usage: JavaDstreamKafkaWriter <groupId> <brokers> <topic>");
            System.exit(1);
        }

        final String groupId = args[0];
        final String brokers = args[1];
        final String topic = args[2];

        SparkConf sparkConf = new SparkConf().setAppName("KafkaWriter");

        // Populate Kafka properties
        Map<String, Object> kafkaParams = new HashMap<String, Object>();
        kafkaParams.put("value.deserializer", "org.apache.kafka.common.serialization.StringDeserializer");
        kafkaParams.put("key.deserializer", "org.apache.kafka.common.serialization.StringDeserializer");
        kafkaParams.put("value.serializer", "org.apache.kafka.common.serialization.ByteArraySerializer");
        kafkaParams.put("key.serializer", "org.apache.kafka.common.serialization.StringSerializer");
        kafkaParams.put("bootstrap.servers", brokers);
        kafkaParams.put("group.id", groupId);
        kafkaParams.put("auto.offset.reset", "smallest");

        // Create Spark Java streaming context
        JavaStreamingContext ssc = new JavaStreamingContext(sparkConf, Durations.milliseconds(500));

        // Populate data to write to kafka
        List<String> sentData = new ArrayList();
        sentData.add("kafka_writer_test_msg_01");
        sentData.add("kafka_writer_test_msg_02");
        sentData.add("kafka_writer_test_msg_03");

        // Create Java RDD queue
        Queue<JavaRDD<String>> sent = new LinkedList();
        sent.add(ssc.sparkContext().parallelize(sentData));

        // Create java Dstream with the data to be written
        JavaDStream wStream = ssc.queueStream(sent);

        // Write to kafka
        JavaDStreamKafkaWriterFactory.fromJavaDStream(wStream).writeToKafka(
            JavaConverters.mapAsScalaMapConverter(kafkaParams).asScala(),
            new Function<String, ProducerRecord<String, byte[]>>() {
                public ProducerRecord<String, byte[]> call(String s) throws Exception {
                    return new ProducerRecord(topic, s.toString().getBytes());
                }
            });
    }

    ssc.start();
    ssc.awaitTermination();
}
```

```
}
```

### 1.21.3.7.3 Scala Example Code

#### Function

In Spark applications, use Streaming to invoke Kafka interface to obtain word records. Collect the statistics of records for each word, and write the data to Kafka 0-10.

#### Example Code (Streaming Read Data from Kafka 0-10)

The following code is an example. For details, see [com.huawei.bigdata.spark.examples.SecurityKafkaWordCount](#).

```
/*
 * Consumes messages from one or more topics in Kafka.
 * <checkPointDir> is the Spark Streaming checkpoint directory.
 * <brokers> is for bootstrapping and the producer will only use it for getting metadata
 * <topics> is a list of one or more kafka topics to consume from
 * <batchTime> is the Spark Streaming batch duration in seconds.
 */
object SecurityKafkaWordCount {

    def main(args: Array[String]) {
        val ssc = createContext(args)

        //The Streaming system starts.
        ssc.start()
        ssc.awaitTermination()
    }

    def createContext(args : Array[String]) : StreamingContext = {

        val Array(checkPointDir, brokers, topics, batchSize) = args

        // Create a Streaming startup environment.
        val sparkConf = new SparkConf().setAppName("KafkaWordCount")
        val ssc = new StreamingContext(sparkConf, Seconds(batchSize.toLong))

        //Configure the CheckPoint directory for the Streaming.
        //This parameter is mandatory because of existence of the window concept.
        ssc.checkpoint(checkPointDir)

        // Get the list of topic used by kafka
        val topicArr = topics.split(",")
        val topicSet = topicArr.toSet
        val kafkaParams = Map[String, String](
            "bootstrap.servers" -> brokers,
            "value.deserializer" -> "org.apache.kafka.common.serialization.StringDeserializer",
            "key.deserializer" -> "org.apache.kafka.common.serialization.StringDeserializer",
            "group.id" -> "DemoConsumer",
            "security.protocol" -> "SASL_PLAINTEXT",
            "sasl.kerberos.service.name" -> "kafka",
            "kerberos.domain.name" -> "hadoop.<system domain name>"
        );

        val locationStrategy = LocationStrategies.PreferConsistent
        val consumerStrategy = ConsumerStrategies.Subscribe[String, String](topicSet, kafkaParams)

        // Create direct kafka stream with brokers and topics
        // Receive data from the Kafka and generate the corresponding DStream
        val stream = KafkaUtils.createDirectStream[String, String](ssc, locationStrategy, consumerStrategy)

        // Obtain field properties in each row.
    }
}
```

```
val tf = stream.transform ( rdd =>
    rdd.map(r => (r.value, 1L))
)

// Aggregate the total time that calculate word count
val wordCounts = tf.reduceByKey(_ + _)
val totalCounts = wordCounts.updateStateByKey(updataFunc)
totalCounts.print()

ssc
}

def updataFunc(values : Seq[Long], state : Option[Long]) : Option[Long] =
  Some(values.sum + state.getOrElse(0L))
}
```

## Example Code (Streaming Write To Kafka 0-10)

The following code segment is only an example. For details, see [com.huawei.bigdata.spark.examples.DstreamKafkaWriter](#).

### NOTE

After updates to Spark, it is advisable to use the new API `createDirectStream` instead of the old API `createStream` for application development. The old API continues to exist, but its performance and stability are worse than the new API.

```
package com.huawei.bigdata.spark.examples

import scala.collection.mutable
import scala.language.postfixOps

import com.huawei.spark.streaming.kafka010.KafkaWriter._
import org.apache.kafka.clients.producer.ProducerRecord
import org.apache.spark.SparkConf
import org.apache.spark.rdd.RDD
import org.apache.spark.streaming.{Milliseconds, StreamingContext}

/**
 * Example code to demonstrate the usage of dstream.writeToKafka API
 *
 * Parameter description:
 * <groupId> is the group ID for the consumer.
 * <brokers> is for bootstrapping and the producer will only use
 * <topic> is a kafka topic to consume from.
 */
object DstreamKafkaWriter {
  def main(args: Array[String]) {

    if (args.length != 3) {
      System.err.println("Usage: DstreamKafkaWriter <groupId> <brokers> <topic>")
      System.exit(1)
    }

    val Array(groupId, brokers, topic) = args
    val sparkConf = new SparkConf().setAppName("KafkaWriter")

    // Populate Kafka properties
    val kafkaParams = Map[String, String](
      "bootstrap.servers" -> brokers,
      "value.deserializer" -> "org.apache.kafka.common.serialization.StringDeserializer",
      "key.deserializer" -> "org.apache.kafka.common.serialization.StringDeserializer",
      "value.serializer" -> "org.apache.kafka.common.serialization.ByteArraySerializer",
      "key.serializer" -> "org.apache.kafka.common.serialization.StringSerializer",
      "group.id" -> groupId,
      "auto.offset.reset" -> "latest"
    )
  }
}
```

```
// Create Spark streaming context
val ssc = new StreamingContext(sparkConf, Milliseconds(500));

// Populate data to write to kafka
val sentData = Seq("kafka_writer_test_msg_01", "kafka_writer_test_msg_02",
    "kafka_writer_test_msg_03")

// Create RDD queue
val sent = new mutable.Queue[RDD[String]]()
sent.enqueue(ssc.sparkContext.makeRDD(sentData))

// Create Dstream with the data to be written
val wStream = ssc.queueStream(sent)

// Write to kafka
wStream.writeToKafka(kafkaParams,
    (x: String) => new ProducerRecord[String, Array[Byte]](topic, x.getBytes))

ssc.start()
ssc.awaitTermination()
}
```

### 1.21.3.8 Structured Streaming Project

#### 1.21.3.8.1 Overview

##### Scenarios

In Spark applications, use StructuredStreaming to invoke Kafka interface to obtain word records. Collect the statistics of records for each word.

##### Data Planning

Sample project data of StructuredStreaming is stored in Kafka. A user with Kafka permission sends data to Kafka.

1. Ensure that the cluster, including HDFS, Yarn, Spark, and Kafka is successfully installed.
2. Change the value of **allow.everyone.if.no.acl.found**, the Broker configuration value of Kafka, to **true**.
3. Create a topic.

{*IP address of the Kafka cluster*} indicates the service IP address of the Broker service.

```
$KAFKA_HOME/bin/kafka-topics.sh --create --bootstrap-server <IP address of the Kafka cluster:21007> --command-config $KAFKA_HOME/config/client.properties --replication-factor 1 --partitions 1 --topic {Topic}
```

4. Start the Producer of Kafka and send data to Kafka.  
{*ClassPath*} indicates the storage path of engineer JAR packages and is specified by the user. For details, see [Compiling and Running the Application](#).

```
java -cp $SPARK_HOME/jars/*:$SPARK_HOME/jars/streamingClient010/*:{ClassPath} com.huawei.bigdata.spark.examples.KafkaWordCountProducer {BrokerList} {Topic} {messagesPerSec} {wordsPerMessage}
```

## Development Approach

1. Receive data from Kafka and generate DataStreamReader.
2. Collect the statistics of word records.
3. Calculate and print the result.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

## Packaging the Project

- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed.
- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).

### NOTE

Before compilation and packaging, change the paths of the user.keytab and krb5.conf files in the sample code to the actual paths on the client server where the files are located. Example: **/opt/female/user.keytab** and **/opt/female/krb5.conf**.

- Upload the JAR package to any directory (for example, **/opt**) on the server where the Spark client is located.

## Running Tasks

- When running the sample application, you need to specify **<brokers>**, **<subscribe-type>**, **<topic>**, **<protocol>**, **<service>**, **<domain>** and **<checkpointDir>**. **<brokers>** indicates the Kafka address (port **21007** is required) for obtaining metadata, **<subscribe-type>** indicates the Kafka subscription type (for example, **subscribe**), and **<topic>** indicates the name of the topic read from Kafka. **<protocol>** indicates the secure access protocol (for example, **SASL\_PLAINTEXT**). **<service>** indicates the Kerberos service name (for example, **kafka**). **<domain>** indicates the Kerberos domain name (for example, **hadoop.<system domain name>**), **<checkpointDir>** indicates the path for storing checkpoint files.

 NOTE

The path of the Spark Structured Streaming Kafka dependency package on the client is different from that of other dependency packages. For example, the path of other dependency packages is **\$SPARK\_HOME/jars**. Whereas the path of the Spark Structured Streaming Kafka dependency package is **\$SPARK\_HOME/jars/streamingClient010**. Therefore, when running an application, you need to add a configuration item to the **spark-submit** command to specify the path of the dependency package of Spark Streaming Kafka, for example, **--jars \$(files=(\$SPARK\_HOME/jars/streamingClient010/\*.jar);IFS=;; echo "\${files[\*]}")**

Because the cluster is security mode, you need to add configuration items and modify the command parameters.

1. Add configuration items to **\$SPARK\_HOME/conf/jaas.conf**:

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=false  
    useTicketCache=true  
    debug=false;  
};
```

2. Add configuration items to **\$SPARK\_HOME/conf/jaas-zk.conf**:

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=true  
    keyTab=".user.keytab"  
    principal="sparkuser@<system domain name>"  
    useTicketCache=false  
    storeKey=true  
    debug=true;  
};
```

3. Use **--files** and relative path to submit the **keytab** file to ensure that the **keytab** file is loaded to the container of the executor.

 CAUTION

When submitting a structured stream task, you need to run the **--jars** command to specify the path of the Kafka-related JAR file. For the current version, you need to copy the kafka-clients jar file from the **\$SPARK\_HOME/jars/streamingClient010** directory to the **\$SPARK\_HOME/jars** directory. Otherwise, the "class not found" error is reported.

Go to the Spark client directory and run the following commands to invoke the **bin/spark-submit** script to run the code (the class name and file name must be the same as those in the actual code. The following is only an example):

- Run Java or Scala sample code:

```
bin/spark-submit --master yarn --deploy-mode client --conf  
spark.driver.userClassPathFirst=true --conf  
spark.executor.userClassPathFirst=true --files <local Path>/jaas.conf,<local  
path>/user.keytab --jars $(files=($SPARK_HOME/jars/streamingClient010/  
*.jar);IFS=;; echo "${files[*]}") --class  
com.huawei.bigdata.spark.examples.SecurityKafkaWordCount /opt/  
SparkStructuredStreamingScalaExample-1.0.jar <brokers> <subscribe-type>  
<topic> <protocol> <service> <domain> <checkpointDir>
```

The configuration example is as follows:

```
-files <local Path>/jaas.conf,<local Path>/user.keytab //Use --files to specify the jaas.conf and keytab  
files.
```

- Run the Python sample code:

 NOTE

When running the Python sample code, you need to add the JAR package of the Java project to the **streamingClient010/** directory.

```
bin/spark-submit --master yarn --deploy-mode client --deploy-mode
client --conf spark.driver.userClassPathFirst=true --conf
spark.executor.userClassPathFirst=true --files /opt/FIclient/user.keytab --
jars ${files=(${SPARK_HOME/jars/streamingClient010/*.jar});IFS=,;echo "${files[*]}"} /opt/female/SparkStructuredStreamingPythonExample/
SecurityKafkaWordCount.py <brokers> <subscribe-type> <topic> <protocol>
<service> <domain> <checkpointDir>
```

### 1.21.3.8.2 Java Sample Code

#### Function

In Spark applications, use StructuredStreaming to invoke Kafka interface to obtain word records. Collect the statistics of records for each word.

#### Code Sample

The following code is an example. For details, see [com.huawei.bigdata.spark.examples.SecurityKafkaWordCount](#).

 NOTE

When new data is available in Streaming DataFrame/Dataset, **outputMode** is used for configuring data written to the Streaming receiver. The default value is **append**. To change the value, see the **outputMode** description of [Spark > Scala in MapReduce Service \(MRS\) 3.1-LTS API Reference \(for Huawei Cloud Stack 8.3.1\)](#).

```
public class SecurityKafkaWordCount
{
    public static void main(String[] args) throws Exception {
        if (args.length < 6) {
            System.err.println("Usage: SecurityKafkaWordCount <bootstrap-servers> " +
                "<subscribe-type> <topics> <protocol> <service> <domain>");
            System.exit(1);
        }

        String bootstrapServers = args[0];
        String subscribeType = args[1];
        String topics = args[2];
        String protocol = args[3];
        String service = args[4];
        String domain = args[5];

        SparkSession spark = SparkSession
            .builder()
            .appName("SecurityKafkaWordCount")
            .getOrCreate();

        // Create DataSet representing the stream of input lines from kafka
        Dataset<String> lines = spark
            .readStream()
            .format("kafka")
            .option("kafka.bootstrap.servers", bootstrapServers)
            .option(subscribeType, topics)
            .option("kafka.security.protocol", protocol)
```

```
.option("kafka.sasl.kerberos.service.name", service)
.option("kafka.kerberos.domain.name", domain)
.load()
.selectExpr("CAST(value AS STRING)")
.as(Encoders.STRING());

// Generate running word count
Dataset<Row> wordCounts = lines.flatMap(new FlatMapFunction<String, String>() {
    @Override
    public Iterator<String> call(String x) {
        return Arrays.asList(x.split(" ")).iterator();
    }
}, Encoders.STRING()).groupByKey("value").count();

// Start running the query that prints the running counts to the console
StreamingQuery query = wordCounts.writeStream()
    .outputMode("complete")
    .format("console")
    .start();

query.awaitTermination();
}
```

### 1.21.3.8.3 Scala Sample Code

#### Function

In Spark applications, use StructuredStreaming to invoke Kafka interface to obtain word records. Collect the statistics of records for each word.

#### Code Sample

The following code is an example. For details, see [com.huawei.bigdata.spark.examples.SecurityKafkaWordCount](#).

##### NOTE

When new data is available in Streaming DataFrame/Dataset, **outputMode** is used for configuring data written to the Streaming receiver. The default value is **append**. To change the value, see the **outputMode** description of [Spark > Scala in MapReduce Service \(MRS\) 3.3.1-LTS API Reference \(for Huawei Cloud Stack 8.3.1\)](#).

```
object SecurityKafkaWordCount {
    def main(args: Array[String]): Unit = {
        if (args.length < 6) {
            System.err.println("Usage: SecurityKafkaWordCount <bootstrap-servers> " +
                "<subscribe-type> <topics> <protocol> <service> <domain>")
            System.exit(1)
        }

        val Array(bootstrapServers, subscribeType, topics, protocol, service, domain) = args

        val spark = SparkSession
            .builder
            .appName("SecurityKafkaWordCount")
            .getOrCreate()

        import spark.implicits._

        // Create DataSet representing the stream of input lines from kafka
        val lines = spark
            .readStream
            .format("kafka")
            .option("kafka.bootstrap.servers", bootstrapServers)
            .option(subscribeType, topics)
```

```
.option("kafka.security.protocol", protocol)
.option("kafka.sasl.kerberos.service.name", service)
.option("kafka.kerberos.domain.name", domain)
.load()
.selectExpr("CAST(value AS STRING)")
.as[String]

// Generate running word count
val wordCounts = lines.flatMap(_.split(" ")).groupBy("value").count()

// Start running the query that prints the running counts to the console
val query = wordCounts.writeStream
    .outputMode("complete")
    .format("console")
    .start()

query.awaitTermination()
}
```

### 1.21.3.8.4 Python Sample Code

## Function

In Spark applications, use StructuredStreaming to invoke Kafka APIs to obtain word records. Classify word records to obtain the number of records of each word.

## Sample Code

The following code segment is only an example. For details, see [SecurityKafkaWordCount](#)

When there is new available data in Streaming DataFrame/Dataset, **outputMode** indicates data written to the Streaming receiver. The default value is **append**. To change the value, see the **outputMode** description of **Spark > Scala** in *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

```
#!/usr/bin/python
# -*- coding: utf-8 -*-

import sys
from pyspark.sql import SparkSession
from pyspark.sql.functions import explode, split

if __name__ == "__main__":
    if len(sys.argv) < 6:
        print("Usage: <bootstrapServers> <subscribeType> <topics> <protocol> <service> <domain>")
        exit(-1)

    bootstrapServers = sys.argv[1]
    subscribeType = sys.argv[2]
    topics = sys.argv[3]
    protocol = sys.argv[4]
    service = sys.argv[5]
    domain = sys.argv[6]

    # Initialize the SparkSession.
    spark = SparkSession.builder.appName("SecurityKafkaWordCount").getOrCreate()

    # Create the DataFrame of input lines stream from Kafka.
    # In security mode, set spark/conf/jaas.conf and jaas-zk.conf to KafkaClient.
    lines = spark.readStream.format("kafka")\
        .option("kafka.bootstrap.servers", bootstrapServers)\
```

```
.option(subscribeType, topics)\\
.option("kafka.security.protocol", protocol)\\
.option("kafka.sasl.kerberos.service.name", service)\\
.option("kafka.kerberos.domain.name", domain)\\
.load()\\
.selectExpr("CAST(value AS STRING)")

# Split lines into words.
words = lines.select(explode(split(lines.value, " ")).alias("word"))
# Generate the running word count.
wordCounts = words.groupBy("word").count()

# Start to query whether the running counts are printed to the console.
query = wordCounts.writeStream\\
.outputMode("complete")\\
.format("console")\\
.start()

query.awaitTermination()
```

### 1.21.3.9 Structured Streaming Stream-Stream Join

#### 1.21.3.9.1 Overview

##### Scenarios

An advertisement service involves advertisement request events, advertisement display events, and advertisement click events. The advertiser needs to collect statistics on valid advertisement displays and advertisement click data.

Known conditions are as follows:

1. Each time a user requests an advertisement, an advertisement request event is generated and saved to the adRequest topic of Kafka.
2. After an advertisement is requested, the advertisement may be displayed for multiple times. Each time the advertisement is displayed, an advertisement display event is generated and saved to the adShow topic of Kafka.
3. Each advertisement may be clicked for multiple times. Each time it is clicked, an advertisement click event is generated and saved to the adClick topic of Kafka.
4. For advertisement display:
  - a. If the duration from the time when a request is generated to the time when the advertisement is displayed exceeds A minutes, the display is invalid.
  - b. Advertisement display events generated during A minutes are valid events.
5. For advertisement click:
  - a. If the duration from the display event to the click event exceeds B minutes, the click is invalid.
  - b. If there are multiple click events within B minutes, only the first click event is valid.

The simple data structure in this scenario is as follows:

- Advertisement request event  
Data structure: adID<sup>reqTime</sup>
- Advertisement display event  
Data structure: adID<sup>showID</sup><sup>showTime</sup>
- Advertisement click event  
Data structure: adID<sup>showID</sup><sup>clickTime</sup>

Data association relationships are as follows:

- The advertisement request event is associated with the advertisement display event through the adID.
- The advertisement display event is associated with the advertisement click event through the adID and showID.

Data requirements:

- The delay from the time when data is generated to the time when the data reaches the stream processing engine does not exceed two hours.
- The time for advertisement request events, advertisement display events, and advertisement click events reach the stream processing engine may not be in sequence or be aligned with each other.

## Data Planning

1. Enable users with the Kafka permission to generate simulation data in Kafka.

```
java -cp $SPARK_HOME/conf:$SPARK_HOME/jars/*:$SPARK_HOME/jars/
streamingClient010/*:{ClassPath}
com.huawei.bigdata.spark.examples.KafkaADEventProducer {BrokerList}
{timeOfProduceReqEvent} {eventTimeBeforeCurrentTime} {reqTopic}
{reqEventCount} {showTopic} {showEventMaxDelay} {clickTopic}
{clickEventMaxDelay}
```

### NOTE

- Ensure that the clusters are installed, including HDFS, Yarn, Spark, and Kafka.
- Set the **allow.everyone.if.no.acl.found** parameter of Kafka Broker to **true**.
- Start Kafka Producer and enable it to send data to Kafka.
- **{ClassPath}** indicates the path for storing the JAR package of the project. The path is specified by users. For details, see the step of exporting JAR packages in [Compiling and Running the Application](#).

Command example:

```
java -cp /opt/hadoopclient/Spark/spark/conf:/opt/
StructuredStreamingADScalaExample-1.0.jar:/opt/hadoopclient/Spark/
spark/jars/*:/opt/hadoopclient/Spark/spark/jars/streamingClient010/*
com.huawei.bigdata.spark.examples.KafkaADEventProducer
10.132.190.170:21005,10.132.190.165:21005 2h 1h req 10000000 show 5m
click 5m
```

This command creates three topics on Kafka: req, show, and click. Ten million data records of request events are generated in two hours. The time range of the request events is from one hour ahead of the current time to the current time, and up to five display events are randomly generated for each request event. The time range of the display events is from the request event time to

five minutes after the request event time. Up to five click events are randomly generated for each display event. The time range of the click events is from the display event time to five minutes after the display event time.

## Development Guideline

1. Use structured streaming to receive data from Kafka and generate request flows, display flows, and click flows.
2. Perform join query of data in request flows, display flows, and click flows.
3. Write the statistics result to Kafka.
4. Monitor the flow processing task status in the application.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

## Packaging the Project

- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed.
- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).

### NOTE

Before compilation and packaging, change the paths of the user.keytab and krb5.conf files in the sample code to the actual paths on the client server where the files are located. Example: /opt/female/user.keytab or /opt/female/krb5.conf.

- Upload the JAR package to any directory (for example, /opt) on the server where the Spark client is located.

## Running Tasks

When running the sample program, you need to specify **<kafkaBootstrapServers>**, **<maxEventDelay>**, **<reqTopic>**, **<showTopic>**, **<maxShowDelay>**, **<clickTopic>**, **<maxClickDelay>**, **<triggerInterval>**, **<checkpointDir>**, **<kafkaProtocol>**, **<kafkaService>**, and **<kafkaDomain>**. **<kafkaBootstrapServers>** indicates the Kafka address for obtaining metadata (port 21007 is required), and **<maxEventDelay>** indicates the maximum delay from data generation to stream processing. **<reqTopic>** indicates the topic name of the request event. **<showTopic>** indicates the topic name of the display event. **<maxShowDelay>** indicates the maximum delay for displaying the event, and **<clickTopic>** indicates the topic name of the click event. **<maxClickDelay>** indicates the maximum delay time of a valid click event. **<triggerInterval>** indicates the interval for triggering a stream processing task. **<checkpointDir>** indicates the path for storing the checkpoint file, and **<kafkaProtocol>** indicates the secure access protocol (for example, **SASL\_PLAINTEXT**). **<kafkaService>** indicates the Kerberos service name (for example, **kafka**), and **<kafkaDomain>** indicates the Kerberos domain name (for example, **hadoop.<system domain name>**).

 NOTE

The path of the Spark Structured Streaming Kafka dependency package on the client is different from that of other dependency packages. For example, the path of other dependency packages is **\$SPARK\_HOME/jars**. Whereas the path of the Spark Structured Streaming Kafka dependency package is **\$SPARK\_HOME/jars/streamingClient010**. Therefore, when running an application, you need to add a configuration item to the **spark-submit** command to specify the path of the dependency package of Spark Streaming Kafka, for example, `--jars ${files=($SPARK_HOME/jars/streamingClient010/*.jar); IFS=,:; echo "${files[*]}"}`

Because the cluster is security mode, you need to add configuration items and modify the command parameters.

1. Add configuration items to **\$SPARK\_HOME/conf/jaas.conf**:

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=false  
    useTicketCache=true  
    debug=false;  
};
```

2. Add configuration items to **\$SPARK\_HOME/conf/jaas-zk.conf**

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=true  
    keyTab=".:/user.keytab"  
    principal="sparkuser@<System domain name>"  
    useTicketCache=false  
    storeKey=true  
    debug=true;  
};
```

3. Use **--files** and relative path to submit the **keytab** file to ensure that the **keytab** file is loaded to the container of the executor.

 CAUTION

When submitting a structured stream task, you need to run the **--jars** command to specify the path of the Kafka-related JAR file. For the current version, you need to copy the `kafka-clientsjar` file from the **\$SPARK\_HOME/jars/streamingClient010** directory to the **\$SPARK\_HOME/jars** directory. Otherwise, the "class not found" error is reported.

Go to the Spark client directory and run the following command to invoke the **bin/spark-submit** script to run the code (the class name and file name must be the same as those in the actual code. The following is only an example):

```
bin/spark-submit --master yarn --deploy-mode client --files <local Path>/  
jaas.conf,<local path>/user.keytab --jars ${files=($SPARK_HOME/jars/  
streamingClient010/*.jar); IFS=,:; echo "${files[*]}"} --conf  
"spark.sql.streaming.statefulOperator.checkCorrectness.enabled=false" --class  
com.huawei.bigdata.spark.examples.KafkaADCount /opt/  
StructuredStreamingADScalaExample-1.0.jar <kafkaBootstrapServers>  
<maxEventDelay> <reqTopic> <showTopic> <maxShowDelay> <clickTopic>  
<maxClickDelay> <triggerInterval> <checkpointDir> <kafkaProtocol>  
<kafkaService> <kafkaDomain>
```

Go to the Spark client directory and run the following command to invoke the **bin/spark-submit** script to run the code:

```
--files ./jaas.conf,./user.keytab //Use --files to specify the jaas.conf and keytab files.
```

### 1.21.3.9.2 Scala Example Code

#### Function

Structured Streaming is used to read advertisement request data, display data, and click data from Kafka, obtain effective display statistics and click statistics in real time, and write the statistics to Kafka.

#### Example code

The following code snippets are used as an example. For complete codes, see com.huawei.bigdata.spark.examples.KafkaADCount.

```
/*
 * Run the Structured Streaming task to collect statistics on valid advertisement display and click data. The
result is written into Kafka.
 */

object KafkaADCount {
    def main(args: Array[String]): Unit = {
        if (args.length < 12) {
            System.err.println("Usage: KafkaWordCount <bootstrap-servers> " +
                "<maxEventDelay> <reqTopic> <showTopic> <maxShowDelay> " +
                "<clickTopic> <maxClickDelay> <triggerInterver> " +
                "<checkpointLocation> <protocol> <service> <domain>")
            System.exit(1)
        }

        val Array(bootstrapServers, maxEventDelay, reqTopic, showTopic,
            maxShowDelay, clickTopic, maxClickDelay, triggerInterver, checkpointLocation,
            protocol, service, domain) = args

        val maxEventDelayMills = JavaUtils.timeStringAs(maxEventDelay, TimeUnit.MILLISECONDS)
        val maxShowDelayMills = JavaUtils.timeStringAs(maxShowDelay, TimeUnit.MILLISECONDS)
        val maxClickDelayMills = JavaUtils.timeStringAs(maxClickDelay, TimeUnit.MILLISECONDS)
        val triggerMills = JavaUtils.timeStringAs(triggerInterver, TimeUnit.MILLISECONDS)

        val spark = SparkSession
            .builder
            .appName("KafkaADCount")
            .getOrCreate()

        spark.conf.set("spark.sql.streaming.checkpointLocation", checkpointLocation)

        import spark.implicits._

        // Create DataSet representing the stream of input lines from kafka
        val reqDf = spark
            .readStream
            .format("kafka")
            .option("kafka.bootstrap.servers", bootstrapServers)
            .option("kafka.security.protocol", protocol)
            .option("kafka.sasl.kerberos.service.name", service)
            .option("kafka.kerberos.domain.name", domain)
            .option("subscribe", reqTopic)
            .load()
            .selectExpr("CAST(value AS STRING)")
            .as[String]
            .map{
                _split('^') match {
                    case Array(reqAdID, reqTime) => ReqEvent(reqAdID,
                        Timestamp.valueOf(reqTime))
                }
            }
            .as[ReqEvent]
            .withWatermark("reqTime", maxEventDelayMills +
```

```
maxShowDelayMills + " millisecond")

val showDf = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers", bootstrapServers)
    .option("kafka.security.protocol", protocol)
    .option("kafka.sasl.kerberos.service.name", service)
    .option("kafka.kerberos.domain.name", domain)
    .option("subscribe", showTopic)
    .load()
    .selectExpr("CAST(value AS STRING)")
    .as[String]
    .map{
        _split('^') match {
            case Array(showAdID, showID, showTime) => ShowEvent(showAdID,
                showID, Timestamp.valueOf(showTime))
        }
    }
    .as[ShowEvent]
    .withWatermark("showTime", maxEventDelayMills +
        maxShowDelayMills + maxClickDelayMills + " millisecond")

val clickDf = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers", bootstrapServers)
    .option("kafka.security.protocol", protocol)
    .option("kafka.sasl.kerberos.service.name", service)
    .option("kafka.kerberos.domain.name", domain)
    .option("subscribe", clickTopic)
    .load()
    .selectExpr("CAST(value AS STRING)")
    .as[String]
    .map{
        _split('^') match {
            case Array(clickAdID, clickShowID, clickTime) => ClickEvent(clickAdID,
                clickShowID, Timestamp.valueOf(clickTime))
        }
    }
    .as[ClickEvent]
    .withWatermark("clickTime", maxEventDelayMills + " millisecond")

val showStaticsQuery = reqDf.join(showDf,
    expr(s"""
        reqAdID = showAdID
        AND showTime >= reqTime + interval ${maxShowDelayMills} millisecond
    """))
    .selectExpr("concat_ws('^', showAdID, showID, showTime) as value")
    .writeStream
    .queryName("showEventStatics")
    .outputMode("append")
    .trigger(Trigger.ProcessingTime(triggerMills.millis))
    .format("kafka")
    .option("kafka.bootstrap.servers", bootstrapServers)
    .option("kafka.security.protocol", protocol)
    .option("kafka.sasl.kerberos.service.name", service)
    .option("kafka.kerberos.domain.name", domain)
    .option("topic", "showEventStatics")
    .start()

val clickStaticsQuery = showDf.join(clickDf,
    expr(s"""
        showAdID = clickAdID AND
        showID = clickShowID AND
        clickTime >= showTime + interval ${maxClickDelayMills} millisecond
    """), joinType = "rightouter")
    .dropDuplicates("showAdID")
    .selectExpr("concat_ws('^', clickAdID, clickShowID, clickTime) as value")
```

```
.writeStream
.queryName("clickEventStatics")
.outputMode("append")
.trigger(Trigger.ProcessingTime(triggerMills.millis))
.format("kafka")
.option("kafka.bootstrap.servers", bootstrapServers)
.option("kafka.security.protocol", protocol)
.option("kafka.sasl.kerberos.service.name", service)
.option("kafka.kerberos.domain.name", domain)
.option("topic", "clickEventStatics")
.start()

new Thread(new Runnable {
    override def run(): Unit = {
        while(true) {
            println("-----get showStatic progress-----")
            //println(showStaticsQuery.lastProgress)
            println(showStaticsQuery.status)
            println("-----get clickStatic progress-----")
            //println(clickStaticsQuery.lastProgress)
            println(clickStaticsQuery.status)
            Thread.sleep(10000)
        }
    }
}).start

spark.streams.awaitAnyTermination()
}
```

### 1.21.3.10 Spark on Elasticsearch

#### 1.21.3.10.1 Overview

##### Scenarios

In Spark, you can create, delete, and query indexes using Elasticsearch native APIs and the APIs provided by elasticsearch-spark.

##### Data Planning

Perform the following operations to save the data files in HDFS:

1. Obtain a test data file and obtain the **people.json** file in the **data** directory of the sample code.
2. Create the **spark-on-es** folder in HDFS and upload the **people.json** file to the directory **/user/spark-on-es** of HDFS. The command is as follows:
  - a. On the HDFS client, run the following commands to obtain security authentication:  
**cd /opt/hadoopclient**  
**kinit <Service user for authentication>**
  - b. On a Linux-based HDFS client, run the **hadoop fs -mkdir /user/spark-on-es** command (the **hdfs dfs** command provides the same function).
  - c. On a Linux-based HDFS client, run the **hadoop fs -put people.json /user/spark-on-es** command.

## Development Idea

1. Initialize basic configuration parameters of Elasticsearch.
2. Create an Elasticsearch client.
3. Create indexes of Elasticsearch.
4. Initialize the SparkContext.
5. Use the **BulkRequest** command to add data in batches in Elasticsearch.
6. Spark reads the test data (the **people.json** file obtained in **Data Planning**) from HDFS and adds the data to the Elasticsearch indexes created in 3 using the elasticsearch-spark API.
7. Query data in the Elasticsearch indexes. Two query methods displayed in the sample are as follows:
  - Query data using the elasticsearch-spark API.
  - Query data using the Elasticsearch Scroll API.
8. Operate the queried data by using the Spark Application. The sample demonstrates how to group and sort the queried data.

## Configuration Files

The content of the **esParams.properties** configuration file is as follows:

```
# IP address and port number of the node in the Elasticsearch cluster. Enter a value in the format of "IP
address:port number". Separate multiple values with commas (,).
esServerHost=10.10.10.11:24100,10.10.10.12:24100,10.10.10.13:24100
# Whether to enable the sniffer function.
snifferEnable=true
connectTimeout=5000
socketTimeout=60000
connectionRequestTimeout=3000
# Maximum number of connections on a single route.
maxConnPerRoute=100
maxConnTotal=1000
maxRetryTimeoutMillis=60000

# Whether the cluster is in security mode. If yes, set the parameter to true; if no, set it to false.
isSecureMode=true
# Whether to enable the SSL mode of Elasticsearch. If the cluster is in security mode, set the parameter to
true; otherwise, set it to false.
sslEnabled=true
# The jaas.conf file path. If the parameter is left blank, the path is generated automatically.
customJaasPath=
# Authentication usernames of the Spark and Elasticsearch cluster.
principal=sparkuser
# If sslEnabled is set to true, userPassword must be set, or the Elasticsearch security cluster will fail to be
connected.
userPassword=xxxxxx

# Field to be returned. Separate multiple values with commas (,).
# For example: https://www.elastic.co/guide/en/elasticsearch/hadoop/current/configuration.html
esFilterField=name,age,createdTime
# The maximum of Elasticsearch batch query is 10,000 by default.
# It is recommended that the value be less than 50,000. Otherwise, out of memory (OOM) may occur.
esScrollSize=10000
# This parameter is used to set the number of Spark data partitions. It is supported by Elasticsearch 5.0 and
later.
# This parameter, together with scroll.size, can improve the throughput and task concurrency.
# If it is not set, the number of Spark partitions is equal to that of index shards in Elasticsearch.
esInputMaxDocsPerPartition=500000

# The name of the index to be operated in Elasticsearch, the number of shards, and the number of replicas.
```

```
esIndex=people
esShardNum=5
esReplicaNum=1

# Information required for group statistics and range query in Elasticsearch.
esGroupField=age
esQueryField=createdTime
# Start value of the range query, which is included in the range.
esQueryRangeBegin=2010-01-01T00:00:00Z
# End value of the range query, which is not included in the range.
esQueryRangeEnd=2015-12-31T23:59:59
# JSON character string of Elasticsearch DSL, which cannot contain line breaks.
# Only the query parameter is supported. Other parameters such as _source and size are not supported.
esQueryJsonString={"query": {"range": { "%s": {"gte": "%s", "lt": "%s"} } } }
```

## Preparation Operations Before Running

In security mode, the **user.keytab** file, the **krb5.conf** file, and the **eParams.properties** file are needed in the SparkOnEs sample code. For details about the **eParams.properties** file, see the example in the **conf** directory of the sample code. The **user.keytab** and **krb5.conf** files are authentication files in security mode. The authentication credential of the **principal** user needs to be downloaded on FusionInsight Manager. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

For the Python sample, you need to modify the Python code and set **es.nodes** in **SparkOnEsPythonExample.py** to the IP address of the node where EsNode resides in the cluster.

## Packaging the Project

1. Modify the project configuration to make it the same as that of the cluster to be tested (You can find the Python sample configuration in the **SparkOnEsPythonExample.py** file.).
2. Use the Maven tool provided by IDEA to package the project and generate **target\SparkOnEs-1.0.jar**. For details, see [Compiling and Running the Application](#).
3. Upload the generated JAR package to any directory (for example, **/opt/spark-on-es/**) on the server where the Spark client is located.
4. Upload the **esParams.properties**, **user.keytab**, and **krb5.conf** files to the directory in **3**.
5. Prepare the dependency package. Upload the following JAR package to the **/opt/spark-on-es/libs/** directory on the server where the Spark client is located.

The following JAR packages are required for running the sample code:

- **elasticsearch-xxx.cbu.mrs.xxx.jar**
- **elasticsearch-core-xxx.cbu.mrs.xxx.jar**
- **elasticsearch-rest-client-xxx.cbu.mrs.xxx.jar**
- **elasticsearch-rest-high-level-client-xxx.cbu.mrs.xxx.jar**
- **elasticsearch-spark-20\_2.12-7.12.0.jar**
- **elasticsearch-x-content-xxx.cbu.mrs.xxx.jar**
- **lang-mustache-client-xxx.cbu.mrs.xxx.jar**

- log4j-api-2.12.0.jar
- log4j-core-2.12.0.jar
- lucene-core-8.7.0.jar
- rank-eval-client-xxx.cbu.mrs.xxx.jar
- commons-httpclient-\*jar

## Running a Task

After kinit authentication, run the following commands (the class name and file name must be the same as those in the actual code. The following is only an example):

1. In client mode:

```
cd /opt/spark-on-es
spark-submit --class com.huawei.bigdata.spark.examples.SparkOnEs --
master yarn --deploy-mode client --conf
spark.driver.userClassPathFirst=true --jars $(files=(/opt/spark-on-es/libs/
*.jar); IFS=,; echo "${files[*]}") ./SparkOnEs-1.0.jar
```

In the preceding command, `/opt/spark-on-es/libs/` indicates the path of the external dependency JAR package.

2. In cluster mode:

```
cd /opt/spark-on-es
spark-submit --class com.huawei.bigdata.spark.examples.SparkOnEs --
master yarn --deploy-mode cluster --conf
spark.driver.userClassPathFirst=true --jars $(files=(/opt/spark-on-es/libs/
*.jar); IFS=,; echo "${files[*]}") --files ./user.keytab./krb5.conf./
esParams.properties ./SparkOnEs-1.0.jar
```

In the preceding command, the `--files` parameter specifies the configuration files required for program running. Use commas (,) to separate multiple files.

## Querying Results

1. Query data in Elasticsearch

```
# After kinit authentication, check the index in Elasticsearch.
curl -XGET --tlsv1.2 --negotiate -k -u : 'https://10.10.10.11:24100/_cat/indices?v'

# Run the following commands to query the range of data in the people index.
curl -XPOST --tlsv1.2 --negotiate -k -u : 'https://10.10.10.11:24100/people/_search?pretty' -H 'Content-
Type:application/json' -d '
{
    "query": {
        "range": {
            "createdTime": {"gte": "2010-01-01T00:00:00Z", "lt": "2015-12-31T23:59:59Z"}
        }
    }
}'
```

2. Query files in HDFS.

```
# After kinit authentication, view the grouping result file saved in HDFS.
hdfs dfs -ls /user/spark-on-es/group-result

# View the content of a file. For example, view the content of file part-00001.
hdfs dfs -cat /user/spark-on-es/group-result/part-00001
```

### 1.21.3.10.2 Java Sample Code

#### Function Description

In Spark, you can read, write, and collect statistics on the data in Elasticsearch using Elasticsearch native APIs and the APIs provided by **elasticsearch-spark**.

#### Code Example

The following code snippets are used as an example. For complete codes, see the following `SparkOnEsJavaExample` project:

```
public static void main(String[] args) {
    LOG.info("***** Start to run the Spark on ES test.");

    try {
        // init the global properties
        initProperties();

        // login with keytab
        String userKeytabPath = System.getProperty("user.dir") + File.separator + "user.keytab";
        String krb5ConfPath = System.getProperty("user.dir") + File.separator + "krb5.conf";
        // generate jaas file, which is in the same dir with keytab file
        LoginUtil.setJaasFile(principal, userKeytabPath);
        Configuration hadoopConf = new Configuration();
        LoginUtil.login(principal, userKeytabPath, krb5ConfPath, hadoopConf);

        String path = System.getProperty("user.dir") + File.separator;
        HwRestClient hwRestClient = new HwRestClient(path);
        restClient = hwRestClient.getRestClient();
        highLevelClient = new RestHighLevelClient((hwRestClient.getRestClientBuilder()));

        // Check whether the index to be added has already exist, remove the exist one
        if (exist(esIndex)) {
            deleteIndex(esIndex);
        }
        createIndex(esIndex);

        SparkOnEs instance = new SparkOnEs();
        // Put data by ES bulk request
        instance.putDataByBulk(highLevelClient);

        // Create a configuration class SparkConf,
        // meanwhile set the Secure configuration that the Elasticsearch Cluster needed,
        // finally create a SparkContext.
        SparkConf conf =
            new SparkConf()
                .setAppName("SparkOnEs")
                .set("es.nodes", esServerHost)
                // when you specified in es.nodes, then es.port is not necessary
                // .set("es.port", "24100")
                .set("es.nodes.discovery", "true")
                .set("es.index.auto.create", "true")
                .set("es.internal.spark.sql.pushdown", "true")
                .set("es.net.ssl", sslEnabled)
                .set("es.net.http.auth.user", principal)
                .set("es.net.http.auth.pass", userPassword)
                .set("es.read.source.filter", esFilterField)
                .set("es.scroll.size", esScrollSize)
                .set("es.input.max.docs.per.partition", esInputMaxDocsPerPartition);

        JavaSparkContext jsc = new JavaSparkContext(conf);

        instance.putHdfsData(jsc); // Put data from HDFS into ES
        instance.queryDataByDataset(conf); // Query data from ES
        instance.queryDataByRestClient(highLevelClient, jsc);
        instance.groupBySpark(jsc); // Group data from ES
```

```
        jsc.stop();
    } catch (IOException e) {
        LOG.error("***** There are exceptions in main.", e);
    } finally {
        closeResources();
    }
}
```

### 1.21.3.10.3 Scala Sample Code

## Function

In Spark, you can read, write, and collect statistics on the data in Elasticsearch using Elasticsearch native APIs and the APIs provided by elasticsearch-spark.

## Sample Code

The following code snippets are used as an example. For complete codes, see the following `SparkOnEsScalaExample` project:

```
object SparkOnEs {
  def main(args: Array[String]): Unit = {
    val sparkOnEs = new SparkOnEs
    sparkOnEs.LOG.info("***** Start to run the Spark on ES test.")

    try {
      // init the global properties
      sparkOnEs.initProperties()

      // login with keytab
      val userKeytabPath = System.getProperty("user.dir") + File.separator + "user.keytab"
      val krb5ConfPath = System.getProperty("user.dir") + File.separator + "krb5.conf"
      // generate jaas file, which is in the same dir with keytab file
      LoginUtil.setJaasFile(sparkOnEs.principal, userKeytabPath)
      val hadoopConf = new Configuration
      LoginUtil.login(sparkOnEs.principal, userKeytabPath, krb5ConfPath, hadoopConf)

      val path = System.getProperty("user.dir") + File.separator
      val hwRestClient: HwRestClient = new HwRestClient(path)
      sparkOnEs.restClient = hwRestClient.getRestClient
      sparkOnEs.highLevelClient = new RestHighLevelClient(hwRestClient.getRestClientBuilder)

      // Check whether the index to be added has already exist, remove the exist one
      if (sparkOnEs.exist(sparkOnEs.esIndex)) sparkOnEs.deleteIndex(sparkOnEs.esIndex)
      sparkOnEs.createIndex(sparkOnEs.esIndex)

      // Put data by ES bulk request
      sparkOnEs.putDataByBulk(sparkOnEs.highLevelClient)

      // Create a configuration class SparkConf,
      // meanwhile set the Secure configuration that the Elasticsearch Cluster needed,
      // finally create a SparkContext.
      val conf: SparkConf = new SparkConf().setAppName("SparkOnEs")
        .set("es.nodes", sparkOnEs.esServerHost)
        // when you specified in es.nodes, then es.port is not necessary
        // .set("es.port", "24100")
        .set("es.nodes.discovery", "true")
        .set("es.index.auto.create", "true")
        .set("es.internal.spark.sql.pushdown", "true")
        .set("es.net.ssl", sparkOnEs.sslEnabled)
        .set("es.net.http.auth.user", sparkOnEs.principal)
        .set("es.net.http.auth.pass", sparkOnEs.userPassword)
        .set("es.read.source.filter", sparkOnEs.esFilterField)
        .set("es.scroll.size", sparkOnEs.esScrollSize)
        .set("es.input.max.docs.per.partition", sparkOnEs.esInputMaxDocsPerPartition)
```

```
val jsc: JavaSparkContext = new JavaSparkContext(conf)

sparkOnEs.putHdfsData(jsc) // Put data from HDFS into ES
sparkOnEs.queryDataByDataset(conf) // Query data from ES
sparkOnEs.queryDataByRestClient(sparkOnEs.highLevelClient, jsc)
sparkOnEs.groupBySpark(jsc) // Group data from ES

jsc.close()
} catch {
  case e: IOException =>
    sparkOnEs.LOG.error("***** There are exceptions in main.", e)
} finally {
  sparkOnEs.closeResources()
}
}
```

### 1.21.3.10.4 Python Sample Code

## Function

In Spark, you can read, write, and collect statistics on the data in Elasticsearch using Elasticsearch native APIs and the APIs provided by elasticsearch-spark.

## Sample Code

The following code snippets are used as an example. For complete codes, see the following `SparkOnEsPythonExample` project.

```
# -*- coding:utf-8 -*-
"""
[Note] Since PySpark doesn't support the Elasticsearch, this example calls Java code through Python.
"""

from py4j.java_gateway import java_import
from pyspark import SparkConf, SparkContext

# create the SparkConf
conf = SparkConf().setAppName("SparkOnEs")

# the configurations for Elasticsearch cluster
conf.set("es.nodes", "10.10.10.11:24100,10.10.10.12:24100,10.10.10.13:24100")
# when you specified in es.nodes, then es.port is not necessary
# conf.set("es.port", "24100")
conf.set("es.nodes.discovery", "true")
conf.set("es.index.auto.create", "true")
conf.set("es.internal.spark.sql.pushdown", "true")
conf.set("es.net.ssl", "true")
conf.set("es.net.http.auth.user", "sparkuser")
conf.set("es.net.http.auth.pass", "xxxxxx")
conf.set("es.read.source.filter", "name,age,createdTime")
conf.set("es.scroll.size", "10000")
conf.set("es.input.max.docs.per.partition", "500000")

# create the SparkContext
sc = SparkContext(conf = conf)

# import the program's class to sc._jvm
java_import(sc._jvm, "com.huawei.bigdata.spark.examples.SparkOnEs")

# create an instance of the above class, then invoke its method to run the program
sc._jvm.SparkOnEs().main(sc._jsc)

# stop the SparkContext
sc.stop()
```

## Running a Task

PySpark does not provide APIs for operating Elasticsearch. In this sample code, Python is used to invoke Java for task running. When running the task, you need to add the JAR package of the Java project to the **libs/** directory and upload the JAR package and other dependency packages to the class path.

After kinit authentication, run the following commands:

1. In client mode:

```
cd /opt/spark-on-es  
spark-submit --master yarn --deploy-mode client --conf  
spark.driver.userClassPathFirst=true --jars $(files=(/opt/spark-on-es/libs/  
*.jar); IFS=,; echo "${files[*]}") SparkOnEsPythonExample.py
```

In the preceding command, `/opt/spark-on-es/libs/` indicates the path of the external dependency JAR package, **including the sample JAR package**.

2. In cluster mode:

```
cd /opt/spark-on-es  
spark-submit --master yarn --deploy-mode cluster --conf  
spark.driver.userClassPathFirst=true --jars $(files=(/opt/spark-on-es/libs/  
*.jar); IFS=,; echo "${files[*]}") --files ./user.keytab,./krb5.conf,./  
esParams.properties SparkOnEsPythonExample.py
```

In the preceding command, the `--files` parameter specifies the configuration files required for program running. Use commas (,) to separate multiple files.

## 1.21.3.11 Spark on Solr

### 1.21.3.11.1 Overview

#### Scenarios

Users can use Spark to invoke Solr APIs to operate data in Solr. In the Spark application, users can use the Solr APIs to create, query, and delete indexes.

#### Development Idea

1. Initialize the Solr configuration and obtain a Solr client.
2. Create Solr indexes.
3. Add the data to the indexes.
4. Read the data in the indexes and use Spark to perform simple operations.
5. Delete the created indexes.
6. Read the data in the indexes again.

#### Dependency

- `solr-solrj-xxx.jar`
- `junit-4.11.jar`
- `spark-core_2.12-xxx.jar`

- hadoop-common-xxx.jar
- hadoop-mapreduce-client-core-xxx.jar
- slf4j-log4jxxx.jar
- commons-logging-xxx.jar
- commons-langxxx.jar
- jackson-databind-xxx.jar
- jetty-client-xxx.jar
- httpmime-xxx.jar

## Configuration Files

`solr-example.properties`

```
#zookeeper address
zkHost=10.111.111.111:24002/solr
ZOOKEEPER_DEFAULT_SERVER_PRINCIPAL=zookeeper/hadoop.<system domain name>
#users to be authenticated can be specified explicitly in the code (the user is explicitly specified as super in
the sample code)
principal=super
zkClientTimeout=20000
zkConnectTimeout=30000
#Whether it is security mode, if it is security mode, set it to true; if it is non-security mode, set to false
SOLR_KBS_ENABLED=true
COLLECTION_NAME=col_test
DEFAULT_CONFIG_NAME=confWithSchema
#Set this parameter based on the number of instance nodes. You are advised to set this parameter to the
number of instance nodes.
shardNum=3
replicaNum=1
maxShardsPerNode=1
autoAddReplicas=false
assignToSpecifiedNodeSet=false
#Solr service SolrServer instance IP
createNodeSet=10.111.111.111:21101_solr,10.222.222.222:21101_solr
```

## Preparation Operations Before Running

In security mode, the **user.keytab** file, the **krb5.conf** file, and the **solr-example.properties** file need to be used in the SparkOnSolr sample code. For details about the **solr-example.properties** file, see the example in the **conf** directory of the sample code. The **user.keytab** and **krb5.conf** files are authentication files in security mode. Download the authentication credentials of the corresponding users on the FusionInsight\_Manager page. The user in the sample code is **super**, change the value to the prepared development user name.

### Yarn-client mode

1. Copy the **user.keytab** file, the **krb5.conf** file, and the **solr-example.properties** file to the **\$SPARK\_HOME/bin** running directory on the client.
2. Extra JAR packages are required for running Solr. Therefore, you need to add the JAR package that is required by the Spark application and not included by the cluster to the class path of Driver. Modify **spark.driver.extraClassPath** in the **spark-defaults.conf** configuration file on the client. The configuration method is as follows:

**spark.driver.extraClassPath = /opt/hadoopclient/Spark/customJars/\***

#### NOTE

The JAR packages to be added to the sample code include **httpmime-xxx.jar** and **jetty-client-xxx.jar** (xxx indicates the version number of the JAR package, which can be obtained from the **\$SOLR\_HOME/lib/** directory). Add or delete as required.

3. Run the following command (the class name and file name must be the same as those in the actual code. The following is only an example):

```
./spark-submit --class com.huawei.bigdata.spark.examples.SparkOnSolr --  
jars /opt/hadoopclient/Spark/customJars/jetty-client-xxx.jar,/opt/  
hadoopclient/Spark/customJars/httpmime-xxx.jar --master yarn --deploy-  
mode client ./SparkOnSolr.jar
```

#### Yarn-cluster mode

1. Copy the **user.keytab** file, the **krb5.conf** file, and the **es-example.properties** file to any directory on the node on which the client is located.
2. Extra JAR packages are required for running Solr. Therefore, you need to add the JAR package required by the Spark application to the cluster and modify **spark.yarn.dist.innerfiles** and **spark.yarn.cluster.driver.extraClassPath** in the **spark-defaults.conf** file on the client. The configuration method is as follows:
  - Distribute the extra JAR packages to each node of the cluster by using the configuration item.  
**spark.yarn.dist.files = /opt/hadoopclient/Spark/customJars/httpmime-xxx.jar,/opt/hadoopclient/Spark/customJars/jetty-client-xxx.jar**
  - Add the specified JAR package to the class path of Driver in Yarn-cluster mode by using the configuration item.  
**spark.yarn.cluster.driver.extraClassPath = \$PWD/httpmime-xxx.jar:\$PWD/jetty-client-xxx.jar**
3. When running the Spark program, add -file and paths of the **user.keytab** file, the **krb5.conf** file, and the **es-example.properties** file to the command. For example:  

```
./spark-submit --class com.huawei.bigdata.spark.examples.SparkOnSolr --  
files ./user.keytab,/krb5.conf,/solr-example.properties --master yarn --  
deploy-mode cluster ./SparkOnSolr.jar
```

### 1.21.3.11.2 Java Sample Code

#### Function

In the Spark application, Solr client APIs are used to create indexes, insert data, and search for data.

#### Sample Code

The following code snippets are used as an example. For complete codes, see the following SparkOnSolrJavaExample project:

```
/**  
 * 1-Initialize Solr configuration and obtain the Solr client;  
 * 2-Create Solr indexes;  
 * 3-Add data to the indexes;  
 * 4-Read the data in the indexes and use Spark to perform simple operations;  
 * 5>Delete the created indexes;
```

```
* 6-Read the data in the indexes again.  
*/  
  
public class SparkOnSolr{  
    public static void main(String[] args) throws Exception {  
        SparkOnSolr testSample = new SparkOnSolr();  
        testSample.initProperties();  
        SparkConf conf = new SparkConf().setAppName("SparkOnSolr");  
        JavaSparkContext jsc = new JavaSparkContext(conf);  
        CloudSolrClient cloudSolrClient = null;  
        try {  
            cloudSolrClient = testSample.getCloudSolrClient(zkHost);  
            List<String> collectionNames = testSample.queryAllCollections(cloudSolrClient);  
            //delete the collection if exists  
            if (collectionNames.contains(collectionName)) {  
                testSample.deleteCollection(cloudSolrClient);  
            }  
            testSample.createCollection(cloudSolrClient);  
            cloudSolrClient.setDefaultCollection(collectionName);  
            testSample.addDocs(cloudSolrClient);  
            testSample.addDocs2(cloudSolrClient);  
            //Some time is needed to build the index  
            try {  
                Thread.sleep(2000);  
            } catch (InterruptedException e) {}  
            List<Map<String, Object>> queryResult1 = testSample.queryIndex(cloudSolrClient);  
            List<List<String>> resultList = new ArrayList<>();  
            for(int i=0; i < queryResult1.size(); i++){  
                resultList.add(testSample.transferMapToList(queryResult1.get(i)));  
            }  
            JavaRDD<List<String>> resultRDD = jsc.parallelize(resultList);  
            System.out.println("Before delete, the total count is:" + resultRDD.count() + "\n");  
            testSample.removeIndex(cloudSolrClient);  
            //Some time is needed to delete the index  
            try {  
                Thread.sleep(2000);  
            } catch (InterruptedException e) {}  
            List<Map<String, Object>> queryResult2 = testSample.queryIndex(cloudSolrClient);  
            JavaRDD<Map<String, Object>> resultRDD2 = jsc.parallelize(queryResult2);  
            System.out.println("After delete, the total count is:" + resultRDD2.count() + "\n");  
        } catch (SolrException e) {  
            throw new SolrException(e.getMessage());  
        } finally {  
            if (cloudSolrClient != null) {  
                try {  
                    cloudSolrClient.close();  
                } catch (IOException e) {  
                    LOG.warn("Failed to close cloudSolrClient", e);  
                }  
            }  
            jsc.stop();  
        }  
    }  
}
```

### 1.21.3.11.3 Scala Sample Code

#### Function

In the Spark application, Solr client APIs are used to create indexes, insert data, and search for data. Finally, Spark performs simple operations on the queried data.

#### Sample Code

The following code snippets are used as an example. For complete codes, see the following [SparkOnSolrScalaExample](#) project:

```
/*
 * 1-Initialize Solr configuration and obtain the Solr client;
 * 2>Create Solr indexes;
 * 3-Add data to the indexes;
 * 4-Read the data in the indexes and use Spark to perform simple operations;
 * 5>Delete the created indexes;
 * 6-Read the data in the indexes again.
 */
object SparkOnSolr{
  def main(args: Array[String]): Unit ={
    val testSample = new SparkOnSolr
    testSample.initProperties()
    val conf = new SparkConf().setAppName("SparkOnSolr")
    val sc = new SparkContext(conf)
    var cloudSolrClient: CloudSolrClient = null
    try {
      cloudSolrClient = testSample.getCloudSolrClient(testSample.zkHost)
      val collectionNames = testSample.queryAllCollections(cloudSolrClient)
      //delete the collection if exists
      if (collectionNames.contains(testSample.collectionName)) testSample.deleteCollection(cloudSolrClient)
      testSample.createCollection(cloudSolrClient)
      cloudSolrClient.setDefaultCollection(testSample.collectionName)
      testSample.addDocs(cloudSolrClient)
      testSample.addDocs2(cloudSolrClient)
      //Some time is needed to build the index
      try
        Thread.sleep(2000)
      catch {
        case e: InterruptedException =>
      }
      val queryResult1 = testSample.queryIndex(cloudSolrClient)
      import collection.JavaConversions._
      val resultRDD = sc.parallelize(queryResult1)
      System.out.println("Before delete, the total count is:" + resultRDD.count + "\n")
      testSample.removeIndex(cloudSolrClient)
      //Some time is needed to delete the index
      try
        Thread.sleep(2000)
      catch {
        case e: InterruptedException =>
      }
      val queryResult2 = testSample.queryIndex(cloudSolrClient)
      val resultRDD2 = sc.parallelize(queryResult2)
      System.out.println("After delete, the total count is:" + resultRDD2.count + "\n")
    } catch {
      case e: SolrException =>
        throw new SolrException(e.getMessage, null)
    } finally if (cloudSolrClient != null) try
      cloudSolrClient.close()
    catch {
      case e: IOException =>
        testSample.LOG.warn("Failed to close cloudSolrClient", e)
    }
    sc.stop()
  }
}
```

#### 1.21.3.11.4 Python Sample Code

### Function

In the Spark application, Solr client APIs are used to create indexes, insert data, and search for data. Finally, Spark performs simple operations on the queried data.

## Sample Code

PySpark does not provide Solr APIs. This example is implemented by using Python to invoke Java. When the application is running, you need to add some JAR packages of Java to the class path.

1. In Yarn-client mode, use the **--jars** parameter to load the Java **SparkOnSolr.jar** package to be invoked.

```
./spark-submit --jars SparkOnSolr.jar --master yarn-client  
SparkOnSolrPythonExample.py
```

2. In Yarn-cluster mode, modify the configuration item in the **spark-defaults.conf** file to add the **SparkOnSolr.jar** file to the class path. The configuration method is as follows:

- Distribute the extra JAR packages to each node of the cluster by using the configuration item.

```
spark.yarn.dist.innerfiles = /opt/hadoopclient/Spark/customJars/  
SparkOnSolr.jar,/opt/hadoopclient/Spark/customJars/  
httpmime-4.4.1.jar
```

- Add the specified JAR package to the class path of Driver in Yarn-cluster mode by using the configuration item.

```
spark.yarn.cluster.driver.extraClassPath = $PWD/  
SparkOnSolr.jar:$PWD/httpmime-4.4.1.jar
```

- Run the following command in Yarn-cluster mode:

```
./spark-submit --files ./user.keytab,./krb5.conf,./solr-  
example.properties --master yarn-cluster --jars SparkOnSolr.jar  
SparkOnSolrPythonExample.py
```

The following code snippets are used as an example. For complete codes, see the following **SparkOnSolrPythonExample** project:

```
# -*- coding:utf-8 -*-
from py4j.java_gateway import java_import
from pyspark import SparkContext

# Create SparkContext
spark = SparkContext(appName='SparkOnSolr')
# Import the class to be run to sc._jvm
java_import(spark._jvm, 'com.huawei.bigdata.spark.examples.SparkOnSolr')

# Create class instances and invoke the method
spark._jvm.SparkOnSolr().sparkonsolr(spark._jsc)

# Stop SparkContext
spark.stop()
```

### 1.21.3.12 Structured Streaming Status Operation

#### 1.21.3.12.1 Overview

##### Scenarios

Assume that you need to collect statistics on the number of events in each session and the start and end timestamp of the sessions.

You need to export the sessions that are in the updated state in this batch.

## Data Planning

1. Generate simulated data in Kafka (the Kafka permission is required).
2. Ensure that the cluster has been installed, including the HDFS, Yarn, Spark, and Kafka services.
3. Set the **allow.everyone.if.no.acl.found** parameter of Kafka Broker to **true**.
4. Create a topic.

{*IP address of the Kafka cluster*} indicates the service IP address of the Broker service.

```
$KAFKA_HOME/bin/kafka-topics.sh --create --bootstrap-server <IP address of the Kafka cluster:21007> --command-config $KAFKA_HOME/config/client.properties --replication-factor 1 --partitions 1 --topic {Topic}
```

5. Start the Producer of Kafka and send data to Kafka.

{*ClassPath*} indicates the storage path of the project JAR package that is specified by the user. For details, see [Compiling and Running the Application](#).

```
java -cp $SPARK_HOME/conf:$SPARK_HOME/jars/*:$SPARK_HOME/jars/streamingClient010/*:{ClassPath} com.huawei.bigdata.spark.examples.KafkaProducer {brokerlist} {topic} {number of events produce every 0.02s}
```

Example:

```
java -cp /opt/hadoopclient/Spark/spark/conf:/opt/StructuredStreamingState-1.0.jar:/opt/hadoopclient/Spark/spark/jars/*:/opt/hadoopclient/Spark/spark/jars/streamingClient010/* com.huawei.bigdata.spark.examples.KafkaProducer xxx.xxx.xxx:21005,xxx.xxx.xxx:21005,xxx.xxx.xxx:21005 mytopic 10
```

## Development Guideline

1. Receive data from Kafka and generate the corresponding DataStreamReader.
2. Collect statistics by category.
3. Calculate the result and print it.

## Configuration Operations Before Running

In security mode, the Spark Core sample code needs to read two files (**user.keytab** and **krb5.conf**). The **user.keytab** and **krb5.conf** files are authentication files in the security mode. Download the authentication credentials of the user **principal** on the FusionInsight Manager page. The user in the sample code is **sparkuser**, change the value to the prepared development user name.

## Packaging the Project

- Use the Maven tool provided by IDEA to pack the project and generate a JAR file. For details, see [Compiling and Running the Application](#).
- Upload the JAR package to any directory (for example, `/opt`) on the server where the Spark client is located.

- Upload the **user.keytab** and **krb5.conf** files to the server where the client is installed. (The file upload path must be the same as the path of the generated JAR file).

## Running Tasks

When running the example program, you need to specify **<brokers>**, **<subscribe-type>**, **<kafkaProtocol>**, **<kafkaService>**, **<kafkaDomain>**, **<topic>**, and **<checkpointLocation>**, where **<brokers>** indicates the Kafka address for obtaining metadata (port 21007 is required). **<subscribe-type>** indicates the Kafka consumption mode, and **<kafkaProtocol>** indicates the secure access protocol (such as **SASL\_PLAINTEXT**). **<kafkaService>** indicates the Kerberos service name (for example, **kafka**). **<kafkaDomain>** indicates the Kerberos domain name (for example, **hadoop.<system domain name>**). **<topic>** indicates the Kafka topic to be consumed, and **<checkpointLocation>** indicates the path for storing the checkpoint of the Spark task.

### NOTE

The path of the Spark Structured Streaming Kafka dependency package on the client is different from that of other dependency packages. For example, the path of other dependency packages is **\$SPARK\_HOME/jars**. Whereas the path of the Spark Streaming Structured Kafka dependency package is **\$SPARK\_HOME/jars/streamingClient010**. Therefore, when running an application, you need to add a configuration item to the **spark-submit** command to specify the path of the dependency package of Spark Streaming Kafka, for example, **--jars \$(files=(\$SPARK\_HOME/jars/streamingClient010/\*.jar); IFS=;; echo "\${files[\*]}")**

Because the cluster is security mode, you need to add configuration items and modify the command parameters.

1. Add configuration items to **\$SPARK\_HOME/conf/jaas.conf**:

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=false  
    useTicketCache=true  
    debug=false;  
};
```

2. Add configuration items to **\$SPARK\_HOME/conf/jaas-zk.conf**:

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=true  
    keyTab=".user.keytab"  
    principal="sparkuser@<system domain name>"  
    useTicketCache=false  
    storeKey=true  
    debug=true;  
};
```

3. Use **--files** and relative path to submit the **keytab** file to ensure that the **keytab** file is loaded to the container of the executor.

Go to the Spark client directory and run the following command to invoke the **bin/spark-submit** script to run the code (the class name and file name must be the same as those in the actual code. The following is only an example):

- **bin/spark-submit --master yarn --deploy-mode client --files <local Path>/jaas.conf,<local path>/user.keytab --jars \$(files=(\$SPARK\_HOME/jars/streamingClient010/\*.jar); IFS=;; echo "\${files[\*]}") --class com.huawei.bigdata.spark.examples.kafkaSessionization /opt/StructuredStreamingState-1.0.jar <brokers> <subscribe-type> <kafkaProtocol> <kafkaService> <kafkaDomain> <topic> <checkpointLocation>**

The configuration example is as follows:

```
--files ./jaas.conf,./user.keytab //Use --files to specify the jaas.conf and keytab files.
```

 CAUTION

When submitting a structured stream task, you need to run the **--jars** command to specify the path of the Kafka-related JAR file. For the current version, you need to copy the kafka-clientsjar file from the **\$SPARK\_HOME/jars/streamingClient010** directory to the **\$SPARK\_HOME/jars** directory. Otherwise, the "class not found" error is reported.

### 1.21.3.12.2 Scala Sample Code

#### Function

In the Spark structure flow application, the number of events in each session and the start and end timestamp of the sessions are collected in different batches. At the same time, the system exports the sessions that are in the updated state in this batch.

#### Code Example

The following code snippets are used as an example. For complete codes, see [com.huawei.bigdata.spark.examples.kafkaSessionization](#).

 NOTE

When new data is available in Streaming DataFrame/Dataset, **outputMode** is used for configuring data written to the Streaming receiver. The default value is **append**. If you want to change the export mode, see the **outputMode** description of **Spark > Scala** in MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1).

```
object kafkaSessionization {
  def main(args: Array[String]): Unit = {
    if (args.length < 7) {
      System.err.println("Usage: kafkaSessionization <bootstrap-servers> " +
        "<subscribe-type> <protocol> <service> <domain> <topics> <checkpointLocation>")
      System.exit(1)
    }

    val Array(bootstrapServers, subscribeType, protocol, service, domain, topics, checkpointLocation) = args

    val spark = SparkSession
      .builder
      .appName("kafkaSessionization")
      .getOrCreate()

    spark.conf.set("spark.sql.streaming.checkpointLocation", checkpointLocation)

    spark.streams.addListener(new StreamingQueryListener {

      @volatile private var startTime: Long = 0L
      @volatile private var endTime: Long = 0L
      @volatile private var numRecs: Long = 0L

      override def onQueryStarted(event: StreamingQueryListener.QueryStartedEvent): Unit = {
        println("Query started: " + event.id)
        startTime = System.currentTimeMillis
      }
    })
  }
}
```

```
override def onQueryProgress(event: StreamingQueryListener.QueryProgressEvent): Unit = {
    println("Query made progress: " + event.progress)
    numRecs += event.progress.numInputRows
}

override def onQueryTerminated(event: StreamingQueryListener.QueryTerminatedEvent): Unit = {
    println("Query terminated: " + event.id)
    endTime = System.currentTimeMillis
}
}

import spark.implicits._

val df = spark
    .readStream
    .format("kafka")
    .option("kafka.bootstrap.servers", bootstrapServers)
    .option("kafka.security.protocol", protocol)
    .option("kafka.sasl.kerberos.service.name", service)
    .option("kafka.kerberos.domain.name", domain)
    .option(subscribeType, topics)
    .load()
    .selectExpr("CAST(value AS STRING)")
    .as[String]
    .map { x =>
        val splitStr = x.split(",")
        (splitStr(0), Timestamp.valueOf(splitStr(1)))
    }.as[(String, Timestamp)].flatMap { case(line, timestamp) =>
    line.split(" ").map(word => Event(sessionId = word, timestamp))}

// Sessionize the events. Track number of events, start and end timestamps of session, and
// and report session updates.
val sessionUpdates = df
    .groupByKey(event => event.sessionId)
    .mapGroupsWithState[SessionInfo, SessionUpdate](GroupStateTimeout.ProcessingTimeTimeout) {

    case (sessionId: String, events: Iterator[Event], state: GroupState[SessionInfo]) =>

        // If timed out, then remove session and send final update
        if (state.hasTimedOut) {
            val finalUpdate =
                SessionUpdate(sessionId, state.get.durationMs, state.get.numEvents, expired = true)
            state.remove()
            finalUpdate
        } else {
            // Update start and end timestamps in session
            val timestamps = events.map(_.timestamp.getTime).toSeq
            val updatedSession = if (state.exists) {
                val oldSession = state.get
                SessionInfo(
                    oldSession.numEvents + timestamps.size,
                    oldSession.startTimestampMs,
                    math.max(oldSession.endTimestampMs, timestamps.max))
            } else {
                SessionInfo(timestamps.size, timestamps.min, timestamps.max)
            }
            state.update(updatedSession)

            // Set timeout such that the session will be expired if no data received for 10 seconds
            state.setTimeoutDuration("10 seconds")
            SessionUpdate(sessionId, state.get.durationMs, state.get.numEvents, expired = false)
        }
    }

// Start running the query that prints the session updates to the console
val query = sessionUpdates
    .writeStream
    .outputMode("update")
```

```
.format("console")
.start()

query.awaitTermination()
}
```

### 1.21.3.13 Concurrent Access from Spark to HBase in Two Clusters

#### 1.21.3.13.1 Overview

##### Scenarios

Spark can access HBase in two clusters concurrently on condition that mutual trust has been configured between these two clusters.

##### Data Planning

1. Configure the IP addresses and host names of all ZooKeeper and HBase nodes in **cluster2** to the **/etc/hosts** file on the client node of **cluster1**.
2. In **cluster1** and **cluster2**, find the **hbase-site.xml** file in the **conf** directory of the Spark client, and save it to the **/opt/example/A** and **/opt/example/B** directories.
3. Run the following **spark-submit** command:

###### NOTE

Before running the sample program, set the **spark.yarn.security.credentials.hbase.enabled** configuration item to **true** in the **spark-defaults.conf** configuration file of Spark client. (The default value is **false**. Changing the value to **true** does not affect existing services.) If you want to uninstall the HBase service, change the value back to **false** first.

```
spark-submit --master yarn --deploy-mode client --files /opt/example/B/hbase-site.xml --keytab /opt/
Flclient/user.keytab --principal sparkuser --class com.huawei.spark.examples.SparkOnMultiHbase /opt/
example/SparkOnMultiHbase-1.0.jar
```

##### Development Approach

1. When accessing HBase, you need to use the configuration file of the corresponding cluster to create a **Configuration** object for creating a **Connection** object.
2. Use the **Connection** object you create to perform operations on the HBase table, such as creating a table and inserting, viewing, and printing data.

#### 1.21.3.13.2 Scala Sample Code

The following code snippets are used as an example. For complete codes, see **com.huawei.spark.examples.SparkOnMultiHbase**

```
def main(args: Array[String]): Unit = {
    val conf = new SparkConf().setAppName("SparkOnMultiHbaseExample")
    conf.set("spark.serializer", "org.apache.spark.serializer.KryoSerializer")
    conf.set("spark.kryo.registrator", "com.huawei.spark.examples.MyRegistrar")
    val sc = new SparkContext(conf)
    val tableName = "SparkOnMultiHbase"
    val clusterFlagList = List("B", "A")
    clusterFlagList.foreach{ item =>
        val hbaseConf = getConf(item)
    }
}
```

```
    println(hbaseConf.get("hbase.zookeeper.quorum"))
    val hbaseUtil = new HbaseUtil(sc,hbaseConf)
    hbaseUtil.writeToHbase(tableName)
    hbaseUtil.readFromHbase(tableName)
}
sc.stop()
}
private def getConf(item:String):Configuration={
    val conf: Configuration = HBaseConfiguration.create()
    val url = "/opt" + File.separator + "example" + File.separator + item + File.separator + "hbase-site.xml"
    conf.addResource(new File(url).toURI.toURL)
    conf
}
```

### 1.21.3.14 Synchronizing HBase Data from Spark to CarbonData

#### 1.21.3.14.1 Overview

##### Scenarios

Data is written to HBase in real time for point query services and is synchronized to CarbonData tables in batches at a specified interval for analytical query services.

##### Configuration Operations Before Running

In security mode, the sample code needs to read the **user.keytab** and **krb5.conf** files. The **user.keytab** and **krb5.conf** files are the authentication files in security mode. You need to download the authentication credential of the principal user on FusionInsight Manager. The user used in the sample code is **sparkuser**, which needs to be changed to the prepared development user.

##### Packaging the Project

1. Upload the **user.keytab** and **krb5.conf** files to the server where the client is located.
2. Use the Maven tool provided by IDEA to package the project and generate the JAR file. For details, see [Compiling and Running the Application](#).

###### NOTE

- Before compilation and packaging, change the paths of the **user.keytab** and **krb5.conf** files in the sample code to the actual paths on the client server, for example, **/opt/user.keytab** and **/opt/krb5.conf**.
  - Before running the sample program, set the **spark.yarn.security.credentials.hbase.enabled** configuration item to **true** in the **spark-defaults.conf** configuration file of Spark client. (The default value is **false**. Changing the value to **true** does not affect existing services.) If you want to uninstall the HBase service, change the value back to **false** first.
3. Upload the generated JAR package to any directory (for example, **/opt/**) on the server where the Spark client is located.

##### Data Preparation

1. Create an HBase table and construct data with **key**, **modify\_time**, and **valid** columns. **key** of each data record is unique in the table. **modify\_time**

indicates the modification time, and **valid** indicates whether the data is valid. In this example, **1** indicates that the data is valid, and **0** indicates that the data is invalid.

For example, go to HBase Shell and run the following commands:

```
create 'hbase_table','key','info'  
put 'hbase_table','1','info:modify_time','2019-11-22 23:28:39  
put 'hbase_table','1','info:valid','1'  
put 'hbase_table','2','info:modify_time','2019-11-22 23:28:39  
put 'hbase_table','2','info:valid','1'  
put 'hbase_table','3','info:modify_time','2019-11-22 23:28:39  
put 'hbase_table','3','info:valid','0'  
put 'hbase_table','4','info:modify_time','2019-11-22 23:28:39  
put 'hbase_table','4','info:valid','1'
```

#### NOTE

The values of **modify\_time** in the preceding information can be set to the time earlier than the current time.

```
put 'hbase_table','5','info:modify_time','2021-03-03 15:20:39  
put 'hbase_table','5','info:valid','1'  
put 'hbase_table','6','info:modify_time','2021-03-03 15:20:39  
put 'hbase_table','6','info:valid','1'  
put 'hbase_table','7','info:modify_time','2021-03-03 15:20:39  
put 'hbase_table','7','info:valid','0'  
put 'hbase_table','8','info:modify_time','2021-03-03 15:20:39  
put 'hbase_table','8','info:valid','1'  
put 'hbase_table','4','info:valid','0'  
put 'hbase_table','4','info:modify_time','2021-03-03 15:20:39
```

#### NOTE

The values of **modify\_time** in the preceding information can be set to the time within 30 minutes after the sample program is started. (30 minutes is the default synchronization interval of the sample program and can be modified.)

```
put 'hbase_table','9','info:modify_time','2021-03-03 15:32:39  
put 'hbase_table','9','info:valid','1'  
put 'hbase_table','10','info:modify_time','2021-03-03 15:32:39  
put 'hbase_table','10','info:valid','1'  
put 'hbase_table','11','info:modify_time','2021-03-03 15:32:39  
put 'hbase_table','11','info:valid','0'  
put 'hbase_table','12','info:modify_time','2021-03-03 15:32:39  
put 'hbase_table','12','info:valid','1'
```

#### NOTE

The values of **modify\_time** in the preceding information can be set to the time from 30 minutes to 60 minutes after the sample program is started, that is, the second synchronization period.

2. Run the following commands to create a Hive foreign table for HBase in SparkSQL:

```
create table external_hbase_table(key string ,modify_time STRING, valid STRING)
```

```
using org.apache.spark.sql.hbase.HBaseSource
```

```
options(hbaseTableName "hbase_table", keyCols "key", colsMapping "modify_time=info.modify_time,valid=info.valid");
```

3. Run the following command to create a CarbonData table in SparkSQL:

```
create table carbon01(key string,modify_time STRING, valid STRING) stored as carbondata;
```

4. Initialize and load all data in the current HBase table to the CarbonData table.

```
insert into table carbon01 select * from external_hbase_table where valid='1';
```

5. Run the following **spark-submit** command:

```
spark-submit --master yarn --deploy-mode client --keytab /opt/FIclient/user.keytab --principal sparkuser --class com.huawei.bigdata.spark.examples.HBaseExternalHivetoCarbon /opt/example/HBaseExternalHivetoCarbon-1.0.jar
```

#### 1.21.3.14.2 Java Example Code

The following code snippets are used as an example. For complete code, see [com.huawei.spark.examples.HBaseExternalHivetoCarbon](#).

```
public static void main(String[] args) throws Exception {
    spark = SparkSession.builder().appName("HBaseExternalHiveToCarbon").getOrCreate();

    Timer timer = new Timer();
    timer.schedule(new TimerTask() {
        public void run() {
            timeEnd = timeStart + TIMEWINDOW;

            queryTimeStart = transferDateToStr(timeStart);
            queryTimeEnd = transferDateToStr(timeEnd);

            //run delete logic
            cmdsb = new StringBuilder();
            cmdsb.append("delete from ")
                .append(carbonTableName)
                .append(" where key in (select key from ")
                .append(externalHiveTableName)
                .append(" where modify_time>'")
                .append(queryTimeStart)
                .append("' and modify_time<'")
                .append(queryTimeEnd)
                .append("' and valid='0')");
            spark.sql(cmdsb.toString());

            //run insert logic
            cmdsb = new StringBuilder();
            cmdsb.append("insert into ")
                .append(carbonTableName)
                .append(" select * from ")
                .append(externalHiveTableName)
                .append(" where modify_time>'")
                .append(queryTimeStart)
                .append("' and modify_time<'")
                .append(queryTimeEnd)
                .append("' and valid='1'");
            spark.sql(cmdsb.toString());

            timeStart = timeEnd;
        }
    }, 0, TIMEWINDOW);
}
```

```
    }, TIMEWINDOW, TIMEWINDOW);
}
```

### 1.21.3.15 Using Spark to Perform Basic Hudi Operations

#### 1.21.3.15.1 Overview

##### Scenarios

This section describes how to use Spark to perform operations such as data insertion, query, update, incremental query, query at a specific time point, and data deletion on Hudi.

For details, see the sample code.

#### Packaging the Project

1. Upload the **user.keytab** and **krb5.conf** files to the server where the client is located.
2. Use the Maven tool provided by IDEA to package the project and generate the JAR file. For details, see [Compiling and Running the Application](#).

##### NOTE

- Before compilation and packaging, change the paths of the **user.keytab** and **krb5.conf** files in the sample code to the actual paths on the client server.
  - The Python sample code does not need to be packaged using Maven.
3. Upload the generated JAR file to any directory (for example, **/opt/example/**) on the server where the Spark client is located.

#### Running tasks

1. Log in to the Spark client node and run the following commands:  
**source Client installation directory/bigdata\_env**  
**source Client installation directory/Hudi/component\_env**  
**kinit Hudi development user**
2. Use the **spark-submit** command to perform the write, update, query, and delete operations in sequence after compiling and building the sample code.
  - Run the Java sample program.  
**spark-submit --keytab <user\_keytab\_path> --principal=<principal\_name> --class com.huawei.bigdata.hudi.examples.HoodieWriteClientExample /opt/example/hudi-java-security-examples-1.0.jar hdfs://hacluster/tmp/example/hoodie\_java hoodie\_java**  
**<user\_keytab\_path>** indicates the authentication file path,  
**<principal\_name>** indicates the authentication user name, **/opt/example/hudi-java-examples-1.0.jar** indicates the JAR file path, **hdfs://hacluster/tmp/example/hoodie\_java** indicates the storage path of the Hudi table, and **hoodie\_java** indicates the name of the Hudi table.

- Run the Scala sample program.

```
spark-submit --keytab <user_keytab_path> --
principal=<principal_name> --class
com.huawei.bigdata.hudi.examples.HoodieDataSourceExample /opt/
example/hudi-scala-security-examples-1.0.jar hdfs://hacluster/tmp/
example/hoodie_scala hoodie_scala
```

`/opt/example/hudi-scala-examples-1.0.jar` indicates the JAR file path, `<user_keytab_path>` indicates the authentication file path, `<principal_name>` indicates the authentication user name, `hdfs://hacluster/tmp/example/hoodie_scala` indicates the storage path of the Hudi table, and `hoodie_Scala` indicates the name of the Hudi table.

- Run the Python sample program.

```
spark-submit /opt/example/HudiPythonExample.py hdfs://
hacluster/tmp/huditest/example/python hudi_trips_cow
```

`hdfs://hacluster/tmp/huditest/example/python` indicates the storage path of the Hudi table, and `hudi_trips_cow` indicates the name of the Hudi table.

### 1.21.3.15.2 Java Example Code

The following code snippets are used as an example. For complete code, see [com.huawei.bigdata.hudi.examples.HoodieWriteClientExample](#).

Create a client object to operate Hudi:

```
String tablePath = args[0];
String tableName = args[1];
SparkConf sparkConf = HoodieExampleSparkUtils.defaultSparkConf("hoodie-client-example");
JavaSparkContext jsc = new JavaSparkContext(sparkConf);
// Generator of some records to be loaded in.
HoodieExampleDataGenerator<HoodieAvroPayload> dataGen = new HoodieExampleDataGenerator<>();
// initialize the table, if not done already
Path path = new Path(tablePath);
FileSystem fs = FSUtils.getFs(tablePath, jsc.hadoopConfiguration());
if (!fs.exists(path)) {
    HoodieTableMetaClient.initTableType(jsc.hadoopConfiguration(), tablePath,
    HoodieTableType.valueOf(tableName),
    tableName, HoodieAvroPayload.class.getName());
}

// Create the write client to write some records in
HoodieWriteConfig cfg = HoodieWriteConfig.newBuilder().withPath(tablePath)
    .withSchema(HoodieExampleDataGenerator.TRIP_EXAMPLE_SCHEMA).withParallelism(2, 2)
    .withDeleteParallelism(2).forTable(tableName)
    .withIndexConfig(HoodieIndexConfig.newBuilder().withIndexType(HoodieIndex.IndexType.BLOOM).build()
)
    .withCompactionConfig(HoodieCompactionConfig.newBuilder().archiveCommitsWith(20,
30).build()).build();
SparkRDDWriteClient<HoodieAvroPayload> client = new SparkRDDWriteClient<>(new
HoodieSparkEngineContext(jsc), cfg);
```

Insert data:

```
String newCommitTime = client.startCommit();
LOG.info("Starting commit " + newCommitTime);
List<HoodieRecord<HoodieAvroPayload>> records = dataGen.generateInserts(newCommitTime, 10);
List<HoodieRecord<HoodieAvroPayload>> recordsSoFar = new ArrayList<>(records);
JavaRDD<HoodieRecord<HoodieAvroPayload>> writeRecords = jsc.parallelize(records, 1);
client.upsert(writeRecords, newCommitTime);
```

Update data:

```

newCommitTime = client.startCommit();
LOG.info("Starting commit " + newCommitTime);
List<HoodieRecord<HoodieAvroPayload>> toBeUpdated = dataGen.generateUpdates(newCommitTime, 2);
records.addAll(toBeUpdated);
recordsSoFar.addAll(toBeUpdated);
writeRecords = jsc.parallelize(records, 1);
client.upsert(writeRecords, newCommitTime);

```

Delete data:

```

newCommitTime = client.startCommit();
LOG.info("Starting commit " + newCommitTime);
// just delete half of the records
int numToDelete = recordsSoFar.size() / 2;
List<HoodieKey> toBeDeleted =
recordsSoFar.stream().map(HoodieRecord::getKey).limit(numToDelete).collect(Collectors.toList());
JavaRDD<HoodieKey> deleteRecords = jsc.parallelize(toBeDeleted, 1);
client.delete(deleteRecords, newCommitTime);

```

Compress data.

```

if (HoodieTableType.valueOf(tableType) == HoodieTableType.MERGE_ON_READ) {
    Option<String> instant = client.scheduleCompaction(Option.empty());
    JavaRDD<WriteStatus> writeStatuses = client.compact(instant.get());
    client.commitCompaction(instant.get(), writeStatuses, Option.empty());
}

```

### 1.21.3.15.3 Scala Example Code

The following code snippets are used as an example. For complete code, see [com.huawei.bigdata.hudi.examples.HoodieDataSourceExample](#).

Insert data:

```

def insertData(spark: SparkSession, tablePath: String, tableName: String, dataGen: HoodieExampleDataGenerator[HoodieAvroPayload]): Unit = {
val commitTime: String = System.currentTimeMillis().toString
val inserts = dataGen.convertToStringList(dataGen.generateInserts(commitTime, 20))
spark.sparkContext.parallelize(inserts, 2)
val df = spark.read.json(spark.sparkContext.parallelize(inserts, 1)).write.format("org.apache.hudi").
    options(getQuickstartWriteConfigs).
    option(PRECOMBINE_FIELD_OPT_KEY, "ts").
    option(RECORDKEY_FIELD_OPT_KEY, "uuid").
    option(PARTITIONPATH_FIELD_OPT_KEY, "partitionpath").
    option(TABLE_NAME, tableName).
    mode(Overwrite).
    save(tablePath)}

```

Query data.

```

def queryData(spark: SparkSession, tablePath: String, tableName: String, dataGen: HoodieExampleDataGenerator[HoodieAvroPayload]): Unit = {
val roViewDF = spark.
    read.
    format("org.apache.hudi").
    load(tablePath + "/*/*/*")
roViewDF.createOrReplaceTempView("hudi_ro_table")
spark.sql("select fare, begin_lon, begin_lat, ts from hudi_ro_table where fare > 20.0").show()
// +-----+-----+-----+-----+
// |      fare|    begin_lon|    begin_lat| ts|
// +-----+-----+-----+-----+
// |98.88075495133515|0.39556048623031603|0.17851135255091155|0.0|
// ...
spark.sql("select _hoodie_commit_time, _hoodie_record_key, _hoodie_partition_path, rider, driver, fare from hudi_ro_table").show()
// +-----+-----+-----+-----+-----+
// |_hoodie_commit_time| _hoodie_record_key|_hoodie_partition_path|      rider|
// |driver|      fare|
// +-----+-----+-----+-----+

```

### Update data:

```
def updateData(spark: SparkSession, tablePath: String, tableName: String, dataGen: HoodieExampleDataGenerator[HoodieAvroPayload]): Unit = {
  val commitTime: String = System.currentTimeMillis().toString
  val updates = dataGen.convertToStringList(dataGen.generateUpdates(commitTime, 10))
  val df = spark.read.json(spark.sparkContext.parallelize(updates, 1))
  df.write.format("org.apache.hudi").
    options(getQuickstartWriteConfigs).
    option(PRECOMBINE_FIELD_OPT_KEY, "ts").
    option(RECORDKEY_FIELD_OPT_KEY, "uuid").
    option(PARTITIONPATH_FIELD_OPT_KEY, "partitionpath").
    option(TABLE_NAME, tableName).
    mode(Append).
    save(tablePath)}
```

### Incremental query:

```
def incrementalQuery(spark: SparkSession, tablePath: String, tableName: String) {
  import spark.implicits._
  val commits = spark.sql("select distinct(_hoodie_commit_time) as commitTime from hudi_ro_table order by commitTime").map(k => k.getString(0)).take(50)
  val beginTime = commits(commits.length - 2)

  val incViewDF = spark.
    read.
    format("org.apache.hudi").
    option(QUERY_TYPE_OPT_KEY, QUERY_TYPE_INCREMENTAL_OPT_VAL).
    option(BEGIN_INSTANTTIME_OPT_KEY, beginTime).
    load(tablePath)
  incViewDF.createOrReplaceTempView("hudi_incr_table")
  spark.sql("select `_hoodie_commit_time`, fare, begin_lon, begin_lat, ts from hudi_incr_table where fare > 20.0").show()
```

### Query at a specific time point:

```
def pointInTimeQuery(spark: SparkSession, tablePath: String, tableName: String) {
  import spark.implicits._
  val commits = spark.sql("select distinct(_hoodie_commit_time) as commitTime from hudi_ro_table order by commitTime").map(k => k.getString(0)).take(50)
  val beginTime = "000"
  // Represents all commits > this time.
  val endTime = commits(commits.length - 2)
  // commit time we are interested in
  //incrementally query data
  val incViewDF = spark.read.format("org.apache.hudi").
    option(QUERY_TYPE_OPT_KEY, QUERY_TYPE_INCREMENTAL_OPT_VAL).
    option(BEGIN_INSTANTTIME_OPT_KEY, beginTime).
    option(END_INSTANTTIME_OPT_KEY, endTime).
    load(tablePath)
  incViewDF.createOrReplaceTempView("hudi_incr_table")
  spark.sql("select `_hoodie_commit_time`, fare, begin_lon, begin_lat, ts from hudi_incr_table where fare > 20.0").show()}
```

## 1.21.3.15.4 Python Example Code

The following code snippets are used as an example. For complete code, see [HudiPythonExample.py](#).

### Insert data:

```
#insert
inserts = sc._jvm.org.apache.hudi.QuickstartUtils.convertToStringList(dataGen.generateInserts(10))
```

```
df = spark.read.json(spark.sparkContext.parallelize(inserts, 2))
hudi_options = {
    'hoodie.table.name': tableName,
    'hoodie.datasource.write.recordkey.field': 'uuid',
    'hoodie.datasource.write.partitionpath.field': 'partitionpath',
    'hoodie.datasource.write.table.name': tableName,
    'hoodie.datasource.write.operation': 'insert',
    'hoodie.datasource.write.precombine.field': 'ts',
    'hoodie.upsert.shuffle.parallelism': 2,
    'hoodie.insert.shuffle.parallelism': 2
}
df.write.format("hudi"). \
    options(**hudi_options). \
    mode("overwrite"). \
    save(basePath)
```

### Query data.

```
tripsSnapshotDF = spark. \
    read. \
    format("hudi"). \
    load(basePath + "/*/*/*/*")
tripsSnapshotDF.createOrReplaceTempView("hudi_trips_snapshot")
spark.sql("select fare, begin_lon, begin_lat, ts from hudi_trips_snapshot where fare > 20.0").show()
spark.sql("select _hoodie_commit_time, _hoodie_record_key, _hoodie_partition_path, rider, driver, fare from hudi_trips_snapshot").show()
```

### Update data:

```
updates = sc._jvm.org.apache.hudi.QuickstartUtils.convertToStringList(dataGen.generateUpdates(10))
df = spark.read.json(spark.sparkContext.parallelize(updates, 2))
df.write.format("hudi"). \
    options(**hudi_options). \
    mode("append"). \
    save(basePath)
```

### Incremental query:

```
spark. \
    read. \
    format("hudi"). \
    load(basePath + "/*/*/*/*"). \
    createOrReplaceTempView("hudi_trips_snapshot")
incremental_read_options = {
    'hoodie.datasource.query.type': 'incremental',
    'hoodie.datasource.read.begin.instanttime': beginTime,
}
tripsIncrementalDF = spark.read.format("hudi"). \
    options(**incremental_read_options). \
    load(basePath)
tripsIncrementalDF.createOrReplaceTempView("hudi_trips_incremental")
spark.sql("select `_hoodie_commit_time`, fare, begin_lon, begin_lat, ts from hudi_trips_incremental where fare > 20.0").show()
```

### Query at a specific time point:

```
# Represents all commits > this time.
beginTime = "000"
endTime = commits[len(commits) - 2]
point_in_time_read_options = {
    'hoodie.datasource.query.type': 'incremental',
    'hoodie.datasource.read.end.instanttime': endTime,
    'hoodie.datasource.read.begin.instanttime': beginTime
}
tripsPointInTimeDF = spark.read.format("hudi"). \
    options(**point_in_time_read_options). \
    load(basePath)
tripsPointInTimeDF.createOrReplaceTempView("hudi_trips_point_in_time")
```

```
spark.sql("select `_hoodie_commit_time`, fare, begin_lon, begin_lat, ts from hudi_trips_point_in_time where fare > 20.0").show()
```

Delete data:

```
# Obtain the total number of records.  
spark.sql("select uuid, partitionpath from hudi_trips_snapshot").count()  
# Obtain two records to be deleted.  
ds = spark.sql("select uuid, partitionpath from hudi_trips_snapshot").limit(2)  
# Delete the records.  
hudi_delete_options = {  
    'hoodie.table.name': tableName,  
    'hoodie.datasource.write.recordkey.field': 'uuid',  
    'hoodie.datasource.write.partitionpath.field': 'partitionpath',  
    'hoodie.datasource.write.table.name': tableName,  
    'hoodie.datasource.write.operation': 'delete',  
    'hoodie.datasource.write.precombine.field': 'ts',  
    'hoodie.upsert.shuffle.parallelism': 2,  
    'hoodie.insert.shuffle.parallelism': 2  
}  
from pyspark.sql.functions import lit  
deletes = list(map(lambda row: (row[0], row[1]), ds.collect()))  
df = spark.sparkContext.parallelize(deletes).toDF(['uuid', 'partitionpath']).withColumn('ts', lit(0.0))  
df.write.format("hudi"). \  
    options(**hudi_delete_options). \  
    mode("append"). \  
    save(basePath)  
# Perform the query in the same way.  
roAfterDeleteViewDF = spark. \  
    read. \  
    format("hudi"). \  
    load(basePath + "/*/*/*")  
roAfterDeleteViewDF.registerTempTable("hudi_trips_snapshot")  
# Return (total - 2) records.  
spark.sql("select uuid, partitionpath from hudi_trips_snapshot").count()  
spark.sql("select uuid, partitionpath from hudi_trips_snapshot").show()
```

### 1.21.3.16 Compiling User-defined Configuration Items for Hudi

#### 1.21.3.16.1 HoodieDeltaStreamer

Compile a user-defined conversion class for **Transformer**.

Compile a user-defined schema for **SchemaProvider**.

Add the following parameters when running **HoodieDeltaStreamer**:

```
--schemaprovider-class Defined schema class --transformer-class Defined transform class
```

Examples of **Transformer** and **SchemaProvider**:

```
public class TransformerExample implements Transformer, Serializable {  
    @Override  
    public Dataset<Row> apply(JavaSparkContext jsc, SparkSession sparkSession, Dataset<Row> rowDataset,  
        TypedProperties properties) {  
        JavaRDD<Row> rowJavaRdd = rowDataset.toJavaRDD();  
        List<Row> rowList = new ArrayList<>();  
        for(Row row: rowJavaRdd.collect()){  
            rowList.add(buildRow(row));  
        }  
        JavaRDD<Row> stringJavaRdd = jsc.parallelize(rowList);  
        List<StructField> fields = new ArrayList<>();  
        buildFields(fields);  
        StructType schema = DataTypes.createStructType(fields);  
        Dataset<Row> dataFrame = sparkSession.createDataFrame(stringJavaRdd, schema);  
        return dataFrame;  
    }  
}
```

```

    }

    private void buildFields(List<StructField> fields) {
        fields.add(DataTypes.createStructField("age", DataTypes.StringType, true));
        fields.add(DataTypes.createStructField("id", DataTypes.StringType, true));
        fields.add(DataTypes.createStructField("name", DataTypes.StringType, true));
        fields.add(DataTypes.createStructField("job", DataTypes.StringType, true));
    }

    private Row buildRow(Row row){
        String age = row.getString(0);
        String id = row.getString(1);
        String job = row.getString(2);
        String name = row.getString(3);
        Row returnRow = RowFactory.create(age, id, job, name);
        return returnRow;
    }
}

public class DataSchemaProviderExample extends SchemaProvider {

    public DataSchemaProviderExample(TypedProperties props, JavaSparkContext jssc) {
        super(props, jssc);
    }

    @Override
    public Schema getSourceSchema() {
        Schema avroSchema = new Schema.Parser().parse(
            "{\"type\":\"record\",\"name\":\"hoodie_source\",\"fields\":[{\"name\":\"age\",\"type\":\"string\"},\"name\":\"id\",\"type\":\"string\"},{\"name\":\"job\",\"type\":\"string\"},{\"name\":\"name\",\"type\":\"string\"}]}");
        return avroSchema;
    }

    @Override
    public Schema getTargetSchema() {
        Schema avroSchema = new Schema.Parser().parse(
            "{\"type\":\"record\",\"name\":\"mytest_record\",\"namespace\":\"hoodie.mytest\",\"fields\":[{\"name\":\"age\",\"type\":\"string\"},{\"name\":\"id\",\"type\":\"string\"},{\"name\":\"job\",\"type\":\"string\"},{\"name\":\"name\",\"type\":\"string\"}]}");
        return avroSchema;
    }
}

```

### 1.21.3.16.2 User-defined Partitioner

Compile a user-defined partitioner class that inherits **BulkInsertPartitioner** and add the following configuration when writing data to Hudi:

```
.option(BULKINSERT_USER_DEFINED_PARTITIONER_CLASS, <User-defined partitioner class package name + class name>)
```

Example of the user-defined partitioner:

```

public class HoodieSortExample<T extends HoodieRecordPayload>
    implements BulkInsertPartitioner<JavaRDD<HoodieRecord<T>>> {
    @Override
    public JavaRDD<HoodieRecord<T>> repartitionRecords(JavaRDD<HoodieRecord<T>> records, int
    outputSparkPartitions) {
        JavaPairRDD<String,
        HoodieRecord<T>> stringHoodieRecordJavaPairRDD = records.coalesce(outputSparkPartitions)
            .mapToPair(record -> new Tuple2<>(new StringBuilder().append(record.getPartitionPath())
                .append("+")
                .append(record.getRecordKey())
                .toString(), record));
        JavaRDD<HoodieRecord<T>> hoodieRecordJavaRDD =
        stringHoodieRecordJavaPairRDD.mapPartitions(partition -> {
            List<Tuple2<String, HoodieRecord<T>>> recordList = new ArrayList<>();

```

```
        for (; partition.hasNext();) {
            recordList.add(partition.next());
        }
        Collections.sort(recordList, (o1, o2) -> {
            if (o1._1().split("[+])[0] == o2._1().split("[+])[0]) {
                return Integer.parseInt(o1._1().split("[+])[1]) - Integer.parseInt(o2._1().split("[+])[1]);
            } else {
                return o1._1().split("[+])[0].compareTo(o2._1().split("[+])[0]);
            }
        });
        return recordList.stream().map(e -> e._2).iterator();
    });

    @Override
    public boolean arePartitionRecordsSorted() {
        return true;
    }
}
```

### 1.21.3.17 Using Spark to Write Data to ClickHouse

#### 1.21.3.17.1 Overview

##### Scenarios

In Spark applications, users can use the native APIs of ClickHouse JDBC and the Spark JDBC driver to create, query, and insert ClickHouse databases and tables.

##### Development Guidelines

Use the ClickHouse JDBC driver to create databases and tables, and insert data. Then, call the Spark JDBC APIs to read data from the ClickHouse table, convert the data, and write the converted data to the ClickHouse table.

The process is as follows:

- Create a ClickHouse database and table, and insert data into the table.
- Use the Spark JDBC API to read data from the ClickHouse table.
- Register a temporary table, process the field ID in the table, and return a new data set.
- Append the new data set to the ClickHouse table.

##### Preparations

- Prepare user information, including the username and password. The user must have the ClickHouse administrator rights.
- Prepare the names of ClickHouse database and table to be created. The database and table names must be different from the existing ones. In addition, you need to create a ClickHouse logical cluster in advance. For details, see "Creating a User-defined ClickHouse Logical Cluster" in MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1) in the MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1). For example, creating logical cluster **default\_cluster**.

## Packaging the Project

1. Use the Maven tool provided by IDEA to package the project and generate the JAR file.
2. Upload the generated JAR file to the Spark client directory, for example, **/opt/hadoopclient/Spark/spark**.
3. ClickHouse JDBC driver package **clickhouse-jdbc\*.jar** is automatically downloaded to the local Maven library during JAR file packaging and compilation. Upload the package to the Spark client directory on the server, for example, **/opt/hadoopclient/Spark/spark**. The JAR package version in the following steps is only an example.

## Running tasks

Go to the Spark client directory, source environment variables, and perform user authentication. Assume that the following commands are executed in the **spark** directory of the Spark client. Call the **bin/spark-submit** script to run the code. The running commands are as follows (the class name and file name must be consistent with those in the actual code. The following is only an example):

- Run the Java sample program.  
**bin/spark-submit --master yarn --deploy-mode client/cluster --jars clickhouse-jdbc-0.3.1-h0.cbu.mrs.313.r1-SNAPSHOT.jar --class com.huawei.bigdata.spark.examples.SparkOnClickHouseExample SparkOnClickHouseJavaExample-1.0.jar <jdbcurl> <clickHouseDBName> <clickHouseTableName> <userName> <password>**
- Run the Scala sample program.  
**bin/spark-submit --master yarn --deploy-mode client/cluster --jars clickhouse-jdbc-0.3.1-h0.cbu.mrs.313.r1-SNAPSHOT.jar --class com.huawei.bigdata.spark.examples.SparkOnClickHouseExample SparkOnClickHouseScalaExample-1.0.jar <jdbcurl> <clickHouseDBName> <clickHouseTableName> <userName> <password>**
- Run the Python sample program.  
**bin/spark-submit --master yarn --deploy-mode client/cluster --jars SparkOnClickHousePythonExample-1.0.jar,clickhouse-jdbc-0.3.1-h0.cbu.mrs.313.r1-SNAPSHOT.jar SparkOnClickHousePythonExample.py <jdbcurl> <clickHouseDBName> <clickHouseTableName> <userName> <password>**

### NOTE

- **jdbcurl** is the ClickHouse JDBC connection string, for example, **jdbc:clickhouse://{ip}:{port}**. To query the port number, perform the following steps:  
Log in to FusionInsight Manager, choose **Cluster > Services > ClickHouse**, click **Logic Cluster**, and obtain the port number from the **HTTP Balancer Port** column in the cluster list.
- **clickHouseDBName** is the name of the ClickHouse database to be created, for example, **ckdb001**.
- **clickHouseTableName** is the name of the ClickHouse table to be created, for example, **ckdb01**.
- **userName** is the username, and **password** is the corresponding password.

### 1.21.3.17.2 Java Sample Code

The following code snippets are used as an example. For complete code, see:  
<com/huawei/bigdata/spark/examples/SparkOnClickHouseExample.java>.

## Prerequisites

Create a user, user group (**hadoop** and **hive**), and primary group (**hadoop**) with the ClickHouse permission. For example, create user **sparkuser**.

## Procedure

**Step 1** Prepare the spark-clickhouse sample code. For details, see [Overview](#).

**Step 2** Import the sample project to IDEA.

**Step 3** Create a table and insert data using the ClickHouse JDBC API.

```
private static void clickHouseExecute(ClickHouseStatement ckStatement, String clickHouseDB, String clickHouseTable) throws SQLException {
    String createDB = "CREATE DATABASE " + clickHouseDB + " ON CLUSTER default_cluster";
    String createTable = "CREATE TABLE " + clickHouseDB + "." + clickHouseTable + " ON CLUSTER
default_cluster" +
        "('EventDate` DateTime,`id` UInt64,`name` String,`age` UInt8,`address` String)" +
        "ENGINE = ReplicatedMergeTree('/clickhouse/tables/{shard}'" + clickHouseDB + "/" + clickHouseTable
+ "", '{replica}')"
        + "PARTITION BY toYYYYMM(EventDate) ORDER BY id";
    String insertData = "insert into " + clickHouseDB + "." + clickHouseTable + " (id, name, age, address)
values (1, 'zhangsan', 17, 'xian'), (2, 'lisi', 36, 'beijing')";
    ckStatement.execute(createDB);
    ckStatement.execute(createTable);
    ckStatement.execute(insertData);
}
```

**Step 4** Package the code and upload it to the Spark client directory, for example, **/opt/hadoopclient/Spark/spark**.

**Step 5** Go to the client directory and run the following commands:

```
cd Cluster client installation directory
source bigdata_env
source Spark/component_env
kinit sparkuser
```

**Step 6** Run the task.

```
dbName: ckdb001

### 1.21.3.17.3 Scala Sample Code

The following code snippets are used as an example. For complete code, see:  
<com/huawei/bigdata/spark/examples/SparkOnClickHouseExample.Scala>.

## Prerequisites

Create a user, user group (**hadoop** and **hive**), and primary group (**hadoop**) with the ClickHouse permission. For example, create user **sparkuser**.

## Procedure

**Step 1** Prepare the spark-clickhouse sample code. For details, see [Overview](#).

**Step 2** Import the sample project to IDEA.

**Step 3** Create a table and insert data using the ClickHouse JDBC API.

```
def clickHouseExecute(ckStatement: ClickHouseStatement, clickHouseDB: String, clickHouseTable: String) {  
    val createDB = s"CREATE DATABASE ${clickHouseDB} ON CLUSTER default_cluster"  
    val createTable = s"CREATE TABLE ${clickHouseDB}.${clickHouseTable} ON CLUSTER default_cluster "  
    +"(`EventDate` DateTime, `id` UInt64, `name` String, `age` UInt8, `address` String)" +s"ENGINE =  
    ReplicatedMergeTree('/clickhouse/tables/{shard}/${clickHouseDB}/${clickHouseTable}', '{replica}')"  
    +"PARTITION BY toYYYYMM(EventDate) ORDER BY id"  
    val insertData = s"insert into ${clickHouseDB}.${clickHouseTable} (id, name, age, address) values (1,  
    'zhangsan', 17, 'xian'), (2, 'lisi', 36, 'beijing')"  
    executeSqlText(ckStatement, createDB)  
    executeSqlText(ckStatement, createTable)  
    executeSqlText(ckStatement, insertData)  
}
```

**Step 4** Package the code and upload it to the Spark client directory, for example, **/opt/hadoopclient/Spark/spark**.

**Step 5** Go to the client directory and run the following commands:

**cd** *Cluster client installation directory*

**source** **bigdata\_env**

**source** **Spark/component\_env**

**kinit** **sparkuser**

**Step 6** Run the task.

```

#### 1.21.3.17.4 Python Sample Code

The following code snippets are used as an example. For complete code, see:  
[com/huawei/bigdata/spark/examples/SparkOnClickHouseExample.java](https://github.com/huawei/bigdata/spark/examples/SparkOnClickHouseExample.java).

### Prerequisites

Create a user, user group (**hadoop** and **hive**), and primary group (**hadoop**) with the ClickHouse permission. For example, create user **sparkuser**.

### Procedure

**Step 1** Prepare the spark-clickhouse sample code. For details, see [Overview](#).

**Step 2** Import the sample project to IDEA.

**Step 3** Create a table and insert data using the ClickHouse JDBC API.

```
private static void clickHouseExecute(ClickHouseStatement ckStatement, String clickHouseDB, String clickHouseTable) throws SQLException {
    String createDB = "CREATE DATABASE " + clickHouseDB + " ON CLUSTER default_cluster";
    String createTable = "CREATE TABLE " + clickHouseDB + "." + clickHouseTable + " ON CLUSTER default_cluster" +
        "(EventDate` DateTime, `id` UInt64, `name` String, `age` UInt8, `address` String)" +
        "ENGINE = ReplicatedMergeTree('/clickhouse/tables/{shard}' /" + clickHouseDB + "/" + clickHouseTable +
        "+ "", '{replica}')"
    String insertData = "insert into " + clickHouseDB + "." + clickHouseTable + " (id, name, age, address)" +
        "values (1, 'zhangsan', 17, 'xian'), (2, 'lisi', 36, 'beijing')";
    ckStatement.execute(createDB);
    ckStatement.execute(createTable);
    ckStatement.execute(insertData);
}
```

**Step 4** Package the code and upload it to the Spark client directory, for example, `/opt/hadoopclient/Spark/spark`.

**Step 5** Go to the client directory and run the following commands:

```
cd Cluster client installation directory  
source bigdata_env  
source Spark/component_env  
kinit sparkuser
```

**Step 6** Run the task.

```

### 1.21.3.17.5 SQL Example

Spark allows you to use SQL statements to create a Spark table and associate it with the ClickHouse table. When running the **Spark SQL CLI** command, you need to add **--jars clickhouse-jdbc-xxxjar**. For details about the actual JAR package name, see [Using Spark to Write Data to ClickHouse](#). The syntax for creating a table is as follows:

```
create table spark_cktb01 using org.apache.spark.sql.jdbc options(url
"url", ssl "true", isCheckConnection "true", sslMode "none", driver
"ru.yandex.clickhouse.ClickHouseDriver", dbtable
"clickHouseDBName.clickHouseTableName", user "userName", password
"password");
```

#### NOTE

- **jdbcurl** is the ClickHouse JDBC connection string, for example, **jdbc:clickhouse://{IP address}:{Port number}**. The port number is **21426**.
- **clickHouseDBName** is the name of the ClickHouse database to be created, for example, **ckdb001**.
- **clickHouseTableName** is the name of the ClickHouse table to be created, for example, **cktb01**.
- **userName** is the username.
- **password** is the password of the user.

After the ClickHouse table is created, you can read, write, and query the **spark\_cktb01** table to perform the same operations on the ClickHouse table.

## 1.21.4 Commissioning the Application

### 1.21.4.1 Commissioning Applications on Windows

### 1.21.4.1.1 Compiling and Running Applications

#### Scenario

You can run applications in the Windows environment after application code development is complete. The procedures for running applications developed using Scala or Java are the same on IDEA.

##### NOTE

- In the Windows environment, only the sample code for accessing Spark SQL using JDBC is provided.
- Ensure that the Maven image repository of the SDK in the Huawei image site has been configured for Maven. For details, see [Configuring Huawei Open-Source Mirrors](#).

#### Procedure

##### Step 1 Obtain the sample code.

Download the Maven project source code and configuration file of the sample project. For details, see [Obtaining Sample Projects](#).

Import the sample code to IDEA.

##### Step 2 Obtain configuration files.

1. Obtain the files from the cluster client. Download the **hive-site.xml** and **spark-defaults.conf** files from **\$SPARK\_HOME/conf** to a local directory.
2. On the FusionInsight Manager page of the cluster, download the user authentication file to a local directory.

##### Step 3 Upload data to HDFS.

1. Create a data text file on Linux and save the following data to the data file:

```
Miranda,32
Karlie,23
Candice,27
```
2. On the HDFS client, run the following commands for authentication:  
**cd {Client installation directory}**  
**kinit <Service user for authentication>**
3. On the HDFS client running the Linux OS, run the **hadoop fs -mkdir /data** command (or the **hdfs dfs** command) to create a directory.
4. On the HDFS client running the Linux OS, run the **hadoop fs -put data /data** command to upload the data file.

##### Step 4 Configure related parameters in the sample code.

1. Configure the authentication information.  
Set **userPrincipal** to the username.  
Set **userKeytabPath** to the path of the downloaded **keytab** file.  
Set **Krb5ConfPath** to the path of the downloaded **krb5.conf** file.

```

public class ThriftServerQueriesTest {
    public static void main(String[] args) throws SQLException, ClassNotFoundException, IOException {
        String userPrincipal = "admin@test";
        String userKeytabPath = "D:\\conf\\keytab\\user.keytab";
        String krb5ConfPath = "D:\\conf\\keytab\\krb5.conf";
        String principalName = KerberosUtil.DEFAULT_REALM;
        String ZKServerPrincipal = "zookeeper/hadoop." + principalName;

        String ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME = "Client";
        String ZOOKEEPER_SERVER_PRINCIPAL_KEY = "zookeeper.server.principal";
    }
}

```

Set the domain name to **DEFAULT\_REALM**. In the **KerberosUtil** class, change **DEFAULT\_REALM** to the domain name of the cluster.

```

public class KerberosUtil {
    private static Logger logger = Logger.getLogger(KerberosUtil.class);

    public static final String JAVA_VENDOR = "java.vendor";
    public static final String IBM_FLAG = "IBM";
    public static final String CONFIG_CLASS_FOR_IBM = "com.ibm.security.krb5.internal.Config";
    public static final String CONFIG_CLASS_FOR_SUN = "sun.security.krb5.Config";
    public static final String METHOD_GET_INSTANCE = "getInstance";
    public static final String METHOD_GET_DEFAULT_REALM = "getDefaultValue";
    public static final String DEFAULT_REALM = "HADOOP.COM";
}

```

2. Change **user.principal** and **user.keytab** in the string concatenated by **securityConfig** to the corresponding username and path. Note that the path of the **keytab** file must use slashes (/).

```

String securityConfig = "saslQop=auth-conf;auth=KERBEROS;principal=spark2x/hadoop." + principalName + "@"
    + principalName + ";user.principal=admin@test;user.keytab=D:/conf/keytab/user.keytab;";

```

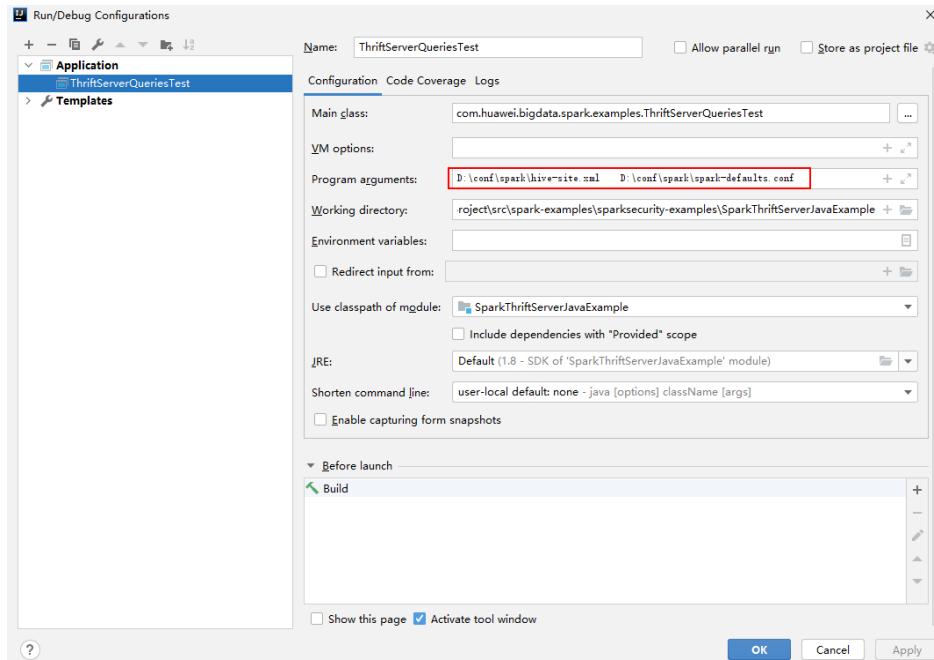

3. Change the SQL statement for loading data to **LOAD DATA INPATH 'hdfs:/data/data' INTO TABLE CHILD**.

```

ArrayList<String> sqlList = new ArrayList<>();
sqlList.add("CREATE TABLE IF NOT EXISTS child (name STRING, age INT) ROW FORMAT DELIMITED FIELDS TERMINATED BY"
    + " ' '");
sqlList.add("LOAD DATA INPATH 'hdfs:/data/data' INTO TABLE child");
sqlList.add("SELECT * FROM child");
sqlList.add("DROP TABLE child");
executeSql(url, sqlList);

```

**Step 5** Add running parameters to the **hive-site.xml** and **spark-defaults.conf** files when the application is running.

**Step 6** Run the application.

----End

#### 1.21.4.1.2 View Debugging Results

```

```

#### 1.21.4.2 Commissioning an Application in Linux

### 1.21.4.2.1 Compiling and Running the Application

#### Scenario

After the program codes are developed, you can upload the codes to the Linux client for running. The running procedures of applications developed in Scala or Java are the same.

##### NOTE

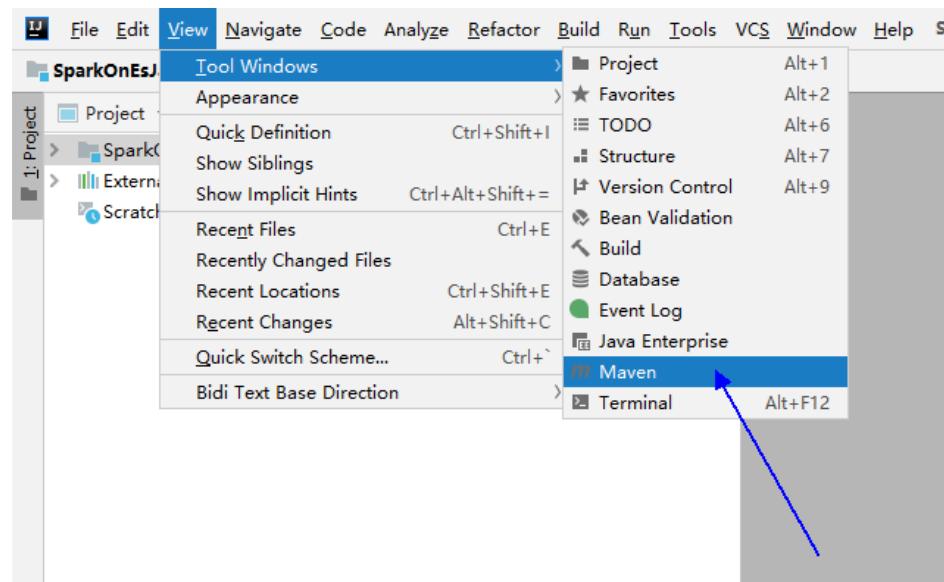

- The Spark application developed in Python does not need to build Artifacts as a jar. You just need to copy the sample projects to the compiler.
- It is needed to ensure that the version of Python installed on the worker and driver is consistent, otherwise the following error will be reported: "Python in worker has different version %s than that in driver %s."
- Ensure that Maven image repository of the SDK in the Huawei image site has been configured in Maven. For details, see [Configuring Huawei Open-Source Mirrors](#).

#### Procedure

##### Step 1 In the IntelliJ IDEA, open the Maven tool window.

On the main page of the IDEA, choose **View > Tool Windows > Maven** to open the Maven tool window.

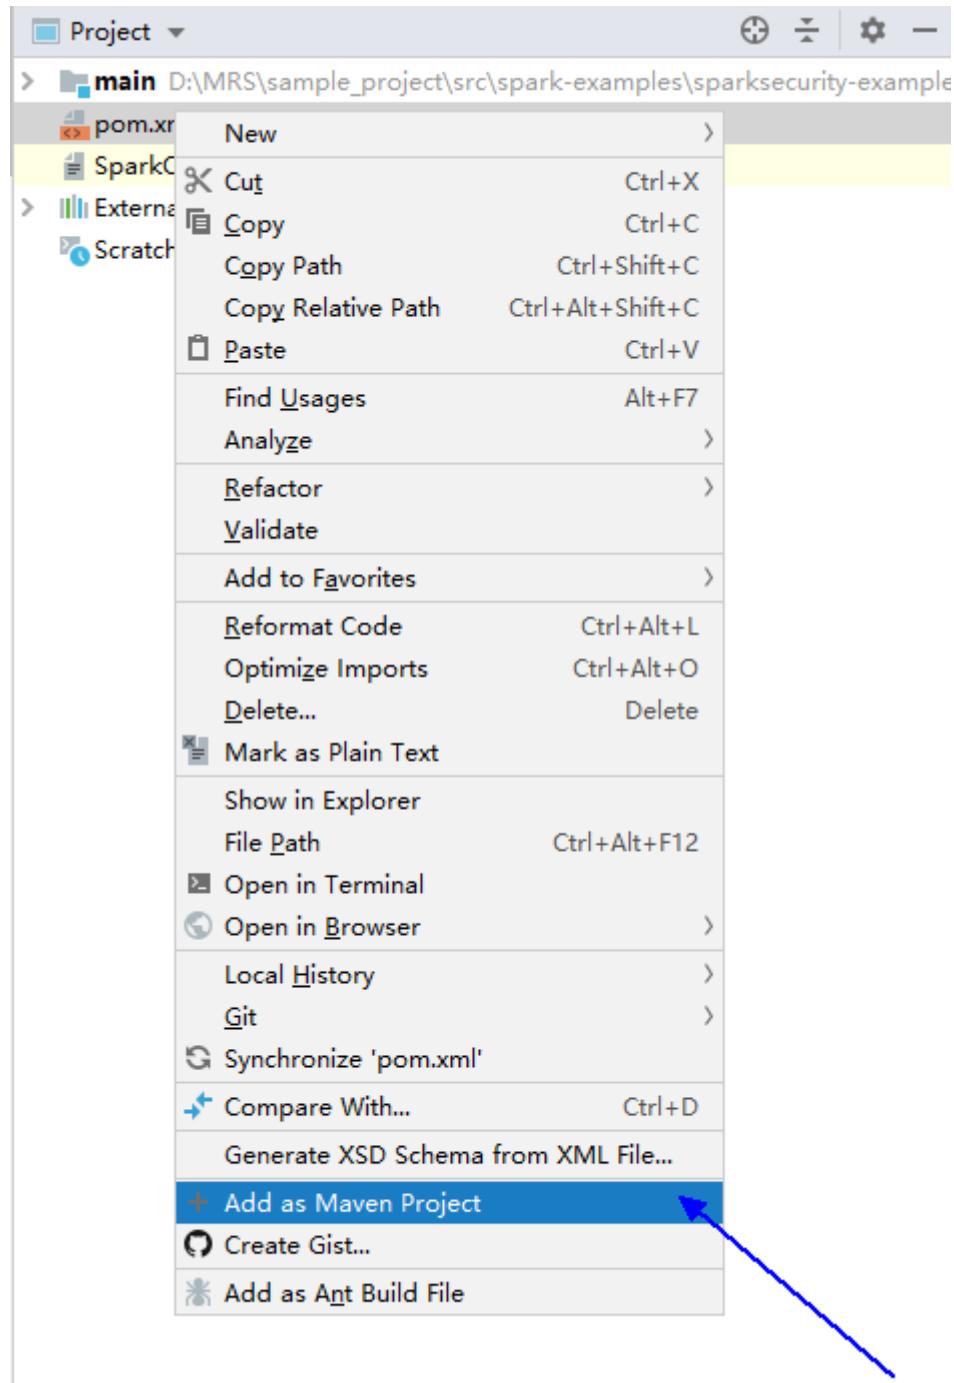

**Figure 1-295** Opening the Maven tool window

If the project is not imported using Maven, perform the following operations:

Right-click the **pom** file in the sample code project and choose **Add as Maven Project** from the shortcut menu to add a Maven project.

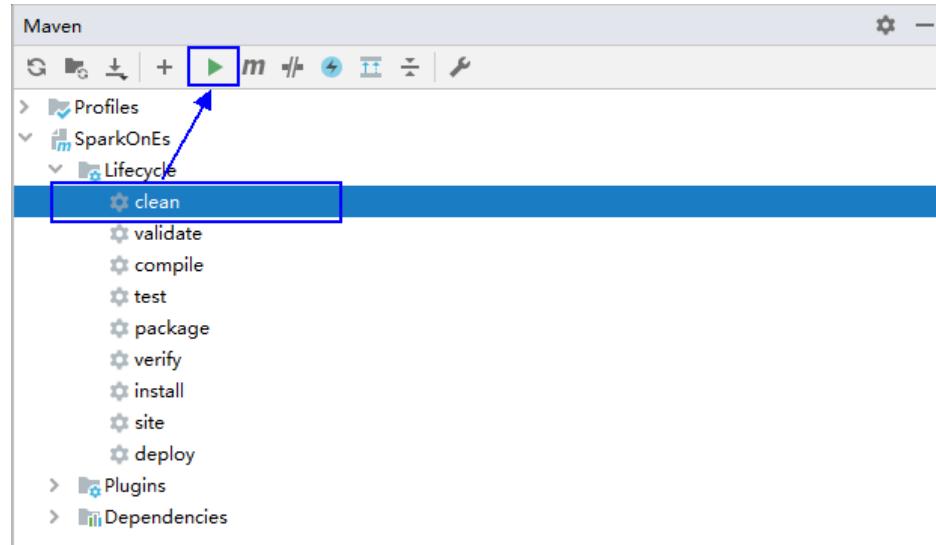

Figure 1-296 Adding a Maven project

**Step 2** Use Maven to generate a JAR file.

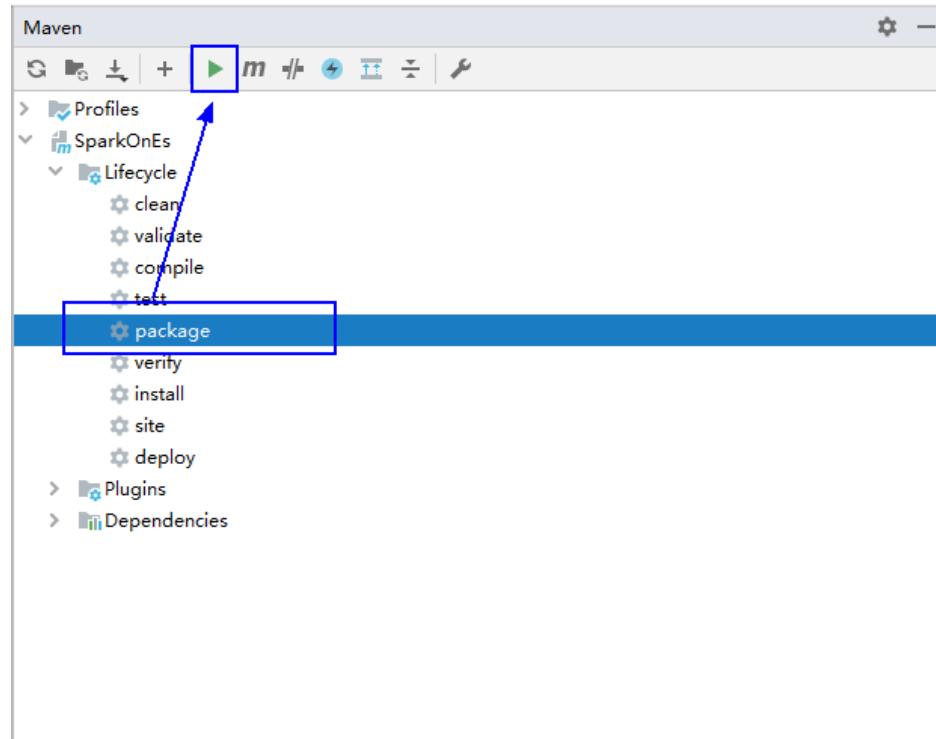

1. In the Maven tool window, select **clean** from **Lifecycle** to execute the Maven building process.

**Figure 1-297** Selecting **clean** from **Lifecycle** and execute the Maven building process

2. In the Maven tool window, select **package** from **Lifecycle** and execute the Maven building process.

**Figure 1-298** Selecting **package** from **Lifecycle** and executing the Maven build process

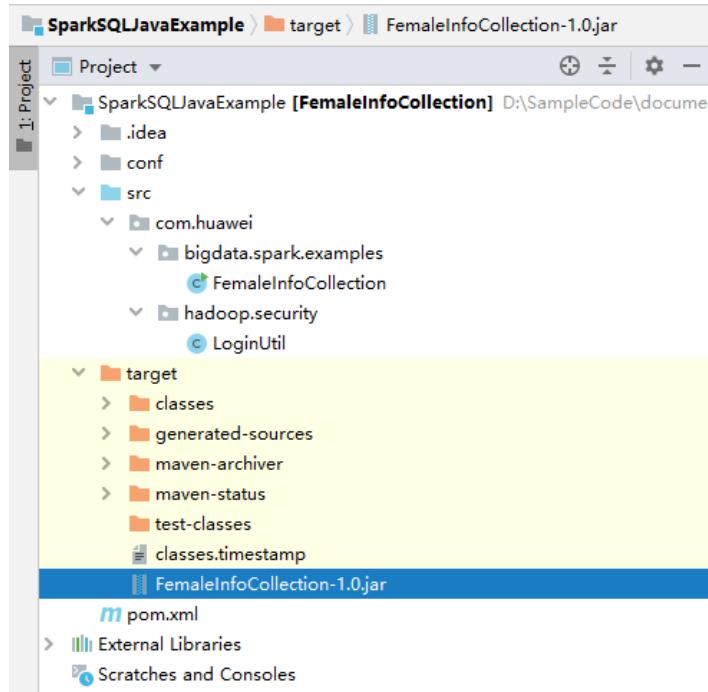

If the following information is displayed in **Run:**, the packaging is successful.

**Figure 1-299** Packaging success message

```
[INFO] [INFO] --- maven-surefire-plugin:2.12.4:test (default-test) @ FemaleInfoCollection ---
[INFO] [INFO] --- maven-jar-plugin:2.4:jar (default-jar) @ FemaleInfoCollection ---
[INFO] Building jar: D:\SampleCode\document\VT\code\sparksecurity-examples\SparkSQLJavaExample\target\FemaleInfoCollection-1.0.jar
[INFO] -----
[INFO] BUILD SUCCESS
[INFO] -----
[INFO] Total time: 19.427 s
[INFO] Finished at: 2020-09-21T11:17:31+08:00
[INFO] -----
```

3. You can obtain the JAR package from the target folder in the project directory.

**Figure 1-300** Obtaining the JAR Package

**Step 3** Copy the JAR file generated in **Step 2** (for example, **CollectFemaleInfo.jar**) to the Spark operating environment (that is, the Spark client), for example, **/opt/female**. Run the Spark application. For details about the example application, see [Developing the Project](#).

**⚠ CAUTION**

Do not restart the HDFS service or all DataNode instances during Spark job running. Otherwise, the job may fail and some JobHistory data may be lost.

----End

#### 1.21.4.2.2 Checking the Commissioning Result

##### Scenario

After a Spark application is run, you can check the running result through one of the following methods:

- Viewing the command output.
- Logging in to the Spark web UI.
- Viewing Spark logs.

## Procedure

- **Check the operating result data of the Spark application.**  
The data storage directory and format are specified by users in the Spark application. You can obtain the data in the specified file.
- **Check the status of the Spark application.**  
The Spark contains the following two web UIs:
  - The Spark UI displays the status of applications being executed.  
The Spark UI contains the **Spark Jobs**, **Spark Stages**, **Storage**, **Environment**, and **Executors** parts. Besides these parts, **Streaming** is displayed for the Streaming application.  
Access to the interface: On the web UI of the YARN, find the corresponding Spark application, and click **ApplicationMaster** in the last column of the application information. The Spark UI page is displayed.
  - The History Server UI displays the status of all Spark applications.  
The History Server UI displays information such as the application ID, application name, start time, end time, execution time, and user to whom the application belongs. After the application ID is clicked, the Spark UI of the application is displayed.
- **View Spark logs to learn application running conditions.**  
The logs of Spark offer immediate visibility into application running conditions. You can adjust application programs based on the logs. Log related information can be referenced to "Component Operation Guide" > "Using Spark" > "Spark Logs" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

## 1.21.5 More Information

### 1.21.5.1 Common APIs

#### 1.21.5.1.1 Java

To avoid API compatibility or reliability issues after updates to the open-source Spark, it is advisable to use APIs of the version you are currently using. For details about APIs, see *MapReduce Service (MRS) 3.3.1-LTS Manager Rest API Reference (for Huawei Cloud Stack 8.3.1)*.

## Spark Core Common Interfaces

Spark mainly uses the following classes:

- **JavaSparkContext**: external interface of Spark, which is used to provide the functions of Spark for Java applications that invoke this class, for example,

connecting Spark clusters and generating RDDs, accumulations, and broadcasts. It functions as a container.

- **SparkConf:** Spark application configuration class, which is used to configure the application name, execution model, and executor memory.
- **JavaRDD:** class used to define the JavaRDD in the Java application, which functions like the RDD(Resilient Distributed Dataset) class of Scala.
- **JavaPairRDD:** indicates the JavaRDD in the key-value format. This class provides methods such as groupByKey and reduceByKey.
- **Broadcast:** broadcast variable class. This class retains one read-only variable, and caches it on each machine, instead of saving a copy for each task.
- **StorageLevel:** data storage levels, including memory (MEMORY\_ONLY), disk (DISK\_ONLY), and memory+disk (MEMORY\_AND\_DISK).

The JavaRDD supports two types of operations, transformation and action. [Table 1-181](#) and [Table 1-182](#) show the common methods.

**Table 1-181** Transformation

| Method                                                                             | Description                                                                                                  |
|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <R> JavaRDD<R><br>map(Function<T,R> f)                                             | Returns a new RDD by applying a function to all elements of this RDD.                                        |
| JavaRDD<T><br>filter(Function<T,Boolean> f)                                        | Invokes Function on all elements of the RDD and returns the element that is <b>true</b> .                    |
| <U> JavaRDD<U><br>flatMap(FlatMapFunction<T,U> f)                                  | Returns a new RDD by first applying a function to all elements of this RDD, and then flattening the results. |
| JavaRDD<T><br>sample(boolean<br>withReplacement,<br>double fraction, long<br>seed) | Returns a sampled subset of this RDD.                                                                        |
| JavaRDD<T><br>distinct(int<br>numPartitions)                                       | Returns a new RDD containing the distinct elements in this RDD.                                              |
| JavaPairRDD<K,Iterable<V>><br>groupByKey(int<br>numPartitions)                     | Returns (K,Seq[V]) and combines the values of the same key to a set.                                         |
| JavaPairRDD<K,V><br>reduceByKey(Function<br>2<V,V> func, int<br>numPartitions)     | Invokes Function on the values of the same key.                                                              |
| JavaPairRDD<K,V><br>sortByKey(boolean<br>ascending, int<br>numPartitions)          | Sorts by key in ascending or descending order.<br>Ascending is of the boolean type.                          |

| Method                                                                                                      | Description                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JavaPairRDD<K,scala.Tuple2<V,W>><br>join(JavaPairRDD<K,W> other)                                            | Returns the dataset of (K,(V,W)) when the (K,V) and (K,W) datasets exist. <b>numTasks</b> indicates the number of concurrent tasks.                                 |
| JavaPairRDD<K,scala.Tuple2<Iterable<V>,Iterable<W>>><br>cogroup(JavaPairRDD <K,W> other, int numPartitions) | Returns the dataset of <K,scala.Tuple2<Iterable<V>,Iterable<W>>> when the (K,V) and (K,W) datasets exist. <b>numTasks</b> indicates the number of concurrent tasks. |
| JavaPairRDD<T,U><br>cartesian(JavaRDDLike<U,?> other)                                                       | Returns the Cartesian product of the RDD and other RDDs.                                                                                                            |

**Table 1-182 Action**

| Method                                                                                                               | Description                                                                                                                                               |
|----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| T<br>reduce(Function2<T,T,<br>T> f)                                                                                  | Invokes Function2 on elements of the RDD.                                                                                                                 |
| java.util.List<T><br>collect()                                                                                       | Returns an array that contains all of the elements in this RDD.                                                                                           |
| long count()                                                                                                         | Returns the number of elements in the dataset.                                                                                                            |
| T first()                                                                                                            | Returns the first element in the dataset.                                                                                                                 |
| java.util.List<T><br>take(int num)                                                                                   | Returns the first <i>n</i> elements in this RDD.                                                                                                          |
| java.util.List<T><br>takeSample(boolean<br>withReplacement, int<br>num, long seed)                                   | Samples the dataset randomly and returns a dataset of num elements. <b>withReplacement</b> indicates whether replacement is used.                         |
| void<br>saveAsTextFile(String<br>path, Class<? extends<br>org.apache.hadoop.io.<br>compress.CompressionCodec> codec) | Writes the dataset to a text file, HDFS, or file system supported by HDFS. Spark converts each record to a row of records and then writes it to the file. |
| java.util.Map<K,Object<br>> countByKey()                                                                             | Counts the appearance times of each key.                                                                                                                  |
| void<br>foreach(VoidFunction<br><T> f)                                                                               | Runs a function <i>func</i> on each element of the RDD.                                                                                                   |

| Method                                  | Description                                           |
|-----------------------------------------|-------------------------------------------------------|
| java.util.Map<T,Long><br>countByValue() | Counts the times that each element of the RDD occurs. |

| API                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public<br>java.util.concurrent.atomic.AtomicBool<br>ean isSparkContextDown() | Determines whether sparkContext is shut down completely. The initial value is <b>false</b> .<br><br>The value <b>true</b> indicates that sparkContext is shut down completely.<br>The value <b>false</b> indicates that sparkContext is not shut down.<br><br>For example,<br><b>jsc.sc().isSparkContextDown().get() == true</b> indicates that sparkContext is shut down completely. |

## Spark Streaming Common Interfaces

Spark Streaming mainly uses the following classes:

- JavaStreamingContext: main entrance of the Spark Streaming, which is used to provide methods for creating DStream. Intervals by batch need to be set in the input parameter.
- JavaDStream: a type of data which indicates the RDDs continuous sequence. It indicates the continuous data flow.
- JavaPairDStream: interface of KV DStream, which is used to provide the reduceByKey and join operations.
- JavaReceiverInputDStream<T>: specifies any inflow accepting data from the network.

Common methods of Spark Streaming are the same as those of Spark Core. The following table describes some special Spark Streaming methods.

**Table 1-184** Spark Streaming methods

| Method                                                                                              | Description                                                                                                                                                                                    |
|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JavaReceiverInputD-<br>Stream<java.lang.String><br>socketStream(java.lang.String hostname,int port) | Creates an inflow to receive data from the corresponding hostname and port through the TCP socket. Received data is resolved to the UTF8 format. The default storage level is the Memory+Disk. |

| Method                                                                                                                                            | Description                                                                                                                                                          |
|---------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JavaDStream<java.lang.String><br>textFileStream(java.lang.String directory)                                                                       | Creates an inflow to detect new files compatible with the Hadoop file system, and read it as a text file. The directory of the input parameter is an HDFS directory. |
| void start()                                                                                                                                      | Starts the Spark Streaming computing.                                                                                                                                |
| void awaitTermination()                                                                                                                           | Terminates the await of the process, which is similar to pressing <b>Ctrl+C</b> .                                                                                    |
| void stop()                                                                                                                                       | Stops the Spark Streaming computing.                                                                                                                                 |
| <T> JavaDStream<T><br>transform(java.util.List<JavaDStream<?>><br>dstreams,Function2<java.util.List<JavaRDD<?>,Time,JavaRDD<T>><br>transformFunc) | Performs the Function operation on each RDD to obtain a new DStream. In this function, the sequence of the JavaRDDs must be the same as the corresponding DStreams.  |
| <T> JavaDStream<T><br>union(JavaDStream<T><br>first,java.util.List<JavaDStream<T>> rest)                                                          | Creates a unified DStream from multiple DStreams with the same type and sliding window.                                                                              |

**Table 1-185** Spark Streaming enhancement interface

| Method                                        | Description                                     |
|-----------------------------------------------|-------------------------------------------------|
| JAVADStreamKafkaWriter.writeToKafka()         | Writes data from DStream into Kafka in batch.   |
| JAVADStreamKafkaWriter.writeToKafkaBySingle() | Writes data from DStream into Kafka one by one. |

## Spark SQL Common Interfaces

Spark SQL mainly uses the following classes:

- **SQLContext**: main entrance of the Spark SQL function and DataFrame.
- **DataFrame**: a distributed dataset organized by naming columns.
- **DataFrameReader**: interface for loading the DataFrame from external storage systems.
- **DataFrameStatFunctions**: implementation the statistic function of the DataFrame.
- **UserDefinedFunction**: function defined by users.

Common Actions methods are described in the following table.

**Table 1-186** Spark SQL methods

| Method                                       | Description                                                                                                                   |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Row[] collect()                              | Returns an array containing all DataFrame columns.                                                                            |
| long count()                                 | Returns the number of DataFrame rows.                                                                                         |
| DataFrame describe(java.lang.String... cols) | Counts the statistic information, including the counting, average value, standard deviation, minimum value and maximum value. |
| Row first()                                  | Returns the first row.                                                                                                        |
| Row[] head(int n)                            | Returns the first <i>n</i> rows.                                                                                              |
| void show()                                  | Displays the first 20 rows in table.                                                                                          |
| Row[] take(int n)                            | Returns the first <i>n</i> rows in the DataFrame.                                                                             |

**Table 1-187** Basic DataFrame Functions

| Method                                                                | Description                                                                            |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| void explain(boolean extended)                                        | Prints the logical plan and physical plan of the SQL.                                  |
| void printSchema()                                                    | Prints the schema information to the console.                                          |
| registerTempTable                                                     | Registers the DataFrame as a temporary table, whose period is bound to the SQLContext. |
| DataFrame toDF(java.lang.String.. colNames)                           | Returns a DataFrame whose columns are renamed.                                         |
| DataFrame sort(java.lang.String sortCol,java.lang.String... sortCols) | Sorts columns in ascending or descending orders based on different columns.            |
| GroupedData rollup(Column... cols)                                    | Performs multiple-dimension crankback on the specified columns in the DataFrame.       |

### 1.21.5.1.2 Scala

To avoid API compatibility or reliability issues after updates to the open-source Spark, it is advisable to use APIs of the version you are currently using. For details about APIs, see *MapReduce Service (MRS) 3.3.1-LTS Manager Rest API Reference (for Huawei Cloud Stack 8.3.1)*.

## Spark Core Common Interfaces

Spark mainly uses the following classes:

- `SparkContext`: external interface of Spark, which is used to provide the functions of Spark for Scala applications that invoke this class, for example, connecting Spark clusters and generating RDDs.
- `SparkConf`: Spark application configuration class, which is used to configure the application name, execution model, and executor memory.
- `Resilient Distributed Dataset (RDD)`: defines the RDD class in the Spark application. The class provides the data collection operation methods, such as `map` and `filter`.
- `PairRDDFunctions`: provides computation operations for the RDD data of the key-value pair, such as `groupByKey`.
- `Broadcast`: broadcast variable class. This class retains one read-only variable, and caches it on each machine, instead of saving a copy for each task.
- `StorageLevel`: data storage levels, including memory (MEMORY\_ONLY), disk (DISK\_ONLY), and memory+disk (MEMORY\_AND\_DISK).

RDD supports two types of operations, transformation and action. [Table 1-188](#) and [Table 1-189](#) describe the common methods.

**Table 1-188** Transformation

| Method                                                                                                        | Description                                                                                                     |
|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <code>map[U](f: (T) =&gt; U): RDD[U]</code>                                                                   | Returns a new RDD by applying a function to all elements of this RDD.                                           |
| <code>filter(f: (T) =&gt; Boolean): RDD[T]</code>                                                             | Invokes the f method for all RDD elements to generate a satisfied data set that is returned in the form of RDD. |
| <code>flatMap[U](f: (T) =&gt; TraversableOnce[U]) (implicit arg0: ClassTag[U]): RDD[U]</code>                 | Returns a new RDD by first applying a function to all elements of this RDD, and then flattening the results.    |
| <code>sample(withReplacement: Boolean, fraction: Double, seed: Long = Utils.random.nextLong()): RDD[T]</code> | Returns a sampled subset of this RDD.                                                                           |
| <code>union(other: RDD[T]): RDD[T]</code>                                                                     | Returns a new RDD, contains source RDD and the group of RDD's elements.                                         |
| <code>distinct([numPartitions: Int]): RDD[T]</code>                                                           | Returns a new RDD containing the distinct elements in this RDD.                                                 |
| <code>groupByKey(): RDD[(K, Iterable[V])]</code>                                                              | Returns (K,Iterable[V]) and combines the values of the same key to a set.                                       |
| <code>reduceByKey(func: (V, V) =&gt; V[, numPartitions: Int]): RDD[(K, V)]</code>                             | Invokes func on the values of the same key.                                                                     |

| Method                                                                                         | Description                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sortByKey(ascending: Boolean = true, numPartitions: Int = self.partitions.length): RDD[(K, V)] | Sorts by key in ascending or descending order. Ascending is of the boolean type.                                                                                                      |
| join[W](other: RDD[(K, W)][, numPartitions: Int]): RDD[(K, (V, W))]                            | Returns the dataset of (K,(V,W)) when the (K,V) and (K,W) datasets exist. <b>numPartitions</b> indicates the number of concurrent tasks.                                              |
| cogroup[W](other: RDD[(K, W)], numPartitions: Int): RDD[(K, (Iterable[V], Iterable[W]))]       | Returns the dataset of (K, (Iterable[V], Iterable[W])) when the (K,V) and (K,W) datasets of two key-value pairs exist. <b>numPartitions</b> indicates the number of concurrent tasks. |
| cartesian[U](other: RDD[U])(implicit arg0: ClassTag[U]): RDD[(T, U)]                           | Returns the Cartesian product of the RDD and other RDDs.                                                                                                                              |

**Table 1-189** Action

| API                                                                                            | Description                                                                                                                                               |
|------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| reduce(f: (T, T) => T):                                                                        | Invokes f on elements of the RDD.                                                                                                                         |
| collect(): Array[T]                                                                            | Returns an array that contains all of the elements in this RDD.                                                                                           |
| count(): Long                                                                                  | Returns the number of elements in the dataset.                                                                                                            |
| first(): T                                                                                     | Returns the first element in the dataset.                                                                                                                 |
| take(num: Int): Array[T]                                                                       | Returns the first <i>n</i> elements in this RDD.                                                                                                          |
| takeSample(withReplacement: Boolean, num: Int, seed: Long = Utils.random.nextLong()): Array[T] | Samples the dataset randomly and returns a dataset of num elements. <b>withReplacement</b> indicates whether replacement is used.                         |
| saveAsTextFile(path: String): Unit                                                             | Writes the dataset to a text file, HDFS, or file system supported by HDFS. Spark converts each record to a row of records and then writes it to the file. |

| API                                                                                        | Description                                                                                                                                 |
|--------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| saveAsSequenceFile(path: String, codec: Option[Class[_ <: CompressionCodec]] = None): Unit | This API can be used only on the key-value pair, and then it generates SequenceFile and writes the file to the local or Hadoop file system. |
| countByKey(): Map[K, Long]                                                                 | Counts the appearance times of each key.                                                                                                    |
| foreach(func: (T) => Unit): Unit                                                           | Applies a function f to all elements of this RDD.                                                                                           |
| countByValue()(implicit ord: Ordering[T] = null): Map[T, Long]                             | Counts the times that each element of the RDD occurs.                                                                                       |

**Table 1-190** New APIs of Spark core

| API                              | Description                                                                                                                                                                                                                                                                                                                                                              |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| isSparkContextDown:AtomicBoolean | Determines whether sparkContext is shut down completely. The initial value is <b>false</b> .<br>The value <b>true</b> indicates that sparkContext is shut down completely.<br>The value <b>false</b> indicates that sparkContext is not shut down.<br>For example,<br><b>sc.isSparkContextDown.get() == true</b><br>indicates that sparkContext is shut down completely. |

## Spark Streaming Common Interfaces

Spark Streaming mainly uses the following classes:

- `StreamingContext`: main entrance of the Spark Streaming, which is used to provide methods for creating DStream. Intervals by batch need to be set in the input parameter.
- `dstream.DStream`: a type of data which indicates the RDDs continuous sequence. It indicates the continuous data flow.
- `dstream.PairDStreamFunctions`: DStream of key-value, common operations are `groupByKey` and `reduceByKey`.

The cooperated Java API of Spark Streaming are `JavaStreamingContext`, `JavaDStream`, `JavaPairDStream`.

Common methods of Spark Streaming are the same as those of Spark Core. The following table describes some special Spark Streaming methods.

**Table 1-191** Spark Streaming methods

| Method                                                                                                                                       | Description                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| socketTextStream(hostname: String, port: Int, storageLevel: StorageLevel = StorageLevel.MEMORY_AND_DISK_SER_2): ReceiverInputDStream[String] | Creates an input stream from the TCP source host:port.                                                                                                                                             |
| start():Unit                                                                                                                                 | Starts the Spark Streaming computing.                                                                                                                                                              |
| awaitTermination(timeout: long):Unit                                                                                                         | Terminates the await of the process, which is similar to pressing <b>Ctrl+C</b> .                                                                                                                  |
| stop(stopSparkContext: Boolean, stopGracefully: Boolean): Unit                                                                               | Stops the Spark Streaming computing.                                                                                                                                                               |
| transform[T](dstreams: Seq[DStream[_]], transformFunc: (Seq[RDD[_]], Time) ? RDD[T])(implicit arg0: ClassTag[T]): DStream[T]                 | Performs the function operation on each RDD to obtain a new DStream.                                                                                                                               |
| UpdateStateByKey(func)                                                                                                                       | Updates the status of DStream. To use this method, you need to define the state and state update functions.                                                                                        |
| window(windowLength, slideInterval)                                                                                                          | Generates a new DStream by batch calculating according to the window of the source DStream.                                                                                                        |
| countByWindow(windowLength, slideInterval)                                                                                                   | Returns the number of sliding window elements in the stream.                                                                                                                                       |
| reduceByWindow(func, windowLength, slideInterval)                                                                                            | When the key-value pair of DStream is invoked, a new key-value pair of DStream is returned. The value of each key is obtained by aggregating the reduce function in batches in the sliding window. |
| join(otherStream, [numTasks])                                                                                                                | Performs a join operation between different Spark Streamings.                                                                                                                                      |
| DStreamKafkaWriter.writeToKafka()                                                                                                            | Writes data from DStream into Kafka in batch.                                                                                                                                                      |

| Method                                    | Description                                     |
|-------------------------------------------|-------------------------------------------------|
| DStreamKafkaWriter.writeToKafkaBySingle() | Writes data from DStream into Kafka one by one. |

**Table 1-192** Spark Streaming enhancement interface

| Method                                    | Description                                     |
|-------------------------------------------|-------------------------------------------------|
| DStreamKafkaWriter.writeToKafka()         | Writes data from DStream into Kafka in batch.   |
| DStreamKafkaWriter.writeToKafkaBySingle() | Writes data from DStream into Kafka one by one. |

## SparkSQL Common Interfaces

Spark SQL mainly uses the following classes:

- SQLContext: main entrance of the Spark SQL function and DataFrame.
- DataFrame: a distributed dataset organized by naming columns.
- HiveContext: An instance of the Spark SQL execution engine that integrates with data stored in Hive.

**Table 1-193** Common Actions methods

| Method                                      | Description                                                                                                                   |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| collect(): Array[Row]                       | Returns an array containing all DataFrame columns.                                                                            |
| count(): Long                               | Returns the number of DataFrame rows.                                                                                         |
| describe(cols: String*): DataFrame          | Counts the statistic information, including the counting, average value, standard deviation, minimum value and maximum value. |
| first(): Row                                | Returns the first row.                                                                                                        |
| Head(n:Int): Row                            | Returns the first <i>n</i> rows.                                                                                              |
| show numRows: Int, truncate: Boolean): Unit | Displays DataFrame in a table.                                                                                                |
| take(n:Int): Array[Row]                     | Returns the first <i>n</i> rows in the DataFrame.                                                                             |

**Table 1-194** Basic DataFrame Functions

| Method                                     | Description                                                                            |
|--------------------------------------------|----------------------------------------------------------------------------------------|
| explain(): Unit                            | Prints the logical plan and physical plan of the SQL.                                  |
| printSchema(): Unit                        | Prints the schema information to the console.                                          |
| registerTempTable(tableName: String): Unit | Registers the DataFrame as a temporary table, whose period is bound to the SQLContext. |
| toDF(colNames: String*): DataFrame         | Returns a DataFrame whose columns are renamed.                                         |

### 1.21.5.1.3 Python

To avoid API compatibility or reliability issues after updates to the open-source Spark, it is advisable to use APIs of the version you are currently using. For details about APIs, see *MapReduce Service (MRS) 3.3.1-LTS Manager Rest API Reference (for Huawei Cloud Stack 8.3.1)*

## Spark Core Common Interfaces

Spark mainly uses the following classes:

- pyspark.SparkContext: external API of Spark. It provides the functions of Spark for Python applications that invoke this class, for example, connecting Spark clusters, creating RDDs, and broadcasting variables.
- pyspark.SparkConf: Spark application configuration class. It is used to set an application name, execution mode, and executor memory.
- pyspark.RDD: class used to define the RDD in the Spark application. The class provides the data collection operation methods, such as map and filter.
- pyspark.Broadcast: broadcast variable class. This class retains one read-only variable, and caches it on each machine, instead of saving a copy for each task.
- pyspark.StorageLevel: data storage levels, including memory (MEMORY\_ONLY), disk (DISK\_ONLY), and memory+disk (MEMORY\_AND\_DISK).
- pyspark.sql.SQLContext: Main entry point for SparkSQL functionality. It can be used to create DataFrame, register DataFrame as a table, and execute SQL on a table.
- pyspark.sql.DataFrame: A distributed collection of data grouped into named columns. A DataFrame is equivalent to a relational table in Spark SQL, and can be created using various functions in SQLContext.
- pyspark.sql.DataFrameNaFunctions: Functionality for working with missing data in DataFrame.
- pyspark.sql.DataFrameStatFunctions: Functionality for statistic functions with DataFrame.

The RDD supports two types of operations, transformation and action. [Table 1-195](#) and [Table 1-196](#) show the common methods.

**Table 1-195** Transformation

| Method                                                                             | Description                                                                                                                                                                           |
|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| map(f,<br>preservesPartition-<br>ing=False)                                        | Returns a new RDD by applying a function to all elements of this RDD.                                                                                                                 |
| filter(f)                                                                          | Invokes the Func method for all RDD elements to generate a satisfied data set that is returned in the form of RDD.                                                                    |
| flatMap(f,<br>preservesPartition-<br>ing=False)                                    | Returns a new RDD by first applying a function to all elements of this RDD, and then flattening the results.                                                                          |
| sample(withReplace-<br>ment, fraction,<br>seed=None)                               | Returns a sampled subset of this RDD.                                                                                                                                                 |
| union(rdds)                                                                        | Returns a new RDD, contains source RDD and the group of RDD's elements.                                                                                                               |
| distinct([numPartitions: Int]): RDD[T]                                             | Returns a new RDD containing the distinct elements in this RDD.                                                                                                                       |
| groupByKey():<br>RDD[(K, Iterable[V])]                                             | Returns (K,Iterable[V]) and combines the values of the same key to a set.                                                                                                             |
| reduceByKey(func,<br>numPartitions=None)                                           | Invokes Func on the values of the same key.                                                                                                                                           |
| sortByKey(ascending= True,<br>numPartitions=None,<br>keyfunc=function<br><lambda>) | Sorts by key in ascending or descending order.<br>Ascending is of the boolean type.                                                                                                   |
| join(other,<br>numPartitions)                                                      | Returns the dataset of (K,(V,W)) when the (K,V) and (K,W) datasets exist. <b>numPartitions</b> indicates the number of concurrent tasks.                                              |
| cogroup(other,<br>numPartitions)                                                   | Returns the dataset of (K, (Iterable[V], Iterable[W])) when the (K,V) and (K,W) datasets of two key-value pairs exist. <b>numPartitions</b> indicates the number of concurrent tasks. |
| cartesian(other)                                                                   | Returns the Cartesian product of the RDD and other RDDs.                                                                                                                              |

**Table 1-196** Action

| API       | Description                          |
|-----------|--------------------------------------|
| reduce(f) | Invokes Func on elements of the RDD. |

| API                                                  | Description                                                                                                                                               |
|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| collect()                                            | Returns an array that contains all of the elements in this RDD.                                                                                           |
| count()                                              | Returns the number of elements in the dataset.                                                                                                            |
| first()                                              | Returns the first element in the dataset.                                                                                                                 |
| take(num)                                            | Returns the first num elements of the RDD.                                                                                                                |
| takeSample(withReplacement, num, seed)               | Samples the dataset randomly and returns a dataset of num elements. <b>withReplacement</b> indicates whether replacement is used.                         |
| saveAsTextFile(path, compressionCodecClass)          | Writes the dataset to a text file, HDFS, or file system supported by HDFS. Spark converts each record to a row of records and then writes it to the file. |
| saveAsSequenceFile(path, compressionCodecClass=None) | This API can be used only on the key-value pair, and then it generates SequenceFile and writes the file to the local or Hadoop file system.               |
| countByKey()                                         | Counts the appearance times of each key.                                                                                                                  |
| foreach(func)                                        | Applies a function f to all elements of this RDD.                                                                                                         |
| countByValue()                                       | Counts the times that each value of the RDD occurs.                                                                                                       |

## Spark Streaming Common Interfaces

Spark Streaming mainly uses the following classes:

- `pyspark.streaming.StreamingContext`: main entrance of Spark Streaming. It provides methods for creating the DStream. A batch interval needs to be set in the input parameter.
- `pyspark.streaming.DStream`: A Discretized Stream (DStream), the basic abstraction in Spark Streaming, is a continuous sequence of RDDs (of the same type) representing a continuous stream of data.
- `dstream.PairDStreamFunctions`: DStream of key-value, common operations are `groupByKey` and `reduceByKey`.

The cooperated Java API of Spark Streaming are `JavaStreamingContext`, `JavaDStream`, `JavaPairDStream`.

Common methods of Spark Streaming are the same as those of Spark Core. The following table describes some special Spark Streaming methods.

**Table 1-197** Spark Streaming common interfaces

| Method                                            | Description                                                                                                                                                                                                                      |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| socketTextStream(hostName, port, storageLevel)    | Creates an input stream from the TCP source host:port.                                                                                                                                                                           |
| start()                                           | Starts the Spark Streaming computing.                                                                                                                                                                                            |
| awaitTermination(timeout)                         | Terminates the await of the process, which is similar to pressing <b>Ctrl+C</b> .                                                                                                                                                |
| stop(stopSparkContext, stopGracefully)            | Stops Spark Streaming computing. <b>stopSparkContext</b> is used to determine whether SparkContext needs to be terminated. <b>StopGracefully</b> is used to determine whether to wait for all the received data to be processed. |
| updateStateByKey(func)                            | Updates the status of DStream. To use this method, you need to define the state and state update functions.                                                                                                                      |
| window(windowLength, slideInterval)               | Generates a new DStream by batch calculating according to the window of the source DStream.                                                                                                                                      |
| countByWindow(windowLength, slideInterval)        | Returns the number of sliding window elements in the stream.                                                                                                                                                                     |
| reduceByWindow(func, windowLength, slideInterval) | When the key-value pair of DStream is invoked, a new key-value pair of DStream is returned. The value of each key is obtained by aggregating the reduce function in batches in the sliding window.                               |
| join(other, numPartitions)                        | Performs a join operation between different Spark Streamings.                                                                                                                                                                    |

## SparkSQL Common Interfaces

Spark SQL mainly uses the following classes:

- `pyspark.sql.SQLContext`: main entrance of the Spark SQL function and `DataFrame`.
- `pyspark.sql.DataFrame`: a distributed dataset organized by naming columns.
- `pyspark.sql.HiveContext`: main entrance for obtaining data stored in Hive.
- `pyspark.sql.DataFrameStatFunctions`: Functionality for statistic functions with `DataFrame`.
- `pyspark.sql.functions`: A collection of builtin functions.
- `pyspark.sql.Window`: window function provided by SQL

**Table 1-198** Spark SQL common Actions

| Method     | Description                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------------------|
| collect()  | Returns an array containing all DataFrame columns.                                                                            |
| count()    | Returns the number of DataFrame rows.                                                                                         |
| describe() | Counts the statistic information, including the counting, average value, standard deviation, minimum value and maximum value. |
| first()    | Returns the first row.                                                                                                        |
| head(n)    | Returns the first <i>n</i> rows.                                                                                              |
| show()     | Displays DataFrame in a table.                                                                                                |
| take(num)  | Returns the first num rows in the DataFrame.                                                                                  |

**Table 1-199** Basic DataFrame Functions

| Method                  | Description                                                                            |
|-------------------------|----------------------------------------------------------------------------------------|
| explain()               | Prints the logical plan and physical plan of the SQL.                                  |
| printSchema()           | Prints the schema information to the console.                                          |
| registerTempTable(name) | Registers the DataFrame as a temporary table, whose period is bound to the SQLContext. |
| toDF()                  | Returns a DataFrame whose columns are renamed.                                         |

#### 1.21.5.1.4 REST API

##### Function Description

The Spark REST API presents some web UI metrics in the JSON format, providing users with a simpler method to create new visualization and monitoring tools. The REST API can be used to query information about running and historical applications. The open-source Spark REST API allows users to query information about Jobs, Stages, Storage, Environment, and Executors. In the FusionInsight version, the REST API used to query SQL, JDBC server, and Streaming information is added. For more information about the open-source REST API, see <https://spark.apache.org/docs/3.3.1/monitoring.html#rest-api>.

##### Preparing Running Environment

Install the FusionInsight client. Install a FusionInsight client on the node. For example, install the client in the **/opt/hadoopclient** directory.

## REST API

You can use the following commands to dodge the REST API filter and directly obtain the application information:

### NOTICE

- In security mode, the JobHistory supports only the HTTPS protocol. Therefore, use the HTTPS protocol in the URL of the following command.
- In security mode, you need to set **spark.ui.customErrorPage** to **false** and restart Spark. Change the value of this parameter for the JobHistory, JDBCServer, and SparkResource instances.

### NOTE

Perform the following steps to upgrade the curl version on the node:

1. Download the curl installation package from the following website: <http://curl.haxx.se/download/>
2. Run the following command to decompress the installation package:  
**tar -xzvf curl-x.x.x.tar.gz**
3. Run the following commands to overwrite the old curl version with the new one:  
**cd curl-x.x.x**  
**./configure**  
**make**  
**make install**
4. Run the following command to update the dynamic link library of curl:  
**ldconfig**
5. After the installation is successful, log in to the node again and run the following command to check whether the curl version is successfully updated:  
**curl --version**

- Obtaining information about all applications on the JobHistory node:

- Command:

```
curl -k -i --negotiate -u: "https://192.168.227.16:22500/api/v1/applications"
```

**192.168.227.16** indicates the service IP address of the JobHistory node and **22500** indicates the port number of the JobHistory node.

- Command output:

```
[ {  
    "id" : "application_1517290848707_0008",  
    "name" : "Spark Pi",  
    "attempts" : [ {  
        "startTime" : "2018-01-30T15:05:37.433CST",  
        "endTime" : "2018-01-30T15:06:04.625CST",  
        "lastUpdated" : "2018-01-30T15:06:04.848CST",  
        "duration" : 27192,  
        "sparkUser" : "sparkuser",  
        "completed" : true,  
        "startTimeEpoch" : 1517295937433,  
        "endTimeEpoch" : 1517295964625,  
        "lastUpdatedEpoch" : 1517295964848  
    } ]  
, {  
    "  
id" : "application_1517290848707_0145",  
}
```

```
"name" : "Spark shell",
"attempts" : [ {
  "startTime" : "2018-01-31T15:20:31.286CST",
  "endTime" : "1970-01-01T07:59:59.999CST",
  "lastUpdated" : "2018-01-31T15:20:47.086CST",
  "duration" : 0,
  "sparkUser" : "admintest",
  "completed" : false,
  "startTimeEpoch" : 1517383231286,
  "endTimeEpoch" : -1,
  "lastUpdatedEpoch" : 1517383247086
} ]
}]
```

- Analysis:

With this command, you can query information about all Spark applications in the current cluster, including running applications and the completed applications. **Table 1-200** provides information about each application.

**Table 1-200** Parameter description

| Parameter | Description                                                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id        | Application ID.                                                                                                                                                                      |
| name      | Application name.                                                                                                                                                                    |
| attempts  | Attempts executed by the application, including the attempt start time, attempt end time, user who initiates the attempts, and status indicating whether the attempts are completed. |

- Obtaining information about a specific application on the JobHistory node:

- Command:

```
curl -k -i --negotiate -u: "https://192.168.227.16:22500/api/v1/applications/
application_1517290848707_0008"
```

**192.168.227.16** indicates the service IP address of the JobHistory node, **22500** indicates the port number of the JobHistory node, and **application\_1517290848707\_0008** indicates the application ID.

- Command output:

```
{
  "id" : "application_1517290848707_0008",
  "name" : "Spark Pi",
  "attempts" : [ {
    "startTime" : "2018-01-30T15:05:37.433CST",
    "endTime" : "2018-01-30T15:06:04.625CST",
    "lastUpdated" : "2018-01-30T15:06:04.848CST",
    "duration" : 27192,
    "sparkUser" : "sparkuser",
    "completed" : true,
    "startTimeEpoch" : 1517295937433,
    "endTimeEpoch" : 1517295964625,
    "lastUpdatedEpoch" : 1517295964848
  } ]
}
```

- Analysis:

With this command, you can query information about a Spark application. [Table 1-200](#) provides information about the application.

- Obtaining information about the executor of a running application:

- Command of alive executors list:

```
curl -k -i --negotiate -u: "https://192.168.169.84:26001/proxy/  
application_1478570725074_0046/api/v1/applications/application_1478570725074_0046/  
executors"
```

- Command of all executors (alive and dead) list:

```
curl -k -i --negotiate -u: "https://192.168.169.84:26001/proxy/  
application_1478570725074_0046/api/v1/applications/application_1478570725074_0046/  
allexecutors"
```

**192.168.169.84** indicates the service IP address of the master node of the ResourceManager, **26001** indicates the port number of the ResourceManager, and **application\_1478570725074\_0046** indicates the application ID in YARN.

- Command output:

```
[  
  {  
    "id" : "driver",  
    "hostPort" : "192.168.169.84:23886",  
    "isActive" : true,  
    "rddBlocks" : 0,  
    "memoryUsed" : 0,  
    "diskUsed" : 0,  
    "activeTasks" : 0,  
    "failedTasks" : 0,  
    "completedTasks" : 0,  
    "totalTasks" : 0,  
    "totalDuration" : 0,  
    "totalInputBytes" : 0,  
    "totalShuffleRead" : 0,  
    "totalShuffleWrite" : 0,  
    "maxMemory" : 278019440,  
    "executorLogs" : {}  
  }, {  
    "id" : "1",  
    "hostPort" : "192.168.169.84:23902",  
    "isActive" : true,  
    "rddBlocks" : 0,  
    "memoryUsed" : 0,  
    "diskUsed" : 0,  
    "totalCores" : 1,  
    "maxTasks" : 1,  
    "activeTasks" : 0,  
    "failedTasks" : 0,  
    "completedTasks" : 0,  
    "totalTasks" : 0,  
    "totalDuration" : 0,  
    "totalGCTime" : 139,  
    "totalInputBytes" : 0,  
    "totalShuffleRead" : 0,  
    "totalShuffleWrite" : 0,  
    "maxMemory" : 555755765,  
    "executorLogs" : {  
      "stdout" : "https://XTJ-224:26010/node/containerlogs/  
container_1478570725074_0049_01_000002/admin/stdout?start=-4096",  
      "stderr" : "https://XTJ-224:26010/node/containerlogs/  
container_1478570725074_0049_01_000002/admin/stderr?start=-4096"  
    }  
  }]  
]
```

- Analysis:

With this command, you can query information about all executors including drivers of the current application. [Table 1-201](#) provides basic information about each executor.

**Table 1-201** Parameter description

| Parameter    | Description                                                                                                   |
|--------------|---------------------------------------------------------------------------------------------------------------|
| id           | Executor ID.                                                                                                  |
| hostPort     | IP address and port number of the node where the Executor resides.<br>Format: <i>IP address:port number</i> . |
| executorLogs | Path to Executor logs.                                                                                        |

## Enhanced REST API

- SQL related: obtaining all the SQL statements and those with the longest execution time.

- SparkUI command:

```
curl -k -i --negotiate -u: "https://192.168.195.232:26001/proxy/  
application_1476947670799_0053/api/v1/applications/application_1476947670799_0053/SQL"
```

**192.168.195.232** indicates the service IP address of the master node of the ResourceManager, **26001** indicates the port number of the ResourceManager, and **application\_1476947670799\_0053** indicates the application ID in YARN.

### NOTE

You can add parameters to the URL after the command to search for the corresponding SQL statements.

For example, run the following command to view 100 SQL statements:

```
curl -k -i --negotiate -u: "https://192.168.195.232:26001/proxy/  
application_1476947670799_0053/api/v1/applications/application_1476947670799_0053/  
SQL?limit=100"
```

Run the following command to view running parameters:

```
curl -k -i --negotiate -u: "https://192.168.195.232:26001/proxy/  
application_1476947670799_0053/api/v1/applications/application_1476947670799_0053/  
SQL?completed=false"
```

- JobHistory command:

```
curl -k -i --negotiate -u: "https://192.168.227.16:22500/api/v1/applications/  
application_1478570725074_0004/SQL"
```

**192.168.227.16** indicates the service IP address of the JobHistory node, **22500** indicates the port number of the JobHistory node, and **application\_1478570725074\_0004** indicates the application ID.

- Command output:

The command output of the SparkUI and JobHistory commands is as follows:

```
{  
  "longestDurationOfCompletedSQL" : [ {  
    "id" : 0,  
    "status" : "COMPLETED",  
    "description" : "getCallSite at SQLExecution.scala:48",  
    "submissionTime" : "2016/11/08 15:39:00",  
    "duration" : "2 s",  
    "runningJobs" : [],  
    "successtedJobs" : [ 0 ],  
    "failedJobs" : []  
  } ],
```

```
"sqls" : [ {
    "id" : 0,
    "status" : "COMPLETED",
    "description" : "getCallSite at SQLExecution.scala:48",
    "submissionTime" : "2016/11/08 15:39:00",
    "duration" : "2 s",
    "runningJobs" : [ ],
    "successedJobs" : [ 0 ],
    "failedJobs" : [ ]
  }
}
```

- Analysis:

After running this command, you can obtain all the SQL statements executed by the current application (the **sqls** part of the command output) and the SQL statements with the longest execution time (the **longestDurationOfCompletedSQL** part of the command output). The information about each SQL statement is listed in [Table 1-202](#).

**Table 1-202** Parameter description

| Parameter     | Description                                                                          |
|---------------|--------------------------------------------------------------------------------------|
| id            | SQL statement ID.                                                                    |
| status        | Execution status of the SQL statement, which can be: running, completed, and failed. |
| runningJobs   | Jobs that are being executed generated by the SQL statement.                         |
| successedJobs | Jobs that are successfully executed generated by the SQL statement.                  |
| failedJobs    | Job that fails to be executed generated by the SQL statement.                        |

- JDBC server related: obtaining the number of sessions, number of being-executed SQL statements, information about all sessions, and information about SQL statements.

- Command:

```
curl -k -i --negotiate -u: "https://192.168.195.232:26001/proxy/
application_1476947670799_0053/api/v1/applications/application_1476947670799_0053/
sqlserver"
```

**192.168.195.232** indicates the service IP address of the master node of the ResourceManager, **26001** indicates the port number of the ResourceManager, and **application\_1476947670799\_0053** indicates the application ID in YARN.

- Command output:

```
{
  "sessionNum" : 1,
  "runningSqlNum" : 0,
  "sessions" : [ {
    "user" : "spark",
    "ip" : "192.168.169.84",
    "sessionId" : "9dfec575-48b4-4187-876a-71711d3d7a97",
    "startTime" : "2016/10/29 15:21:10",
    "finishTime" : ""
  }
}
```

```
        "duration" : "1 minute 50 seconds",
        "totalExecute" : 1
    },
    "sqls" : [ {
        "user" : "spark",
        "jobId" : [ ],
        "groupId" : "e49ff81a-230f-4892-a209-a48abea2d969",
        "startTime" : "2016/10/29 15:21:13",
        "finishTime" : "2016/10/29 15:21:14",
        "duration" : "555 ms",
        "statement" : "show tables",
        "state" : "FINISHED",
        "detail" : "== Parsed Logical Plan ==\nShowTablesCommand None\n== Analyzed Logical\nPlan ==\ntableName: string, isTemporary: boolean\nShowTablesCommand None\n== Cached\nLogical Plan ==\nShowTablesCommand None\n== Optimized Logical Plan ==\nShowTablesCommand None\n== Physical Plan ==\nExecutedCommand\nShowTablesCommand None\n==\nCode Generation: true"
    }
}
```

- Analysis:

After running this command, you can query the number of sessions in the current JDBC application, number of being-executed SQL statements, and information about all sessions and SQL statements. The information about each session is listed in [Table 1-203](#), and the information about each SQL statement is listed in [Table 1-204](#):

**Table 1-203** Session parameter description

| Parameter    | Description                                       |
|--------------|---------------------------------------------------|
| user         | User to whom the session connects.                |
| ip           | IP address of the node where the session resides. |
| sessionId    | Session ID.                                       |
| startTime    | Time when the session starts the connection.      |
| finishTime   | Time when the session ends the connection.        |
| duration     | Connection duration of the session.               |
| totalExecute | Number of SQL statements executed by the session. |

**Table 1-204** SQL parameter description

| Parameter | Description                          |
|-----------|--------------------------------------|
| user      | User who executes the SQL statement. |

| Parameter  | Description                                      |
|------------|--------------------------------------------------|
| jobId      | IDs of jobs contained in the SQL statement.      |
| groupId    | ID of the group where the SQL statement resides. |
| startTime  | Start time.                                      |
| finishTime | End time.                                        |
| duration   | SQL statement execution duration.                |
| statement  | SQL statement.                                   |
| detail     | Logical/Physical plan.                           |

- JDBC API enhancement cancels the SQL statement that is being executed by using the execution ID obtained from the beeline.
  - Commands for the operation:  
`curl -k -i --negotiate -X PUT -u: "https://192.168.195.232:26001/proxy/application_1477722033672_0008/api/v1/applications/application_1477722033672_0008/cancel/execution?executionId=8"`
  - Command output:  
 Cancel the job whose execution ID is 8.
  - Remarks:  
 Run the SQL statement in spark-beeline. If the SQL statement generates a Spark task, the execution ID of the SQL statement will be printed in beeline. To cancel the execution of the SQL statement, run the preceding command.
- Streaming related: obtaining the average input frequency, average scheduling delay, average execution duration, and average value of the overall delay.
  - Command:  
`curl -k -i --negotiate -u: "https://192.168.195.232:26001/proxy/application_1477722033672_0008/api/v1/applications/application_1477722033672_0008/streaming/statistics"`

**192.168.195.232** indicates the service IP address of the master node of the ResourceManager, **26001** indicates the port number of the ResourceManager, and **application\_1477722033672\_0008** indicates the application ID in YARN.
  - Command:  
`{
 "startTime" : "2018-12-25T08:58:10.836GMT",
 "batchDuration" : 1000,
 "numReceivers" : 1,
 "numActiveReceivers" : 1,
 "numInactiveReceivers" : 0,
 "numTotalCompletedBatches" : 373,
 "numRetainedCompletedBatches" : 373,
 "numActiveBatches" : 0,
 "numProcessedRecords" : 1,
 "numReceivedRecords" : 1,
 "avgInputRate" : 0.002680965147453083,
 "avgSchedulingDelay" : 14,
 "avgProcessingTime" : 47,`

```
    "avgTotalDelay" : 62
}
```

- Analysis:

After running this command, you can query the average input frequency (unit: events/sec), average scheduling delay (unit: ms), average execution time (unit: ms), and average value of the total delay (unit: ms) of the current Streaming application.

### 1.21.5.2 Common CLIs

For details about how to use the Spark CLIs, visit the official website <http://spark.apache.org/docs/3.3.1/quick-start.html>.

#### Common CLI

Common Spark CLIs are described as follows:

- **spark-shell**

It provides an easy way to learn APIs, which is similar to the tool for interactive data analysis. It supports two languages including Scala and Python. In the Spark directory, run the `./bin/spark-shell` command to access the interactive interface of Scala, obtain data from HDFS, and then perform the RDD.

For example: a row of codes can count all words in a file.

```
scala> sc.textFile("hdfs://10.96.1.57:9000//wordcount_data.txt").flatMap(l => l.split(" ")).map(w => (w,1)).reduceByKey(_ + _).collect()
```

You can directly specify the Keytab and Principal in the command line to obtain authentication, and regularly update the keytab and authorized tokens to avoid the authentication expiry. The following command is used as an example.

```
spark-shell --principal spark2x/hadoop.<System domain name>@<System domain name> --keytab ${BIGDATA_HOME}/FusionInsight_Spark_8.3.1/install/FusionInsight-Spark-3.3.1/keytab/spark/SparkResource/spark2x.keytab --master yarn
```

- **spark-submit**

It is used to submit the Spark application to the Spark cluster for running and return the running results. The class, master, jar and input parameter need to be specified.

For example: Run the GroupByTest example in the jar. There are four input parameters and the specified running mode of the cluster is local single platform.

```
./bin/spark-submit --class org.apache.spark.examples.GroupByTest --master local[1] examples/jars/spark-examples_xxx.cbu.mrs.xxx.jar 6 10 10 3
```

You can directly specify the Keytab and Principal in the command line to obtain authentication, and regularly update the keytab and authorized tokens to avoid the authentication expiry. The following command is used as an example.

```
spark-submit --class org.apache.spark.examples.GroupByTest --master yarn --principal spark2x/hadoop.<System domain name>@<System domain
```

```
name> --keytab ${BIGDATA_HOME}/FusionInsight_Spark_8.3.1/install/
FusionInsight-Spark-3.3.1/keytab/spark/SparkResource/spark2x.keytab
examples/jars/spark-examples_xxx.cbu.mrs.xxx.jar 6 10 10 3
```

- **spark-sql**

It is used to perform the Hive metadata service and query command lines in the local mode. If its logical plan needs to be queried, add the explain extended before the SQL statement.

For example:

**Select key from src group by key**

You can directly specify the Keytab and Principal in the command line to obtain authentication, and regularly update the keytab and authorized tokens to avoid the authentication expiry. The following command is used as an example.

```
spark-sql --principal spark2x/hadoop.<System domain name>@<System
domain name> --keytab ${BIGDATA_HOME}/FusionInsight_Spark_8.3.1/
install/FusionInsight-Spark-3.3.1/keytab/spark/SparkResource/
spark2x.keytab --master yarn
```

- **run-example**

It is used to run or debug the default example in the Spark open-source community.

For example: Run the SparkPi.

```
./run-example SparkPi 100
```

### 1.21.5.3 JDBCServer Interface

#### Overview

The JDBCServer is another implement of HiveServer2 in the Hive. The Spark SQL is used to process the SQL statement at its bottom. Therefore, the JDBCServer has better performance than the Hive.

The JDBCServer is a JDBC interface. Users can log in to the JDBCServer and access the Spark SQL data through the JDBC. When the JDBCServer is started, a Spark SQL application is started, and the clients connected through the JDBC share the resources in this application. That is, various users can share data. When the JDBCServer is started, a listener is also started to wait for the connection of the JDBC client and submit the query after the connection. Therefore, during the configuration of the JDBCServer, at least the host name and port of the JDBCServer must be configured. If Hive data is required, the uris of the hive metastore needs to be provided.

JDBCServer starts a JDBC service on port 22550 of the installation node by default. (If you want to change the port, configure the **hive.server2.thrift.port** parameter.) You can connect to JDBCServer using Beeline or running the JDBC client code to run SQL statements.

For other information about the JDBCServer, visit the Spark official website: <http://spark.apache.org/docs/3.3.1/sql-programming-guide.html#distributed-sql-engine>.

## Beeline

For connection methods of the Beeline provided by the open-source community, visit <https://cwiki.apache.org/confluence/display/Hive/HiveServer2+Clients>.

To solve the connection problem in two scenarios of the Beeline, the authentication information is added in the Beeline connection. The **user.keytab** and **user.principal** parameters are added in the URL of the JDBC. When the key tab expires, the login information of the client can be read automatically and the connection succeeds again.

Users do not want to perform the key tab authentication by running the **kinit** command because the key tab expires every 24 hours. The Keytab file and principal information can be obtained from the administrator. The following command is used as a connection example of Beeline.

```
sh CLIENT_HOME/spark/bin/beeline -u "jdbc:hive2://<zkNode1_IP>:<zkNode1_Port>,<zkNode2_IP>:<zkNode2_Port>,<zkNode3_IP>:<zkNode3_Port>;serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=spark thriftserver;user.principal=spark2x/hadoop.<System domain name>@<System domain name>;saslQop=auth-conf;auth=KERBEROS;principal=spark2x/hadoop.<System domain name>@<System domain name>;"
```

### NOTE

- <zkNode1\_IP>:<zkNode1\_Port>,<zkNode2\_IP>:<zkNode2\_Port>,<zkNode3\_IP>:<zkNode3\_Port> indicates the URL of ZooKeeper. Multiple URLs are separated by comma. For example: 192.168.81.37:24002,192.168.195.232:24002,192.168.169.84:24002.
- **sparkthriftserver** indicates the directory in Zookeeper where a random JDBCServer instance is selected for the connection to the client.

## JDBC Client Codes

Log in to the JDBCServer by using the JDBC client codes and access the Spark SQL data. For details, see [Accessing the Spark SQL Through JDBC](#).

## Enhanced Features

Compared with the open-source community, Huawei provides two enhanced features: the JDBCServer HA solution and timeout of configuring the JDBCServer.

- The JDBCServer HA solution is described as follows:  
When multiple active nodes of JDBCServer provides services at the same time, a new client will be connected to another active node if a fault occurs on one node, ensuring continuous services for clusters. The operations of Beeline and JDBC client code connection are the same.
- Configure the timeout of the connection between the client and JDBCServer.
  - Beeline  
In network congestion, this feature can avoid the suspending of Beeline due to timeless wait of the return from the server. The method is described as follows:  
When the Beeline is started, add **--socketTimeOut=n**. The n indicates the timeout waiting for the service return. The unit is second and the default

- value is 0 (indicating never timing out). Set the maximum timeout waiting time as required.
- JDBC Client Codes  
In the scenario of network congestion, this feature can avoid the suspending of the client due to limitless wait of the return of server. The method to use is shown as follows:  
Before the obtaining of the JDBC by using the DriverManager.getConnection method, add the DriverManager.setLoginTimeout(n) method to configure the timeout length. n indicates the timeout length of waiting for the service return. The unit is second and the type is Int. The default value is 0 (indicating never timing out). Set the maximum timeout waiting time as required.

#### 1.21.5.4 Structured Streaming Functions and Reliability

##### Functions Supported by Structured Streaming

1. ETL operations on streaming data are supported.
2. Schema inference and partitioning of streaming DataFrames or Datasets are supported.
3. Operations on the streaming DataFrames or Datasets are supported, including SQL-like operations without types (such as select, where, and groupBy) and RDD operations with types (such as map, filter, and flatMap).
4. Aggregation calculation based on Event Time and processing of delay data are supported.
5. Deduplication of streaming data is supported.
6. Status computing is supported.
7. Stream processing tasks can be monitored.
8. Batch-stream join and stream join are supported.

The following table lists the supported join operations.

| Left Table | Right Table | Supported Join Type | Description                                                                                      |
|------------|-------------|---------------------|--------------------------------------------------------------------------------------------------|
| Static     | Static      | All types           | In stream processing, join operations with no streaming data involved are supported.             |
| Stream     | Static      | Inner               | Supported, but stateless.                                                                        |
|            |             | Left Outer          | Supported, but stateless.                                                                        |
|            |             | Right Outer         | Not supported.                                                                                   |
|            |             | Full Outer          | Not supported.                                                                                   |
| Stream     | Stream      | Inner               | Supported. The watermark or time range can be used to clear status of the left and right tables. |

| Left Table | Right Table | Supported Join Type | Description                                                                                                                                          |
|------------|-------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
|            |             | Left Outer          | Conditionally supported. The watermark can be used to clear status of the left table, and watermark and time range must be used for the right table. |
|            |             | Right Outer         | Conditionally supported. The watermark can be used to clear status of the right table, and watermark and time range must be used for the left table. |
|            |             | Full Outer          | Not supported.                                                                                                                                       |

## Functions Not Supported by Structured Streaming

1. Multi-stream aggregation is not supported.
2. The following operations of obtaining multiple rows are not supported: limit, first, and take.
3. Distinct is not supported.
4. Sorting is supported only when output mode is complete.
5. The external connection between streams and static data sets is conditionally supported.
6. Immediate query and result return on some data sets are not supported.
  - count(): Instead of returning a single count from streaming data sets, it uses ds.groupBy().count() to return a streaming data set containing the running count.
  - foreach(): The ds.writeStream.foreach(...) is used to replace it.
  - show(): The output console sink is used to replace it.

## Structured Streaming Reliability

Based on the checkpoint and WAL mechanisms, Structured Streaming provides end-to-end exactly-once error tolerance semantics for the sources that can be replayed and the idempotent sinks that support repeated processing.

1. You can enable the checkpoint function by setting option ("checkpointLocation", "checkpoint path") in the program.

When data is restored from checkpoint, the application or configuration may change. Some changes may result in the failure in restoring data from the checkpoint. The restrictions are as follows:

- a. The number or type of sources cannot be changed.
- b. The source type and query statement determine whether the source parameter can change. For example:
  - The parameters related to rate control can be added, deleted, or modified. For example:

`spark.readStream.format("kafka").option("subscribe", "topic")` is changed to `spark.readStream.format("kafka").option("subscribe", "topic").option("maxOffsetsPerTrigger", ...)`.

- Unexpected problems may occur when the topic/file of the consumption is modified. For example:  
`spark.readStream.format("kafka").option("subscribe", "topic")` is changed to `spark.readStream.format("kafka").option("subscribe", "newTopic")`.

- c. The type of sink changes. Specific sinks can be combined. The specific scenarios need to be verified. For example:

- File sink can be changed to kafka sink. Kafka processes only new data.
- Kafka sink cannot be changed to file sink.
- Kafka sink can be changed to foreach sink, and vice versa.

- d. The sink type and query statement determine whether the sink parameter can change. For example:

- The output path of file sink cannot be changed.
- The output topic of Kafka sink can be changed.
- The custom operator code in foreach sink can be changed, but the change result depends on the user code.

- e. The projection, filter, and map-like operations can be changed in some scenarios. For example:

- Filters can be added and deleted. For example: `sdf.selectExpr("a")` is changed to `sdf.where(...).selectExpr("a").filter(...)`.
- When Output schema is the same, projections can be changed. For example: `sdf.selectExpr("stringColumn AS json").writeStream` is changed to `sdf.select(to_json(...).as("json")).writeStream`.
- If Output schema is different, projections can be changed in some conditions. For example: when `sdf.selectExpr("a").writeStream` is changed to `sdf.selectExpr("b").writeStream`, no error occurs only when the sink supports schema conversion from a to b.

- f. In some scenarios, the status restoration will fail after status is changed.

- Streaming aggregation: For example, in the `sdf.groupBy("a").agg(...)` operation, the type or quantity of the grouping key or the aggregation key cannot be changed.
- Streaming deduplication: For example, in the `sdf.dropDuplicates("a")` operation, the type or quantity of the grouping key or the aggregation key cannot be changed.
- Stream-stream join: For example, in the `sdf1.join(sdf2, ...)` operation, the schema of the association key cannot be changed, and the join type cannot be changed. Change of other join conditions may lead to uncertainty results.

- Any status computing: For example, in the `sdf.groupByKey(...).mapGroupsWithState(...)` or `sdf.groupByKey(...).flatMapGroupsWithState(...)` operation, the schema or timeout type of the user-defined status cannot be changed. Users can customize the state-mapping function change, but the change result depends on the user code. If schema changes are required, users can encode or decode the status data into binary data to support schema migration.

## 2. Fault tolerance list of Source

| Sources       | Supported Options                                                                                                                                                                                                                                                                                                                                                                                                      | Fault Tolerance Supported | Description                                                                                                                                                                                                                     |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| File source   | <b>path:</b> file path, which is mandatory.<br><b>maxFilesPerTrigger:</b> maximum number of files in each trigger. The default value is infinity.<br><b>latestFirst:</b> whether to process limited number of new files. The default value is <b>false</b> .<br><b>fileNameOnly:</b> whether the file name is used as the new file for verification instead of using the complete path. (Default value: <b>false</b> ) | Supported                 | Paths with wildcard are supported, but multiple paths separated by commas (,) are not supported. Files must be placed in a given directory in atomic mode, which can be implemented through file movement in most file systems. |
| Socket Source | <b>host:</b> IP address of the connected node, which is mandatory.<br><b>port:</b> connected port, which is mandatory.                                                                                                                                                                                                                                                                                                 | Not supported.            | -                                                                                                                                                                                                                               |
| Rate Source   | <b>rowsPerSecond:</b> number of rows generated per second. The default value is 1.<br><b>rampUpTime:</b> rising time before the speed specified by <b>rowsPerSecond</b> is reached.<br><b>numPartitions:</b> concurrency degree for generating data rows.                                                                                                                                                              | Supported                 | -                                                                                                                                                                                                                               |
| Kafka Source  | For details, see <a href="https://spark.apache.org/docs/3.3.1/structured-streaming-kafka-integration.html">https://spark.apache.org/docs/3.3.1/structured-streaming-kafka-integration.html</a> .                                                                                                                                                                                                                       | Supported                 | -                                                                                                                                                                                                                               |

### 3. Fault tolerance list of Sink

| Sinks             | Supported Output Mode    | Supported Options                                                                                                                                                                                      | Fault Tolerance            | Description                                                                                                                                                                                                                                                      |
|-------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| File Sink         | Append                   | <b>Path:</b> The specified file format must be specified.<br>For details, see APIs in DataFrameWriter .                                                                                                | exactly-once               | Data can be written to partition tables. Time-based partition is better.                                                                                                                                                                                         |
| Kafka Sink        | Append, Update, Complete | For details, see <a href="https://spark.apache.org/docs/3.3.1/structured-streaming-kafka-integration.html">https://spark.apache.org/docs/3.3.1/structured-streaming-kafka-integration.html</a> .       | at-least-once              | For details, see <a href="https://spark.apache.org/docs/3.3.1/structured-streaming-kafka-integration.html">https://spark.apache.org/docs/3.3.1/structured-streaming-kafka-integration.html</a> .                                                                 |

## 1.21.5.5 FAQ

### 1.21.5.5.1 How to Add a User-Defined Library

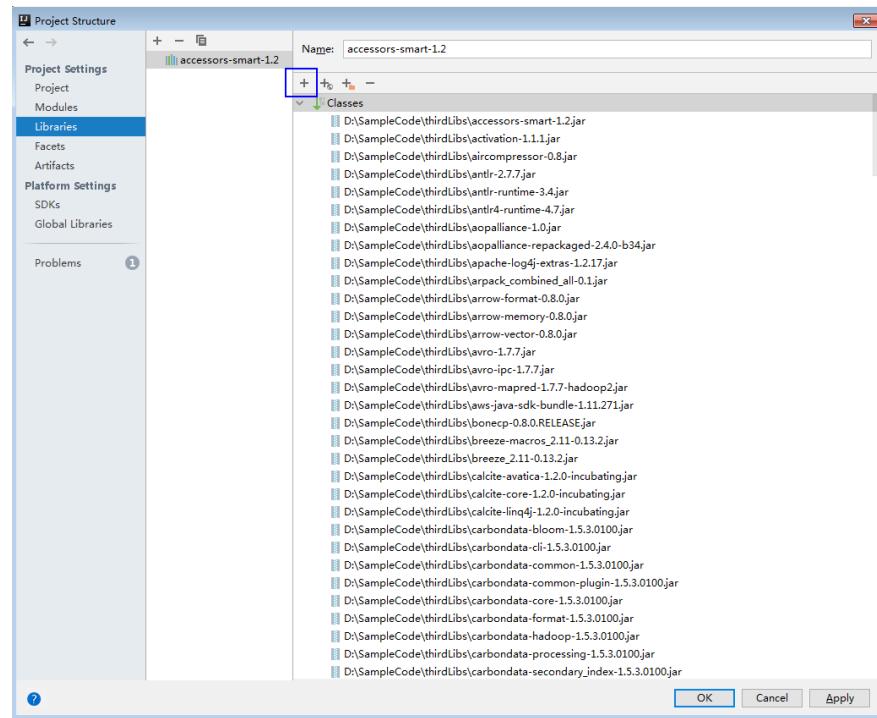

#### Question

In the development of the Spark application, users may add a user-defined dependent library which is different from the sample project. This section describes how to add a dependent library with user-defined codes into the project.

#### Answer

- Step 1** On the main page of the IDEA, choose **File > Project Structures...** to access the **Project Structure** page.
- Step 2** Select the **Libraries** tab, click the icon "+" on the following page, and add the local dependent library.

Figure 1-301 Add the Dependent Library

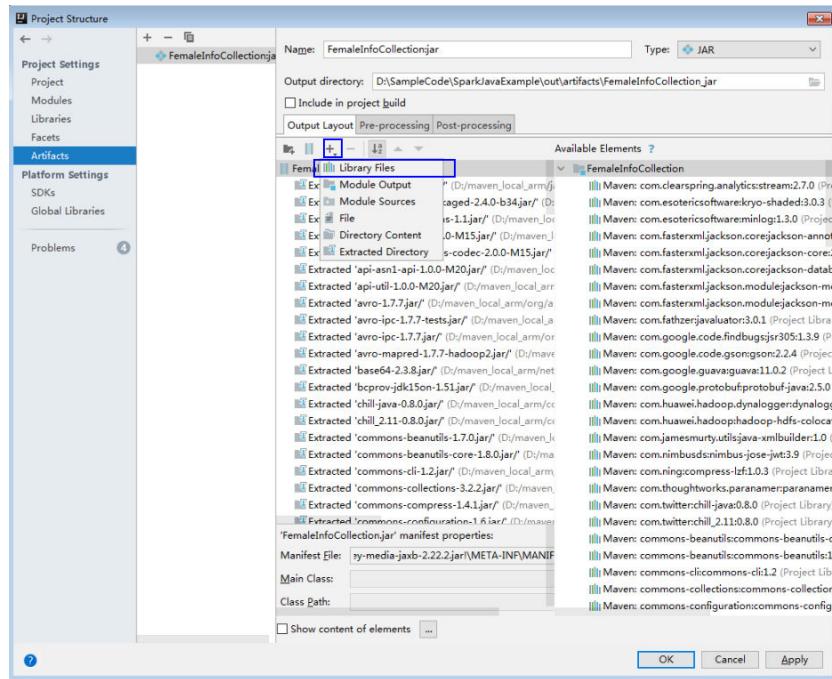

**Step 3** Click **Apply** to load the dependent library and click **OK** to complete the configuration.

**Step 4** Add the dependent library when building Artifacts. This is because the user-defined dependent library does not exist in the operating environment. By adding the library, the created jar contains the user-defined dependent library, which ensures that the Spark application runs properly.

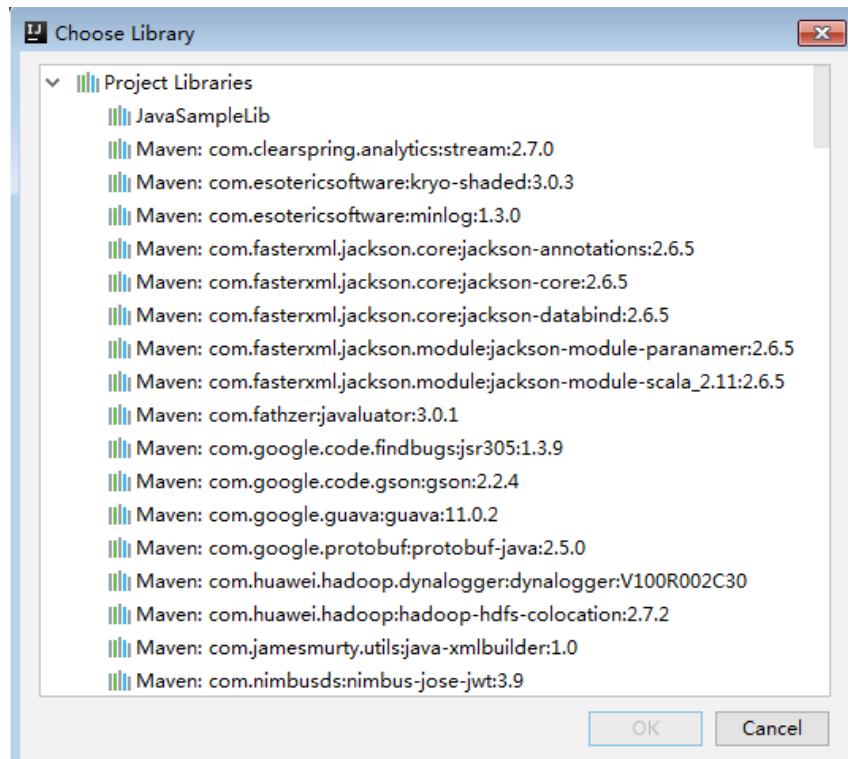

1. On the **Project Structure** page, select the **Artifacts** tab.
2. Click the icon "+" and select **Library Files** in the right window to add the dependent library.

**Figure 1-302 Add Library Files**

3. Choose the dependent library to be added and click **OK**.

**Figure 1-303 Choose Libraries**

4. Click **Apply** to load the dependent library and click **OK** to complete the configuration.

----End

### 1.21.5.5.2 How to Automatically Load Jars Packages?

#### Question

Before importing a project by using the IDEA tool, if Maven has been configured in the IDEA tool, the IDEA tool will automatically load the Jars packages in the Maven configuration. When the automatically loaded Jars packages do not match with the application, the project fails to be built. How to Automatically Load Jars Packages?

#### Answer

After a project is imported, to manually delete the automatically loaded Jars packages, perform the following steps:

1. On the IDEA tool, choose **File > Project Structures....**
2. Select **Libraries** and select the Jars packages that are automatically imported. Right-click the mouse and select **Delete**.

### 1.21.5.5.3 Why the "Class Does not Exist" Error Is Reported While the SparkStresmingKafka Project Is Running?

#### Question

While the KafkaWordCount task (`org.apache.spark.examples.streaming.KafkaWordCount`) is being submitted by running the `spark-submit` script, the log file shows that the Kafka-related class does not exist. The KafkaWordCount sample is provided by the Spark open-source community.

#### Answer

When Spark is deployed, the following JAR files are saved in the `$SPARK_HOME/jars/streamingClient010` directory on the client and the `$BIGDATA_HOME/FusionInsight_Spark_8.3.1/install/FusionInsight-Spark-3.3.1/spark/jars/streamingClient010` directory on the server.

- `kafka-clients-xxx.jar`
- `kafka_2.12-xxx.jar`
- `spark-streaming-kafka-xxx.cbu.mrs.xxx.jar`
- `spark-token-provider-kafka-xxx.cbu.mrs.xxx.jar`

Because `$SPARK_HOME/jars/streamingClient010/*` is not added in to classpath by default, you need to configure manually.

When the application is submitted and run, add following parameters in the command. See [Compiling and Running the Application](#).

`--jars $SPARK_CLIENT_HOME/jars/streamingClient010/kafka-client-2.4.0.jar,$SPARK_CLIENT_HOME/jars/streamingClient010/kafka_2.12-.jar,$SPARK_CLIENT_HOME/jars/streamingClient010/spark-streaming-kafka-xxx.cbu.mrs.xxx.jar`

You can run the preceding command to submit the self-developed applications and sample projects.

To submit the sample projects such as KafkaWordCount provided by Spark open source community, you need to add other parameters in addition to **--jars**. Otherwise, the `ClassNotFoundException` error will occur. The configurations in `yarn-client` and `yarn-cluster` modes are as follows:

- `yarn-client` mode

In the configuration file **spark-defaults.conf** on the client, add the path of the client dependency package, for example `$SPARK_HOME/jars/streamingClient010/*`, (in addition to **--jars**) to the **spark.driver.extraClassPath** parameter.

- `yarn-cluster` mode

Perform any one of the following configurations in addition to **--jars**:

- In the configuration file **spark-defaults.conf** on the client, add the path of the server dependency package, for example,  `${BIGDATA_HOME}/FusionInsight_Spark_8.3.1/install/FusionInsight-Spark-3.3.1/spark/jars/streamingClient010/*`, to the **spark.yarn.cluster.driver.extraClassPath** parameter.
- Delete the `original-spark-examples_2.12-3.3.1-xxx.jar` packages from all the server nodes.
- In the **spark-defaults.conf** configuration file on the client, modify (or add and modify) the parameter **spark.driver.userClassPathFirst** to **true**.

#### 1.21.5.5.4 Privilege Control Mechanism of SparkSQL UDF Feature

##### Question

What are the privilege control mechanism for UDF in SparkSQL?

##### Answer

When the SQL statement unable to meet user scenarios, the user can use the UDF feature to do the operations on HDFS or HBase data.

To ensure data security, SparkSQL UDF can only be used by admin users, meanwhile the users must make sure those self-defined functions do not contain malicious codes.

#### 1.21.5.5 Why Does Kafka Fail to Receive the Data Written Back by SLog in to the node where the client is installed as the client installation user.park Streaming?

##### Question

While a running Spark Streaming task is writing data back to Kafka, Kafka cannot receive the written data and Kafka logs contain the following error information:

```
2016-03-02 17:46:19,017 | INFO | [kafka-network-thread-21005-1] | Closing socket connection to /  
10.91.8.208 due to invalid request: Request of length  
122371301 is not valid, it is larger than the maximum size of 104857600 bytes. | kafka.network.Processor  
(Logging.scala:68)  
2016-03-02 17:46:19,155 | INFO | [kafka-network-thread-21005-2] | Closing socket connection to /  
10.91.8.208. | kafka.network.Processor (Logging.scala:68)
```

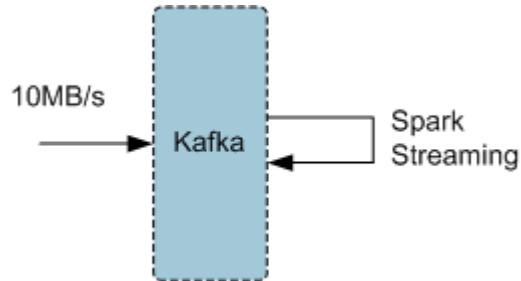

```
2016-03-02 17:46:19,270 | INFO | [kafka-network-thread-21005-0] | Closing socket connection to /  
10.91.8.208 due to invalid request:  
Request of length 122371301 is not valid, it is larger than the maximum size of 104857600 bytes. |

2016-03-02 17:46:19,763 | INFO | [kafka-network-thread-21005-2] | Closing socket connection to /  
10.91.8.208 due to invalid request:  
Request of length 122371301 is not valid, it is larger than the maximum size of 104857600 bytes. |  
kafka.network.Processor (Logging.scala:68)  
53393 [main] INFO org.apache.hadoop.mapreduce.Job - Counters: 50
```

## Answer

As shown in the figure below, the logic defined in Spark Streaming applications is as follows: reading data from Kafka -> executing processing -> writing result data back to Kafka.

Imagine that data is written into Kafka at a data rate of 10 MB/s, the interval (defined in Spark Streaming) between write-back operations is 60s, and a total of 600-MB data needs to be written back into Kafka. If Kafka defines that a maximum of 500-MB data can be received at a time, then the size of written-back data exceeds the threshold, triggering the error information.

**Figure 1-304 Application scenario**

Solution:

- Method 1: On Spark Streaming, reduce the interval between write-back operations to avoid the size of written-back data exceeding the threshold defined by Kafka. The recommended interval is 5-10 seconds.
- Method 2: Increase the threshold defined in Kafka. It is advisable to increase the threshold by adjusting the **socket.request.max.bytes** parameter of Kafka service on FusionInsight Manager.

### 1.21.5.5.6 Why a Spark Core Application Is Suspended Instead of Being Exited When Driver Memory Is Insufficient to Store Collected Intensive Data?

## Question

A Spark Core application is attempting to collect intensive data and store it into the Driver. When the Driver runs out of memory, the Spark Core application is suspended. Why does the Spark Core application not exit?

The following is the log information displayed at the time of out-of-memory (OOM) error.

```
16/04/19 15:56:22 ERROR Utils: Uncaught exception in thread task-result-getter-2

```

## Answer

If memory of the Driver is insufficient to store the intensive data that has been collected, the OOM error is reported and the Driver performs garbage collection repeatedly to reclaim the memory occupied by garbage. The Spark Core application remains suspended while garbage collection is under way.

If you expect the Spark Core application to exit forcibly in the event of OOM error, add the following information to the configuration option

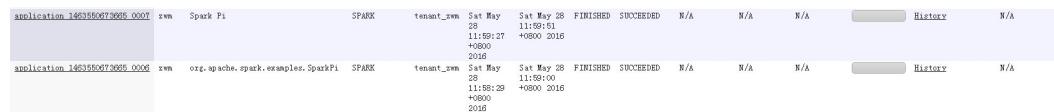

**spark.driver.extraJavaOptions** in the Spark client configuration file **\$SPARK\_HOME/conf/spark-defaults.conf** when you start the Spark Core application for the first time:  
`-XX:OnOutOfMemoryError='kill -9 %p'`

### 1.21.5.5.7 Why the Name of the Spark Application Submitted in Yarn-Cluster Mode Does not Take Effect?

#### Question

The name of the Spark application submitted in yarn-cluster mode does not take effect, whereas the Spark application name submitted in yarn-client mode takes effect. As shown in **Figure 1-305**, the first application is submitted in yarn-client mode and the application name **Spark Pi** takes effect. However, the setAppName execution sequence of a task submitted in yarn-client mode is different from that submitted in yarn-cluster mode.

**Figure 1-305** Submitting the application

#### Answer

The reason is that the setAppName execution sequence of a task submitted in yarn-client mode is different from that submitted in yarn-cluster mode. In yarn-client mode, the setAppName is read before the application is registered in yarn. However, in yarn-cluster mode, the setAppName is read after the application registers with yarn, so the name of the second application does not take effect.

#### Troubleshooting solution

When submitting tasks using the spark-submit script, set **--name** the same as the application name in sparkconf.setAppName (appname).

For example, if the application name is **Spark Pi**, run the following command to add the application name after **--name** when submitting the application in yarn-cluster mode:

```
./spark-submit --class org.apache.spark.examples.SparkPi --master yarn --deploy-mode cluster --name SparkPi jars/original-spark-examples*.jar 10
```

### 1.21.5.5.8 How to Perform Remote Debugging Using IDEA?

#### Question

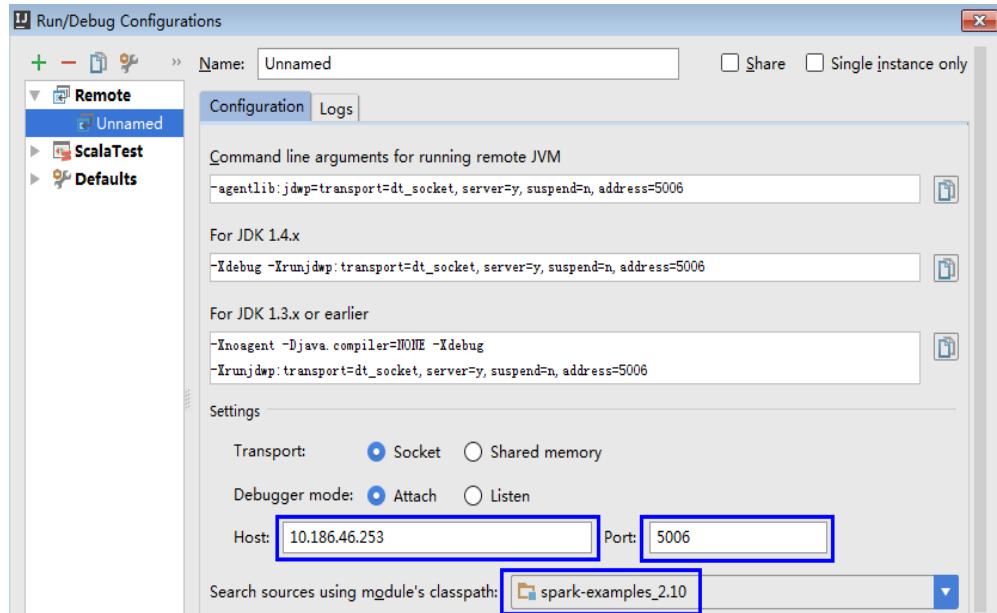

How to perform remote debugging using IDEA during Spark secondary development?

#### Answer

The SparkPi application is used as an example here to illustrate how to perform remote debugging using IDEA.

1. Open the project and choose **Run > Edit Configurations**.
2. In the displayed window, click  at the upper left corner, and then choose **Remote** on the drop-down menu, as shown in [Figure 1-306](#).

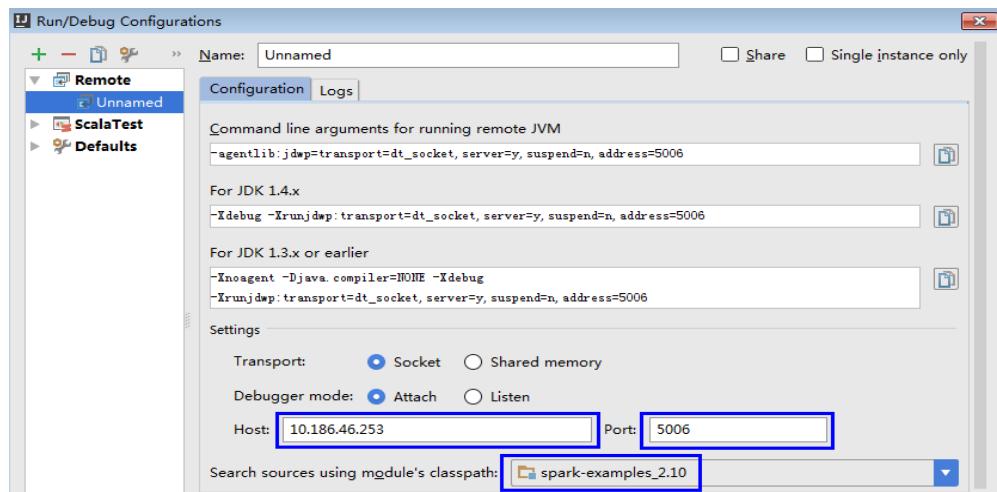

**Figure 1-306** Choosing **Remote**

3. Configure the **Host**, **Port**, and **Search source using module's classpath**, as shown in [Figure 1-307](#).

**Host** indicates the IP address of the Spark client and **Port** indicates the debugging port. Ensure that the port is available on the VM.

**Figure 1-307** Configuring parameters

 NOTE

If the value of **Port** is changed, the debugging command of **For JDK1.4.x** must be changed accordingly. For example, if the value of **Port** is changed to **5006**, the debugging command must be changed to **-Xdebug -Xrunjdwp:transport=dt\_socket,server=y,suspend=y,address=5006**, which will be used during the startup of Spark.

- Run the following command to remotely start SparkPi on the Spark client:

```
./spark-submit --master yarn-client --driver-java-options "-Xdebug -Xrunjdwp:transport=dt_socket,server=y,suspend=y,address=5006" --class org.apache.spark.examples.SparkPi /opt/Fl-Client/Spark/spark/examples/jars/spark-examples_2.12-3.3.1-xxx.jar
```

Change the **--class** and JAR package in the preceding command to the **--class** and JAR package of the actual application. Change the **-Xdebug -Xrunjdwp:transport=dt\_socket,server=y,suspend=y,address=5006** to the **For JDK1.4.x** debugging command obtained in **3**.

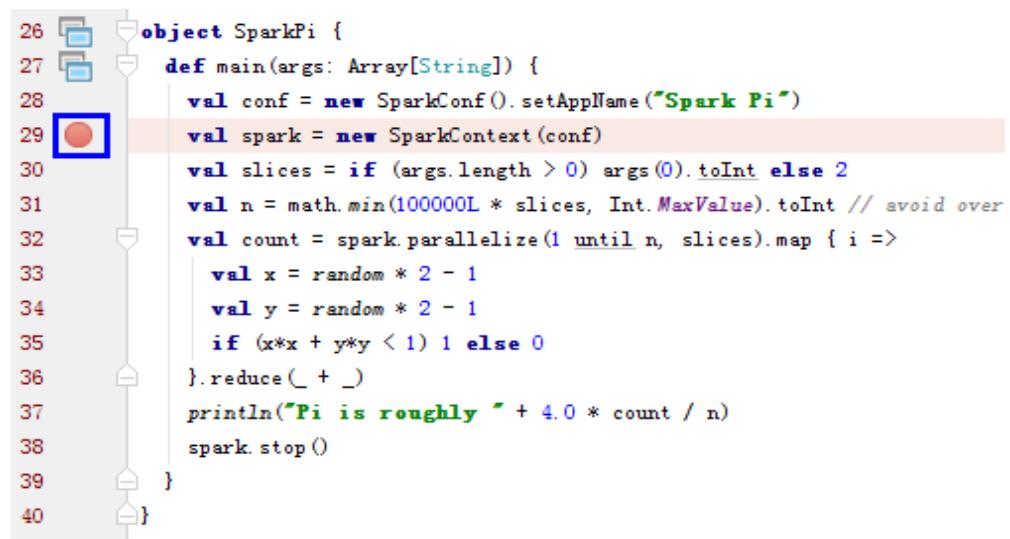

**Figure 1-308** Command for running Spark

```
[root@host2 bin]# ./spark-submit --master yarn-client --driver-java-options "-Xdebug -Xrunjdwp:transport=dt_socket,server=y,suspend=y,address=5006" --class org.apache.spark.examples.SparkPi /opt/client/Spark2x/spark/examples/jars/spark-examples_2.11-2.1.0.jar
Listening for transport dt_socket at address: 5006
```

- Set the debugging breakpoint.

Click the blank area on the left of the code editing window to select the breakpoint of code. **Figure 1-309** illustrates how to select the breakpoint of the code in row 29 of **SparkPi.scala**.

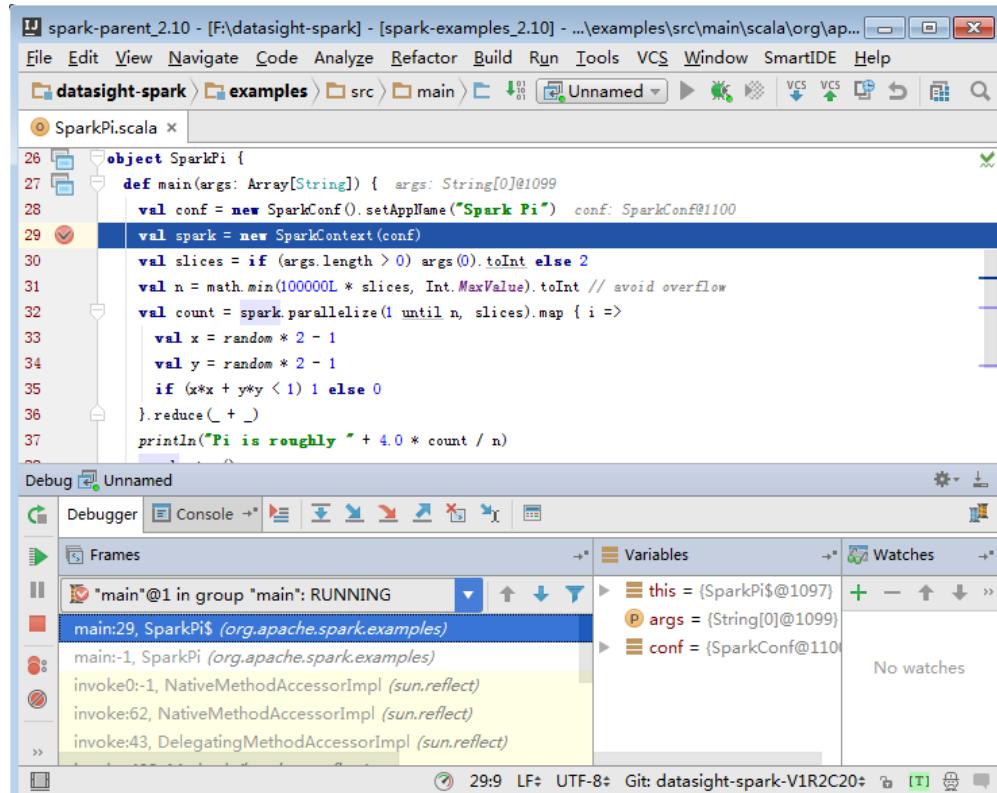

**Figure 1-309** Setting the breakpoint

- Start the debugging.

On the menu bar of IDEA, choose **Run > Debug 'Unnamed'** to open a debugging window. Start the debugging of **SparkPi**, for example, performing step-by-step debugging, checking call stack information, and tracking variable values, as shown in **Figure 1-310**.

Figure 1-310 Debugging

### 1.21.5.5.9 How to Submit the Spark Application Using Java Commands?

#### Question

How to submit the Spark application using Java commands in addition to spark-submit commands?

#### Answer

Use the org.apache.spark.launcher.SparkLauncher class and run Java command to submit the Spark application. The procedure is as follows:

**Step 1** Define the org.apache.spark.launcher.SparkLauncher class. The SparkLauncherJavaExample and SparkLauncherScalaExample are provided by default as sample codes. You can modify the input parameters of sample codes as required.

- If you use Java as the development language, you can compile the SparkLauncher class by referring to the following code:

```
public static void main(String[] args) throws Exception {
    System.out.println("com.huawei.bigdata.spark.examples.SparkLauncherExample <mode>
<jarPath> <app_main_class> <appArgs>");
    SparkLauncher launcher = new SparkLauncher();
    launcher.setMaster(args[0])
        .setAppResource(args[1]) // Specify user app jar path
        .setMainClass(args[2]);
    if (args.length > 3) {
        String[] list = new String[args.length - 3];
        for (int i = 3; i < args.length; i++) {
            list[i-3] = args[i];
        }
    }
}
```

```
// Set app args
launcher.addAppArgs(list);
}

// Launch the app
Process process = launcher.launch();
// Get Spark driver log
new Thread(new ISRRunnable(process.getErrorStream())).start();
int exitCode = process.waitFor();
System.out.println("Finished! Exit code is " + exitCode);
}
```

- If you use Scala as the development language, you can compile the `SparkLauncher` class by referring to the following code:

```
def main(args: Array[String]) {
    println(s"com.huawei.bigdata.spark.examples.SparkLauncherExample <mode> <jarPath>
<app_main_class> <appArgs>")
    val launcher = new SparkLauncher()
    launcher.setMaster(args(0))
    .setAppResource(args(1)) // Specify user app jar path
    .setMainClass(args(2))
    if (args.drop(3).length > 0) {
        // Set app args
        launcher.addAppArgs(args.drop(3): _*)
    }

    // Launch the app
    val process = launcher.launch()
    // Get Spark driver log
    new Thread(new ISRRunnable(process.getErrorStream())).start()
    val exitCode = process.waitFor()
    println(s"Finished! Exit code is $exitCode")
}
```

**Step 2** Develop the Spark application based on the service logic and configure constant values such as the main class of the user-compiled Spark application. For details about different scenarios, see [Developing the Project](#).

- If you use the security mode, you are advised to prepare the security authentication code, service application code, and related configurations according to the security requirements.

#### NOTE

In yarn-cluster mode, security authentication cannot be added to the Spark project. Therefore, users need to add security authentication code or run commands to perform security authentication. There is security authentication code in the sample code. In yarn-cluster mode, modify the corresponding security code before running the operation.

- In normal mode, prepare the service application code and related configurations.

**Step 3** Call the `org.apache.spark.launcher.SparkLauncher.launch()` function to submit user applications.

1. Generate jar packages from the `SparkLauncher` application and user applications, and upload the jar packages to the Spark node of the application. For details about how to generate jar packages, see [Compiling and Running the Application](#).
  - The compilation dependency package of `SparkLauncher` is **spark-launcher\_xxx.cbu.mrs.xxx.jar**. Please obtain it from the **jars** directory of **FusionInsight\_Spark\_8.3.1.tar.gz** in **Software**.

- The compilation dependency packages of user applications vary with the code. You need to load the dependency package based on the compiled code.
- 2. Upload the dependency jar package of the application to a directory, for example, **\$SPARK\_HOME/jars** (the node where the application will run).  
Upload the dependency packages of the SparkLauncher class and the application to the **jars** directory on the client. The dependency package of the sample code has existed in the **jars** directory on the client.

 **NOTE**

If you want to use the Spark Launcher class, the node where the application runs must have the Spark client installed. The running of the Spark Launcher class is dependent on the configured environment variables, running dependency package, and configuration files.

- 3. In the node where the Spark application is running, run the following command to submit the application. Then you can check the running situation through Spark web UI and check the result by obtaining specified files. See [Checking the Commissioning Result](#) for details.

```
java -cp $SPARK_HOME/conf:$SPARK_HOME/jars/  
*:SparkLauncherExample.jar  
com.huawei.bigdata.spark.examples.SparkLauncherExample yarn-  
client /opt/female/FemaleInfoCollection.jar  
com.huawei.bigdata.spark.examples.FemaleInfoCollection <inputPath>
```

----End

### 1.21.5.5.10 A Message Stating "Problem performing GSS wrap" Is Displayed When IBM JDK Is Used

#### Question

A Message Stating "Problem performing GSS wrap" Is Displayed When IBM JDK Is Used.

#### Answer

##### Possible Causes

The authentication fails because the duration for creating a JDBC connection on IBM JDK exceeds the timeout duration for user authentication (one day by default).

 **NOTE**

The authentication mechanism of IBM JDK differs from that of Oracle JDK. IBM JDK checks time but does not detect external time update. Therefore, time is not updated even though **relogin** is called.

##### Solution

When one JDBC connection fails, disable this connection, and create a new connection to continue performing previous operations.

### 1.21.5.5.11 Application Fails When ApplicationManager Is Terminated During Data Processing in the Cluster Mode of Structured Streaming

#### Question

If ApplicationManager is terminated during data processing in the cluster mode of Structured Streaming, the following information is displayed when the application is executed, indicating an error:

```
2017-05-09 20:46:02,393 | INFO | main |
  client token: Token { kind: YARN_CLIENT_TOKEN, service: }
  diagnostics: User class threw exception: org.apache.spark.sql.AnalysisException: This query does not
  support recovering from checkpoint location. Delete hdfs://hacluster/structuredtest/checkpoint/offsets to
  start over;
  ApplicationMaster host: 10.96.101.170
  ApplicationMaster RPC port: 0
  queue: default
  start time: 1494333891969
  final status: FAILED
  tracking URL: https://9-96-101-191:26001/proxy/application_1493689105146_0052/
  user: spark2x | org.apache.spark.internal.Logging$class.logInfo(Logging.scala:54)
Exception in thread "main" org.apache.spark.SparkException: Application application_1493689105146_0052
finished with failed status
```

#### Answer

**Possible causes:** The error occurs because **recoverFromCheckpointLocation** is determined as **false** but the checkpoint directory is configured.

The value of the **recoverFromCheckpointLocation** parameter is the result of the **outputMode == OutputMode.Complete()** statement in the code. (The default **outputMode** is **append**.)

**Solution:** When compiling an application, you can change the data output mode based on the actual conditions. For operations to change the output mode by calling **outputMode**, see the **outputMode** description of **Spark > Scala** in *MapReduce Service (MRS) 3.3.1-LTS Manager Rest API Reference (for Huawei Cloud Stack 8.3.1)*.

When the output mode is changed to **complete**, the value of **recoverFromCheckpointLocation** is determined as **true**. No error would be indicated if the checkpoint directory is configured at the time.

### 1.21.5.5.12 Restrictions on Restoring the Spark Application from the checkpoint

#### Question

The Spark application can be restored from the checkpoint and continues to execute the task from the breakpoint of the last task, ensuring that data is not lost. However, in some cases, the Spark application fails to be restored from the checkpoint.

#### Answer

The checkpoint contains the object serialization information, task execution status information, and configuration information of the Spark application. Therefore, the Spark application cannot be restored from the checkpoint if the following problems exist:

1. The service code is changed and the serialVersionUID is not specified in the changed class.
2. The internal Spark class is changed and the serialVersionUID is not specified in the changed class.

Besides, some configuration items are stored in the checkpoint. Therefore, if some configuration items of the service are modified, the configuration items may remain unchanged when the service is restored from the checkpoint. Currently, only the following configurations are reloaded when the service is restored from the checkpoint.

```
"spark.yarn.app.id",
"spark.yarn.app.attemptId",
"spark.driver.host",
"spark.driver.bindAddress",
"spark.driver.port",
"spark.master",
"spark.yarn.jars",
"spark.yarn.keytab",
"spark.yarn.principal",
"spark.yarn.credentials.file",
"spark.yarn.credentials.renewalTime",
"spark.yarn.credentials.updateTime",
"spark.ui.filters",
"spark.mesos.driver.frameworkId",
"spark.yarn.jars"
```

## Solution

Manually delete the checkpoint directory and restart the service program.

Deleting a file is a high-risk operation. Ensure that the files are no longer needed before performing this operation.

### 1.21.5.5.13 Support for Third-party JAR Packages on x86 and TaiShan Platforms

#### Question

How to enable Spark to support the third-party JAR packages (for example, custom UDF packages) if these packages have two versions (x86 and TaiShan)?

#### Answer

Use the hybrid solution.

- Step 1** Go to the installation directory of the Spark SparkResource on the server. The cluster may be installed on multiple nodes. You can go to any SparkResource node to go to the installation directory of the SparkResource.
- Step 2** Prepare the .jar package, for example, xx.jar packages for the x86 and TaiShan platforms. Copy the xx.jar packages of x86 and TaiShan to the x86 and TaiShan folders respectively.
- Step 3** Run the following commands in the current directory to compress the JAR packages:

```
zip -qDj spark-archive-x86.zip x86/*
```

```
zip -qDj spark-archive-arm.zip arm/*
```

```
total 20210

rw----- 1 omm wheel      244 Dec 14 17:57 version.properties
lwx----- 2 omm wheel      63 Dec 14 17:57 x86
lwx----- 2 omm wheel      42 Dec 14 17:54 yarn
```

- Step 4** Run the following command to check the .jar package on which the Spark of HDFS depends:

```
hdfs dfs -ls /user/spark/jars/8.3.1
```

Change the version number 8.3.1 as required.

Run the following commands to move the .jar package files from HDFS, for example, **/tmp**.

```
hdfs dfs -mv /user/spark/jars/8.3.1/spark-archive-arm.zip /tmp
```

```
hdfs dfs -mv /user/spark/jars/8.3.1/spark-archive-x86.zip /tmp
```

- Step 5** Run the following commands to upload the **spark-archive-arm.zip** and **spark-archive-x86.zip** packages in [Step 3](#) to the **/user/spark/jars/8.3.1** directory of HDFS:

```
hdfs dfs -put spark-archive-arm.zip /user/spark/jars/8.3.1/
```

```
hdfs dfs -put spark-archive-x86.zip /user/spark/jars/8.3.1/
```

After the upload is complete, delete local files **spark-archive-arm.zip** and **spark-archive-x86.zip**.

- Step 6** Perform [Step 1](#) to [Step 2](#) for other SparkResource nodes.

- Step 7** Log in to the web UI and restart the jdbcServer instance of Spark.

- Step 8** After the restart, update the client configuration. Copy *xx.jar* for the corresponding platform to the Spark installation directory  **\${install\_home}/Spark/spark/jars** on the client according to client server type (x86 or TaiShan).  **\${install\_home}** indicates the installation path of the client. Replace it with the actual one. If the local installation directory is **/opt/hadoopclient**, copy the corresponding *xx.jar* to the **/opt/hadoopclient/Spark/spark/jars** folder.

----End

### 1.21.5.5.14 What Should I Do If a Large Number of Directories Whose Names Start with **blockmgr-** or **spark-** Exist in the /tmp Directory on the Client Installation Node?

#### Question

After the system runs for a long time, there are many directories whose names start with **blockmgr-** or **spark-** in the **/tmp** directory on the node where the client is installed.

**Figure 1-311** Residual directory example

```
blockmgr-934dc20a-d5f0-4adf-a28f-c376ef0fe01d  
blockmgr-f514f38b-209c-4a65-985a-2a6c61d0ee00  
spark-33f95b4b-be82-4290-bde3-07b76c797085  
spark-988e28a7-0416-4115-8d6e-3a62a75f1f46
```

#### Answer

During the running of Spark tasks, the driver creates a local temporary directory whose name starts with **spark-** for storing service JAR packages and configuration files. In addition, the driver creates a local temporary directory with the name starting with **blockmgr-** for storing block data. The two directories are automatically deleted when the Spark application running is finished.

The path for storing the two directories is preferentially specified by the environment variable **SPARK\_LOCAL\_DIRS**. If the environment variable is not configured, use the value of **spark.local.dir** as the path for storing the directories. If the environment variable and the preceding parameter both are not configured, use the value of **java.io.tmpdir**. By default, **spark.local.dir** is set to **/tmp** on the client. Therefore, the **/tmp** directory is used by default.

In some special cases, for example, the driver process does not exit normally, for example, the **kill -9** command ends the process, or the Java virtual machine crashes. As a result, the directory cannot be deleted and remains in the system.

Currently, only the driver processes in yarn-client mode and local mode may confront the preceding problem. In yarn-cluster mode, the temporary directory of the process in the container is configured as the temporary directory of the container. When the container exits, the container automatically clears the directory. Therefore, this problem does not occur in yarn-cluster mode.

#### Solution

In Linux, you can configure automatic directory clearing for the **/tmp** temporary directory. Alternatively, you can change the value of **spark.local.dir** in the **spark-defaults.conf** configuration file on the client, specify the temporary directory to a specified directory, and configure a clear mechanism for the directory.

### 1.21.5.5.15 Error Code 139 Is Reported When Python Pipeline Runs in the Arm Environment

#### Question

Error code 139 is displayed when the pipeline of the Python plug-in is used on the TaiShan server. The error information is as follows:

```
subprocess exited with status 139
```

#### Answer

The python program uses both **libcrypto.so** and **libssl.so**. If the native library directory of Hadoop is added to **LD\_LIBRARY\_PATH**, the **libcrypto.so** in the **hadoop native** library is used and the **libssl.so** provided by the system is used (because the **hadoop native** directory does not contain this package). The versions of the two libraries do not match. As a result, a segment error occurs when the Python file is running.

#### Solution

Modify the **spark-default.conf** file in the **conf** directory of the Spark client. Clear the values of **spark.driver.extraLibraryPath**, **spark.yarn.cluster.driver.extraLibraryPath**, and **spark.executor.extraLibraryPath**.

### 1.21.5.5.16 What Should I Do If the Structured Streaming Task Submission Way Is Changed?

#### Question

When submitting a structured streaming task, users need to run the **--jars** command to specify the Kafka JAR package path, for example, **--jars /kafkadir/kafka-clients-x.x.x.jar,/kafkadir/kafka\_2.11-x.x.x.jar**. However, in the current version, users need to configure additional items. Otherwise, an error is reported, indicating that the class is not found.

#### Answer

The Spark kernel of the current version depends on the Kafka JAR package, which is used by the structured streaming. Therefore, when submitting a structured streaming task, you need to add the Kafka JAR package path to the library directory of the driver of this task to ensure that the driver can properly load the Kafka package.

#### Solution

1. The following operations need to be performed additionally when a structured streaming task in Yarn-client mode is submitted:

Copy the path of **spark.driver.extraClassPath** in the **spark-default.conf** file in the Spark client directory, and add the Kafka JAR package path to its end. When submitting a structured stream task, add the **--conf** statement to combine these two configuration items. For example, if the Kafka JAR package path is **/kafkadir**, you need to add **--conf**

- spark.driver.extraClassPath=/opt/hadoopclient/Spark/spark/conf:/opt/hadoopclient/Spark/spark/jars/\*:/opt/hadoopclient/Spark/spark/x86/\*:/kafkadir/\*** when submitting the task.
2. The following operations need to be performed additionally when a structured streaming task in **Yarn-cluster** mode is submitted:  
Copy the path of **spark.yarn.cluster.driver.extraClassPath** in the **spark-default.conf** file in the Spark client directory, and add relative paths of Kafka JAR packages to its end. When submitting a structured stream task, add the **--conf** statement to combine these two configuration items. For example, if the Kafka JAR package paths are **kafka-clients-x.x.x.jar** and **kafka\_2.11-x.x.x.jar**, you need to add **--conf spark.yarn.cluster.driver.extraClassPath=/home/huawei/Bigdata/common/runtime/security:/kafka-clients-x.x.x.jar:/kafka\_2.11-x.x.x.jar** when submitting the task.
  3. In the current version, the structured streaming of Spark does not support versions earlier than Kafka2.x. In the upgrade scenario, use the client of earlier versions.

## 1.21.5.5.17 Migrating Spark Streaming's Interconnection from Kafka 0.8 to Kafka 0.10

### Overview

Kafka 0.8 is not recommended for interconnection with Spark 2.3, and is not supported in Spark 3.0.0. If **spark-streaming-kafka-0-8** is used in Spark Streaming after Spark 2.3 is upgraded to Spark 3.1.1, you need to change the dependency to **spark-streaming-kafka-0-10** after the upgrade.

### Difference Analysis

- Maven dependency versions  
After Spark Streaming is interconnected to **spark-streaming-kafka-0-10**, the Maven dependency versions in the code change. The related dependencies are as follows:  
**org.apache.spark:**
  - **spark-core\_2.11:** Change **artifactId** to **spark-core\_2.12** as Scala is upgraded to 2.12.
  - **spark-streaming\_2.11:** Change **artifactId** to **spark-streaming\_2.12** as Scala is upgraded to 2.12.
  - **spark-streaming-kafka-0-8\_2.11:** Replace this with **spark-streaming-kafka-0-10\_2.12**.
  - **spark-streaming-kafkaWriter-0-8\_2.11:** Replace this with **spark-streaming-kafkaWriter-0-10\_2.12**.  
**org.apache.kafka:**
  - **kafka\_2.11:** Upgrade from version 0.8.2.1 to the corresponding version of the cluster.
  - **kafka-clients:** Add this dependency, and its version number should be the same as that of the cluster.
- Related interfaces

**spark-streaming-kafka-0-8** can obtain data from Kafka APIs **Receiver-based Approach** and **Direct Approach (No Receivers)**. In **spark-streaming-kafka-0-10**, only the method using **Direct Approach** is retained.

Differences exist in related APIs. For details, see the sample code **SparkStreamingKafka010ScalaExample** and **SparkStreamingKafka010JavaExample**

- Job submission mode

In security mode, **spark-streaming-kafka-0-8** does not support security authentication, but **spark-streaming-kafka-0-10** does. Security authentication is required when **spark-streaming-kafka-0-10** is used for task submission.

## Solution

- Maven dependency versions

Change the dependency versions referenced in the code. Add dependencies if no one exists.

### **org.apache.spark**

- **spark-core\_2.11**: Change **artifactId** to **spark-core\_2.12** and upgrade its version number to the one of the cluster as Scala is upgraded to 2.12.
- **spark-streaming\_2.11**: Change to **spark-streaming\_2.12**, change the version number to the one of Spark in the cluster, and upgrade the version number to the one of the cluster.
- **spark-streaming-kafka-0-8\_2.11**: Replace it with **spark-streaming-kafka-0-10\_2.12**, change the version number to the one of Spark in the cluster, and upgrade the version number to the one of the cluster.
- **spark-streaming-kafkaWriter-0-8\_2.11**: Replace it with **spark-streaming-kafkaWriter-0-10\_2.12**, change the version number to the one of Spark in the cluster, and upgrade the version number to the one of the cluster.

### **org.apache.kafka**

- **kafka\_2.11**: Change the version number from 0.8.2.1 to the one of Kafka in the cluster.
- **kafka-clients**: Add this dependency, and its version number should be the same as that of the cluster.

- For details about related APIs, see the sample code **SparkStreamingKafka010ScalaExample** and **SparkStreamingKafka010JavaExample**.

- Job submission mode

For clusters in security mode, configure security authentication as follows:

- Set the **allow.everyone.if.no.acl.found** parameter of Kafka Broker to **true**.
- Start Kafka producers. Brokers need to use port **21005**, for example, **IP address of the Kafka service Broker instance:21005**.
- The path of Spark Streaming's Kafka dependency package on the client is different from that of other dependency packages. For example, the path of other dependency packages is **\$SPARK\_HOME/jars**, and the path of the Kafka dependency package is **\$SPARK\_HOME/jars/**

**streamingClient010**. Therefore, when running an application, you need to add a configuration item to the **spark-submit** command to specify the path of the Spark Streaming's Kafka dependency package, for example, **--jars \${files=(\$SPARK\_HOME/jars/streamingClient010/\*.jar);IFS=;echo "\${files[\*]}"}**.

- The running sample depends on the **kafka-clients** component. Therefore, if there is no **kafka-clients-xxx.jar** package in the **\$CLIENT/Spark/spark/jars** directory, copy the **kafka-clients-xxx.jar** file from the **\$CLIENT/Spark/spark/jars/streamingClient010** directory to the **\$CLIENT/Spark/spark/jars** directory. Download the JAR file of the **spark-streaming-kafkaWriter-0-10** cluster version from the Maven repository and save the file to the **\$CLIENT/Spark/spark/jars/streamingClient010** directory.
- When you run the sample, an error is reported indicating that the class does not exist. For details, see [Why the "Class Does not Exist" Error Is Reported While the SparkStresmingKafka Project Is Running?](#).
- New configurations need to be added and command parameters need to be modified.
  - Add the following configuration to the **\$SPARK\_HOME/conf/jaas.conf** file:

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=false  
    useTicketCache=true  
    debug=false;  
};
```
  - Add the following configuration to the **\$SPARK\_HOME/conf/zk.conf** file:

```
KafkaClient {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=true  
    keyTab="/user.keytab"  
    principal=<Username>@<System domain name>  
    useTicketCache=false  
    storeKey=true  
    debug=true;  
};
```

Use the **SASL\_PLAINTEXT** protocol port number (for example, **10.111.111.111:21007**) for brokers when consumers are started.

Use the **--files** command to specify the **jaas.conf** and **keytab** files, for example, **--files ./jaas.conf, ./user.keytab**.

## 1.22 YARN Development Guide

## 1.22.1 Overview

### Intended Audience

This document is intended for development personnel who are experienced in Java development and want to develop YARN applications.

### YARN Introduction

YARN is a distributed resource management system that is used to improve resource usage in the distributed cluster environment. Resources include memory, I/O, network, and disk resources. YARN is developed to address the shortage of the original MapReduce framework. At the beginning, MapReduce committers periodically modified existing codes. As codes increase and because the original MapReduce framework was designed improperly, modification on the original MapReduce framework becomes more difficult. Therefore, MapReduce committers decided to re-design the MapReduce framework to provide a next-generation MapReduce (MRv2/Yarn) framework that supports high scalability, availability, reliability, backward compatibility, and resource usage. The next-generation MapReduce (MRv2/Yarn) framework supports more computing frameworks in addition to the MapReduce framework.

### Basic Concepts

- **ResourceManager (RM)**

ResourceManager is a global resource manager that manages and allocates resources in the system. ResourceManager consists of two components: Scheduler and Applications Manager.

- **ApplicationMaster (AM)**

Each application submitted by users includes an ApplicationMaster. The ApplicationMaster provides the following functions:

- Negotiates with the ResourceManager Scheduler to obtain resources (represented by Containers).
- Allocates resource to internal tasks.
- Communicates with NodeManager to start or stop tasks.
- Monitors all tasks with the running status, and applies for resources again for tasks when tasks fail to run to restart the tasks.

- **NodeManager (NM)**

NodeManager is the resource and task manager of each node. On one hand, NodeManager periodically reports resource usage of the local node and the running status of each Container to ResourceManager. On the other hand, NodeManager receives and processes requests from ApplicationMaster for starting or stopping Containers.

- **Container**

Container is a resource abstract in YARN. Container encapsulates multidimensional resources of a node, such as memory, CPU, disk, and network resources. When ApplicationMaster applies for resources from ResourceManager, ResourceManager returns resources in a Container to ApplicationMaster.

## 1.22.2 Interfaces

### 1.22.2.1 Command

You can use YARN commands to perform operations on YARN clusters, such as starting ResourceManager, submitting applications, killing applications, querying node status, and downloading container logs.

For details about the commands, see:

<http://hadoop.apache.org/docs/r3.3.1/hadoop-yarn/hadoop-yarn-site/YarnCommands.html>

### Common Commands

YARN commands can be used by common users and administrators. Common users can run a few of YARN commands, such as **jar** and **logs**. Administrators have the permission to run most YARN commands.

Users can run the following command to query usage of YARN.

**yarn --help**

Usage: Go to any directory on the YARN client, execute source command to import the environment variables, and run the command. The command format is as follows.

**yarn [--config confdir] COMMAND**

**Table 1-205** describes the commands.

The version 8.3.1 is used as an example. Replace it with the actual version number.

**Table 1-205** Common commands

| Command         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| rmadmin                      | Runs administrator's tool for dynamically updating information.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| version                      | Displays the version.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| jar <jar>                    | Runs a JAR file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| logs                         | Obtains container logs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| classpath                    | Displays the class path of the Hadoop JAR package and other library files.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| daemonlog                    | Obtains or sets the service log level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CLASSNAME                    | Runs a class named by <i>CLASSNAME</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| top                          | Runs the cluster usage monitor tool.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| -Dmapreduce.job.hdfs-servers | <p>If OBS is connected, but the server still uses HDFS, you need to explicitly use this parameter in the command line to specify the HDFS address. The format is <code>hdfs:// {NAMESERVICE}</code>. Replace <i>NAMESERVICE</i> with the HDFS NameService name.</p> <p>If the current HDFS has multiple NameService instances, you need to specify all NameService instances and separate them with commas (,), for example, <code>hdfs://nameservice1,hdfs://nameservice2</code>.</p>                            |

## Superior Scheduler Command

Superior Scheduler Engine provides a CLI that displays detail information of Superior Scheduler Engine. For executing superior command we need to use the "`<HADOOP_HOME>/bin/superior`" script.

Here is the format of "superior" command.

```
<HADOOP_HOME>/bin/superior

Usage: superior [COMMAND | -help]
Where COMMAND is one of:
resourcepool      prints resource pool status
queue            prints queue status
```

|                    |                                                   |
|--------------------|---------------------------------------------------|
| application policy | prints application status<br>prints policy status |
|--------------------|---------------------------------------------------|

Most commands print help when invoked without parameters.

- Superior **resourcepool** command:

This command displays resourcepool and associated policy related status and configuration information.

#### NOTE

Superior resourcepool command can be used only by admin user and user with yarn admin rights.

Usage output:

```
>superior resourcepool

Usage: resourcepool [-help]
                  [-list]
                  [-status <resourcepoolname>]
-helpprints resource pool usage
-listprints all resource pool summary report
-status <resourcepoolname> prints status and configuration of specified
resource pool
```

- **resourcepool -list** prints resource pool summary in a table format. Here is an example:

```
> superior resourcepool -list
NAME      NUMBER_MEMBER   TOTAL_RESOURCE      AVAILABLE_RESOURCE
Pool1      4              vcores 30,memory 1000  vcores 21,memory 80
Pool2      100             vcores 100,memory 12800 vcores 30,memory 1000
default    2              vcores 64,memory 128   vcores 40,memory 28
```

- **resourcepool -status <resourcepoolname>** prints resource pool detail information in a list format. Here is an example:

```
> superior resourcepool -status default
NAME: default
DESCRIPTION: System generated resource pool
TOTAL_RESOURCE: vcores 64,memory 128
AVAILABLE_RESOURCE: vcores 40,memory 28
NUMBER_MEMBER: 2
MEMBERS: node1,node2
CONFIGURATION:
|-- RESOURCE_SELECT:
|__ RESOURCES:
```

- Superior **queue** command

This command displays hierarchy queue information.

Usage output:

```
>superior queue

Usage: queue [-help]
              [-list] [-e] [[-name <queue_name>] [-r|-c]]
              [-status <queue_name>]
-c           only work with -name <queue_name> option. If this
option is used, command will print information of
specified queue and its direct children.
-e           only work with -list or -list -name option. If
this option is used, command will print effective
state of specified queue and all of its
descendants.
-help        prints queue sub command usage
-list       prints queue summary report. This option can work
with -name <queue_name> and -r options.
-name <queue_name> print specified queue, this can work with -r
option. By default, it will print queue's own
```

- information. When -r is defined, command will print all of its descendant queues. When -c is defined, it will print its direct children queues.
- r only work with -name <queue\_name> option. If this option is used, command will print information of specified queue and all of its descendants.
  - status <queue\_name> prints status of specified queue
  - **queue -list** prints a table format of queue summary information. When command displays, command will display them based on queue hierarchy fashion. With SUBMIT ACL or ADMIN ACL rights for queue, user will be able to see queues. Here is an example:  

```
> superior queue -list
NAME      STATE      NRUN_APP    NPEND_APP    NRUN_CONTAINER
NPEND_REQUEST  RES_INUSE      RES_REQUEST
root      OPEN|ACTIVE   10        20          100          200          vcores 100,memory
1000     vcores 200,memory 2000
root.Q1    OPEN|ACTIVE   5         10          50           100          vcores 50,memory
500      vcores 100,memory 1000
root.Q1.Q11 OPEN|ACTIVE   5         10          50           100          vcores 50,memory
500      vcores 100,memory 1000
root.Q1.Q12 CLOSE|INACTIVE 0         0           0            0            vcores 0,memory
0        vcores 0,memory 0
root.Q2    OPEN|INACTIVE 5         10          50           100          vcores 50,memory
500      vcores 100,memory 1000
root.Q2.Q21 OPEN|ACTIVE   5         10          50           100          vcores 50,memory
500      vcores 100,memory 1000
```
  - **queue -list -name root.Q1** will display root.Q1 only.  

```
> superior queue -list -name root.Q1
NAME      STATE      NRUN_APP    NPEND_APP    NRUN_CONTAINER
NPEND_REQUEST  RES_INUSE      RES_REQUEST
root.Q1    OPEN|ACTIVE   5         10          50           100          vcores 50,memory
500      vcores 100,memory 1000
```
  - **queue -list -name root.Q1 -r** will print out root.Q1 and all of its descendants.  

```
> superior queue -list -name root.Q1 -r
NAME      STATE      NRUN_APP    NPEND_APP    NRUN_CONTAINER
NPEND_REQUEST  RES_INUSE      RES_REQUEST
root.Q1    OPEN|ACTIVE   5         10          50           100          vcores 50,memory
500      vcores 100,memory 1000
root.Q1.Q11 OPEN|ACTIVE   5         10          50           100          vcores 50,memory
500      vcores 100,memory 1000
root.Q1.Q12 CLOSE|INACTIVE 0         0           0            0            vcores 0,memory
0        vcores 0,memory 0
```
  - **queue -list -name root -c** will print out root and all of its direct children  

```
> superior queue -list -name root -c
NAME      STATE      NRUN_APP    NPEND_APP    NRUN_CONTAINER
NPEND_REQUEST  RES_INUSE      RES_REQUEST
root      OPEN|ACTIVE   10        20          100          200          vcores
100,memory 1000  vcores 200,memory 2000
root.Q1    OPEN|ACTIVE   5         10          50           100          vcores
500      vcores 100,memory 1000
root.Q2    OPEN|INACTIVE 5         10          50           100          vcores
500      vcores 100,memory 1000
```
  - **queue -status <queue\_name>** will display detail queue status and configuration.  

With SUBMIT ACL, user will be able to see details except ACLS of queue. User with ADMIN ACL rights for queue will be able to see queue details including ACL.

```
> superior queue -status root.Q1
NAME: root.Q1
OPEN_STATE:CLOSED
ACTIVE_STATE: INACTIVE
EOPEN_STATE: CLOSED
```

```
EACTIVE_STATE: INACTIVE
LEAF_QUEUE: Yes
NUMBER_PENDING_APPLICATION: 100
NUMBER_RUNNING_APPLICATION: 10
NUMBER_PENDING_REQUEST: 10
NUMBER_RUNNING_CONTAINER: 10
NUMBER_RESERVED_CONTAINER: 0

```

- Superior ***application*** command

This command displays application related information.

Usage output:

```
>superior application

Usage: application [-help]
    [-list]
    [-status <application_id>]
-helpprints application sub command usage
-listprints all application summary report
-status <application_id> prints status of specified application
```

With the view access rights to application user can see application related information.

- ***application -list*** provides summary information of all application in a table format. Here is an example:

```
> superior application -list
   ID          QUEUE      USER  NRUN_CONTAINER
NPEND_REQUEST  NRSV_CONTAINER  RES_INUSE
RES_REQUEST    RES_RESERVED
application_1482743319705_0005  root.SEQ.queueB  hbase  1
100           0           vcores 1,memory 1536      vcores 2000,memory
409600         vcores 0,memory 0
application_1482743319705_0006  root.SEQ.queueB  hbase  0
1             0           vcores 0,memory 0      vcores 1,memory
1536          vcores 0,memory 0
```

- ***application -status <app\_id>*** command displays detail information of specified application. Here is an example:

```
> superior application -status application_1443067302606_0609
ID: application_1443067302606_0609

               summary information of resource pool
               distribution on queues, including reserve,
               minimum and maximum
-help          prints policy sub command usage
-list <resourcepoolname>  prints a summary information of resource
                           pool distribution on queue
-status <resourcepoolname> prints pool distribution policy
               configuration and status of specified
               resource pool
-u             only work with -list option to show a
               summary information of resource pool
               distribution on queues and also user
               accounts
```

- ***policy -list <resourcepoolname>*** print out a summary of queue distribution information. Here is an example:

```
>superior policy -list default
NAME: default
TOTAL_RESOURCE: vcores 16, memory 16384
AVAILABLE_RESOURCE: vcores 16, memory 16384

NAMERES_INUSERES_REQUEST
root.defaultvcores 0, memory 0 vcores 0, memory 0
```

```
root.productionvcores 0,memory 0vcores 0,memory 0  
root.production.BU1vcores 0,memory 0vcores 0,memory 0  
root.production.BU2 vcores 0,memory 0vcores 0,memory 0
```

- ***policy -list <resourcepoolname> -u*** prints out also user level summary information

```
> superior policy -list default -u  
NAME: default  
TOTAL_RESOURCE: vcores 16,memory 16384  
AVAILABLE_RESOURCE: vcores 16,memory 16384
```

```
NAMERES_INUSERES_REQUEST  
root.defaultvcores 0,memory 0vcores 0,memory 0  
root.default.[_others_]vcores 0,memory 0vcores 0,memory 0  
root.productionvcores 0,memory 0vcores 0,memory 0  
root.production.BU1vcores 0,memory 0vcores 0,memory 0  
root.production.BU1.[_others_]vcores 0,memory 0vcores 0,memory 0  
root.production.BU2vcores 0,memory 0vcores 0,memory 0  
root.production.BU2.[_others_]vcores 0,memory 0vcores 0,memory 0
```

- ***policy -status <resourcepoolname>*** print out policy detail of specified resource pool. Here is an example:

```
> superior policy -status pool1  
NAME: pool1  
TOTAL_RESOURCE: vcores 64,memory 128  
AVAILABLE_RESOURCE: vcores 40,memory 28  
QUEUES:  
|-- NAME: root.Q1  
|-- RESOURCE_USE: vcores 20, memory 1000  
|-- RESOURCE_REQUEST: vcores 2,memory 100  
|--RESERVE: vcores 10, memory 4096  
|--MINIMUM: vcore 11, memory 4096

|-- MAXIMUM: vcores 10, memory 1000
```

### 1.22.2.2 Java API

For details about YARN application programming interfaces (APIs), see:

<http://hadoop.apache.org/docs/r3.3.1/api/index.html>.

## Common Interfaces

Common YARN Java classes are as follows:

- **ApplicationClientProtocol**

This class is used between the client and ResourceManager. The client submits applications to ResourceManager, queries the running status of applications, and kills applications using this protocol.

**Table 1-206** Common interfaces of ApplicationClientProtocol

| Interface                                                                 | Description                                                                                                                               |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| forceKillApplication(KillApplicationRequest request)                      | The client requests ResourceManager to stop a submitted task through this interface.                                                      |
| getApplicationAttemptReport(GetApplicationAttemptReportRequest request)   | The client obtains the report of specified application attempts from ResourceManager through this interface.                              |
| getApplicationAttemptsReport(GetApplicationAttemptsReportRequest request) | The client obtains the report of all application attempts from ResourceManager through this interface.                                    |
| getApplicationReport(GetApplicationReportRequest request)                 | The client obtains an application report from ResourceManager through this interface.                                                     |
| getApplications(GetApplicationsRequest request)                           | The client obtains information about applications that meet filtering conditions from ResourceManager through this interface.             |
| getClusterMetrics(GetClusterMetricsRequest request)                       | The client obtains metrics of clusters from ResourceManager through this interface.                                                       |
| getClusterNodes(GetClusterNodesRequest request)                           | The client obtains information about all nodes in a cluster from ResourceManager through this interface.                                  |
| getContainerReport(GetContainerReportRequest request)                     | The client obtains the report of a Container from ResourceManager through this interface.                                                 |
| getContainers(GetContainersRequest request)                               | The client obtains the report of all Containers of an application attempt from ResourceManager through this interface.                    |
| getDelegationToken(GetDelegationTokenRequest request)                     | The client obtains the delegation token through this interface. The delegation token is used by the container to access related services. |

| Interface                                                               | Description                                                                                                                |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| getNewApplication(GetNewApplicationRequest request)                     | The client obtains a new application ID through this interface for submitting a new application.                           |
| getQueueInfo(GetQueueInfoRequest request)                               | The client obtains queue information from ResourceManager through this interface.                                          |
| getQueueUserAcls(GetQueueUserAclsInfoRequest request)                   | The client obtains queue access permission information about the current user from ResourceManager through this interface. |
| moveApplicationAcrossQueues(MoveApplicationAcrossQueuesRequest request) | This interface is used to move an application to a new queue.                                                              |
| submitApplication(SubmitApplicationRequest request)                     | The client submits a new application to ResourceManager through this interface.                                            |

- ApplicationMasterProtocol

This class is used between ApplicationMaster and ResourceManager. ApplicationMaster registers with ResourceManager, and applies for resources and obtains the running status of each task from ResourceManager using this protocol.

**Table 1-207** Common interfaces of ApplicationMasterProtocol

| Interface                                                           | Description                                                                                      |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| allocate(AllocateRequest request)                                   | ApplicationMaster submits a resource allocation request through this interface.                  |
| finishApplicationMaster(FinishApplicationMasterRequest request)     | ApplicationMaster notifies ResourceManager of running success or failure through this interface. |
| registerApplicationMaster(RegisterApplicationMasterRequest request) | ApplicationMaster registers with ResourceManager through this interface.                         |

- ContainerManagementProtocol

This class is used between ApplicationMaster and NodeManager. ApplicationMaster requests NodeManager to start or terminate a Container or queries the Container running status using this protocol.

**Table 1-208** Common interfaces of ContainerManagementProtocol

| Interface                                                 | Description                                                                                             |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| getContainerStatuses(GetContainerStatusesRequest request) | ApplicationMaster obtains the current status of the Containers from NodeManager through this interface. |
| startContainers(StartContainersRequest request)           | ApplicationMaster requests NodeManager to start Containers through this interface.                      |
| stopContainers(StopContainersRequest request)             | ApplicationMaster requests NodeManager to stop a series of allocated Containers through this interface. |

### 1.22.2.3 REST API

#### Function Description

Users can use the application programming interface (API) of Representational State Transfer (REST) to query more information about YARN jobs. Currently, on the REST API provided by YARN, you can only query some resources or jobs. For details of the HTTP REST API, see the following official guidelines:

[http://hadoop.apache.org/docs/r3.3.1/hadoop-yarn/hadoop-yarn-site/  
WebServicesIntro.html](http://hadoop.apache.org/docs/r3.3.1/hadoop-yarn/hadoop-yarn-site/WebServicesIntro.html)

#### Preparing Running Environment

1. Install a client on the node. For example, install a client in the `/opt/hadoopclient` directory. See details in "Software Installation > Initial Configuration > Configuring Client > Installing a Client".
2. Go to the `/opt/hadoopclient` directory where the client is installed and run the following commands to initiate environment variables:

```
source bigdata_env  
kinit component service user
```

The validity duration of kinit authentication is 24 hours. After 24 hours, you need to re-authenticate the sample with the kinit to restart the sample.

3. HTTPS-based access is different from HTTP-based access. When you access Yarn using HTTPS, you must ensure that the SSL protocol supported by the `curl` command is supported by the cluster because SSL security encryption is used. If the cluster does not support the SSL protocol, change the SSL protocol in the cluster. For example, if the `Curl` command only supports the TLSv1 protocol, modify the protocol configuration performing following measures:

[Accessing FusionInsight Manager of an MRS Cluster](#) and choose **Cluster > Name of the desired cluster > Service > Yarn > Configuration > All Configurations**. Type `hadoop.ssl.enabled.protocols` in the research box, check whether the parameter value contains `TLSv1`. If the parameter value does not contain `TLSv1`, add `TLSv1` in the `hadoop.ssl.enabled.protocols`

configuration item, and clear the value of `ssl.server.exclude.cipher.list`. Otherwise, Yarn cannot be accessed by using HTTPS. Then click **Save Configuration** and select **Restart the affected services or instances**. Restart the service.

 **NOTE**

TLSv1 has security vulnerabilities. Exercise caution when using it.

## Procedure

### 1. Query the information of the jobs that run on the Yarn.

- Command:

```
curl -k -i --negotiate -u : "https://10-120-85-2:26001/ws/v1/cluster/apps/"
```

 **NOTE**

- **10-120-85-2**: host name of the active ResourceManager node.

You can log in to FusionInsight Manager, choose **Cluster > Services > Yarn > Instance**, and view the **Host Name of ResourceManager(Active)**.

- **26001**: port number of the ResourceManager.

You can log in to FusionInsight Manager, choose **Cluster > Services > Yarn > Configurations > All Configurations**, search for and obtain the value of `yarn.resourcemanager.webapp.https.port`.

- If users have the admin permission, they can check jobs in some columns. To grant users the admin permission on the columns, see sections of "Creating a YARN Role" in the *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

 **NOTE**

If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger.

- The result is displayed as follows:

```
{
  "apps": [
    "app": [
      {
        "id": "application_1461743120947_0001",

]
}
```

- Result analysis:

On the interface, you can query the information of jobs that are running on the YARN and obtain the common information that is displayed in [Table 1](#).

**Table 1-209** Common information of jobs running on Yarn

| Information     | Description                                                  |
|-----------------|--------------------------------------------------------------|
| user            | Indicates the user who runs the job.                         |
| applicationType | Indicates the application types, such as MAPREDUCE or SPARK. |
| finalStatus     | Indicates whether a job is executed successfully.            |
| elapsedTime     | Indicates the time to run a job.                             |

## 2. Obtain the overall information of YARN resources.

- Command:

```
curl -k -i --negotiate -u : "https://10-120-85-102:26001/ws/v1/cluster/metrics"
```

- The result is displayed as follows:

```
{
  "clusterMetrics": {
    "appsSubmitted": 2,
    "appsCompleted": 1,
    "appsPending": 0,
    "appsRunning": 1,
    "appsFailed": 0,
    "appsKilled": 0,
    "reservedMB": 0,
    "availableMB": 23552,
    "allocatedMB": 1024,
    "reservedVirtualCores": 0,
    "availableVirtualCores": 23,
    "allocatedVirtualCores": 1,
    "containersAllocated": 1,
    "containersReserved": 0,
    "containersPending": 0,
    "totalMB": 24576,
    "totalVirtualCores": 24,
    "totalNodes": 3,
    "lostNodes": 0,
    "unhealthyNodes": 0,
    "decommissionedNodes": 0,
    "rebootedNodes": 0,
    "activeNodes": 3,
    "rmMainQueueSize": 0,
    "schedulerQueueSize": 0,
    "stateStoreQueueSize": 0
  }
}
```

- Result analysis:

On the interface, users can query the common information of jobs that are running in the cluster, as displayed in **Table 2**.

**Table 1-210** Common information of jobs running in the cluster

| Information   | Description                                            |
|---------------|--------------------------------------------------------|
| appsSubmitted | Indicates the number of jobs that have been submitted. |

| Information       | Description                                            |
|-------------------|--------------------------------------------------------|
| appsCompleted     | Indicates the number of jobs that have been completed. |
| appsPending       | Indicates the number of jobs that have been suspended. |
| appsRunning       | Indicates the number of jobs that are running.         |
| appsFailed        | Indicates the number of jobs that have failed.         |
| appsKilled        | Indicates the number of jobs that have been killed.    |
| totalMB           | Indicates the total memory of Yarn resources.          |
| totalVirtualCores | Indicates the total VCores of Yarn resources.          |

#### 1.22.2.4 REST APIs of Superior Scheduler

##### Function Description

The REST/HTTP server is part of Superior Scheduler on YARN Resource Manager host and leverage existing YARN resource manager web service port. In the section below, we will denote this YARN *address:port* as *SS\_REST\_SERVER*.

Below uses HTTPS as part of URL and only HTTPS will be supported.

##### Superior Scheduler Interfaces

- **Query Application**
  - Query \*all\* application within scheduler engine.
    - URL  
GET `https://<SS_REST_SERVER>/ws/v1/sscheduler/applications/list`
    -  **NOTE**

`SS_REST_SERVER` indicates *ResourceManager IP address:Port number*.

      - ResourceManager IP address: You can log in to FusionInsight Manager, choose **Cluster > Services > Yarn > Instance**, and view the service IP address of any ResourceManager.
      - Port: HTTPS port number of the ResourceManager. You can log in to FusionInsight Manager, choose **Cluster > Services > Yarn > Configurations > All Configurations**, search for and view the value of `yarn.resourcemanager.webapp.https.port`.
  - Input  
None.

- **Output**

JSON Response:

```
{  
  "applicationlist": [  
    {  
      "id": "1020201_0123_12",  
      "queue": "root.Q1.Q11",  
      "user": "cchen",  
      "resource_request": {  
        "vcores" : 10,  
        "memory" : 100  
      },  
      "resource_inuse": {  
        "vcores" : 100,  
        "memory" : 2000  
      },  
      "number_running_container": 100,  
      "number_pending_request": 10  
    },  
    {  
      "id": "1020201_0123_15",  
      "queue": "root.Q2.Q21",  
      "user": "Jason",  
      "resource_request": {  
        "vcores" : 4,  
        "memory" : 100  
      },  
      "resource_inuse": {  
        "vcores" : 20,  
        "memory" : 200  
      },  
      "resource_reserved": {  
        "vcores" : 10,  
        "memory" : 100  
      },  
      "number_running_container": 20,  
      "number_pending_container": 4,  
      "number_reserved_container": 2  
    }  
  ]  
}
```

**Table 1-211** Parameters of all application

| Attribute                | Type   | Description                                                                 |
|--------------------------|--------|-----------------------------------------------------------------------------|
| applicationlist          | array  | Array of application IDs.                                                   |
| queue                    | String | Name of queue application.                                                  |
| user                     | String | Name of user who submits application.                                       |
| resource_request         | object | Currently requested resource, including vcores, memory, and so on.          |
| resource_inuse           | object | Currently resource in use, including vcores, memory, and so on.             |
| resource_reserved        | object | Currently reserved resource, including vcores, memory, and so on.           |
| number_running_container | int    | Total number of running containers. This maps to superior engine decisions. |

| Attribute                 | Type   | Description                                                                               |
|---------------------------|--------|-------------------------------------------------------------------------------------------|
| number_pending_request    | int    | Total number of pending requests, this is sum of all counts in all demands of allocation. |
| number_reserved_container | int    | Total number of reserved containers, this maps to superior engine decisions.              |
| id                        | String | Application ID.                                                                           |

- Query \*single\* application within scheduler engine.

- URL

```
GET https://<SS_REST_SERVER>/ws/v1/sscheduler/applications/
{application_id}
```

- Input

None.

- Output

JSON Response:

**Table 1-212** Parameters of single application

| Attribute                 | Type    | Description                                                                               |
|---------------------------|---------|-------------------------------------------------------------------------------------------|
| application               | object  | Application object.                                                                       |
| id                        | String  | Application ID.                                                                           |
| queue                     | String  | Name of queue application.                                                                |
| user                      | String  | Name of user who submits application.                                                     |
| resource_request          | object  | Currently requested resource, including vcores, memory, and so on.                        |
| resource_inuse            | object  | Currently resource in use, including vcores, memory, and so on.                           |
| resource_reserved         | object  | Currently reserved resource, including vcores, memory, and so on.                         |
| number_running_container  | int     | Total number of running containers. This maps to superior engine decisions.               |
| number_pending_request    | int     | Total number of pending requests, this is sum of all counts in all demands of allocation. |
| number_reserved_container | int     | Total number of reserved containers, this maps to superior engine decisions.              |
| master_container_id       | String  | The master container ID.                                                                  |
| master_container_resource | String  | The host name that master container running on.                                           |
| demand                    | array   | Array of demand objects.                                                                  |
| priority                  | int     | Priority of demand.                                                                       |
| ismaster                  | boolean | Is the demand corresponding to "application master".                                      |
| capability                | object  | Capability object.                                                                        |
| vcores, memory, ..        | int     | Numeric consumable resource attributes, defining the allocation "unit" for this demand.   |
| count                     | int     | Number of unit required.                                                                  |
| relaxlocality             | boolean | Locality requirement is preference, and not mandatory if it cannot be satisfied.          |

| Attribute                              | Type    | Description                                                                       |
|----------------------------------------|---------|-----------------------------------------------------------------------------------|
| locality                               | object  | Locality object.                                                                  |
| target                                 | string  | Locality target's name (that is, node1, rack1..).                                 |
| count                                  | int     | Number of resource "unit" required with this locality requirement.                |
| strict                                 | boolean | If this particular locality is mandatory or not.                                  |
| resourceselect                         | String  | Resource selection expression for the demand.                                     |
| pending_reason                         | String  | Reason why this demand is outstanding.                                            |
| resource_reserved                      | object  | Currently reserved resource for this demand, including vcores, memory, and so on. |
| reservations                           | array   | Array of reserved container objects.                                              |
| reservations:id                        | String  | Reserved container ID.                                                            |
| reservations:resource                  | String  | Where the container is allocated.                                                 |
| reservations:reserveAmount             | object  | The reserved amount of this reservation.                                          |
| containers                             | array   | Array of allocated container objects.                                             |
| containers:id                          | String  | Container ID.                                                                     |
| containers:resource                    | String  | Where the container is allocated.                                                 |
| containers:capability                  | object  | Capability object.                                                                |
| containers:vcores,mem...<br>,memory... | int     | Numeric consumable resource attributes allocated to this container.               |

**Table 1-213** Parameters of all queues

| Attribute                  | Type   | Description                                                                                                                                                              |
|----------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| queuelist                  | array  | Array of queue names.                                                                                                                                                    |
| name                       | String | Queue name.                                                                                                                                                              |
| open_state                 | String | This is inner state (self state) of queue. Indicate either "OPEN" or "CLOSED" effective state of the queue. A "CLOSED" queue does not accept any new allocation request. |
| eopen_state                | String | This is outer state of queue. An effective state is combination of queue own state and its ancestors. A "CLOSED" queue does not accept any new allocation request.       |
| active_state               | String | This is inner state (self state) of queue. Indicate either "ACTIVE" or "INACTIVE" state of the queue. An "INACTIVE" queue does not schedule any application.             |
| eactive_state              | String | This is outer state of queue. An effective state is combination of queue own state and its ancestors. An "INACTIVE" queue does not schedule any application.             |
| number_pending_application | int    | Total number of pending applications.                                                                                                                                    |
| number_running_application | int    | Total number of running applications.                                                                                                                                    |
| number_pending_request     | int    | Total number of pending request.                                                                                                                                         |
| number_running_container   | int    | Total number of running containers.                                                                                                                                      |
| numbert_reserved_container | int    | Total number of reserved containers.                                                                                                                                     |
| resource_request           | object | Pending resource requests within queue in a form of vcores, memory, and so on.                                                                                           |

| Attribute         | Type   | Description                                                                                                      |
|-------------------|--------|------------------------------------------------------------------------------------------------------------------|
| resource_inuse    | object | In use resource within queue in a form of vcores, memory, and so on.                                             |
| resource_reserved | object | Reserved resource within queue in form of vcores, memory, and so on.                                             |
| active_state      | String | Indicate either "ACTIVE" or "INACTIVE" state of the queue. An "INACTIVE" queue does not schedule any allocation. |

- Query \*single\* queues within scheduler engine, including leaf and all middle queues.

**Table 1-214** Parameters of single queues

| Attribute                  | Type    | Description                                                                                                                                                              |
|----------------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| queue                      | object  | A queue object.                                                                                                                                                          |
| name                       | String  | Queue name.                                                                                                                                                              |
| description                | String  | Purpose of queue.                                                                                                                                                        |
| open_state                 | String  | This is inner state (self state) of queue. Indicate either "OPEN" or "CLOSED" effective state of the queue. A "CLOSED" queue does not accept any new allocation request. |
| eopen_state                | String  | This is outer state of queue. An effective state is combination of queue own state and its ancestors. A "CLOSED" queue does not accept any new allocation request.       |
| active_state               | String  | This is inner state (self state) of queue. Indicate either "ACTIVE" or "INACTIVE" state of the queue. An "INACTIVE" queue does not schedule any application.             |
| eactive_state              | String  | This is outer state of queue. An effective state is combination of queue own state and its ancestors. An "INACTIVE" queue does not schedule any application.             |
| leaf_queue                 | boolean | Indicate whether queue is leaf or middle. Yes means leaf queue.                                                                                                          |
| number_pending_application | int     | Number of pending application currently. In case of middle or parent queue, this is the aggregated number of all children queue.                                         |

| Attribute                        | Type   | Description                                                                                                                                                |
|----------------------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| number_running_application       | int    | Number of running application currently. In case of middle or parent queue, this is the aggregated number of all children queue.                           |
| number_pending_request           | int    | Number of pending demand; sum of count from each outstanding demand. In case of middle/parent queue, this is the aggregated number of all children queues. |
| number_running_container         | int    | Number of running containers. In case of middle or parent queue, this is the aggregated number of all children queues.                                     |
| number_reserved_container        | int    | Number of reserved containers. In case of middle or parent queue, this is the aggregated number of children queues.                                        |
| resource_request                 | object | Pending resource requests within queue in a form of vcores, memory etc.                                                                                    |
| resource_inuse                   | object | In use resource within queue in a form of vcores and memory etc.                                                                                           |
| resource_reserved                | object | Reserved resources within queue in a form of vcores and memory etc.                                                                                        |
| configuration                    | object | A queue configuration object.                                                                                                                              |
| max_pending_application          | int    | Max number of pending application. In case of middle or parent queue, this is the aggregated number of all children queue.                                 |
| max_running_application          | int    | Max number of running application. In case of middle/parent queue, this is the aggregated number of all children queue.                                    |
| allocation_order_policy          | String | Allocation policy, can be FIFO, PRIORITY, or FAIR.                                                                                                         |
| max_running_application_per_user | int    | Maximum number of running application per user.                                                                                                            |
| max_master_share                 | String | Percentage of steady share of this queue.                                                                                                                  |
| max_allocation_unit              | object | Maximum allowed resource per container in vcores and memory format.                                                                                        |
| default_resource_select          | String | Default resource selection expression. It is used when an application does not specify one during its submission.                                          |
| user_acl                         | array  | Array of user, who have been given "user" rights on this queue.                                                                                            |

| Attribute | Type   | Description                                                      |
|-----------|--------|------------------------------------------------------------------|
| admin_acl | array  | Array of user, who have been given "admin" rights on this queue. |
| group     | String | User group name.                                                 |
| user      | String | User name.                                                       |

# 2 Normal Mode

## 2.1 ClickHouse Development Guide

### 2.1.1 Overview

#### 2.1.1.1 Introduction to ClickHouse

##### ClickHouse

ClickHouse is a column-based database oriented to online analysis and processing. It supports SQL query and provides good query performance. The aggregation analysis and query performance based on large and wide tables is excellent, which is one order of magnitude faster than other analytical databases.

Advantages for ClickHouse:

- High data compression ratio
- Multi-core parallel computing
- Vectorized computing engine
- Supporting nested data structure
- Supporting sparse indexes
- Supporting INSERT and UPDATE

##### ClickHouse application scenarios:

- Real-time data warehouse

The streaming computing engine (such as Flink) is used to write real-time data to ClickHouse. With the excellent query performance of ClickHouse, Multi-dimensional and multi-mode real-time query and analysis requests can be responded within subseconds.

- Offline query

Large-scale service data is imported to ClickHouse and constructs a large wide table with hundreds of millions to tens of billions of records and hundreds of dimensions. It supports personalized statistics collection and continuous

exploratory query and analysis at any time to assist business decision-making and provides excellent query experience.

## Introduction to the ClickHouse Development Interface

ClickHouse is developed using C++ and positioned as a DBMS. It supports HTTP and Native TCP network interface protocols and multiple driver modes such as JDBC and ODBC. You are advised to use [clickhouse-jdbc](#) of the community version for application development.

### 2.1.1.2 Basic Concepts

#### Concepts

- **cluster**

Cluster: Cluster is a logical concept in ClickHouse. It can be defined by users as required, which is different from the general understanding of cluster. Multiple ClickHouse nodes are loosely coupled and exist independently.

- **shards**

Shard: A shard is a horizontal division of a cluster. A cluster can consist of multiple shards.

- **replicas**

Replica: One shard can contain multiple replicas.

- **partition**

Partition: A partition is used for local replicas and can be considered as a vertical division.

- **MergeTree**

ClickHouse has a huge table engine system. As the basic table engine of the family system, MergeTree provides functions such as data partitioning, primary indexes, and secondary indexes. When creating a table, you need to specify the table engine. Different table engines determine the final character of a data table, for example, the features of a data table, the form how data is stored, and how data is loaded.

### 2.1.1.3 Development Process

[Figure 2-1](#) and [Table 2-1](#) describe the phases in the development process.

Figure 2-1 ClickHouse application development process

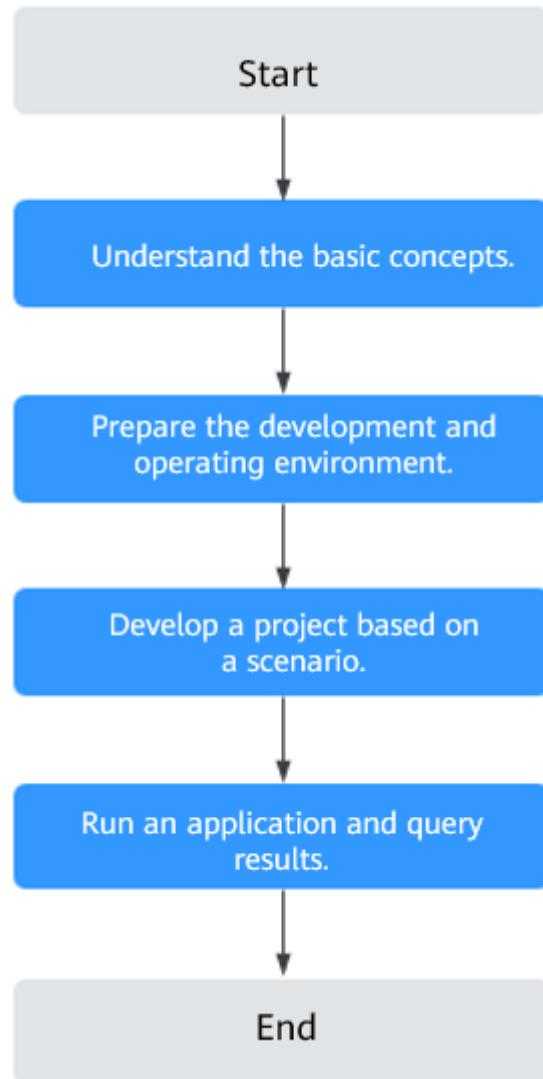

Table 2-1 Description of the ClickHouse application development process

Phase	Description	Reference
Understand the basic concepts.	Before application development, you need to understand basic concepts of ClickHouse.	<a href="#">Basic Concepts</a>
Prepare the development and operating environment.	ClickHouse applications can be developed in multiple languages, mainly Java. The IntelliJ IDEA tool is recommended. Configure the development environment based on the guide.	<a href="#">Preparing the Development and Operating Environment</a>

Phase	Description	Reference
Develop a project based on a scenario.	Sample projects are provided to help you quickly understand APIs of ClickHouse components.	<a href="#">Configuring and Importing a Sample Project</a>
Run application and query results.	You can check the application running status from the running results.	<a href="#">Commissioning Applications on Windows</a> <a href="#">Commissioning Applications on Linux</a>

## 2.1.2 Environment Preparations

### 2.1.2.1 Preparing the Development and Operating Environment

#### Preparing the Development Environment

[Table 2-2](#) describes the environment required for application development.

**Table 2-2** Development environment

Item	Description
Operating System (OS)	<ul style="list-style-type: none"><li>• Development environment: Windows 7 or later.</li><li>• Operating environment: Linux</li></ul> If the program needs to be commissioned locally, the operating environment must be able to communicate with network on the cluster service plane.

Item	Description
JDK installation	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– Oracle JDK 1.8</li><li>– IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>– BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
Installing and configuring IntelliJ IDEA	<p>Basic configuration of the development environment. You are advised to use version 2019.1 or other compatible versions.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you use IBM JDK, ensure that the JDK configured in IntelliJ IDEA is IBM JDK.</li><li>• If you use Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is Oracle JDK.</li><li>• If you use Open JDK, ensure that the JDK configured in IntelliJ IDEA is Open JDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>

Item	Description
Apache Maven installation	Basic configuration of the development environment. This operation is used for project management throughout the lifecycle of software development.
Developer account preparation	Prepare a cluster user for application development and grant permissions to the user by referring to <a href="#">Preparing a Developer Account</a> .
7-zip	This tool is used to decompress *.zip and *.rar files. <b>7-Zip 16.04</b> is supported.

## Preparing the Operating Environment

During application development, you need to prepare the environment for code running and commissioning to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning application; configure the network connection, and commission the application in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#). In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Configuration Files Only**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar**. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles** directory on the local PC. The directory name cannot contain spaces.
  - b. Copy all items from the hosts file in the decompression directory to the hosts file on the node where the client is installed. Ensure that the network communication between the local PC and hosts listed in the hosts file in the decompression directory is normal.

### NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.

- If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client in a directory, for example, **/opt/hadoopclient**, on the node.  
Ensure that the difference between the client time and the cluster time is less than 5 minutes.  
For details about how to install a cluster client, see [Installing a Client](#).
  - b. Check the network connection of the client node.  
During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides. Ensure that the local host can communicate with each host in the cluster on the network.

### 2.1.2.2 Configuring and Importing a Sample Project

#### Context

Obtain the ClickHouse development sample project and import the project to IntelliJ IDEA to learn the sample project.

#### Prerequisites

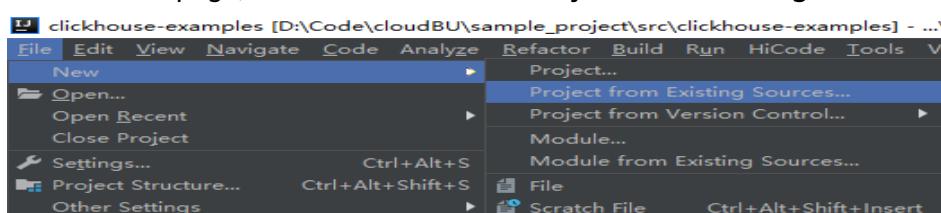

Ensure that the difference between the local PC time and the cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the time of the cluster in the lower-right corner on the FusionInsight Manager page.

#### Scenarios

ClickHouse provides sample projects for multiple scenarios to help you quickly learn ClickHouse projects.

#### Procedure

- Step 1** Obtain the sample project folder **clickhouse-examples** and Maven configurations in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.
  1. On the IDEA page, choose **File > New > Project from Existing Sources**.

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **clickhouse-examples/ClickHouseJDBCJavaExample** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.
4. Select the recommended JDK version and click **Finish**.

**Step 3** After the project is imported, modify the **clickhouse-example.properties** file in the **conf** directory of the sample project based on the actual environment information.

```
loadBalancerIPList=
sslUsed=false
loadBalancerHttpPort=21425
loadBalancerHttpsPort=21426
CLICKHOUSE_SECURITY_ENABLED=true
user=
# Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or
environment variables.
password=
isMachineUser=false
isSupportMachineUser=false
clusterName=default_cluster
databaseName=testdb
tableName=testtb
batchRows=10000
batchNum=10
clickhouse_dataSource_ip_list=
native_dataSource_ip_list=
```

**Table 2-3** Configuration description

Parameter	Default Value	Definition
loadBalancerIPList	-	<p>Mandatory. Set this parameter to the IP address list of LoadBalance.</p> <ul style="list-style-type: none"><li>• Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Instance</b> and check the service IP addresses of all ClickHouseBalancer instances.</li><li>• Use commas (,) to separate multiple IP addresses, for example, <b>10.10.10.100,10.10.10.101</b>.</li><li>• If the IP address is an IPv6 address, convert it, for example, from <b>192:168:0:0:0:158:2</b> to <b>192:168::158:2</b>.</li></ul>

Parameter	Default Value	Definition
sslUsed	true	<p>Whether to enable SSL encryption. You are advised to set this parameter to <b>false</b> for clusters in common mode.</p> <p><b>Note:</b> If this parameter is set to <b>true</b>, SSL connections are used. Common clusters use non-SSL connections by default. If SSL connections are required, log in to FusionInsight Manager, choose <b>Cluster &gt; Services &gt; ClickHouse</b>, click the <b>Configuration</b> tab then the <b>All Configurations</b> sub-tab. On the page that is displayed, search for the <b>SSL_NONESSL_BOTH_ENABLE</b> configuration item, change its value to <b>true</b>, and restart all ClickHouse service instances.</p>
loadBalancerHttpPort	21425	<p>HTTP port number of LoadBalance. If <b>sslUsed</b> is set to <b>false</b>, this parameter cannot be left blank.</p> <p>Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Ssl Port</b> in the <b>HTTP Balancer Port</b> column.</p>
loadBalancerHttpsPort	21426	<p>HTTPS port number of LoadBalance. If <b>sslUsed</b> is set to <b>true</b>, this parameter cannot be empty.</p> <p>Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Ssl Port</b> in the <b>HTTP Balancer Port</b> column.</p>
CLICKHOUSE_SECURITY_ENABLED	true	<p>Whether to enable the security mode. Set this parameter to <b>false</b> for a cluster in normal mode.</p>
user	No default value	Developer user created in <a href="#">Table 1-3</a> .
password	No default value	<p>Password of a human-machine user. This parameter does not need to be set if a machine-machine user is used.</p> <p>Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or environment variables.</p> <p><b>NOTE</b> If the human-machine user is created on FusionInsight Manager, you need to change the initial password upon the first login.</p>

Parameter	Default Value	Definition
isMachineUser	false	<p>Set this parameter to <b>true</b> if a machine-machine user is used for authentication.</p> <p>If this parameter is set to <b>true</b>, the values of <b>user</b> and <b>password</b> are the username and password of the machine-machine user.</p>
isSupportMachineUser	true	<p>Whether to support machine-machine user authentication. Value options are as follows:</p> <p><b>true</b>: Machine-machine user authentication is supported.</p> <p><b>false</b>: Machine-machine user authentication is not supported.</p> <p>To set this parameter, perform the following operations:</p> <p>Log in to FusionInsight Manager, choose <b>Cluster &gt; Services &gt; ClickHouse</b>, click the <b>Configuration</b> tab then the <b>All Configurations</b> sub-tab. In the navigation pane on the left, choose <b>ClickHouseServer(Role) &gt; Security</b>. On the page that is displayed, check the value of <b>SUPPORT_MACHINE_USER</b>.</p>
clusterName	default_c_luster	ClickHouse logical cluster name. Use the actual one.
databaseName	testdb	Name of the database to be created in the sample code project. You can change the database name based on the site requirements.
tableName	testtb	Name of the table to be created in the sample code project. You can change the table name based on the site requirements.
batchRows	10000	Number of data records written in a batch.
batchNum	10	Total number of batches in which data is written.

Parameter	Default Value	Definition
clickhouse_dataSource_ip_list	-	<p>Mandatory. Set this parameter to the IP address list and HTTP port number of the ClickHouseBalancer instance.</p> <ul style="list-style-type: none"><li>• Use commas (,) to separate multiple IP addresses. The format is as follows: <i>ip:port,ip:port,ip:port</i>.</li><li>• IP address: Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Instance</b> and check the service IP addresses of all ClickHouseBalancer instances.</li><li>• Port: Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Ssl Port</b> in the <b>HTTP Balancer Port</b> column.</li><li>• If the IP address is an IPv6 address, convert it to the IP address + Port number format. 192:168:0:0:0:158:2:21425 &gt; [192:168::158:2]:21425</li></ul>
native_dataSource_ip_list	-	<p>Mandatory. Set this parameter to the IP address list and TCP port number of the ClickHouseBalancer instance.</p> <ul style="list-style-type: none"><li>• Use commas (,) to separate multiple IP addresses. The format is as follows: <i>ip:port,ip:port,ip:port</i>.</li><li>• IP address: Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Instances</b> and check the service IP addresses of all ClickHouseBalancer instances.</li><li>• Port: Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Ssl Port</b> in the <b>TCP Balancer Port</b> column.</li><li>• If the IP address is an IPv6 address, convert it to the IP address + Port number format. 192:168:0:0:0:158:2:21424 &gt; [192:168::158:2]:21424</li></ul>

#### NOTE

ClickHouse uses the LoadBalance-based deployment architecture to automatically distribute user access traffic to multiple backend nodes, expanding service capabilities to external systems and improving fault tolerance. When a client application requests a cluster, Nginx-based ClickHouseBalancer is used to distribute traffic. In this way, data read/write load and high availability of application access are guaranteed.

----End

### 2.1.2.3 Configuring and Importing a Transaction Sample Project

#### Context

Obtain the ClickHouse development sample project and import the project to IntelliJ IDEA to learn the sample project.

#### Prerequisites

Ensure that the difference between the local PC time and the cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the time of the cluster in the lower-right corner on the FusionInsight Manager page.

#### Scenarios

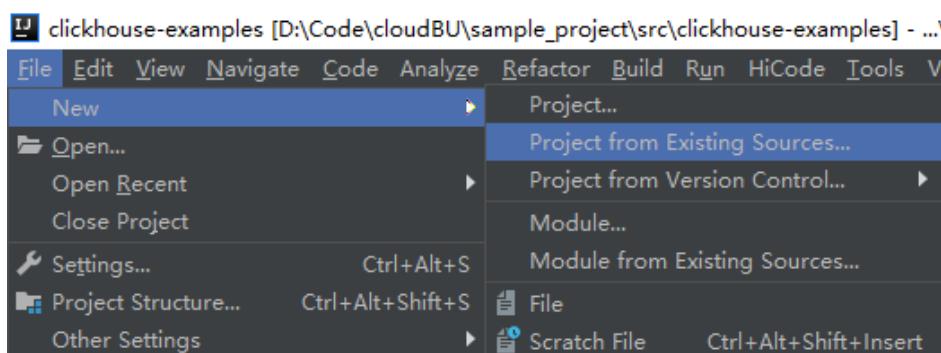

ClickHouse provides sample projects for multiple scenarios to help you quickly learn ClickHouse projects.

#### Procedure

**Step 1** Obtain the sample project folder **clickhouse-examples** and Maven configurations in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.

1. On the IDEA page, choose **File > New > Project from Existing Sources**.

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **clickhouse-examples/ClickHouseJDBC-Transaction-JavaExample** folder and click **OK**.

3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.
4. Select the recommended JDK version and click **Finish**.

**Step 3** After the project is imported, modify the **clickhouse-example.properties** file in the **conf** directory of the sample project based on the actual environment information.

```
loadBalancerIPList=
sslUsed=false
loadBalancerHttpPort=21425
loadBalancerHttpsPort=21426
CLICKHOUSE_SECURITY_ENABLED=true
user=
# Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or
environment variables.
password=
#Whether to use transactions.
useTransaction=true
#Whether to automatically submit SQL statements. The options are true (automatic) and false (manual).
Automatic submission is recommended. Due to the session forwarding mechanism of Balance, SQL
statements cannot be manually submitted by connecting to Balance.
autoCommit=true
clusterName=default_cluster
databaseName=testdb
tableName=testtb
batchRows=10000
batchNum=10
```

**Table 2-4** Parameter description

Parameter	Default Value	Description
loadBalancerIPList	-	<p>Mandatory. Set this parameter to the IP address list of LoadBalance.</p> <ul style="list-style-type: none"><li>• Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Instance</b> and check the service IP addresses of all ClickHouseBalancer instances.</li><li>• Use commas (,) to separate multiple IP addresses, for example, <b>10.10.10.100,10.10.10.101</b>.</li><li>• If the IP address is an IPv6 address, convert it, for example, from <b>192:168:0:0:0:158:2</b> to <b>192:168::158:2</b>.</li></ul>

Parameter	Default Value	Description
sslUsed	true	<p>Whether to enable SSL encryption. You are advised to set this parameter to <b>false</b> for clusters in common mode.</p> <p><b>Note:</b> If this parameter is set to <b>true</b>, SSL connections are used. Common clusters use non-SSL connections by default. If SSL connections are required, log in to FusionInsight Manager, choose <b>Cluster &gt; Services &gt; ClickHouse</b>, click the <b>Configuration</b> tab then the <b>All Configurations</b> sub-tab. On the page that is displayed, search for the <b>SSL_NONESSL_BOTH_ENABLE</b> configuration item, change its value to <b>true</b>, and restart all ClickHouse service instances.</p>
loadBalancerHttpPort	21425	<p>HTTP port number of LoadBalance. If <b>sslUsed</b> is set to <b>false</b>, this parameter cannot be left blank.</p> <p>Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Ssl Port</b> in the <b>HTTP Balancer Port</b> column.</p>
loadBalancerHttpsPort	21426	<p>HTTPS port number of LoadBalance. If <b>sslUsed</b> is set to <b>true</b>, this parameter cannot be empty.</p> <p>Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Ssl Port</b> in the <b>HTTP Balancer Port</b> column.</p>
CLICKHOUSE_SECURITY_ENABLED	true	<p>Whether to enable the security mode. Set this parameter to <b>false</b> for a cluster in normal mode.</p>
user	No default value	Developer user created in <a href="#">Table 1-3</a> .
password	No default value	<p>Password of a human-machine user. This parameter does not need to be set if a machine-machine user is used.</p> <p>Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or environment variables.</p> <p><b>NOTE</b> If the human-machine user is created on FusionInsight Manager, you need to change the initial password upon the first login.</p>

Parameter	Default Value	Description
useTransaction	true	Whether to use transactions. Set this parameter to <b>true</b> . If this parameter is set to <b>true</b> , SQL statements use transactions.
autoCommit	true	Whether to submit data automatically. The available values are: <b>true</b> : The transactions are automatically submitted, which is equivalent to using implicit transactions. <b>false</b> : The transactions are manually submitted.
clusterName	default_c_luster	ClickHouse logical cluster name. Use the actual one.
databaseName	testdb	Name of the database to be created in the sample code project. You can change the database name based on the site requirements.
tableName	testtb	Name of the table to be created in the sample code project. You can change the table name based on the site requirements.
batchRows	10000	Number of data records written in a batch.
batchNum	10	Total number of batches in which data is written.

#### NOTE

ClickHouse uses the LoadBalance-based deployment architecture to automatically distribute user access traffic to multiple backend nodes, expanding service capabilities to external systems and improving fault tolerance. When a client application requests a cluster, Nginx-based ClickHouseBalancer is used to distribute traffic. In this way, data read/write load and high availability of application access are guaranteed.

----End

### 2.1.2.4 Configuring and Importing the Spring Boot Sample Project

#### Scenarios

To run the Spring Boot interface sample code of the ClickHouse component of MRS, perform the following operations.

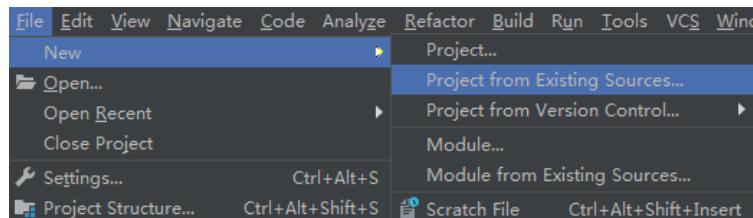

In the following example, an application is developed by compiling a Spring Boot project to connect to ClickHouse in Windows.

## Procedure

**Step 1** Obtain the sample project folder **clickhouse-rest-client-example** in the **src/springboot/clickhouse-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.

1. Choose **File > New > Project from Existing Sources....**

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **clickhouse-rest-client-example** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.

Select the recommended JDK version and click **Finish**.

**Step 3** In the IntelliJ IDEA development environment, open the **clickhouse-example.properties** file in the **conf** directory of the sample project, and change the values of the parameters listed in [Table 1-7](#).

**Step 4** (Optional) If machine-machine user authentication is used, download the **user.keytab** and **krb5.conf** authentication credential files of the machine-machine user by referring to [Step 7](#), and upload the files to the **conf** directory of the sample project.

----End

## 2.1.3 Application Development

### 2.1.3.1 Typical Application Scenario

This section describes the application development in a typical scenario, helping you quickly learn and master the ClickHouse development process and know key functions.

#### Scenario

ClickHouse enables you to perform common service operations by executing SQL statements. The SQL operations involved in sample codes include creating a database, creating a table, inserting data into a table, querying table data, and deleting a table.

Sample codes are described in the following sequence:

1. Setting properties
2. Establishing a connection

3. Creating a database
4. Creating a table
5. Inserting data into a table
6. Querying data
7. Deleting a table

### 2.1.3.2 Development Guideline

#### Development Guideline

As an independent DBMS system, ClickHouse allows you to use the SQL language to perform common operations. In the development program example, the clickhouse-jdbc API is used for description. The development process consists of the following parts:

- Setting properties: Sets the parameters for connecting to a ClickHouse service instance.
- Establishing a connection: Establishes a connection to the ClickHouse service instance.
- Creating a database: Creates a ClickHouse database.
- Creating a table: Creates a table in the ClickHouse database.
- Inserting data: Inserts data into a ClickHouse table.
- Querying data: Queries data in ClickHouse tables.
- Deleting a table: Deletes a ClickHouse table.

### 2.1.4 Sample Code

#### 2.1.4.1 Setting Properties

Set connection properties in the examples of creating connections in the **ClickhouseJDBCHaDemo**, **Demo**, **NativeJDBCHaDemo**, and **Util** files. The following code sets the socket timeout interval to 60 seconds:

```
Properties clickHouseProperties = new Properties();
clickHouseProperties.setProperty(ClickHouseClientOption.CONNECTION_TIMEOUT.getKey(),
Integer.toString(60000));
clickHouseProperties.setProperty(ClickHouseClientOption.SSL.getKey(), Boolean.toString(true));
clickHouseProperties.setProperty(ClickHouseClientOption.SSL_MODE.getKey(), "none");
```

If **sslUsed** in the **clickhouse-example.properties** configuration file in [Configuring and Importing a Sample Project](#) is set to **true**, set the following connection properties in the examples for creating connections in the **ClickhouseJDBCHaDemo**, **Demo**, **NativeJDBCHaDemo**, and **Util** files:

```
clickHouseProperties.setSsl(true);
clickHouseProperties.setSslMode("none");
```

#### 2.1.4.2 Establishing a Connection

The following code snippets are provided in the **initConnection** method of the **ClickhouseJDBCHaDemo** class. During connection creation, the user and

password configured in [Table 2-3](#) are used as authentication credentials. ClickHouse performs security authentication on the server with the user and password.

```
clickHouseProperties.setProperty(ClickHouseDefaults.USER.getKey(), userName);
clickHouseProperties.setProperty(ClickHouseDefaults.PASSWORD.getKey(), userPass);
try {
    clickHouseProperties.setProperty(ClickHouseClientOption.FAILOVER.getKey(), "21");
    clickHouseProperties.setProperty(ClickHouseClientOption.LOAD_BALANCING_POLICY.getKey(),
"roundRobin");
    balancedClickhouseDataSource = new ClickHouseDataSource(JDBC_PREFIX + UriList,
clickHouseProperties);
} catch (Exception e) {
    LOG.error("Failed to create balancedClickHouseProperties.");
    throw e;
}
```

### 2.1.4.3 Creating a Database

Run the **on cluster** statement to create a database whose name is the value of **databaseName** in [Table 2-3](#) in the cluster.

```
private void createDatabase(String databaseName, String clusterName) throws Exception {
    String createDbSql = "create database if not exists " + databaseName + " on cluster " + clusterName;
    util.exeSql(createDbSql);
}
```

### 2.1.4.4 Creating a Table

Run the **on cluster** statement to create the ReplicatedMerge and Distributed tables whose names are the same as the values of **tableName** in [Table 2-3](#).

If multiple ClickHouse services are installed in the cluster, for example, **clickhouse-1**, the ZooKeeper path is **/clickhouse-1**.

```
private void createTable(String databaseName, String tableName, String clusterName) throws Exception {
    String createSql = "create table " + databaseName + "." + tableName + " on cluster " + clusterName +
" (name String, age UInt8, date Date)engine=ReplicatedMergeTree('/clickhouse/tables/{shard}'/" +
databaseName + "." + tableName + "," + "{replica}) partition by toYYYYMM(date) order by age";
    String createDisSql = "create table " + databaseName + "." + tableName + "_all" + " on cluster " +
clusterName + " as " + databaseName + "." + tableName + " ENGINE = Distributed(default_cluster," +
databaseName + "," + tableName + ", rand());"; ArrayList<String> sqlList = new ArrayList<String>();
    sqlList.add(createSql);
    sqlList.add(createDisSql);
    util.exeSql(sqlList);
}
```

### 2.1.4.5 Inserting Data

The table created in [Creating a Table](#) has three fields of the String, UInt8, and Date types.

```
String insertSql = "insert into " + databaseName + "." + tableName + " values (?, ?, ?)";
PreparedStatement preparedStatement = connection.prepareStatement(insertSql);
long allBatchBegin = System.currentTimeMillis();
for (int j = 0; j < batchNum; j++) {
    for (int i = 0; i < batchRows; i++) {
        preparedStatement.setString(1, "huawei_" + (i + j * 10));
        preparedStatement.setInt(2, ((int) (Math.random() * 100)));
        preparedStatement.setDate(3, generateRandomDate("2018-01-01", "2021-12-31"));
        preparedStatement.addBatch();
    }
    long begin = System.currentTimeMillis();
```

```
        preparedStatement.executeBatch();
        long end = System.currentTimeMillis();
        log.info("Inert batch time is {} ms", end - begin);
    }
    long allBatchEnd = System.currentTimeMillis();
    log.info("Inert all batch time is {} ms", allBatchEnd - allBatchBegin);
```

## 2.1.4.6 Querying Data

Query statement 1 **querySql1** queries any 10 records in the **tableName** table created in [Creating a Table](#). Query statement 2 **querySql2** uses a built-in function to combine the year and month fields in the **tableName** table created in [Creating a Table](#).

```
private void queryData(String databaseName, String tableName) throws Exception {
    String querySql1 = "select * from " + databaseName + "." + tableName + "_all" + " order by age limit 10";
    String querySql2 = "select toYYYYMM(date),count(1) from " + databaseName + "." + tableName + "_all"
+ " group by toYYYYMM(date) order by count(1) DESC limit 10";
    ArrayList<String> sqlList = new ArrayList<String>();
    sqlList.add(querySql1);
    sqlList.add(querySql2);
    ArrayList<ArrayList<ArrayList<String>>> result = util.exeSql(sqlList);
    for (ArrayList<ArrayList<String>> singleResult : result) {
        for (ArrayList<String> strings : singleResult) {
            StringBuilder stringBuilder = new StringBuilder();
            for (String string : strings) {
                stringBuilder.append(string).append("\t");
            }
            log.info(stringBuilder.toString());
        }
    }
}
```

## 2.1.4.7 Deleting a Table

Delete the replica table and distributed table created in [Creating a Table](#).

```
private void dropTable(String databaseName, String tableName, String clusterName) throws Exception {
    String dropLocalTableSql = "drop table if exists " + databaseName + "." + tableName + " on cluster " +
clusterName;
    String dropDisTableSql = "drop table if exists " + databaseName + "." + tableName + "_all" + " on cluster "
+ clusterName;
    ArrayList<String> sqlList = new ArrayList<String>();
    sqlList.add(dropLocalTableSql);
    sqlList.add(dropDisTableSql);
    util.exeSql(sqlList);
}
```

## 2.1.4.8 Using BalanceDataSource

BalanceDataSource provides high-availability access connection APIs for applications. When detecting that a ClickHouseBalancer service is abnormal, applications can access the service by using other normal service instances. The following sample code provides examples of ClickHouse JDBC and Native JDBC using BalanceDataSource.

### NOTE

- ClickHouse JDBC uses HTTP to access ClickHouse, and Native JDBC uses TCP to access ClickHouse. For details about the access configurations, see the configuration description of `clickhouse.dataSource_ip_list` and `native.dataSource_ip_list` in [Configuring and Importing a Sample Project](#).
- Native JDBC does not support SSL-encrypted access.

## ClickHouse JDBC Example

### Initial configuration and connection.

```
public void initConnection() throws Exception {
    Properties properties = new Properties();
    String proPath = System.getProperty("user.dir") + File.separator + "conf"
        + File.separator + "clickhouse-example.properties";
    try {
        properties.load(new FileInputStream(proPath));
    } catch (IOException e) {
        LOG.error("Failed to load properties file.");
        throw e;
    }
    Properties clickHouseProperties = new Properties();
    boolean isSec = Boolean.parseBoolean(properties.getProperty("CLICKHOUSE_SECURITY_ENABLED"));
    String UriList = properties.getProperty("clickhouse.dataSource_ip_list");
    String userName = properties.getProperty("user");
    boolean isMachineUser = Boolean.parseBoolean(properties.getProperty("isMachineUser"));
    if (isSec) {
        if (isMachineUser) {
            clickHouseProperties.setProperty("isMachineUser", "true");
            clickHouseProperties.setProperty("keytabPath", System.getProperty("user.dir") + File.separator +
                "conf" + File.separator + "user.keytab");
        }
        String userPass = properties.getProperty("password");
        clickHouseProperties.setProperty(ClickHouseDefaults.PASSWORD.getKey(), userPass);
        clickHouseProperties.setProperty(ClickHouseClientOption.SSL.getKey(), Boolean.toString(true));
        clickHouseProperties.setProperty(ClickHouseClientOption.SSL_MODE.getKey(), "none");
    }
    clickHouseProperties.setProperty(ClickHouseDefaults.USER.getKey(), userName);
    try {
        clickHouseProperties.setProperty(ClickHouseClientOption.FAILOVER.getKey(), "21");
        clickHouseProperties.setProperty(ClickHouseClientOption.LOAD_BALANCING_POLICY.getKey(),
            "roundRobin");
        balancedClickhouseDataSource = new ClickHouseDataSource(JDBC_PREFIX + UriList,
        clickHouseProperties);
    } catch (Exception e) {
        LOG.error("Failed to create balancedClickHouseProperties.");
        throw e;
    }
}
```

### Obtain the connection and send an SQL request.

```
public void queryData(String databaseName, String tableName) {
    String querySql1 = "select name,age from " + databaseName + "." + tableName + "_all" + " order by age
limit 10";
    try (ClickHouseConnection connection = balancedClickhouseDataSource.getConnection();
        ClickHouseStatement statement = connection.createStatement();
        ResultSet set = statement.executeQuery(querySql1)){
        while (set.next()) {
            LOG.info("Name is: " + set.getString(1) + ", age is: " + set.getString(2));
        }
    } catch (SQLException e) {
        //If the return code is 210, the LB server may be disconnected. Check whether the connection is
        available and try again.
        if (e.getErrorCode() == ClickHouseErrorCode.NETWORK_ERROR.code) {
            balancedClickhouseDataSource.actualize();
            try (ClickHouseConnection con = balancedClickhouseDataSource.getConnection());

```

```
        ClickHouseStatement st = con.createStatement();
        ResultSet rs = st.executeQuery(querySql1)) {
        while (rs.next()) {
            LOG.info("Name is: " + rs.getString(1) + ", age is: " + rs.getString(2));
        }
    } catch (SQLException exception) {
        LOG.error("Query data failed.");
    }
} else {
    LOG.error("Query data failed.", e);
}
}
```

## Native JDBC Example

Initial configuration and connection.

```
public void initConnection() throws IOException {
    Properties properties = new Properties();
    String proPath = System.getProperty("user.dir") + File.separator + "conf"
        + File.separator + "clickhouse-example.properties";
    try {
        properties.load(new FileInputStream(proPath));
    } catch (IOException e) {
        LOG.error("Failed to load properties file.");
        throw e;
    }
    String UriList = properties.getProperty("native.dataSource.ip.List");
    //Whether to check connection availability during connection initialization.
    properties.put("is_check_connection", "true");
    balancedClickhouseDataSource = new BalancedClickhouseDataSource(JDBC_PREFIX + UriList, properties)
        //This method periodically checks whether the connection is available in the background and
        maintains a list of available connections. The following configuration indicates that the check is performed
        every 30 seconds.
        .scheduleActualization(30, TimeUnit.SECONDS);
}
```

Obtain the connection and send an SQL request.

```
public void queryData(String databaseName, String tableName) {
    String querySql1 = "select name,age from " + databaseName + "." + tableName + "_all" + " order by age
limit 10";
    try (ClickHouseConnection connection = balancedClickhouseDataSource.getConnection();
        ClickHouseStatement statement = connection.createStatement();
        ResultSet set = statement.executeQuery(querySql1)){
        while (set.next()) {
            LOG.info("Name is: " + set.getString(1) + ", age is: " + set.getString(2));
        }
    } catch (SQLException e) {
        //If the return code is 210, the LB server may be disconnected. Check whether the connection is
        available and try again.
        if (e.getErrorCode() == ClickHouseErrCode.NETWORK_ERROR.code()) {
            balancedClickhouseDataSource.actualize();
            try (Connection con = balancedClickhouseDataSource.getConnection();
                Statement statement = con.createStatement();
                ResultSet rs = st.executeQuery(querySql1)) {
                while (rs.next()) {
                    LOG.info("Name is: " + rs.getString(1) + ", age is: " + rs.getString(2));
                }
            } catch (SQLException exception) {
                LOG.error("Query data failed.");
            }
        } else {
            LOG.error("Query data failed.", e);
        }
    }
}
```

## 2.1.5 Application Commissioning

### 2.1.5.1 Commissioning Applications on Windows

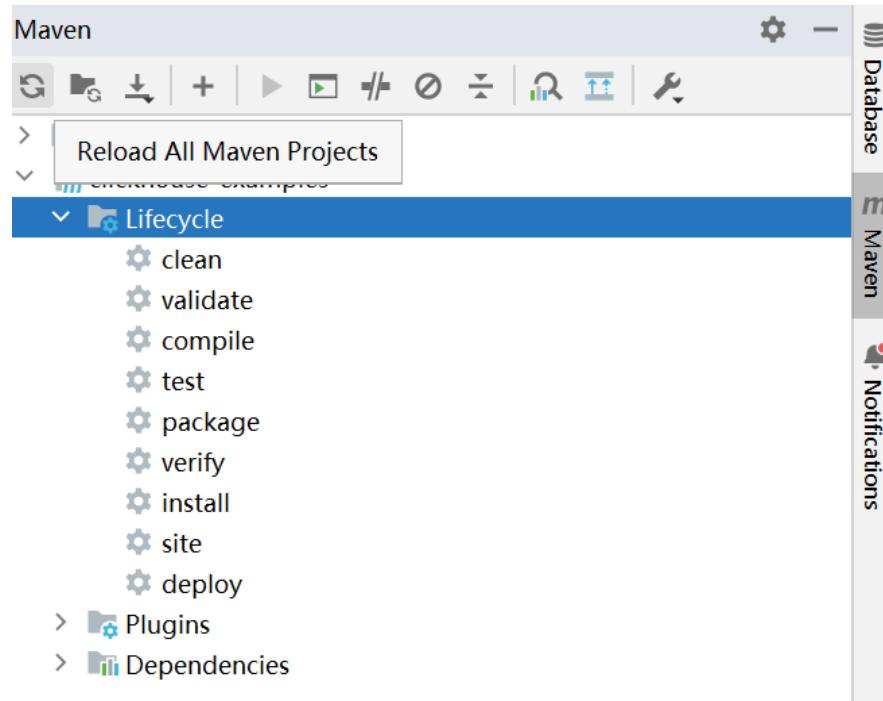

#### Writing and Running an Application

You can run an application in the Windows environment after application code development is complete. If the local and cluster service planes can communicate with each other, you can perform the commissioning on the local host.

#### Procedure

- Step 1** Click **Reload All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

**Figure 2-2** Reloading projects

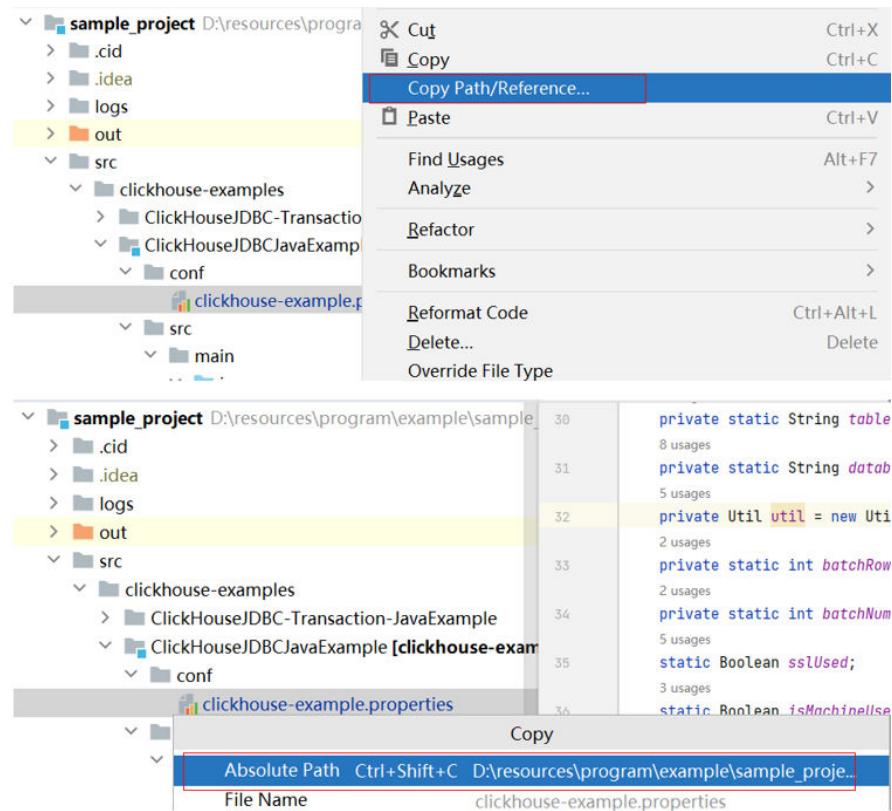

- Step 2** Copy the **clickhouse-example.properties** path on the IDEA page. Right-click **clickhouse-example.properties** and choose **Copy Path/Reference > Absolute Path** from the shortcut menu.

**NOTE**

Skip this step if you are commissioning the transaction sample project.

**Figure 2-3** Copying absolute path of the configuration file

**Step 3** In **Demo.java**, replace the path of **proPath** in the **getProperties()** method with the path **clickhouse-example.properties**.

**Figure 2-4** Replacing the path

```
private void getProperties() throws Exception {
    Properties properties = new Properties();
    String proPath = "D:\\resources\\program\\example\\sample_project\\src\\clickhouse-examples\\ClickHouseJDBCJavaExample\\conf\\clickhouse-example.properties";
    try {
        properties.load(new FileInputStream(new File(proPath)));
    } catch (IOException e) {
        log.error("Failed to load properties file.");
        throw e;
    }
}
```

**Step 4** In **ClickhouseJDBCHaDemo.java**, replace the path of **proPath** in the **initConnection()** method with the path **clickhouse-example.properties**.

#### BOOK NOTE

Skip this step if you are commissioning the transaction sample project.

**Figure 2-5** Replacing the path

```
public void initConnection() throws Exception {
    Properties properties = new Properties();
    String proPath = "D:\\resources\\program\\example\\sample_project\\src\\clickhouse-examples\\ClickHouseJDBCJavaExample\\conf\\clickhouse-example.properties";
    try {
        properties.load(new FileInputStream(proPath));
    } catch (IOException e) {
        LOG.error("Failed to load properties file.");
        throw e;
    }
}
```

**Step 5** If SSL is disabled in the **clickhouse-example.properties** configuration file, replace the **proPath** path in the **initConnection()** method with the **clickhouse-example.properties** path in **NativeJDBCHaDemo.java**.

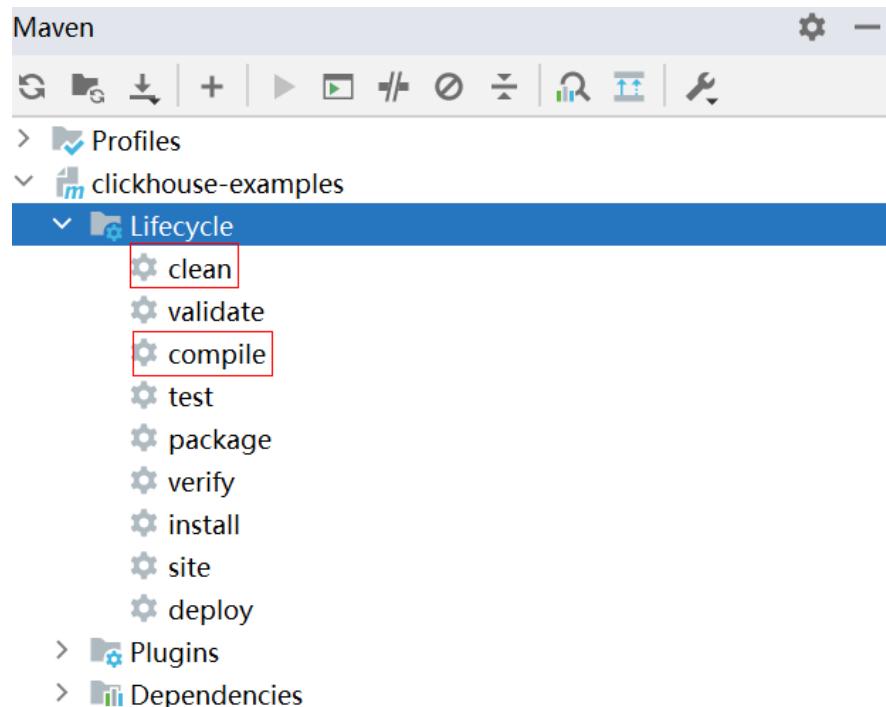

**Figure 2-6** Replacing the path

```
public void initConnection() throws IOException {
    Properties properties = new Properties();
    String proPath = "D:\\resources\\program\\example\\sample_project\\src\\clickhouse-examples\\ClickHouseJDBCJavaExample\\conf\\clickhouse-example.properties";
    try {
        properties.load(new FileInputStream(proPath));
    } catch (IOException e) {
        LOG.error("Failed to load properties file.");
        throw e;
    }
}
```

**Step 6** Compile the application.

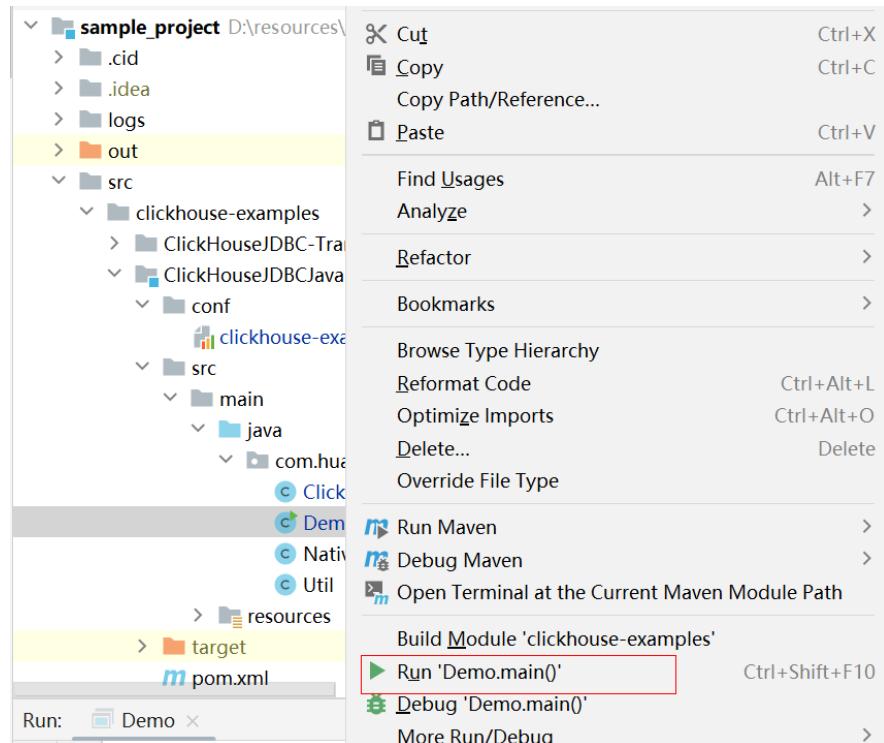

- Select **Maven > clickhouse-examples > Lifecycle > clean** and double-click **clean** to run the **clean** command of Maven.
- Select **Maven > clickhouse-examples > Lifecycle > compile** and double-click **compile** to run the **compile** command of Maven.

**Figure 2-7** Maven commands clean and compile

**Step 7** Click Run'Demo.main()' to run the application.

**Figure 2-8** Running the application

----End

## Viewing the Commissioning Result

After a ClickHouse application finishes running, you can use one of the following methods to view the running result:

- View the running result.
- View the **clickhouse-example.log** file in the **logs** directory to obtain the application running status.

After the complete sample of the **clickhouse-examples** finishes running, the following information is displayed on the console:

```

### 2.1.5.2 Commissioning Applications on Linux

ClickHouse applications can run in a Linux environment. After the application code is developed, you can upload the JAR file to the prepared Linux environment.

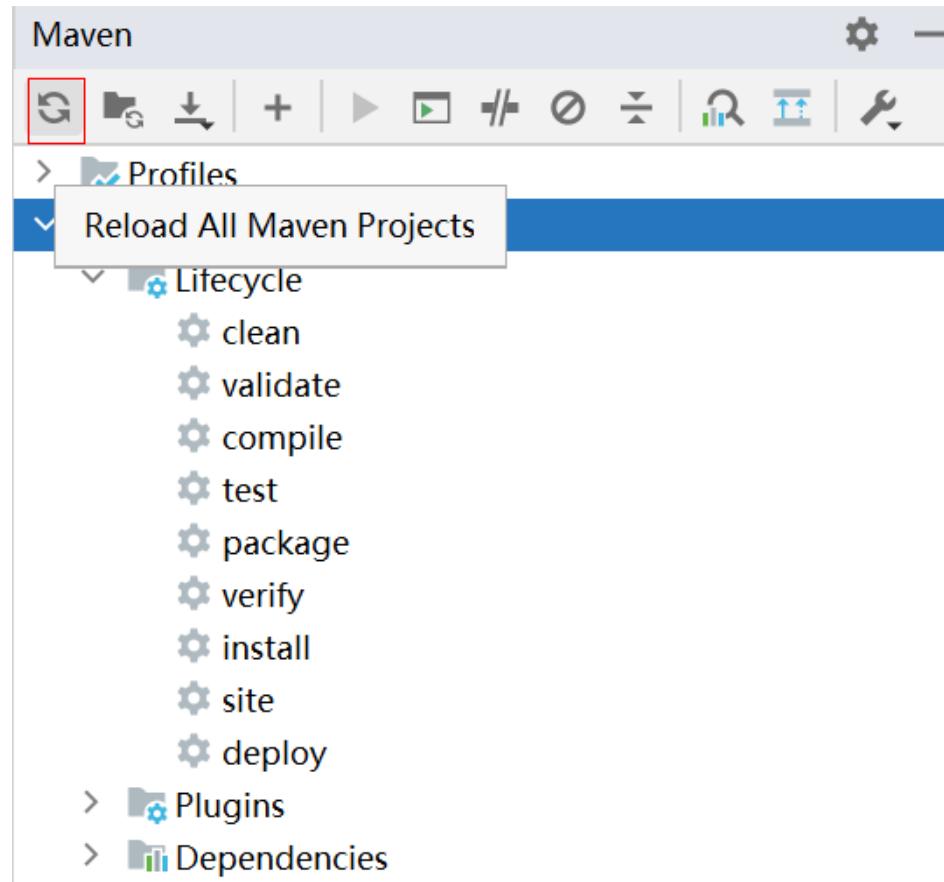

#### Prerequisites

JDK has been installed on Linux. The version must be the same as JDK version of the JAR file exported from IntelliJ IDEA. Java environment variables have been set.

#### Compile and run applications.

**Step 1** Click **Reload All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

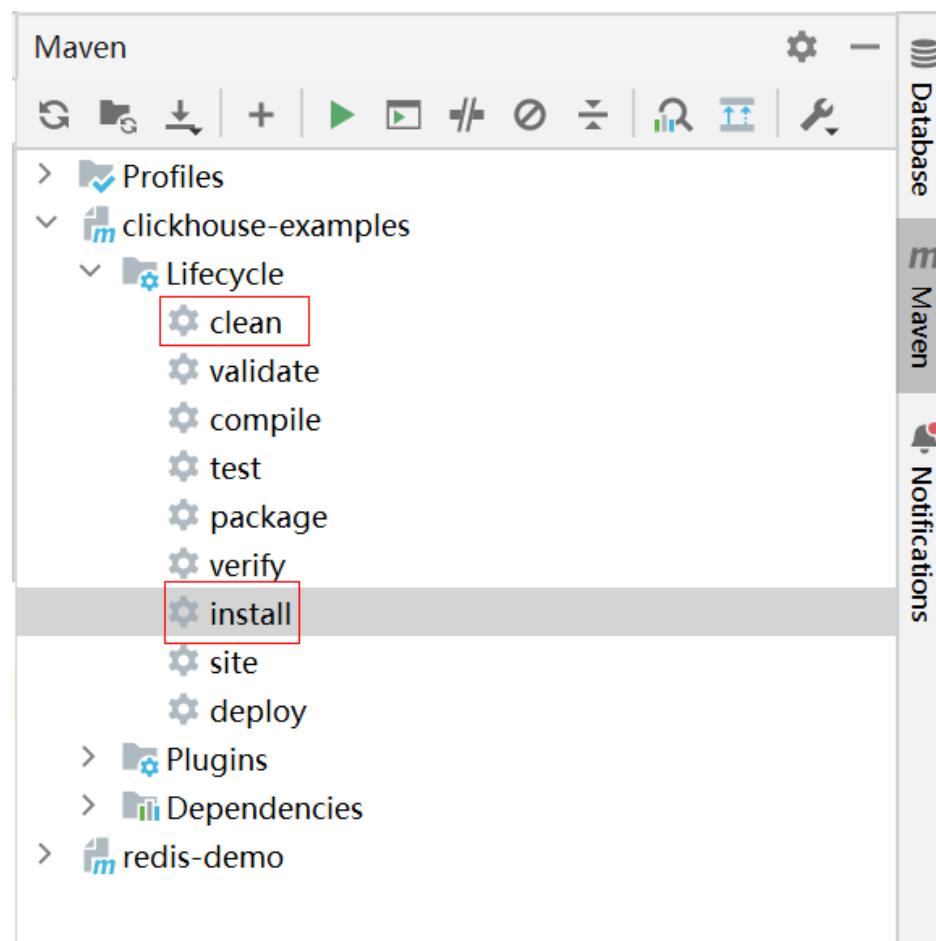

Figure 2-9 reload projects

**Step 2** Export the JAR file.

- Select **Maven > clickhouse-examples > Lifecycle > clean** and double-click **clean** to run the **clean** command of Maven.
- Select **Maven > clickhouse-examples > Lifecycle > install** and double-click **install** to run the **install** command of Maven.

Figure 2-10 Maven clean and install commands

- Step 3** Copy the **clickhouse-examples-\*jar** file from the **target** directory and the **conf** folder from the **clickhouse-examples** directory to the ClickHouse client installation directory, for example, *Client installation directory/JDBC* or *Client installation directory/JDBCTransaction*.

NOTE

The *Client installation directory/JDBC* directory is used to commission JDBC secondary samples.

The *Client installation directory/JDBCTransaction* directory is used to commission secondary transaction samples.

- Step 4** Log in to the client node, go to the directory where the JAR file is uploaded, and change the file permission to 700.

**cd** *Client installation directory/JDBC*

Or **cd** *Client installation directory/JDBCTransaction*

**chmod 700 clickhouse-examples-\*jar**

- Step 5** In the client directory where **clickhouse\_examples.jar** is stored, run the following commands to run the JAR file:

**source** *Client installation directory/bigdata\_env*

**cd** *Client installation directory/JDBC*

Or **cd Client installation directory/JDBCTransaction**

**java -jar clickhouse-examples-\*.jar**

----End

## Viewing Commissioning Results

After a ClickHouse application is run, you can use one of the following methods to view the running result:

- Viewing the command output
- Viewing ClickHouse logs

View the **logs clickhouse-example.log** file in the directory where the current JAR file is located, for example, *Client installation directory/JDBC/logs/ clickhouse-example.log* or *Client installation directory/JDBCTransaction/ logs/clickhouse-example.log*.

The execution result of the JAR file is as follows:

```

## 2.1.5.3 Commissioning the Spring Boot Sample Project

### 2.1.5.3.1 Commissioning the Spring Boot Project in Windows

#### Compiling and Running Applications

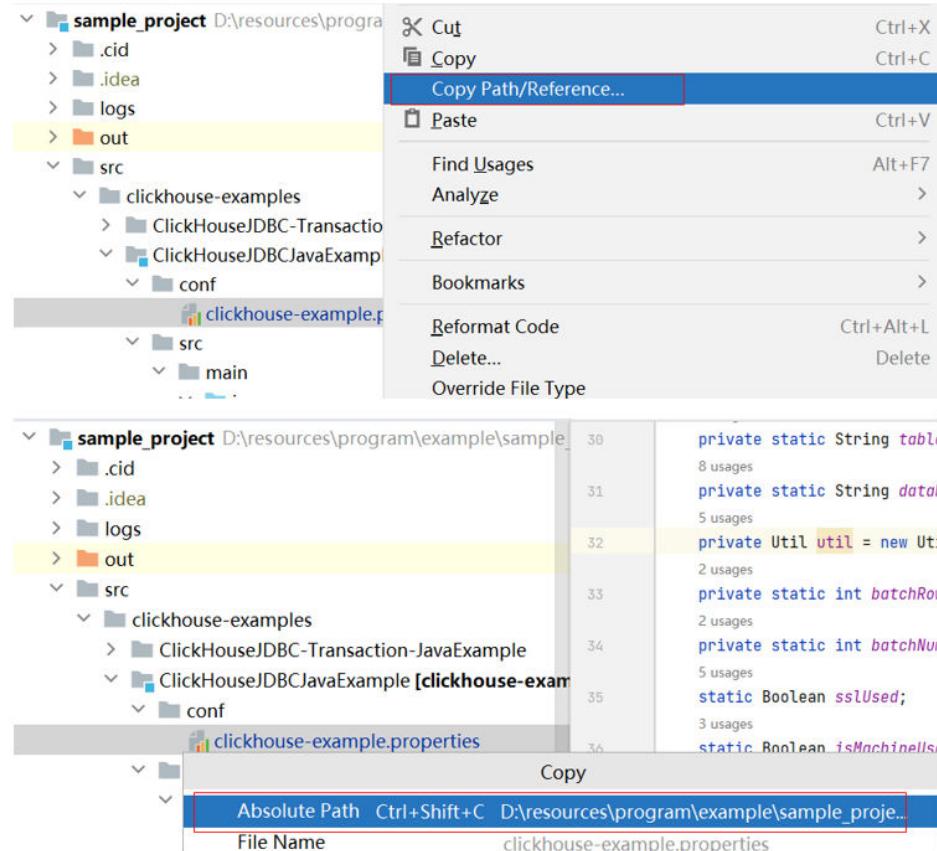

You can run applications in the Windows environment after application code development is complete. If the local and cluster service planes can communicate with each other, you can perform the commissioning on the local host. Right-click **ClickHouseApplication** in IntelliJ IDEA project **clickhouse-rest-client-examples** in the development environment, and then choose **Run ClickHouseApplication** from the shortcut menu to run the application project.

## Procedure

**Step 1** Copy the **clickhouse-example.properties** path on the IDEA page. Right-click **clickhouse-example.properties** and choose **Copy Path/Reference > Absolute Path** from the shortcut menu.

**Figure 2-11** Copying absolute path of the configuration file

**Step 2** In `ClickHouseFunc.java`, replace the path of `proPath` in the `getProperties()` method with `clickhouse-example.properties`.

**Figure 2-12** Replacing the path

----End

# **Viewing Commissioning Results**

1. After the ClickHouse Spring Boot service is started, the ClickHouse sample interface is used to trigger the running of the sample code. Enter the link of the specific operation to be performed in the address box of the browser, for example, <http://localhost:8080/clickhouse/executeQuery>. The following result is returned:  
ClickHouse springboot client runs normally.
  2. View the **clickhouse-springboot-example.log** file to obtain the application running status.

After the `clickhouse-springboot` sample is run, the following information is displayed on the console:

```

### 2.1.5.3.2 Commissioning the Spring Boot Project in Linux

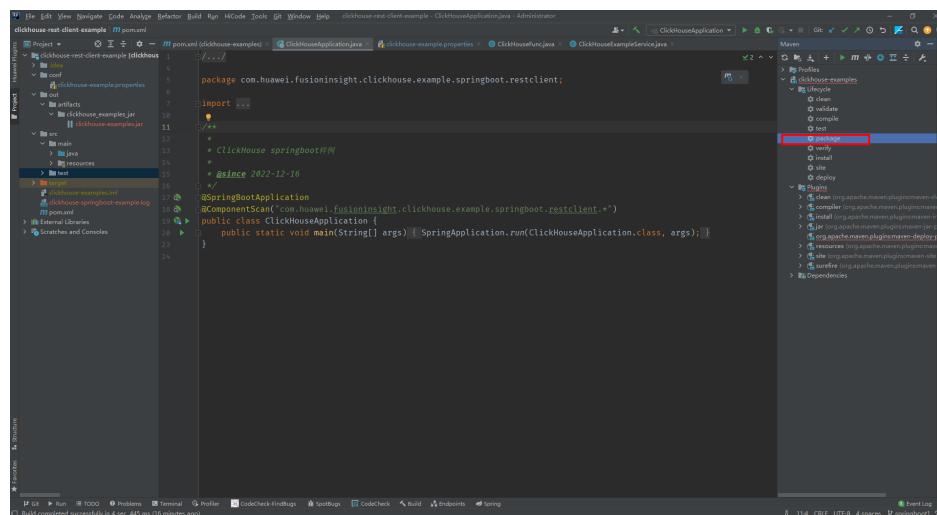

The ClickHouse Spring Boot applications can run in a Linux environment. After the application code is developed, you can upload the JAR file to the prepared Linux environment.

## Prerequisites

JDK has been installed on Linux. The version must be the same as JDK version of the JAR file exported from IntelliJ IDEA. Java environment variables have been set.

## Compiling and Running Applications

**Step 1** Click **Maven** on the right of IDEA, expand **Lifecycle**, and double-click **package** to package the current project.

**Step 2** Log in to the ClickHouse client node as user **root**, create a running directory, for example, **/opt/test**, and obtain the JAR package whose name contains **-with-dependencies** from the **target** directory of IDEA. Upload the JAR package and the **conf** folder in the IDEA to the **/opt/test** directory, as shown in the following figure.

```
[root@host-192-168-6-24 test]#  
[root@host-192-168-6-24 test]# pwd  
/opt/test  
[root@host-192-168-6-24 test]# ll  
total 25048  
-rw-r--r-- 1 root root 25644916 Feb 6 19:24 clickhouse-examples-1.0-SNAPSHOT-jar-with-dependencies.jar  
drwxr-xr-x 2 root root 4096 Feb 6 18:03 conf  
[root@host-192-168-6-24 test]#
```

**Step 3** Run the following commands to set environment variables and run the JAR package:

**cd** *Client installation path*

```
source bigdata_env
```

```
cd /opt/test
```

```
java -jar clickhouse-examples-1.0-SNAPSHOT-jar-with-dependencies.jar
```

The command output is displayed as follows:

```
[root@host-192-168-6-24 test]# java -jar clickhouse-examples-1.0-SNAPSHOT-jar-with-dependencies.jar
[INFO ] 2023-02-06 19:42:04.200 main c.h.f.e.s.r.ClickHouseApplication : Starting ClickHouseApplication using Java 1.8.0_332 on host-192-168-6-24 with PID 42496 [/opt/test	clickhouse-examples-1.0-SNAPSHOT-jar-with-dependencies.jar started by root in /opt/test]
[INFO ] 2023-02-06 19:42:04.203 main c.h.f.e.s.r.ClickHouseApplication : No active profile set, falling back to 1 default profile: "default"
[INFO ] 2023-02-06 19:42:04.396 INFO 24296 --- [main] o.s.b.w.embedded.tomcat.TomcatWebServer : Tomcat initialized with port(s): 8080 (http)
[INFO ] 2023-02-06 19:42:04.409 INFO 24296 --- [main] o.apache.catalina.core.StandardService : Starting service [Tomcat]
[INFO ] 2023-02-06 19:42:04.410 INFO 24296 --- [main] org.apache.catalina.core.StandardEngine : Starting Servlet engine: [Apache Tomcat/9.0.63]
[INFO ] 2023-02-06 19:42:04.410 INFO 24296 --- [main] org.apache.catalina.startup.Tomcat : Initialization completed in 1188 ms
[INFO ] 2023-02-06 19:42:04.476 INFO 24296 --- [main] o.s.b.w.embedded.tomcat.TomcatWebServer : Tomcat started on port(s): 8080 (http) with context path ''
[INFO ] 2023-02-06 19:42:04.074 INFO 24296 --- [main] c.h.f.e.s.r.ClickHouseApplication : Started ClickHouseApplication in 2.718 seconds (JVM running for 3.07)
```

**Step 4** Call the Spring Boot sample API of ClickHouse to trigger running the sample code.

- Running method in Windows:

Open the browser, enter `http://IP address of the ClickHouse client node:8080/clickhouse/executeQuery` in the address box, and check the returned information.

ClickHouse springboot client runs normally.

- Running method in Linux:

Log in to the ClickHouse client node and run the following command to view shell logs and log files in Linux:

```
curl http://localhost:8080/clickhouse/executeQuery
```

## vi clickhouse-springboot-example.log

```
[root@host ~]# test # ll

## 2.2 Doris Development Guide

## 2.2.1 Overview

## 2.2.1.1 Doris Introduction

Doris is a high-performance and real-time analytical database based on the MPP architecture. Doris is well known for its high speed and ease of use. It can return query results in massive data in sub-second response time and supports high-concurrency point query scenarios. It also supports complex analysis scenarios with high throughput. Based on this, Apache Doris can meet the requirements of report analysis, ad hoc query, unified data warehouse construction, and data lake federated query acceleration. Users can build applications such as user behavior analysis, A/B experiment platform, log retrieval analysis, user profile analysis, and order analysis.

Doris uses the MPP model, which is executed concurrently between nodes and within nodes. It is applicable to the distributed join of multiple large tables. Supports the vectorized query engine, adaptive query execution (AQE), optimization policy that combines CBO and RBO, and hot data cache query.

### 2.2.1.2 Common Concepts

In Doris, data is logically described in the form of tables.

- Row&Column

A table consists of rows and columns:

- Row: indicates a row of user data.
  - Column: describes different fields in a row of data.

Columns can be divided into two categories: Key and Value. From the business perspective, Key and Value can correspond to the dimension column and indicator column respectively. From the point of view of the aggregation model, rows with the same key column are aggregated into

one row. The aggregation mode of the Value column is specified by the user when creating a table.

- **Tablet&Partition**

In the storage engine of Doris, user data is horizontally divided into several data fragments (tablets, also called data buckets). Each Tablet contains several rows of data. Tablet data has no intersection and is physically stored independently.

Multiple tablets belong to different partitions logically. A tablet belongs to only one partition, and a partition contains several tablets. Because tablets are physically independent, partitions can be considered as physically independent. A tablet is the smallest physical storage unit for operations such as data movement and replication.

Multiple partitions form a table. A partition can be considered as the smallest logical management unit. Data can be imported and deleted only for one partition.

- **Data model**

Doris data models are classified into three types: Aggregate, Unique, and Duplicate.

- **Aggregate model**

When data is imported, rows with the same Key column are aggregated into one row, and the Value column is aggregated based on the AggregationType parameter. Currently, the AggregationType supports the following aggregation modes:

- SUM: Sum of values in multiple lines.
- Replace: Replace the value in the next batch of data.
- MAX: retain the maximum value.
- MIN: minimum value.

- **Unique model**

In some multidimensional analysis scenarios, users focus more on how to ensure the uniqueness of keys, that is, how to obtain the uniqueness constraint of the primary key. Therefore, the Unique data model is introduced.

- **Read-on-Merge**

The read-on-merge implementation of the Unique model can be completely replaced by the Replace mode in the Aggregate model. Its internal implementation and data storage are exactly the same.

- **Combine on write**

The unique model is implemented by combining data on write. The query performance of the unique model is closer to that of the duplicate model. Compared with the aggregate model, the unique model has higher query performance than the aggregate model in scenarios where primary key constraints are required, especially in aggregate queries and queries where a large amount of data needs to be filtered by indexes.

In the Unique table with the merge-on-write option enabled, the overwritten and updated data is marked and deleted during the import phase, and new data is written to a new file. During query, all data marked for deletion is filtered out at the file level, and the read data is the latest data. This eliminates the data aggregation process during read merge and supports pushdown of multiple predicates in many cases. Therefore, the performance can be greatly improved in many scenarios, especially in the case of aggregated queries.

- **Duplicate model**

In some multidimensional analysis scenarios, data has neither primary keys nor aggregation requirements. The Duplicate data model can be introduced to meet such requirements.

This data model is different from the Aggregate and Unique models. The data is stored exactly as the data in the import file, and there is no aggregation. Even if the two rows of data are identical, they are retained. The DUPLICATE KEY specified in the table creation statement is only used to specify the columns by which the underlying data is sorted.

- **Data Model Selection Suggestions**

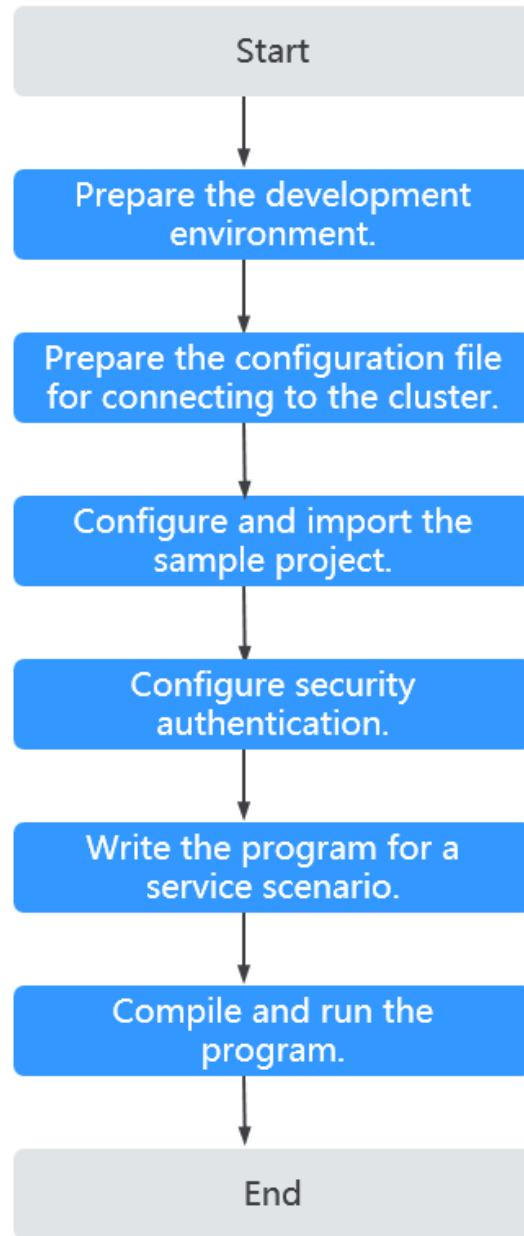

The data model is determined when the table is created and cannot be modified. Therefore, it is important to choose a suitable data model.

- i. The Aggregate model greatly reduces the amount of data to be scanned and the amount of query calculation during aggregation query through pre-aggregation. It is suitable for the report query scenario with fixed mode. However, this model is not friendly to count(\*) queries. In addition, the aggregation mode of the Value column is fixed. Therefore, the semantic correctness needs to be considered when performing other types of aggregation queries.
- ii. The Unique model ensures the uniqueness of primary key constraints in scenarios where unique primary key constraints are required. However, the query advantages of pre-aggregation such as ROLLUP cannot be taken advantage of.
  - 1) For users who have high performance requirements for aggregated queries, the merge-on-write implementation introduced in version 1.2 is recommended.
  - 2) The Unique model supports only the entire row update. If the unique primary key constraint and some columns need to be updated, (e.g., importing multiple source tables into a Doris table), you can use the Aggregate model and set the aggregation type of the non-primary key column to Replaced\_IF\_NOT\_NULL.
  - 3) Duplicate is applicable to Ad-hoc queries in any dimension. Although the pre-aggregation feature cannot be used, it is not restricted by the aggregation model and can take advantage of the column-store model. (Only the relevant columns are read, not all the Key columns).

### 2.2.1.3 Development Process

The following figure shows the phases in the development process.

Figure 2-13 Doris application development process

**Table 2-5 HBase application development process description**

Phase	Description	Reference Document
Prepare the development environment.	Before developing an application, you need to prepare the development environment. You are advised to use the Java language and IntelliJ IDEA tool for development. In addition, you need to complete the initial configuration of the JDK and Maven.	<a href="#">Preparing for Development Environment</a>
Prepare the Configuration File for Connecting to the Cluster.	During application development or running, you need to connect to the MRS cluster through cluster configuration files. The configuration file contains user files used for security authentication. You can obtain related content from the created MRS cluster.  Nodes used for program commissioning or running must be able to communicate with nodes in the MRS cluster and the hosts domain name must be configured.	<a href="#">Preparing the Configuration Files for Connecting to the Cluster</a>
Configure and import the sample project.	Doris provides multiple sample programs in different scenarios. You can obtain sample projects and import them to the local development environment for program learning.	<a href="#">Configuring and Importing JDBC or Stream Load Sample Projects</a> <a href="#">Configuring and Importing SpringBoot Sample Projects</a>

Phase	Description	Reference Document
Configure security authentication.	When using the JDBC or Spring Boot interface to connect to Doris, you need to configure a user with Doris administrator rights for security authentication.	<a href="#">Configuring and Importing JDBC or Stream Load Sample Projects</a> <a href="#">Configuring and Importing SpringBoot Sample Projects</a>
Develop programs based on business scenarios.	Develop programs based on actual service scenarios and invoke component interfaces to implement corresponding functions.	<a href="#">Using Doris Through JDBC and DBalancer</a>
Compile and run the application.	You can commission and run the program in the local Windows development environment, or compile the program into a JAR package and submit it to the Linux node for running.	<a href="#">Application Commissioning</a>

#### 2.2.1.4 Doris Sample Project Introduction

To obtain the MRS sample project, visit <https://github.com/huaweicloud/huaweicloud-mrs-example>. Switch to the version branch that matches the MRS cluster, download the package to the local PC, and decompress the package to obtain the sample code project of each component.

Currently, MRS provides the following Doris-related sample projects:

**Table 2-6** Doris-related sample projects

Sample Project Location	Function Description
doris-examples/doris-jdbc-example	Application development example of Doris data read and write operations. You can invoke Doris APIs to create user tables, insert data into tables, query table data, and delete tables. For details, see <a href="#">Using Doris Through JDBC and DBalancer</a> .

Sample Project Location	Function Description
springboot/doris-examples	SpringBoot application development example for Doris data read and write operations. This section provides an example for connecting Doris to SpringBoot. For details, see <a href="#">Configuring and Importing SpringBoot Sample Projects</a> .
doris-examples/doris-stream-load-example	Application development example of the Doris Stream Load API for importing local CSV files. This section provides an example of using the Stream Load API to import data from a local CSV file to a Doris table. For details about the example, see <a href="#">Loading Data to a Doris Table with Stream Load</a> .

## 2.2.2 Environment Preparation

### 2.2.2.1 Preparing for Development Environment

[Table 2-7](#) describes the environment required for secondary development.

**Table 2-7** Development environment

Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows OS. Windows 7 or later is supported.</li><li>• Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul>

Item	Description
Installing JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>Tool used for developing HBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>
JUnit plug-in installation	Basic configuration for the development environment.

Item	Description
Installation of Maven	Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development.  Huawei provides Huawei Mirrors for you to download all dependency JAR files of sample projects. However, you need to download the rest dependency open-source JAR files from the Maven central repository or other custom repository address. For details, see <a href="#">Configuring Huawei Open-Source Mirrors</a> .
7-zip	Used to decompress .zip and .rar packages. The 7-Zip 16.04 is supported.

### 2.2.2.2 Preparing the Configuration Files for Connecting to the Cluster

#### Preparing a Developer Account

If Kerberos authentication is not enabled for an MRS cluster, you need to prepare a user who has the permission to perform operations on related components for program authentication.

The following Doris permission configuration example is for reference only. You can adjust the permission configuration based on service requirements in actual service scenarios.

**Step 1** Log in to the node where the MySQL client is installed and connect to the Doris service as user **admin**.

```
mysql -uadmin -PDatabase connection port -hDoris FE instance IP address
```

#### NOTE

- The default password of the **admin** user is empty.
- The database connection port is the query connection port of the Doris FE. The default port is 29982. You can also log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and query the **query\_port** parameter of the Doris service.
- To view the IP address of a Doris FE instance, log in to FusionInsight Manager of the MRS cluster and choose **Cluster > Services > Doris > Instances**.
- You can also use the MySQL connection software or Doris WebUI to connect to the database.

**Step 2** Run the following command to create a role:

```
Create Role dorisrole;
```

**Step 3** Run the following command to grant permissions to the role. For details, see "Doris Permission Management" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*. For example, to grant the ADMIN\_PRIV permission to the role, run the following command:

```
GRANT ADMIN_PRIV ON *.* TO ROLE 'dorisrole';
```

**Step 4** Run the following commands to create a user and bind the user to the role:

```
CREATE USER 'dorisuser'@'%' IDENTIFIED BY 'password' DEFAULT ROLE  
'dorisrole';
```

Commands carrying authentication passwords pose security risks. Disable historical command recording before running such commands to prevent information leakage.

----End

## Configuring the Network of the Running Environment

Nodes used for program debugging or running must be able to communicate with nodes within the MRS cluster, and the host domain names must be configured.

- Scenario 1: Configure the network connection between the local Windows environment and MRS cluster nodes.
  - a. Log in to FusionInsight Manager, click **Download Client** in the upper right corner of **Homepage**, select **Configuration Files Only** for **Select Client Type**, and click **OK**. After the client file package is generated, download the client to the local PC as prompted and decompress it.  
For example, if the client configuration file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar**. Then, continue to decompress this file.
  - b. Copy the **hosts** file content from the decompression directory to the **hosts** file of the local PC.

### NOTE

- If you need to debug the application in the local Windows environment, ensure that the local PC can communicate with the hosts listed in the **hosts** file.
- The local **hosts** file in a Windows environment is stored, for example, in **C:\WINDOWS\system32\drivers\etc\hosts**.
- When configuring IPv6 hosts on the local PC running Windows, add **%** and the interface index of the network interface card (NIC) to the end of the IPv6 address. The interface index can be obtained by running the **ipconfig** command.

The following is an example:

fec1:0:0:e505:8:99:5:1%10

- Scenario 2: Configure the network communication between the Linux environment and MRS cluster nodes.
  - a. Install the MRS cluster client on nodes.  
For example, the client installation directory can be **/opt/hadoopclient**.
  - b. Obtain the configuration files.
    - i. Log in to FusionInsight Manager, click **Download Client** in the upper right corner of **Homepage**. Set **Select Client Type** to **Configuration Files Only**, select **Save to Path**, and click **OK** to download the client configuration file to the active OMS node of the cluster.

- ii. Log in to the active OMS node as user **root** and go to the directory where the client configuration file is stored. The default directory is **/tmp/FusionInsight-Client/**.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf  
FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles
```

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If they are not contained, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client is deployed.

### 2.2.2.3 Configuring and Importing JDBC or Stream Load Sample Projects

#### Background

To run the JDBC or Stream Load API sample code of the Doris component, perform the following operations.

#### Procedure

- Step 1** Obtain the sample project folder **doris-jdbc-example** or **doris-stream-load-example** in the **src\doris-examples** directory in the sample code decompression directory by referring to [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Import the sample project to the IntelliJ IDEA development environment.
  1. On the menu bar of IntelliJ IDEA, choose **File > Open...** to display the Open File or Project dialog box.
  2. In the displayed dialog box, select the **doris-jdbc-example** or **doris-stream-load-example** folder and click OK. In Windows, the full path of the folder does not contain spaces.

 NOTE

- This section describes how to develop an application that connects to the Doris service in JDBC mode in Windows.
  - Set the **DORIS\_MY\_USER** and **DORIS\_MY\_PASSWORD** environment variables in the local environment variables. Store the environment variables in ciphertext and decrypt the environment variables to ensure security.
    - **DORIS\_MY\_USER** indicates the user name for logging in to the Doris.
    - **DORIS\_MY\_PASSWORD** indicates the password for logging in to the Doris.
- If the error message "Could not connect to *IP address of the FE instance*.MySQL protocol query connection port" is displayed during the execution of the sample program, the configured local environment variables may not take effect. In this case, restart the computer for the settings to take effect.
- After the **jdbc-example** sample project is imported, modify the following parameters:
    - In the code, change `xxx` in **HOST = "xxx"** to the IP address of the master FE node of the Doris. To obtain the IP address of the master FE node, choose **Cluster > Services > Doris** on Manager and view the **Host Where Leader Locates**.
    - In the code, change `xxx` where **PORT = "xxx"** to the MySQL query connection port of Doris. The default port is 29982. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and search for **query\_port**.

**Step 3** Set the encoding format of the IntelliJ IDEA text file to solve the problem of garbled characters.

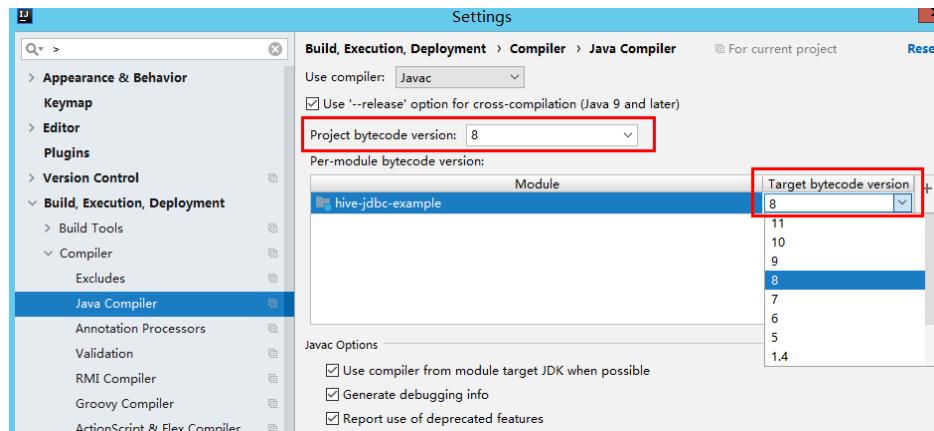

1. Choose **File > Settings...** from the main menu of IntelliJ IDEA.  
The Settings window is displayed.
2. In the navigation tree on the left, choose **Editor > File Encodings**. In the **Project Encoding** and **Global Encoding** areas, set the parameter value to **UTF-8**, click **Apply**, and click **OK**, as shown in [Figure 2-14](#).

**Figure 2-14** Setting the Encoding Format of IntelliJ IDEA

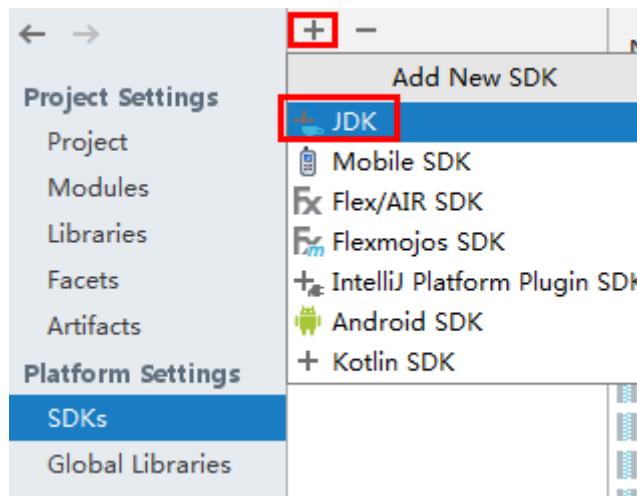

**Step 4** Set the JDK of the project.

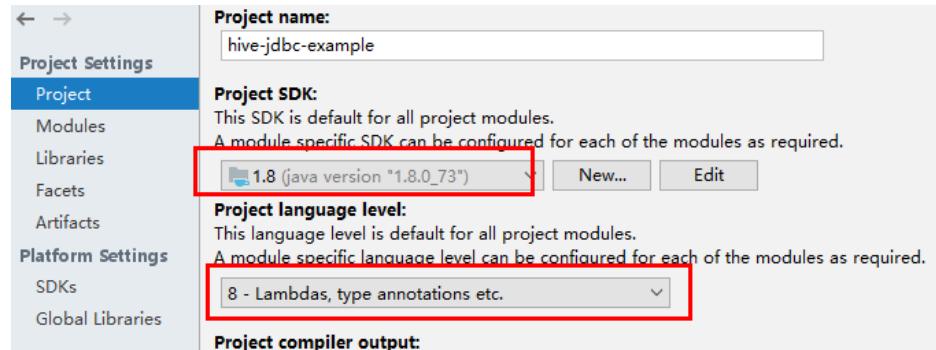

1. On the IntelliJ IDEA menu bar, choose **File > Settings....** The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler**, select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** to **8** for **doris-jdbc-example**.

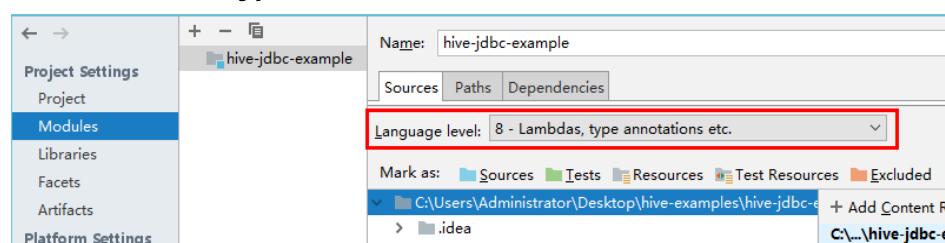

3. Click **Apply** and **OK**.
4. On the IntelliJ IDEA menu bar, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Select **SDKs**, click the plus sign (+), and select **JDK**.

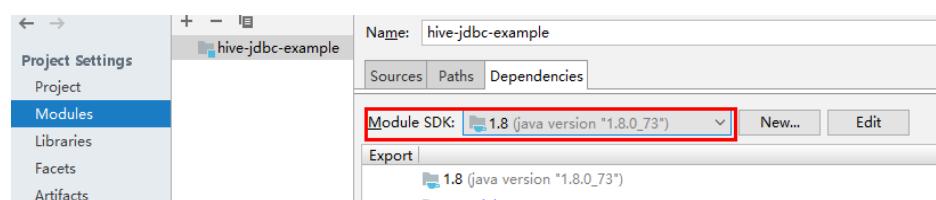

6. On the **Select Home Directory for JDK** page that is displayed, select the **JDK** directory and click **OK**.
7. After selecting the JDK, click **Apply**.
8. Select **Project**, select the JDK added in SDKs from the **Project SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Project language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Source** page, change the value of **Language level** to **8 - Lambdas, type annotations etc.**

On the **Dependencies** page, change the value of **Module SDK** to the JDK added in **SDKs**.

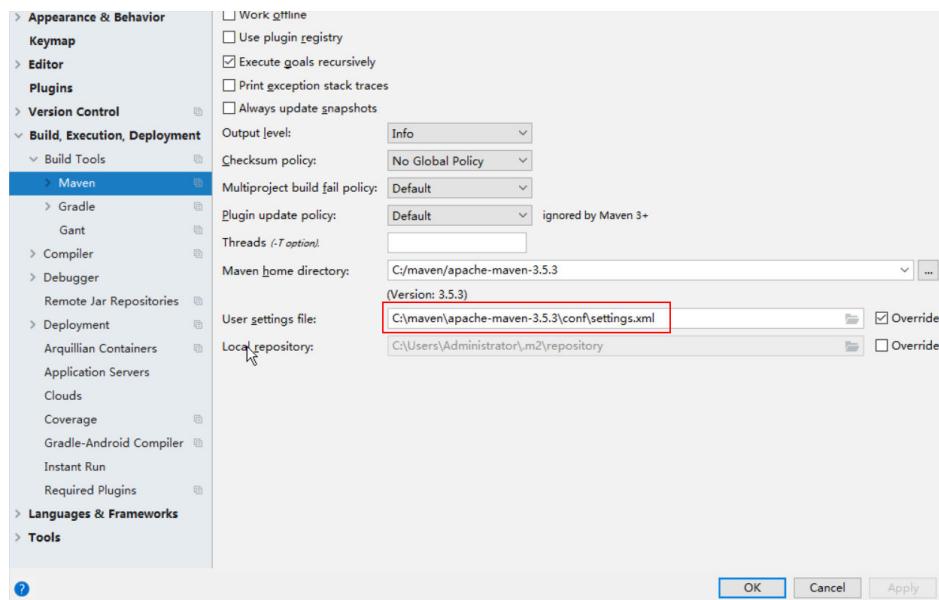

11. Click **Apply** and **OK**.

#### Step 5 Configure Maven.

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, select **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is **<Local Maven installation directory>\conf\settings.xml**.

Figure 2-15 Directory for storing the **settings.xml** file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply**, and then click **OK**.

----End

#### 2.2.2.4 Configuring and Importing SpringBoot Sample Projects

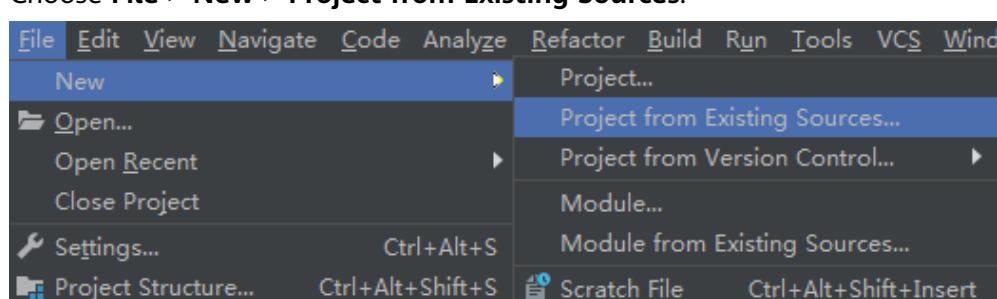

##### Background

To run the SpringBoot API sample code of the Doris component of MRS, perform the following operations:

This section describes how to develop an application that connects to the Doris service in SpringBoot mode in Windows.

##### Procedure

- Step 1** Obtain the sample project folder **doris-rest-client-example** in the **src/springboot/doris-examples** directory in the sample code decompression directory by referring to [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.
1. Choose **File > New > Project from Existing Sources**.

2. In the **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **doris-rest-client-example** folder and click **OK**.
3. Confirm the subsequent configuration and click **Next**. If there is no special requirement, use the default value.

Select the recommended JDK version and click **Finish**.

#### NOTE

- This section describes how to develop an application that connects to the Doris service in SpringBoot mode in Windows.
- Set the **DORIS\_MY\_USER** and **DORIS\_MY\_PASSWORD** environment variables in the local environment variables. Store the environment variables in ciphertext and decrypt the environment variables to ensure security.
  - **DORIS\_MY\_USER** indicates the user name for logging in to the Doris.
  - **DORIS\_MY\_PASSWORD** indicates the password for logging in to the Doris.If the error message "Could not connect to *IP address of the FE instance*.MySQL protocol query connection port" is displayed during the execution of the sample program, the configured local environment variables may not take effect. In this case, restart the computer for the settings to take effect.
- After the **doris-rest-client-example** sample project is imported, modify the following parameters:
  - In the code, change `xxx` in `HOST = "xxx"` to the IP address of the master FE node of the Doris. To obtain the IP address of the master FE node, choose **Cluster > Services > Doris** on Manager and view the **Host Where Leader Locates**.
  - In the code, change `xxx` where `PORT = "xxx"` to the MySQL query connection port of Doris. The default port is 29982. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and search for **query\_port**.

----End

#### NOTE

- This section describes how to develop an application that connects to the Doris service in JDBC mode in Windows.
- After the **jdbc-example** sample project is imported, modify the following parameters:
- Change the value of `xxx` under `USER = "xxx"` in the code to the actual development user, for example, `developuser`.
- Change the value of `xxx` under `PASSWD = "xxx"` in the code to the actual password of the development user.
- In the code, change `xxx` in `HOST = "xxx"` to the IP address of the master FE node of the Doris. You can obtain the IP address of the master FE node by choosing **Cluster > Service > Doris** on FusionInsight Manager and checking the host where the leader resides.
- In the code, change `xxx` where `PORT = "xxx"` to the MySQL query connection port of Doris. The default port is 29982. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Service > Doris > Configuration**, and search for **query\_port**.

## 2.2.3 Doris Application Development

### 2.2.3.1 Using Doris Through JDBC and DBalancer

### 2.2.3.1.1 Service Scenario Description

This section describes how to quickly learn the Doris development process and understand key interface functions.

#### Scenario

Doris can use SQL statements to perform common service operations. The SQL operations involved in the code example include creating a database, creating a table, inserting table data, querying table data, deleting a table, and deleting a database (DBalancer).

The code sample operation process is as follows:

1. Connect to Doris using JDBC or DBalancer.
2. Create a database.
3. Create a table in the database.
4. Inserts data into a table.
5. Query table data.
6. Delete the table.
7. Delete a database. (DBalancer)

### 2.2.3.1.2 Application Development Approach

#### Function Decomposition

Doris is compatible with the MySQL protocol. Common operations can be performed by using the SQL language.

The development process consists of the following parts:

- Establish a connection: Establish a connection to the Doris service instance.
- Create Library: Create a Doris database.
- Create Table: Create a table in the Doris database.
- Insert Data: Insert data into the Doris table.
- Querying data: Query the Doris table data.
- Deleting a table: You can delete a created Doris table.
- Deleting a database (DBalancer): You can delete a created Doris database.

### 2.2.3.1.3 Setting Up a Connection

#### Connecting Doris Using JDBC

The following code snippet uses the **createConnection** method of the **JDBCExample** class in the **com/huawei/bigdata/doris/example** package.

```
private static Connection createConnection() throws Exception {  
    Connection connection = null;  
    try {  
        Class.forName(JDBC_DRIVER);  
        String dbUrl = String.format(DB_URL_PATTERN, HOST, PORT);  
        connection = DriverManager.getConnection(dbUrl, USER, PASSWD);  
    } catch (Exception e) {
```

```
        logger.error("Init doris connection failed.", e);
        throw new Exception(e);
    }
    return connection;
}
```

In the preceding code snippet, HOST and PORT indicate the IP address of the master FE node and the MySQL query connection port for Doris, respectively.

- To obtain the IP address of the master FE node, log in to FusionInsight Manager, choose **Cluster > Services > Doris**, and check the **Host Where Leader Locates**.
- The default MySQL query connection port is 29982. To obtain the port number, log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and search for **query\_port**.

```
private static final String HOST = "192.168.67.78";
private static final int PORT = 29982;
```

## Connecting Doris Using DBalancer

The following code snippet uses the **createConnection** method on the **DBalancerJDBCExample** class in the **com.huawei/bigdata/doris/example** package.

```
private static Connection createConnection() throws Exception {
    Connection connection = null;
    try {
        Class.forName(JDBC_DRIVER);
        String dbUrl = String.format(DB_URL_PATTERN, HOST, PORT);
        connection = DriverManager.getConnection(dbUrl, USER, PASSWD);
    } catch (Exception e) {
        logger.error("Init doris connection failed.", e);
        throw new Exception(e);
    }
    return connection;
}
```

In the preceding code snippet, HOST and PORT indicate the IP address of the DBalancer node and DBalancer TCP access port set in the following example.

- To obtain the IP address of the DBalancer node, log in to FusionInsight Manager and choose **Cluster > Services > Doris > Instances**.
- The default TCP access port of DBalancer is 29992. To obtain the port number, log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and search for **balancer\_tcp\_port**.

```
private static final String HOST = "192.168.20.37";
private static final int PORT = 29992;
```

### 2.2.3.1.4 Creating a Database

Run the SQL statement in Java JDBC mode or Java DBalancer to create the database corresponding to the *dbName* variable in the cluster.

```
String createDatabaseSql = "create database if not exists dbName";
public static void execDDL(Connection connection, String sql) throws Exception {
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.execute();
    } catch (Exception e) {
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

### 2.2.3.1.5 Creating a Table

Run the SQL statement in Java JDBC or Java DBalancer mode to create the table corresponding to *tableName* in the database corresponding to the *dbName* variable in the cluster.

```
String createTableSql = "create table if not exists " + dbName + "." + tableName + " (\n" +
    "c1 int not null,\n" +
    "c2 int not null,\n" +
    "c3 string not null\n" +
    ") engine=olap\n" +
    "unique key(c1, c2)\n" +
    "distributed by hash(c1) buckets 1";
public static void execDDL(Connection connection, String sql) throws Exception {
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.execute();
    } catch (Exception e) {
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

### 2.2.3.1.6 Inserting Data

Run the following SQL statement in Java JDBC or Java DBalancer mode to insert data into the *dbName.tableName* table of the cluster.

```
String insertTableSql = "insert into " + dbName + "." + tableName + " values(?, ?, ?)";
private static void insert(Connection connection, String sql) throws Exception {
    int INSERT_BATCH_SIZE = 10;
    try(PreparedStatement stmt = connection.prepareStatement(sql)) {
        for (int i =0; i < INSERT_BATCH_SIZE; i++) {
            stmt.setInt(1, i);
            stmt.setInt(2, i * 10);
            stmt.setString(3, String.valueOf(i * 100));
            stmt.addBatch();
        }
        stmt.executeBatch();
    } catch (Exception e) {
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

### 2.2.3.1.7 Querying Data

Use Java JDBC to run SQL statements to query data in the *dbName.tableName* table in the cluster.

```
String querySql = "select * from " + dbName + "." + tableName + " limit 10";
private static void query(Connection connection, String sql) throws Exception {
    try (Statement stmt = connection.createStatement());
        ResultSet resultSet = stmt.executeQuery(sql);
        ResultSetMetaData md = resultSet.getMetaData();
        int columnCount = md.getColumnCount();
        StringBuffer stringBuffer = new StringBuffer();
        logger.info("Start to print query result.");
        for (int i = 1; i <= columnCount; i++) {
            stringBuffer.append(md.getColumnName(i));
            stringBuffer.append(" ");
        }
        logger.info(stringBuffer.toString());

        while (resultSet.next()) {
            stringBuffer = new StringBuffer();
            for (int i = 1; i <= columnCount; i++) {
                stringBuffer.append(resultSet.getObject(i));
            }
        }
    }
}
```

```
        stringBuffer.append(" ");
    }
    logger.info(stringBuffer.toString());
}
} catch (Exception e) {
    logger.error("Execute sql {} failed.", sql, e);
    throw new Exception(e);
}
}
```

### 2.2.3.1.8 Deleting a table

Run the SQL statement in Java JDBC mode to delete the *dbName.tableName* table from the cluster.

```
String dropSql = "drop table " + dbName + "." + tableName;
public static void execDDL(Connection connection, String sql) throws Exception {
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.execute();
    } catch (Exception e) {
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

### 2.2.3.1.9 Deleting a Database

Run the SQL statement using Java DBalancer to delete the *dbName* database from the cluster.

```
String dropDb = "drop database " + dbName;
public static void execDDL(Connection connection, String sql) throws Exception {
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.execute();
    } catch (Exception e) {
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

## 2.2.3.2 Loading Data to a Doris Table with Stream Load

The Doris Stream Load sample program imports local CSV file data to a Doris table.

### Example Code

Modify the following parameters in the sample code based on the site requirements:

- **HOST**: IP address of the master FE node of Doris. To obtain the IP address of the master FE node, log in to FusionInsight Manager, choose **Cluster > Services > Doris**, and check **Host Where Leader Locates**.
- **PORT**: HTTPS port of the Doris FE service. The default value is **29980**. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Services > Doris**, click **Configurations**, and search for **http\_port**.
- **JDBC\_PORT**: The value is the MySQL protocol query connection port of the Doris. The default port is **29982**. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and search for **query\_port**.

- **DATABASE:** database of the table storing imported data
- **TABLE:** name of the Doris table that stores imported data
- **getHttpPost:** path of the CSV file to be imported

```
public class DorisStreamLoader {

    // FE IP Address
    private final static String HOST = "192.168.13.178";
    // If Kerberos authentication is enabled for the cluster (the cluster is in security mode), FE port is the value
    // of https_port; If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), FE port
    // is the value of http_port.
    private final static int PORT = 29980;

    private final static int JDBC_PORT = 29982;
    // db name
    private final static String DATABASE = "test_2";
    // table name
    private final static String TABLE = "doris_test_sink";

    private static final String JDBC_DRIVER = "com.mysql.cj.jdbc.Driver";
    private static final String DB_URL_PATTERN = "jdbc:mysql://%s:%d?rewriteBatchedStatements=true";

    private static final String USER = System.getenv("DORIS_MY_USER");
    private static final String PASSWD = System.getenv("DORIS_MY_PASSWORD");

    // If Kerberos authentication is enabled for the cluster (the cluster is in security mode), Start the url with
    // https; If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), start the url
    // with http.
    private final static String loadUrl = String.format("http://%s/api/%s/%s/_stream_load",
            HOST, PORT, DATABASE, TABLE);

    // Call the Curl method.
    public static String execCurl(String[] cmd) {
        ProcessBuilder process = new ProcessBuilder(cmd);
        Process p;
        try {
            p = process.start();
            BufferedReader reader = new BufferedReader(new InputStreamReader(p.getInputStream()));
            StringBuilder builder = new StringBuilder();
            String line;
            while ((line = reader.readLine()) != null) {
                System.out.println(line);
                builder.append(line);
                builder.append(System.getProperty("line.separator"));
            }
            return builder.toString();
        } catch (Exception e) {
            System.out.print("error");
        }
        return null;
    }

    public static void initTable(){
        String createDatabaseSql = "create database if not exists "+DATABASE;

        String createTableSql = "create table if not exists " + DATABASE + "." + TABLE + " (\n" +
            " `id` int NULL COMMENT '\"',\n" +
            " `number` int NULL COMMENT '\"',\n" +
            " `price` DECIMAL(12,2) NULL COMMENT '\"',\n" +

```

## 2.2.4 Application Commissioning

## 2.2.4.1 Commissioning an Application in Windows

### 2.2.4.1.1 Compiling and Running an Application

#### Scenario

After the code development is complete, you can run the application in the Windows development environment.

If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

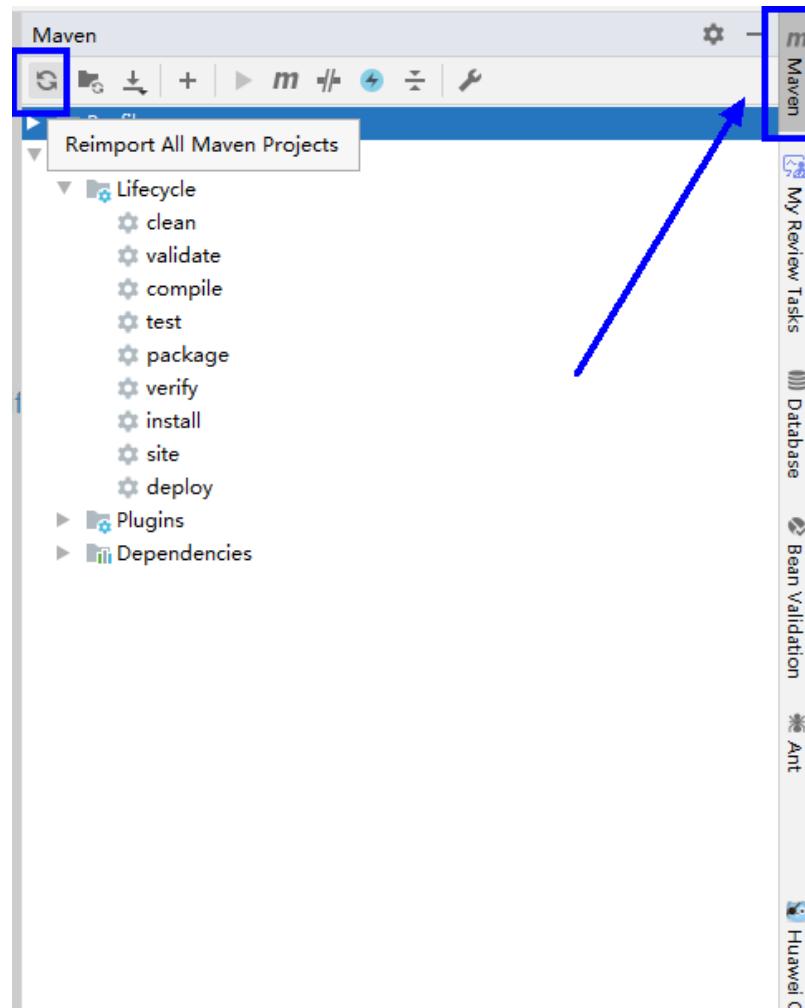

#### NOTE

- If IBM JDK is used in the Windows development environment, the application cannot be run in the Windows environment.
- You need to set the mapping between the host names and IP addresses of the access nodes in the hosts file on the local host where the sample code is run. The host names and IP addresses must be mapped one by one.

#### Procedure

**Step 1** Click **Reimport All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

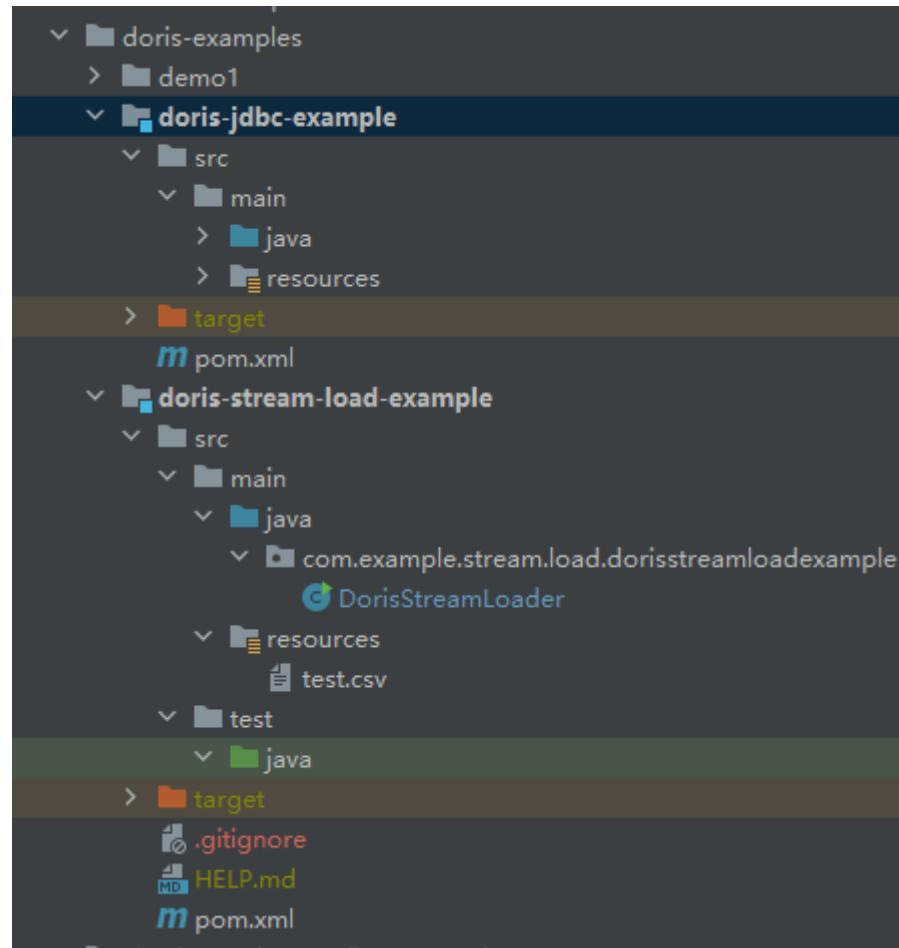

Figure 2-16 reimport projects

**Step 2** Compile and run an application.

Place the configuration file directory and modify the code to match the login user.  
See [Figure 2-17](#).

Figure 2-17 Directory list of Doris to be compiled

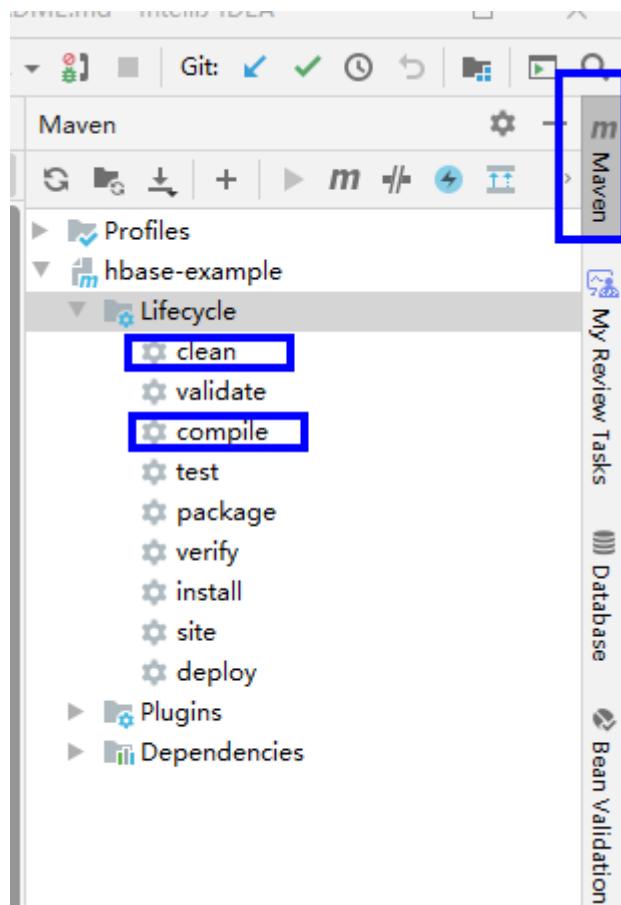

1. Compile an application.

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean** and double-click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **compile**, double click **compile** to run the **compile** command of Maven.

Figure 2-18 clean and compile tools of Maven

- Method 2:

Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean compile** command to compile the **pom.xml** file.

When the compilation is complete, the **Build Success** message is printed and the target directory is generated.

Figure 2-19 doris-jdbc-example compiled

```
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 1.241 s

[INFO] -----
```

 NOTE

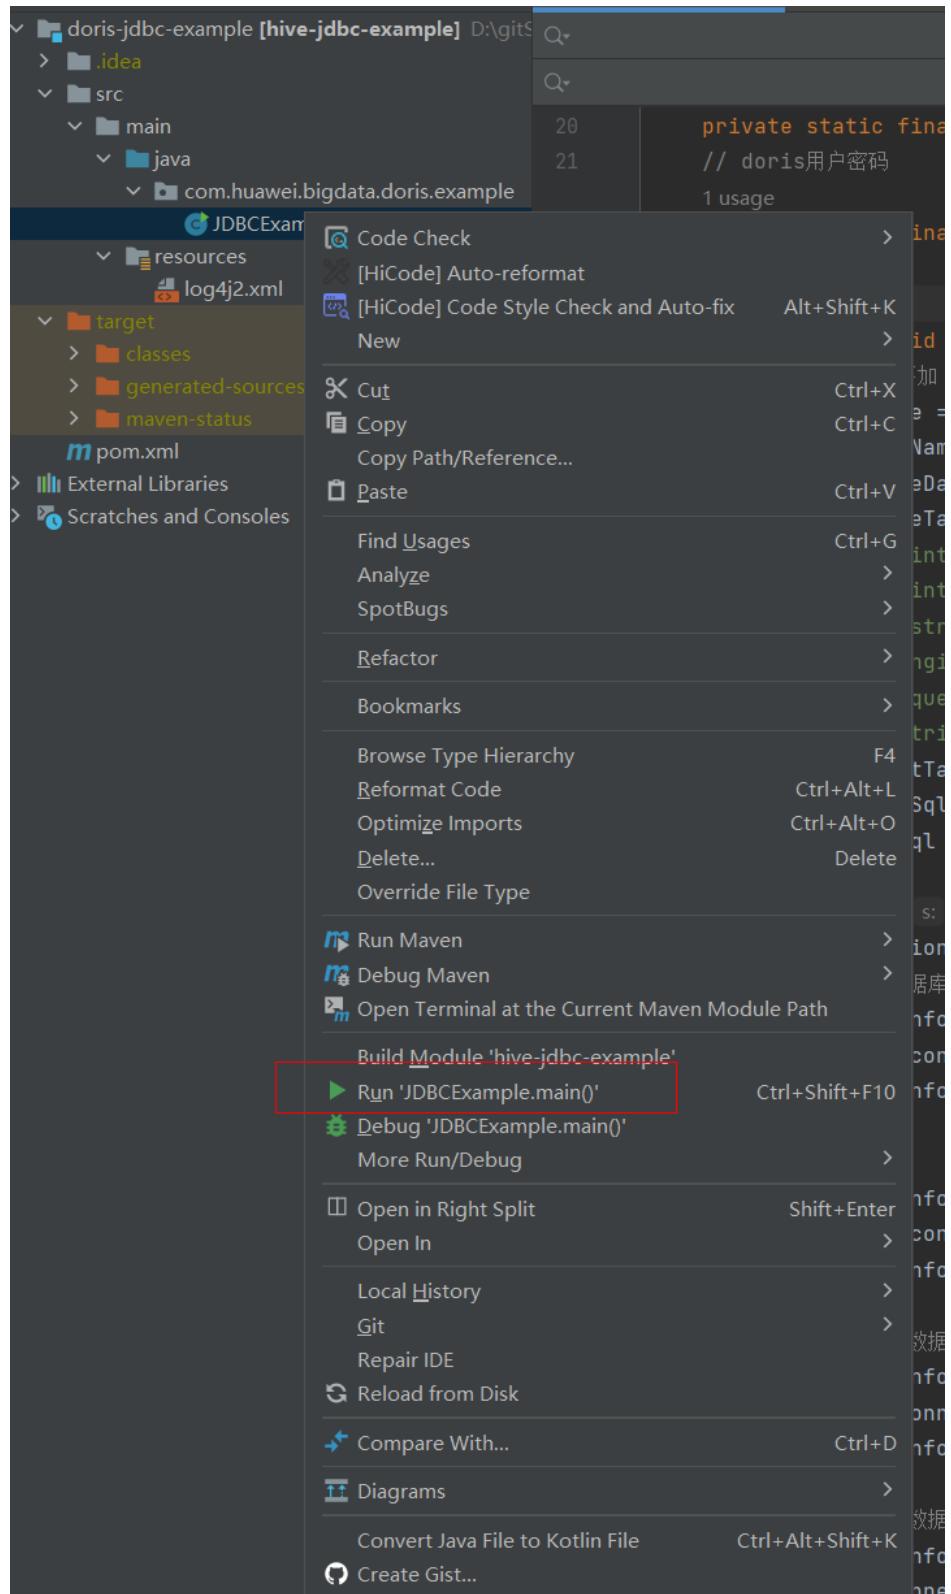

If the error message "Please use -source 7 or later to enable try-with-resources" is displayed during compilation, add the following content to the **properties** tag in the **pom.xml** configuration file:

```
<maven.compiler.source>8</maven.compiler.source>
<maven.compiler.target>8</maven.compiler.target>
```

2. Run the program.

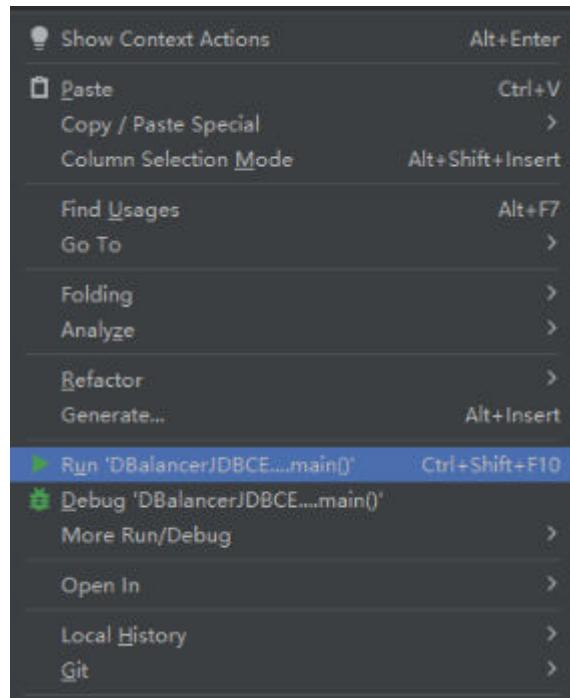

- Right-click the **JDBCExample.java** file and choose **Run 'JDBCExample.main()'**.

Figure 2-21 Run the Doris application.

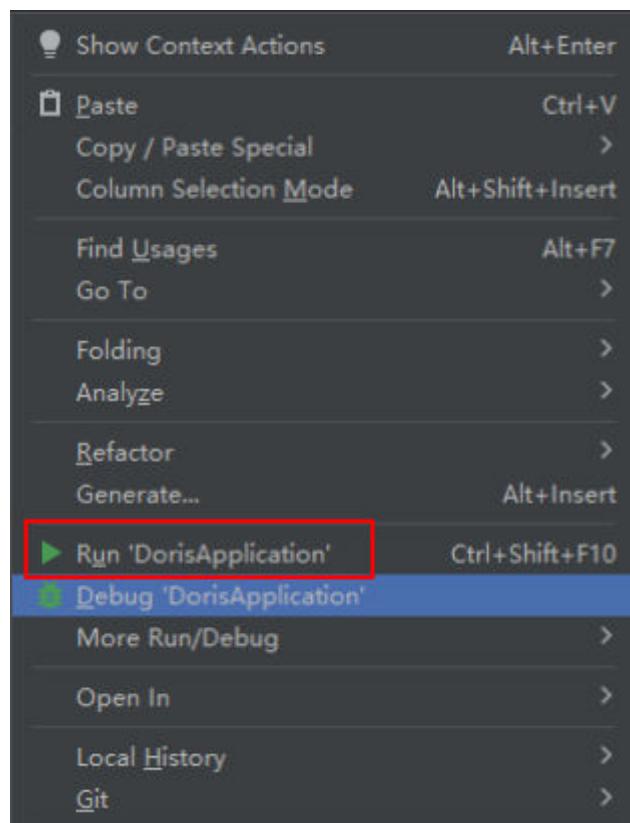

- Right-click the **DBalancerJDBCExample.java** file and choose **Run 'DBalancerJDBCExample.main()'**.

Figure 2-22 Run the DorisDBalancer application.

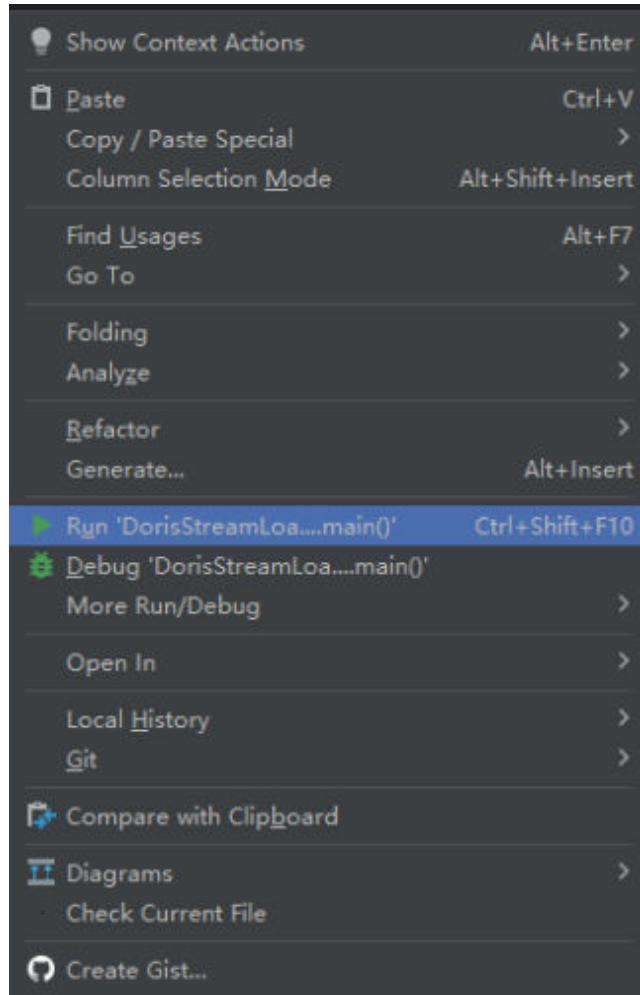

- Right-click the **DorisApplication.java** file and choose **Run 'DorisApplication'**.

Figure 2-23 Run the Doris SpringBoot application.

- Right-click the **DorisStreamLoader.java** file and choose **Run 'DorisStreamLoader.main()'**.

Figure 2-24 Run the Doris Stream Load application.

----End

#### 2.2.4.1.2 Viewing Windows Commissioning Results

##### Operation Scenario

After a Doris application finishes running, you can use one of the following methods to view the running result:

- Check the IntelliJ IDEA.
- Check the Doris log.

##### Procedure

- After the **JDBCExample.java** of **doris-jdbc-example** sample is successfully executed, the following information is displayed:

```

## 2.2.4.2 Commissioning an Application in Linux

### 2.2.4.2.1 Compiling and Running Applications

#### Scenario

After application code development is complete, you can upload a JAR file to the Linux environment to run applications.

#### Prerequisites

- You have installed a JDK in the Linux environment. The version of the JDK must be consistent with that of the JDK used by IntelliJ IDEA to export the JAR file.
- If the host where the Linux environment is deployed is not a node in the cluster, the mapping between the host name and the IP address must be set in the **hosts** file on the node where the Linux environment is deployed. The host names and IP addresses must be mapped one on one.

## Compiling and Running JDBC, DBalancer and SpringBoot Programs

### Step 1 Export a JAR file.

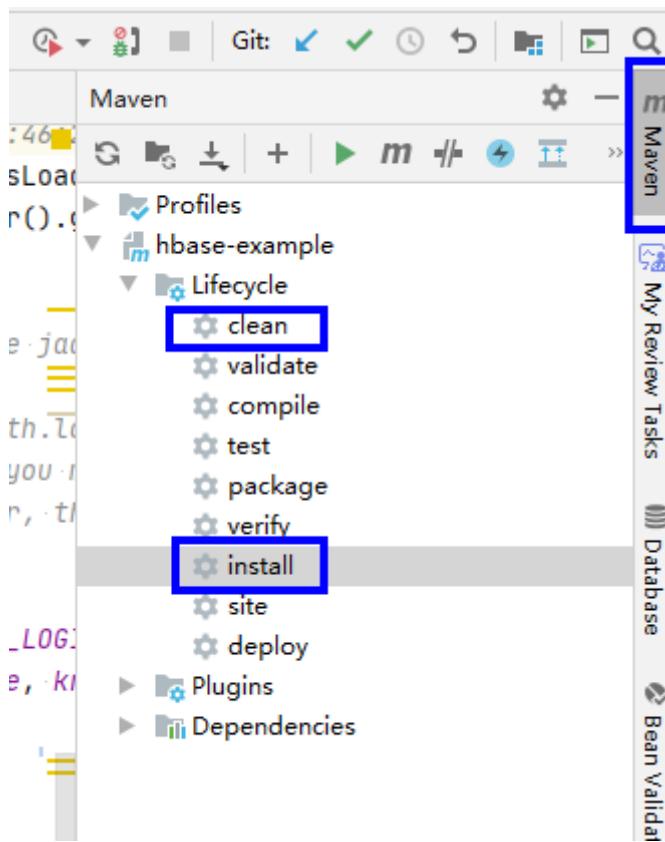

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven**, locate the target project name, and double-click **clean** under **Lifecycle** to run the **clean** command of Maven.

Choose **Maven**, locate the target project name, and double-click **install** under **Lifecycle** to run the **install** command of Maven.

Figure 2-27 Maven clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window of IDEA, and run the **mvn clean install** command to build the file.

After the build is complete, message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

**Step 2** Decide whether to run Doris to connect to SpringBoots.

- If yes, perform the following steps to run the sample:
  - Create a running directory in the Linux environment and save the **doris-rest-client-example-\*jar** file in the **target** directory to this directory.
  - Switch to the running directory and run the following command to run the JAR package:  
**java -jar doris-rest-client-example-\*jar-with-dependencies.jar**
- If no, go to **Step 4**.

**Step 3** Export the JAR package on which the sample project depends.

Go to the directory where the **pom.xml** file is stored in the **Terminal** window at the bottom of the IDEA or in other command line tools. Run the following command:

**mvn dependency:copy-dependencies -DoutputDirectory=lib**

The **lib** folder is generated in the directory where the **pom.xml** file is stored. The **lib** folder contains the JAR packages on which the sample project depends.

**Step 4** Prepare the dependency JAR file and configuration file.

1. In the Linux environment, create a directory, for example, **/opt/test**, and create the subdirectory **lib**. Export the JAR package on which the sample project depends, and upload the JAR package generated in **Step 1** and JAR package generated in **Step 3** to the **lib** directory of the Linux operating system.
2. In the **/opt/test** root directory, create the **run.sh** script, modify the following content, and save the file:

```
#!/bin/sh  
BASEDIR=`cd $(dirname $0);pwd`  
cd ${BASEDIR}  
for file in ${BASEDIR}/lib/*.jar  
do  
i_cp=$i_cp:$file  
echo "$file"  
done  
  
java -cp ${i_cp} com.huawei.bigdata.doris.example.JDBCExample
```

**com.huawei.bigdata.doris.example.JDBCExample** is used as an example. Replace it with the actual code.

**Step 5** Configure the environment variables **DORIS\_MY\_USER** and **DORIS\_MY\_PASSWORD**.

1. Add the following content to the **/etc/profile** file and save the file:  
*DORIS\_MY\_USER=Username for accessing Doris*  
*DORIS\_MY\_PASSWORD=Password for accessing Doris*
2. Run the following command to apply the environment variables:  
**source /etc/profile**

**Step 6** Go to **/opt/test** and run the following command to run the JAR file:

**sh run.sh**

----End

## Compiling and Running the Stream Load Program

- Step 1** Create a directory in the Linux environment, for example, **/opt/test**, and upload the **/src/main/resources/test.csv** file prepared in the **doris-stream-load-example** sample project obtained in **Step 1** to the directory.
- Step 2** Change the value of **getHttpPost** in the **doris-stream-load-example** sample code to **/opt/test/test.csv**.
- Step 3** Export a JAR file.

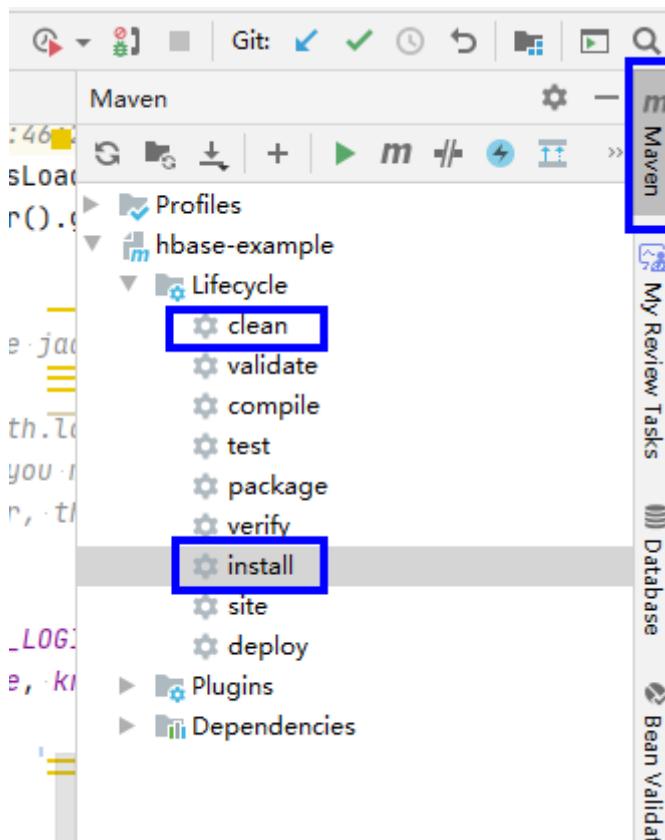

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven**, locate the target project name, and double-click **clean** under **Lifecycle** to run the **clean** command of Maven.

Choose **Maven**, locate the target project name, and double-click **install** under **Lifecycle** to run the **install** command of Maven.

Figure 2-28 Maven clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window of IDEA, and run the **mvn clean install** command to build the file.

After the build is complete, message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

**Step 4** Place **doris-stream-load-example-\*jar** in the **target** directory to the directory created in **Step 1**, for example, **/opt/test**.

**Step 5** Switch to the JDK directory and run the JAR package.

```
java -jar doris-stream-load-example-*jar-with-dependencies.jar
```

----End

#### 2.2.4.2.2 Viewing Linux Commissioning Results

- After the **JDBCExample.java** of **doris-jdbc-example** sample is successfully executed, the following information is displayed:

```
2023-08-17 23:13:13,473 | INFO | main | Start execute doris example. |

## 2.3 Elasticsearch Development Guide

### 2.3.1 Overview

#### 2.3.1.1 Application Development Overview

##### Introduction to Elasticsearch

Elasticsearch, a Lucene-powered search server, provides a distributed full-text search and analysis engine with multi-user capabilities. Designed for big data scenarios, Elasticsearch is easy to install and use and supports stable, fast, and reliable real-time search and analysis.

In addition to the basic functions, such as timestamp-based filtering and exact math provided by traditional relational databases, Elasticsearch can perform full-text search, process synonyms, score documents based on the correlation, and generate analysis and aggregation results based on the same data. Data can be processed in real time if a large number of working processes do not exist.

#### 2.3.1.2 Concepts

##### Basic Concepts

- **cluster**

There are multiple nodes in a cluster, one of which is the master node and the others are the slave nodes. Master node and slave node are defined within a cluster. In Elasticsearch, decentralization is posed. That is, there is no "central node" of the Elasticsearch cluster to external systems. Nodes in an Elasticsearch cluster can be logically considered as an entity. In this way, communication with any node in Elasticsearch is equivalent to the communication with the Elasticsearch cluster.

- **shards**

Indicates the index shard. Elasticsearch can divide a complete index into multiple shards. In this way, a large index can be split into multiple shards and distributed to different nodes, implementing distributed search. The number of shards can only be specified before the index is created and cannot be changed after the index is created.

- **replicas**

Indicates the index replica. Elasticsearch allows you to set multiple replicas for an index. Replication is to improve the fault tolerance of the system. When a shard of a node is damaged or lost, the system can restore it using its replica. In addition, replication is to improve the query efficiency of Elasticsearch. Elasticsearch automatically balances the search requests.

- **recovery**

Indicates data restoration or data redistribution. When a node is added or deleted, Elasticsearch redistributes index shards based on the load of the corresponding physical server. When a faulty node is restarted, data restoration is also performed.

- **river**

Indicates a data source of Elasticsearch. It is also a method of synchronizing data from other storage modes (such as the database) to Elasticsearch. **river** is a plug-in Elasticsearch service. The river plug-in reads data from a river data source and indexes it to Elasticsearch. Official rivers include those from CouchDB, RabbitMQ, Twitter, and Wikipedia.

- **gateway**

Indicates the storage mode of an Elasticsearch index snapshot. By default, Elasticsearch stores an index in the memory. When the memory is full, Elasticsearch persistently saves the index to the local hard disk. A gateway stores index snapshots. When the corresponding Elasticsearch cluster is stopped and then restarted, the index backup data is read from the gateway. Elasticsearch supports multiple types of gateways, including local file systems (default), distributed file systems, and Hadoop HDFS.

- **discovery.zen**

Indicates the automatic node discovery mechanism of Elasticsearch. Elasticsearch is a P2P system. It searches for existing nodes through broadcast and then communicates with nodes through multicast protocols. Elasticsearch supports P2P interaction.

- **Index**

Indicates the data storage mode of Elasticsearch and is similar to a table in relational database .

- **Document**

Is similar to the row of a relational database. Each document of the same index has a unique ID.

- **Field**

Is similar to the column in a relational database, which is the smallest unit of Elasticsearch data storage.

### 2.3.1.3 Application Development Process

[Figure 2-31](#) shows the Elasticsearch application development process.

Figure 2-31 Elasticsearch application development process

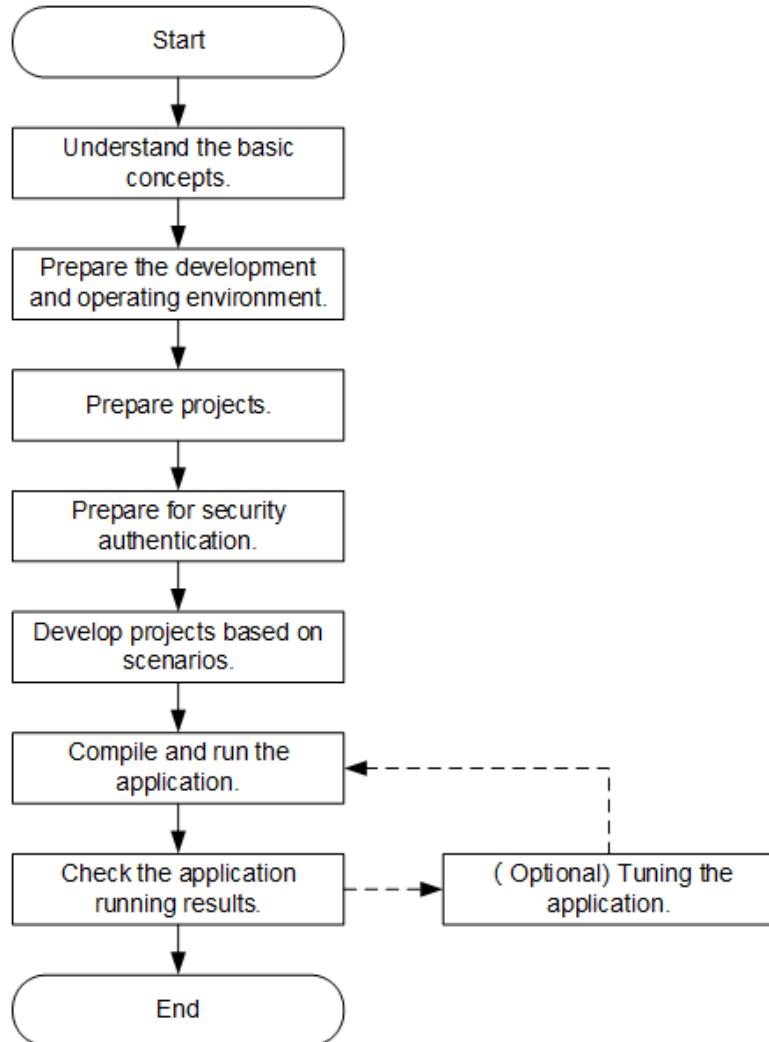

Table 2-8 Description of the Elasticsearch application development process

| Phase   | Description  | Reference   |
|---|--|---|
| Understand basic concepts.                        | Before application development, learn basic concepts of Elasticsearch and understand scenario requirements.  | <a href="#">Concepts</a>  |
| Development Environment and Operating Environment | Elasticsearch applications support RESTful development using Java. You are advised to use the IDEA tool to configure development environments. Elasticsearch runs on an Elasticsearch client. Install and configure the client according to the guide. | <a href="#">Preparing the Development Environment and Operating Environment</a> |

| Phase                                    | Description  | Reference   |
|--|--|---|
| Prepare a project.                       | Elasticsearch provides sample projects for different scenarios. You can import a sample project to learn the application. You can also create an Elasticsearch project according to the guide. | <a href="#">Configuring and Importing Sample Projects</a> |
| Develop a project based on the scenario. | Provide a sample project using Java language, covering an entire process for sample projects from query index to deletion index.   | <a href="#">Development Process</a>                       |
| Compile and run applications .           | You can compile the developed application and submit it for running.   | <a href="#">Commissioning Process</a>                     |
| View application running results.        | Application running results are stored under a user-defined path. You can also view the application running status on the UI.  | <a href="#">Commissioning Process</a>                     |

## 2.3.2 Environment Preparation

### 2.3.2.1 Preparing the Development Environment and Operating Environment Preparing Development Environment

**Table 2-9** describes the development environment and operating environment required for application development.

**Table 2-9** Development environment

| Item | Description   |
|------|---|
| OS   | <ul style="list-style-type: none"><li>• Development environment: Windows (Windows 7 or later is supported.)</li><li>• Operating environment: Windows or Linux. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul> |

| Item                                     | Description   |
|--|---|
| Installing JDK                           | <p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul> |
| Installing and configuring IntelliJ IDEA | <p>Tool used for developing GraphBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you use IBM JDK, ensure that the JDK configured in IntelliJ IDEA is IBM JDK.</li><li>• If you use Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is Oracle JDK.</li><li>• If you use Open JDK, ensure that the JDK configured in IntelliJ IDEA is Open JDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>  |
| Installing the JUnit plug-in             | Basic configurations of the development environment.  |

| Item                  | Description  |
|-----------------------|--|
| Installation of Maven | Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development. |
| 7-zip                 | It is a tool used to decompress *.zip and *.rar files. The 7-Zip 16.04 is supported.   |

## Preparing an Operating Environment

During application development, you need to prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#) and choose **Homepage > Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.
  - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Elasticsearch\config** and manually import the configuration file to the configuration file directory (usually the **conf** folder) of the Elasticsearch sample project.
  - c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

### NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.

- a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.  
Ensure that the difference between the client time and the cluster time is less than 5 minutes.  
For details about how to install a cluster client, see [Installing a Client](#).
- b. **Accessing FusionInsight Manager of an MRS Cluster.** Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig \Elasticsearch\config** directory to the **conf** directory where the compiled JAR package is stored for subsequent commissioning, for example, **/opt/hadoopclient/conf**.  
For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:  

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Elasticsearch/config/* root@/P address of the client node:/opt/hadoopclient/conf
```
- c. Check the network connection of the client node.  
During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

### 2.3.2.2 Configuring and Importing Sample Projects

#### 2.3.2.2.1 Overview

##### Background

Obtain the Elasticsearch development sample project. Import the project to IntelliJ IDEA for learning.

##### Prerequisites

Ensure that the time difference between the local PC and the cluster is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. Time of the cluster can be viewed in the lower-right corner on FusionInsight Manager.

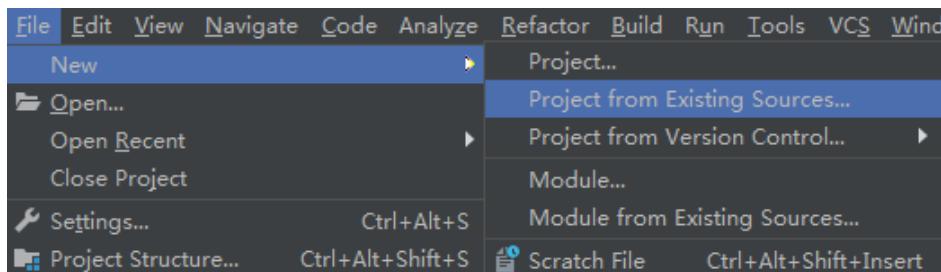

### 2.3.2.2 Importing a RestClient Sample Project

#### Procedure

**Step 1** Obtain the sample project folder **elasticsearch-rest-client-example** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.

1. Choose **File > New > Project from Existing Sources**.

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **elasticsearch-rest-client-example** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.
4. Select the recommended JDK version and click **Finish**.

**Step 3** Find the configuration file **es-rest-client-example.properties** exists in the client folder **Elasticsearch\config** directory. Copy the parameter values in the file to the **esParams.properties** file in the **conf** directory of the sample project.

**Step 4** In the IntelliJ IDEA development environment, open the **esParams.properties** file in the **conf** directory of the sample project, and change the values of the parameters listed in [Table 2-10](#) as required.

**Table 2-10** Configuration table

| Parameter      | Default Value                                     | Description   |
|----------------|---|---|
| esServerHost   | Examples:<br>ip1:port1,ip2:port<br>2,ip3:port3... | Specifies the list of combinations of the IP addresses of nodes in the Elasticsearch cluster and the HTTP ports of the Elasticsearch instances installed on the nodes, except EsMaster instances. |
| connectTimeout | 5000  | Specifies the timeout interval of the connection between the client and the server, in milliseconds.  |
| socketTimeout  | 60,000  | Specifies the server response obtaining timeout interval of the client, in milliseconds.  |

| Parameter                | Default Value | Description   |
|--------------------------|---------------|---|
| connectionRequestTimeout | 100000        | Indicates that the connection timeout interval is obtained from the connection pool, in milliseconds.   |
| maxConnPerRoute          | 100           | Maximum number of connections per route.  |
| maxConnTotal             | 1000          | Maximum number of connections   |
| isSecureMode             | false         | Indicates whether the client is in security mode. The value <b>true</b> indicates that the security mode is enabled, and the value <b>false</b> indicates that the normal mode is enabled.  |
| sslEnabled               | false         | Indicates whether SSL encryption is enabled on the client. The value <b>true</b> indicates that SSL encryption is enabled, and the value <b>false</b> indicates that SSL encryption is disabled. The configuration takes effect only in security mode. In common mode, set this parameter to false. |
| principal                | esuser        | Specifies the authentication subject. The recommended format is "username". You can also use the format of "username@System domain name".   |
| snifferEnable            | true          | Indicates whether the Rest client enables the sniffing function. The value <b>true</b> indicates that the sniffing function is enabled, and the value <b>false</b> indicates that the sniffing function is disabled.  |
| customJaasPath           | null          | User-defined path of the <b>jaas.conf</b> file, which must contain specific file name. If this parameter is not set, the system automatically generates a path.   |

 NOTE

The **principal** and **customJaasPath** parameter is mandatory in security mode and can be ignored in normal mode.

**Step 5** Set **isSecureMode** in the **esParams.properties** file in the **conf** directory of the sample project to **false**, and enable the normal mode.

 NOTE

- If an error is reported during sample code importing, use a later IntelliJ IDEA version.
- The HTTP request function of the EsMaster instance is disabled. The value of the esServerHost parameter does not contain the EsMaster instance, that is, the 24148 port. Otherwise, the request fails.
- Set **esServerHosts** to the list of combinations. The combinations contain the IP addresses of all nodes in the Elasticsearch cluster and the HTTP ports of all Elasticsearch instances installed on the nodes, for example, ip1: Port1, ip2:port2, ip3:port3. You can query the port number as follows: On Manager, choose **Cluster > Name of the desired cluster > Service > Elasticsearch > Configuration > All Configurations**. Click **Port** of the corresponding instance and check the value of **SERVICE\_PORT**.
- To check whether the Elasticsearch cluster is in security mode or normal mode, log in to FusionInsight Manager, choose **Cluster > Name of the desired cluster > Service > Elasticsearch > Configuration > All Configurations**, and search for **ELASTICSEARCH\_SECURITY\_ENABLE** parameter. If this parameter can be queried and its value is **true**, the Elasticsearch cluster is in security mode. If this parameter is not found or its value is **false**, the Elasticsearch cluster is in normal mode.

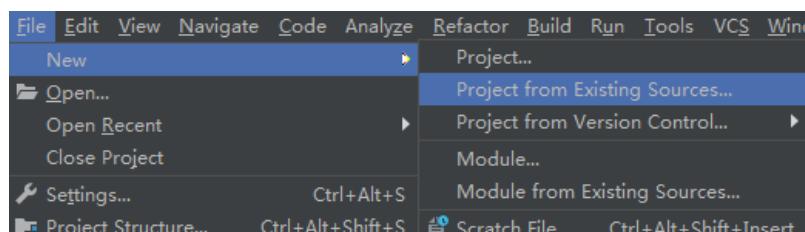

----End

### 2.3.2.2.3 Importing a SpringBoot Sample Project

#### Procedure

- Step 1** Obtain the sample project folder **elasticsearch-rest-client-example** in the **src/springboot/elasticsearch-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Import the sample project to the IntelliJ IDEA development environment in the application development environment.

1. Choose **File > New > Project from Existing Sources....**

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **elasticsearch-rest-client-example** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.
4. Select the recommended JDK version and click **Finish**.

- Step 3** Find configuration file **es-rest-client-example.properties** in the **Elasticsearch \config** directory of the client folder. Copy the parameter values in the file to the **esParams.properties** file in the **conf** directory of the sample project.
- Step 4** In the IntelliJ IDEA development environment, open the **esParams.properties** file in the **conf** directory of the sample project, and change the values of the parameters listed in the following table.

**Table 2-11** Configuration table

| Name                     | Default Value                    | Description  |
|--------------------------|----------------------------------|--|
| esServerHost             | ip1:port1,ip2:port2,ip3:port3... | List of combinations of the IP addresses of nodes in the Elasticsearch cluster and the HTTP ports of the Elasticsearch instances installed on the nodes, except EsMaster instances.  |
| connectTimeout           | 5000                             | Timeout interval of the connection between the client and the server, in milliseconds.   |
| socketTimeout            | 60000                            | Server response obtaining timeout interval of the client, in milliseconds.   |
| connectionRequestTimeout | 100000                           | Connection timeout interval is obtained from the connection pool, in milliseconds.   |
| maxConnPerRoute          | 100                              | Maximum number of connections on each route  |
| maxConnTotal             | 1000                             | Maximum number of connections  |
| isSecureMode             | false                            | Whether the client is in security mode. The value <b>true</b> indicates that the security mode is enabled, and the value <b>false</b> indicates that the normal mode is enabled.   |
| sslEnabled               | false                            | Whether to enable SSL encryption on the client. <b>true</b> indicates that encryption is enabled, and <b>false</b> indicates that encryption is disabled. This configuration takes effect only in security mode. For normal clusters, set this parameter to <b>false</b> . |
| principal                | esuser                           | Authentication subject. The options are as follows: <ul style="list-style-type: none"><li>• <b>Username</b> (recommended)</li><li>• <i>Username@System domain name</i></li></ul>   |
| snifferEnable            | true                             | Whether the REST Client enables the sniffing function. The value <b>true</b> indicates that the sniffing function is enabled, and the value <b>false</b> indicates that the sniffing function is disabled.   |
| customJaasPath           | N/A                              | User-defined path of the <b>jaas.conf</b> file, which must contain specific file name. If this parameter is not set, the system automatically generates a path.  |

 NOTE

The **principal** and **customJaasPath** parameters are mandatory in security mode and can be ignored in normal mode.

**Step 5** Set **isSecureMode** in the **esParams.properties** file in the **conf** directory of the sample project to **false** and enable the normal mode.

 NOTE

- If an error is reported during sample code importing, use the latest Eclipse version.
- The HTTP request function of the EsMaster instance is disabled. The value of the **esServerHost** parameter cannot contain the EsMaster instance, that is, the 24148 port. Otherwise, the request fails.
- Set **esServerHost** to a list of combinations of IP addresses of nodes in the installed Elasticsearch cluster and HTTP ports of Elasticsearch instances installed on the nodes, for example, *ip1:port1,ip2:port2,ip3:port3...*. To query the port number, choose **Cluster > Service > Elasticsearch** on FusionInsight Manager, click **Configuration**, click **All Configurations**, click **Port** of the corresponding instance, and check the value of **SERVER\_PORT**.
- To check whether the current Elasticsearch cluster is in security mode or common mode, log in to FusionInsight Manager, choose **Cluster**, click the name of the desired cluster, and choose **Services > Elasticsearch**. Click **Configuration**, click **All Configurations**, and search for the **ELASTICSEARCH\_SECURITY\_ENABLE** parameter. If the parameter can be queried and its value is **true**, the Elasticsearch cluster is in security mode. If this parameter cannot be queried or the value of this parameter is **false**, the Elasticsearch cluster is in normal mode.

----End

## 2.3.3 Development Process

### 2.3.3.1 Typical Application Scenarios

You can quickly learn and master the Elasticsearch development process and know key API functions in a typical application scenario.

#### Scenarios

Assume that you want to develop an application to search for all library information, provide information about books related to search keywords, and grade the books by score. The search function can be implemented by Elasticsearch. The search process is as follows:

1. Connecting the client to a cluster
2. Querying the health status
3. Checking whether a specified index exists
4. Creating an index for specifying the number of shards
5. Writing index data
6. Writing data in batches
7. Batch write data to specified routes
8. Querying index information
9. Deleting an index

10. Deleting documents in an index
11. Refreshing an index
12. Using a multi-thread sample for query
13. Pre-sorting indices

### 2.3.3.2 Low Level RestClient Sample Java Code

#### 2.3.3.2.1 Connecting the Elasticsearch Client to an Elasticsearch Cluster

##### Function Description

Before using APIs provided by Elasticsearch, you need to obtain the Elasticsearch client. Connect the Elasticsearch client to the desired Elasticsearch cluster by setting the IP address and port number of the cluster.

###### NOTE

Call **RestClient.close()** to close requested resources after the Elasticsearch operation is complete.

```
public static void main(String[] args) {  
    HwRestClient hwRestClient = new HwRestClient();  
    RestClient restClient = hwRestClient.getRestClient();  
    try {  
        /.../  
    } catch (Exception e) {  
        LOG.error("There are exceptions occurred.", e);  
    } finally {  
        if (restClient != null) {  
            try {  
                restClient.close();  
                LOG.info("Close the client successful.");  
            } catch (Exception e1) {  
                LOG.error("Close the client failed.", e1);  
            }  
        }  
    }  
}
```

###### NOTE

By default, the HwRestClient reads the following configuration files from the **conf** directory in the code running path: **esParams.properties**, **krb5.conf**, and **user.keytab**.

The configuration file path can be customized. For example, if the code runs in the Windows operating system, and the configuration files are stored in the root directory of drive D, you can set **HwRestClient hwRestClient** to **new HwRestClient("D:\\")**.

#### 2.3.3.2.2 Querying the Health Status of an Elasticsearch Cluster

##### Function Description

**QueryClusterInfo.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/cluster** directory is used to query the health status of the Elasticsearch cluster in information about the Elasticsearch cluster.

```
/**  
 * Query the cluster's information  
 */
```

```
public static void queryClusterInfo(RestClient restClientTest) {  
  
    Response response;  
    try {  
        Request request=new Request("GET", "/_cluster/health");  
        //Process the returned result to display it more intuitively  
        request.addParameter("pretty", "true");  
        response = restClientTest.performRequest(request);  
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {  
            LOG.info("QueryClusterInfo successful.");  
        } else {  
            LOG.error("QueryClusterInfo failed.");  
        }  
        LOG.info("QueryClusterInfo response entity is : " + EntityUtils.toString(response.getEntity()));  
    } catch (Exception e) {  
        LOG.error("QueryClusterInfo failed, exception occurred.", e);  
    }  
}
```

### 2.3.3.2.3 Checking Whether the Specified Index Exists

#### Function

**IndexIsExist.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/exist** directory is used to check whether a specified index exists.

```
/**  
 * Check the existence of the index or not.  
 */  
public static boolean exist(RestClient restClientTest, String index) {  
  
    Response response;  
    try {  
        Request request = new Request("HEAD", "/" + index);  
        request.addParameter("pretty", "true");  
        response = restClientTest.performRequest(request);  
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {  
            LOG.info("Check index successful,index is exist : {}.", index);  
  
            return true;  
        }  
        if (HttpStatus.SC_NOT_FOUND == response.getStatusLine().getStatusCode()) {  
            LOG.info("Index is not exist : {}.", index);  
  
            return false;  
        }  
    } catch (Exception e) {  
        LOG.error("Check index failed, exception occurred.", e);  
    }  
  
    return false;  
}
```

### 2.3.3.2.4 Creating an Index with the Desired Number of Shards

#### Function Description

**CreateIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/index** directory is used to create an index of numbers of specified primary shards and replica shards. Set

variables *shardNum* and *replicaNum* in the following code, that is, the number of primary shards and the number of replica shards.

```
/*
 * Create one index with customized shard number and replica number.
 */
public static void createIndexWithShardNum(RestClient restClientTest, String index) {

    Response rsp;

    int shardNum = 3;
    int replicaNum = 1;
    String jsonString =
        "{" + "\"settings\":{\"number_of_shards\":\"" + shardNum + "\",\"number_of_replicas\":\"" +
        replicaNum + "\"}}";

    HttpEntity entity = new NStringEntity(jsonString, ContentType.APPLICATION_JSON);
    try {
        Request request = new Request("PUT", "/" + index);
        request.addParameter("pretty", "true");
        request.setEntity(entity);
        rsp = restClientTest.performRequest(request);
        if (HttpStatus.SC_OK == rsp.getStatusLine().getStatusCode()) {
            LOG.info("CreateIndexWithShardNum successful.");
        } else {
            LOG.error("CreateIndexWithShardNum failed.");
        }
        LOG.info("CreateIndexWithShardNum response entity is : {}.", EntityUtils.toString(rsp.getEntity()));
    } catch (Exception e) {
        LOG.error("CreateIndexWithShardNum failed, exception occurred.", e);
    }
}
```

### 2.3.3.2.5 Writing Index Data

#### Function Description

**PutData.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/index** directory is used to insert data into a specified index.

The variable *jsonString* is data to be inserted and can be customized.

```
/*
 * Write one document into the index
 */
public static void putData(RestClient restClientTest, String index, String type, String id) {

    Gson gson = new Gson();
    Map<String, Object> esMap = new HashMap<>();
    esMap.put("name", "Happy");
    esMap.put("author", "Alex Yang");
    esMap.put("pubinfo", "Beijing,China");
    esMap.put("pubtime", "2020-01-01");
    esMap.put("description", "Elasticsearch is a highly scalable open-source full-text search and analytics engine.");
    String jsonString = gson.toJson(esMap);

    HttpEntity entity = new NStringEntity(jsonString, ContentType.APPLICATION_JSON);
    Response rsp;

    try {
        Request request = new Request("POST", "/" + index + "/" + type + "/" + id);
        request.addParameter("pretty", "true");
    }
```

```
request.setEntity(entity);
rsp = restClientTest.performRequest(request);
if (HttpStatus.SC_OK == rsp.getStatusLine().getStatusCode() || HttpStatus.SC_CREATED ==
rsp.getStatusLine().getStatusCode()) {
    LOG.info("PutData successful.");
} else {
    LOG.error("PutData failed.");
}
LOG.info("PutData response entity is : {}.", EntityUtils.toString(rsp.getEntity()));
} catch (Exception e) {
    LOG.error("PutData failed, exception occurred.", e);
}
}
```

### 2.3.3.2.6 Writing Data in Batches

#### Function

**Bulk.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/bulk** directory is used to insert data into a specified index in batches.

**totalRecordNumber** indicates the total number of documents to be inserted, and **oneCommit** indicates the number of documents to be inserted at a time. Data added to **esMap** is the data to be written into the index.

```
/*
 * Send a bulk request
 */
private static void bulk(RestClient restClientTest, String index) {

    //Total number of documents to be written
    long totalRecordNum = 10000;
    //Number of documents written in a bulk
    long oneCommit = 1000;
    long circleNumber = totalRecordNum / oneCommit;
    StringEntity entity;
    Gson gson = new Gson();
    Map<String, Object> esMap = new HashMap<>();
    String str = "{ \"index\" : { \"_index\" : \"\" + index + "\" } }";
    for (int i = 1; i <= circleNumber; i++) {
        StringBuilder builder = new StringBuilder();
        for (int j = 1; j <= oneCommit; j++) {
            esMap.clear();
            esMap.put("name", "Linda");
            esMap.put("age", ThreadLocalRandom.current().nextInt(18, 100));
            esMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
            esMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
            esMap.put("cur_time", System.currentTimeMillis());
            String strJson = gson.toJson(esMap);
            builder.append(str).append("\n");
            builder.append(strJson).append("\n");
        }
        entity = new StringEntity(builder.toString(), ContentType.APPLICATION_JSON);
        entity.setContentEncoding("UTF-8");
        Response response;
        try {
            Request request = new Request("PUT", "/_bulk");
            request.addParameter("pretty", "true");
            request.setEntity(entity);
            response = restClientTest.performRequest(request);
            if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
                LOG.info("Already input documents : " + oneCommit * i);
            } else {

```

```
        LOG.error("Bulk failed.");
    }
    LOG.info("Bulk response entity is : " + EntityUtils.toString(response.getEntity()));
} catch (Exception e) {
    LOG.error("Bulk failed, exception occurred.", e);
}
}
```

### 2.3.3.2.7 Batch write data to specified routes

## Function

**BulkRoutingSample.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/bulk` directory is used to set routing for each request in the bulk, route documents with the same routing to the same segment, and specify routing during query to narrow the query range and improve the query speed.

```
/*
 * Number of documents to be written.
 */
private static final int NUM_OF_DOC = 100;

/**
 * Use bulk to write data and specify routing.
 */
private static void bulkWithRouting(RestClient restClient, String indexName) {
    StringEntity entity;
    Gson gson = new Gson();
    Map<String, Object> esMap = new HashMap<>();
    String str = "{ \"index\" : { \"_index\" : \"" + indexName + "\",";
    StringBuilder sb = new StringBuilder();
    int age;
    for (int i = 1; i <= NUM_OF_DOC; i++) {
        esMap.clear();
        esMap.put("user", "Linda" + i);
        age = ThreadLocalRandom.current().nextInt(18, 100);
        esMap.put("age", age);
        esMap.put("postDate", "2020-01-01");
        esMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
        esMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
        String strJson = gson.toJson(esMap);
        // Route documents of the same age to the same shard based on the age.
        sb.append(str).append("\"routing\":\"").append(age).append("\")").append("\n");
        sb.append(strJson).append("\n");
    }
    entity = new StringEntity(sb.toString(), ContentType.APPLICATION_JSON);
    entity.setContentType("UTF-8");
    Response response;
    try {
        Request request = new Request("PUT", "_bulk");
        request.addParameter("pretty", "true");
        request.setEntity(entity);
        response = restClient.performRequest(request);
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
            LOG.info("Bulk routing is successful.");
        } else {
            LOG.error("Bulk routing is failed.");
        }
    } catch (IOException e) {
        LOG.error("Bulk routing is failed, exception occurred.", e);
    }
}
```

### 2.3.3.2.8 Querying Index Information

#### Function Description

**QueryData.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/search** directory is used to query document information under specified **index**, **type**, and **id**.

```
/*
 * Query all data of one index.
 */
private static void queryData(RestClient restClientTest, String index, String type, String id){

    Response response;
    try {
        Request request = new Request("GET", "/" + index + "/" + type + "/" + id);
        request.addParameter("pretty", "true");
        response = restClientTest.performRequest(request);
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
            LOG.info("QueryData successful.");
        } else {
            LOG.error("QueryData failed.");
        }
        LOG.info("QueryData response entity is : {}.", EntityUtils.toString(response.getEntity()));
    } catch (Exception e) {
        LOG.error("QueryData failed, exception occurred.", e);
    }
}
```

### 2.3.3.2.9 Deleting an Index

#### Function Description

**DeleteIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/delete** directory is used to delete a specified index.

```
/*
 * Delete one index
 */
public static void deleteIndex(RestClient restClientTest, String index) {

    Response response;
    try {
        Request request = new Request("DELETE", "/" + index + "?&pretty=true");
        response = restClientTest.performRequest(request);
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
            LOG.info("DeleteIndex successful.");
        } else {
            LOG.error("DeleteIndex failed.");
        }
        LOG.info("DeleteIndex response entity is : {}.", EntityUtils.toString(response.getEntity()));
    } catch (Exception e) {
        LOG.error("DeleteIndex failed, exception occurred.", e);
    }
}
```

### 2.3.3.2.10 Deleting Some Documents in the Index

#### Function

**DeleteSomeDocumentsInIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/delete** directory is used to refresh a specified index.

```
/*
 * Delete some documents by query in one index
 */
public static void deleteSomeDocumentsInIndex(RestClient restClientTest, String index, String field, String value) {
    String jsonString =
        "\n" + "\"query\": {" + "\n" + " \\"match\\": { \"\\":\"" + field + "\"\\":\"" + value + "\"}\\n" + " }\\n" + "}";
    Map<String, String> params = Collections.singletonMap("pretty", "true");
    HttpEntity entity = new NStringEntity(jsonString, ContentType.APPLICATION_JSON);
    Response rsp;
    try {
        rsp = restClientTest.performRequest("POST", "/" + index + "/_delete_by_query", params, entity);
        if (HttpStatus.SC_OK == rsp.getStatusLine().getStatusCode()) {
            LOG.info("DeleteSomeDocumentsInIndex successful.");
        }
        else {
            LOG.error("DeleteSomeDocumentsInIndex failed.");
        }
        LOG.info("DeleteSomeDocumentsInIndex response entity is : " +
EntityUtils.toString(rsp.getEntity()));
    }
    catch (Exception e) {
        LOG.error("DeleteSomeDocumentsInIndex failed, exception occurred.", e);
    }
}
```

### 2.3.3.2.11 Deleting All Documents in the Index

#### Function

**DeleteAllDocumentsInIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/delete** directory is used to refresh a specified index.

```
/*
 * Delete all documents by query in one index
 */
public static void deleteAllDocumentsInIndex(RestClient restClientTest, String index) {

    String jsonString = "\n" + "\"query\": {" + "\n" + " \\"match_all\\": {}\\n" + " }\\n" + "}";

    HttpEntity entity = new NStringEntity(jsonString, ContentType.APPLICATION_JSON);
    Response response;
    try {
        response = restClientTest.performRequest("POST", "/" + index + "/_delete_by_query", params,
entity);
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
            LOG.info("DeleteAllDocumentsInIndex successful.");
        }
        else {
            LOG.error("DeleteAllDocumentsInIndex failed.");
        }
        LOG.info("DeleteAllDocumentsInIndex response entity is :
{}.",EntityUtils.toString(response.getEntity()));
    }
    catch (Exception e) {
```

```
        LOG.error("DeleteAllDocumentsInIndex failed, exception occurred.", e);
    }
```

### 2.3.3.2.12 Refreshing an Index

#### Refreshing a Single Index

Flush.java in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/flush` directory is used to refresh a specified index.

```
/**
 * Flush one index data to storage and clearing the internal transaction log
 */
public static void flushOneIndex(RestClient restClientTest, String index) {
    Response flushRsp;

    try {
        Request request=new Request("POST", "/" + index + "/_flush");
        request.addParameter("pretty", "true");
        flushRsp = restClientTest.performRequest(request);
        LOG.info(EntityUtils.toString(flushRsp.getEntity()));

        if (HttpStatus.SC_OK == flushRsp.getStatusLine().getStatusCode()) {
            LOG.info("Flush one index successful.");
        } else {
            LOG.error("Flush one index failed.");
        }
        LOG.info("Flush one index response entity is : {}.",EntityUtils.toString(flushRsp.getEntity()));
    } catch (Exception e) {
        LOG.error("Flush one index failed, exception occurred.", e);
    }
}
```

#### Refreshing all Indexes

Flush.java in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/flush` directory is used to refresh all indexes.

```
/**
 * Flush all indexes data to storage and clearing the internal transaction log
 * The user who performs this operation must belong to the "supergroup" group.
 */
private static void flushAllIndexes(RestClient restClientTest) {
    Map<String, String> params = Collections.singletonMap("pretty", "true");
    Response flushRsp;
    try {
        flushRsp = restClientTest.performRequest("POST", "/_all/_flush",params);
        if (HttpStatus.SC_OK == flushRsp.getStatusLine().getStatusCode()) {
            LOG.info("Flush all indexes successful.");
        } else {
            LOG.error("Flush all indexes failed.");
        }
        LOG.info("Flush all indexes response entity is : " + EntityUtils.toString(flushRsp.getEntity()));
    } catch (Exception e) {
        LOG.error("Flush all indexes failed, exception occurred.", e);
    }
}
```

#### NOTE

Only users in the supergroup group can perform this operation.

### 2.3.3.2.13 Multi-Thread Example

#### Function

**MultithreadRequest.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/multithread` directory is used to create a thread class **sendRequestThread**, rewrite a **run** method, implement a **bulk** request, and write data in batches.

```
/*
 * Thread that sends bulk request
 */
public static class sendRequestThread implements Runnable {

    private RestClient restClientTh;
    private HwRestClient hwRestClient;
    @Override
    public void run() {
        LOG.info("Thread begin.");
        try {

            hwRestClient = new HwRestClient();
            restClientTh = hwRestClient.getRestClient();
            LOG.info("Thread name: " + Thread.currentThread().getName());
            bulk(restClientTh, "huawei1", "type1");
        } catch (Exception e) {
            LOG.error("SendRequestThread has exception.", e);
        } finally {
            if (restClientTh != null) {
                try {
                    restClientTh.close();
                    LOG.info("Close the client successful in thread : " + Thread.currentThread().getName());
                } catch (IOException e) {
                    LOG.error("Close the client failed.", e);
                }
            }
        }
    }
}
```

In the main method, the **fixedThreadPool** thread pool is created. By specifying **threadPoolSize** and **jobNumber**, multiple threads are supported to send **bulk** requests and data can be concurrently written in batches.

```
public static void main(String[] args) throws Exception {
    LOG.info("Start to do multithread request !");
    ExecutorService fixedThreadPool;
    HwRestClient hwRestClient = new HwRestClient();
    RestClient restClientThNew;
    restClientThNew = hwRestClient.getRestClient();
    int threadPoolSize = 2;
    int jobNumber = 5;
    try {
        fixedThreadPool = Executors.newFixedThreadPool(threadPoolSize);
        for (int i = 0; i < jobNumber; i++) {
            fixedThreadPool.execute(new sendRequestThread());
        }
        fixedThreadPool.shutdown();
    } catch (Exception e) {
        LOG.error("There are exceptions in sendRequestThread.", e);
    } finally {
        if (restClientThNew != null) {
            try {
                restClientThNew.close();
                LOG.info("Close the client successful.");
            } catch (Exception e1) {
                LOG.error("Close the client failed.", e1);
            }
        }
    }
}
```

```
        }
    }
}
```

### 2.3.3.2.14 Pre-sorting Indices

#### Function Description

The `IndexSorting.java` file in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/index` directory is used to configure the fields to be sorted when an index is created, implement the **bulk** request, write data in batches, and query the top N documents.

During index creation, specify the fields to be sorted and specify whether each field is sorted in descending or ascending order.

```
private static void createIndexWithSorting(RestClient restClient, String index) {
    Response rsp;
    String jsonString;
    jsonString = "{\"settings\":{\"number_of_shards\":\"3\", \"number_of_replicas\":\"1\",
        + "\"sort.field\": [\"height\", \"weight\"], \"sort.order\": [\"desc\", \"asc\"]},\"mappings\":{"
        + "\"properties\":{\"height\":{\"type\":\"float\"},\"weight\":{\"type\":\"float\"}}}}";
    HttpEntity entity = new StringEntity(jsonString, ContentType.APPLICATION_JSON);
    try {
        Request request = new Request("PUT", "/" + index);
        request.addParameter("pretty", "true");
        request.setEntity(entity);
        rsp = restClient.performRequest(request);
        if (rsp.getStatusLine().getStatusCode() == HttpStatus.SC_OK) {
            LOG.info("Create index with sorting successfully.");
        } else {
            LOG.error("Create index with sorting failed.");
        }
        LOG.info("Create index with sorting response entity is {}.", EntityUtils.toString(rsp.getEntity()));
    } catch (IOException | ParseException e) {
        LOG.error("Failed to create index with sorting, exception occurred.", e);
    }
}
```

Then, write data in batches.

```
public static void bulk(RestClient restClientTest, String index) {
    // Total number of documents to be written
    long totalRecordNum = 10000;
    // Number of documents written in each bulk. The recommended size is 5 MB to 15 MB.
    long oneCommit = 1000;
    long circleNumber = totalRecordNum / oneCommit;
    StringEntity entity;
    Gson gson = new Gson();
    Map<String, Object> esMap = new HashMap<>();
    String str = "{ \"index\" : { \"_index\" : \"" + index + "\" } }";

    for (int i = 1; i <= circleNumber; i++) {
        StringBuilder builder = new StringBuilder();
        for (int j = 1; j <= oneCommit; j++) {
            esMap.clear();
            esMap.put("name", "Linda");
            esMap.put("age", ThreadLocalRandom.current().nextInt(18, 100));
            esMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
            esMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
            esMap.put("cur_time", System.currentTimeMillis());

            String strJson = gson.toJson(esMap);
            builder.append(str).append(System.lineSeparator());
            builder.append(strJson).append(System.lineSeparator());
        }
    }
}
```

```
        }
        entity = new StringEntity(builder.toString(), ContentType.APPLICATION_JSON);
        entity.setContentTypeEncoding("UTF-8");
        Response response;
        try {
            Request request = new Request("PUT", "/_bulk");
            request.addParameter("pretty", "true");
            request.setEntity(entity);
            response = restClientTest.performRequest(request);
            if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
                LOG.info("Already input documents : {}.", oneCommit * i);
            } else {
                LOG.error("Bulk failed.");
            }
            LOG.info("Bulk response entity is : {}.", EntityUtils.toString(response.getEntity()));
        } catch (IOException | ParseException e) {
            LOG.error("Bulk failed, exception occurred.", e);
        }
    }
}
```

Perform the refresh operation so that the data can be queried after being written in batches.

```
private static void refresh(RestClient restClient, String index) {
    try {
        Map<String, String> params = Collections.singletonMap("pretty", Boolean.TRUE.toString());
        Response rsp = restClient.performRequest(buildRequest("POST", "/" + index + "/_refresh", params,
null));
        if (rsp.getStatusLine().getStatusCode() == HttpStatus.SC_OK) {
            LOG.info("Refresh sorting index successfully.");
        }
    } catch (IOException e) {
        LOG.error("Failed to refresh sorting index, exception occurred.", e);
    }
}
```

Then, you can query the sorting field. By default, the top 10 documents are obtained.

```
private static void queryData(RestClient restClient, String index) {
    Response response;
    String jsonStr;
    jsonStr = "{\"sort\":[{\"height\": \"desc\", \"weight\": \"asc\"}],\"track_total_hits\": false}";
    StringEntity entity = new StringEntity(jsonStr, ContentType.APPLICATION_JSON);
    try {
        Request request = new Request("GET", "/" + index + "/_search");
        request.addParameter("pretty", "true");
        request.setEntity(entity);
        response = restClient.performRequest(request);
        if (response.getStatusLine().getStatusCode() == HttpStatus.SC_OK) {
            LOG.info("Query sorting index successfully.");
        } else {
            LOG.error("Failed to query sorting index.");
        }
        LOG.info("Query sorting index response entity is {}.", EntityUtils.toString(response.getEntity()));
    } catch (IOException | ParseException e) {
        LOG.error("Failed to query sorting index, exception occurred.", e);
    }
}
```

### 2.3.3.3 High Level RestClient Sample Code

### 2.3.3.3.1 Connecting the Client to a Cluster

#### Function

You can obtain the client and connect to a specific Elasticsearch cluster by setting the IP address and port. This is necessary before you use the API provided by the Elasticsearch.

##### NOTE

Call **RestHighLevelClient.close()** to close requested resources after the Elasticsearch service operation is complete.

```
public static void main(String[] args) {
    RestHighLevelClient highLevelClient = null;
    HwRestClient hwRestClient = new HwRestClient();
    try {
        highLevelClient = new RestHighLevelClient(hwRestClient.getRestClientBuilder());
        ...
    } finally {
        try {
            if (highLevelClient != null) {
                highLevelClient.close();
            }
        } catch (IOException e) {
            LOG.error("Failed to close RestHighLevelClient.", e);
        }
    }
}
```

##### NOTE

- By default, the HwRestClient reads the following configuration files from the **conf** directory in the code running path: **esParams.properties**, **krb5.conf**, and **user.keytab**.
- The configuration file path can be customized. For example, if the code runs in the Windows operating system, and the configuration files are stored in the root directory of drive D, you can set **HwRestClient hwRestClient** to **new HwRestClient("D:\\")**.

### 2.3.3.2 Querying Cluster Information

#### Function

**QueryClusterInfo.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/cluster** directory is used to query information about the Elasticsearch cluster.

```
/**
 * Get cluster information
 */
public static void queryClusterInfo(RestHighLevelClient highLevelClient) {

    try {
        MainResponse response = highLevelClient.info(RequestOptions.DEFAULT);
        ClusterName clusterName = response.getClusterName();
        LOG.info("ClusterName:[{}], clusterUuid:[{}], nodeName:[{}], version:[{}].", new Object[]
        { clusterName.value(),
            response.getClusterUuid(), response.getNodeName(), response.getVersion().toString() });
    } catch (Exception e) {
        LOG.error("QueryClusterInfo is failed,exception occurred.", e);
    }
}
```

### 2.3.3.3 Writing Index Data

Data can be written to a specified index by specifying data sources in different formats, such as a character string in the JSON format, a data source in the Map format, and a data source in the XContentBuilder format.

#### Writing Data by Using the Character String in the JSON Format

**IndexByJson.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/index` directory is used to write data into a specified index by using a data source in the JSON format.

The variable `jsonString` is data to be inserted and can be customized.

```
/*
 * Create or update index by json
 */
public static void indexByJson(RestHighLevelClient highLevelClient, String index, String type, String id) {
    try {
        IndexRequest indexRequest = new IndexRequest(index, type, id);
        String jsonString = "{" + "\"user\":\"kimchy1\"," + "\"age\":100," + "\"postDate\"
\":\\"2020-01-01\",
        + "\"message\":\"trying out Elasticsearch\"," + "\"reason\":\"daily update\",
        + "\"innerObject1\":\"Object1\"," + "\"innerObject2\":\"Object2\",
        + "\"innerObject3\":\"Object3\"," + "\"uid\":\"11\"}";
        indexRequest.source(jsonString, XContentType.JSON);
        IndexResponse indexResponse = highLevelClient.index(indexRequest, RequestOptions.DEFAULT);

        LOG.info("IndexByJson response is {}.", indexResponse.toString());
    } catch (Exception e) {
        LOG.error("IndexByJson is failed,exception occurred.", e);
    }
}
```

#### Writing Data in the Map Format

**IndexByMap.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/index` directory is used to write data into a specified index by using a data source in the Map format.

The variable `dataMap` is data to be inserted and can be customized.

```
/*
 * Create or update index by map
 */
public static void indexByMap(RestHighLevelClient highLevelClient, String index, String type, String id) {
    try {
        Map<String, Object> dataMap = new HashMap<>();
        dataMap.put("user", "kimchy2");
        dataMap.put("age", "200");
        dataMap.put("postDate", new Date());
        dataMap.put("message", "trying out Elasticsearch");
        dataMap.put("reason", "daily update");
        dataMap.put("innerObject1", "Object1");
        dataMap.put("innerObject2", "Object2");
        dataMap.put("innerObject3", "Object3");
        dataMap.put("uid", "22");
        IndexRequest indexRequest = new IndexRequest(index, type, id).source(dataMap);
        IndexResponse indexResponse = highLevelClient.index(indexRequest, RequestOptions.DEFAULT);

        LOG.info("IndexByMap response is {}.", indexResponse.toString());
    } catch (Exception e) {
        LOG.error("IndexByMap is failed,exception occurred.", e);
    }
}
```

## Writing Data in the XContentBuilder Format

**IndexByXContentBuilder.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/index** directory is used to write data into a specified index by using a data source in the XContentBuilder format.

The variable *builder* is data to be inserted and can be customized.

```
/*
 * Create or update index by XContentBuilder
 */
public static void indexByXContentBuilder(RestHighLevelClient highLevelClient, String index, String type, String id) {

    try {
        XContentBuilder builder = XContentFactory.jsonBuilder();
        builder.startObject();
        {
            builder.field("user", "kimchy3");
            builder.field("age", "300");
            builder.field("postDate", "2020-01-01");
            builder.field("message", "trying out Elasticsearch");
            builder.field("reason", "daily update");
            builder.field("innerObject1", "Object1");
            builder.field("innerObject2", "Object2");
            builder.field("innerObject3", "Object3");
            builder.field("uid", "33");
        }
        builder.endObject();
        IndexRequest indexRequest = new IndexRequest(index, type, id).source(builder);
        IndexResponse indexResponse = highLevelClient.index(indexRequest, RequestOptions.DEFAULT);

        LOG.info("IndexByXContentBuilder response is {}", indexResponse.toString());
    } catch (Exception e) {
        LOG.error("IndexByXContentBuilder is failed,exception occurred.", e);
    }
}
```

### 2.3.3.3.4 Operations in Batches

## Function

**Bulk.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/bulk** directory is used to perform operations in batches, for example, create an index, update an index, or delete an index.

```
/*
 * Bulk request can be used to execute multiple index,update or delete
 */
public static void bulk(RestHighLevelClient highLevelClient, String index, String type) {

    try {
        Map<String, Object> jsonMap = new HashMap<>();
        for (int i = 1; i <= 100; i++) {
            BulkRequest request = new BulkRequest();
            for (int j = 1; j <= 1000; j++) {
                jsonMap.clear();
                jsonMap.put("user", "Linda");
                jsonMap.put("age", ThreadLocalRandom.current().nextInt(18, 100));
                jsonMap.put("postDate", "2020-01-01");
                jsonMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
                jsonMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
            }
            request.add(new IndexRequest(index, type, Integer.toString(i), jsonMap));
        }
        highLevelClient.bulk(request);
    } catch (IOException e) {
        LOG.error("bulk error, exception occurred.", e);
    }
}
```

```
        request.add(new IndexRequest(index, type).source(jsonMap));
    }
    BulkResponse bulkResponse = highLevelClient.bulk(request, RequestOptions.DEFAULT);

    if (RestStatus.OK.equals((bulkResponse.status()))) {
        LOG.info("Bulk is successful");
    } else {
        LOG.info("Bulk is failed");
    }
}
} catch (Exception e) {
    LOG.error("Bulk is failed,exception occurred.", e);
}
}
```

### 2.3.3.3.5 Batch write data to specified routes

#### Function

**BulkRoutingSample.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/bulk` directory is used to set routing for each request in the bulk, route documents with the same routing to the same segment, and specify routing during query to narrow the query range and improve the query speed.

```
/**
 * Number of documents to be written.
 */
private static final int NUM_OF_DOC = 100;

/**
 * Use bulk to write data and specify routing.
 */
private static void bulkWithRouting(RestHighLevelClient highLevelClient, String indexName) {
    try {
        Map<String, Object> jsonMap = new HashMap<>();
        BulkRequest request = new BulkRequest();
        int age;
        for (int i = 1; i <= NUM_OF_DOC; i++) {
            jsonMap.clear();
            jsonMap.put("user", "Linda" + i);
            age = ThreadLocalRandom.current().nextInt(18, 100);
            jsonMap.put("age", age);
            jsonMap.put("postDate", "2020-01-01");
            jsonMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
            jsonMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
            // Route documents of the same age to the same shard based on the age.
            request.add(new IndexRequest(indexName).source(jsonMap).routing(String.valueOf(age)));
        }
        BulkResponse bulkResponse = highLevelClient.bulk(request, RequestOptions.DEFAULT);
        if (RestStatus.OK.equals(bulkResponse.status())) {
            LOG.info("Bulk routing is successful.");
        } else {
            LOG.info("Bulk routing is failed.");
        }
    } catch (IOException e) {
        LOG.error("Bulk routing is failed, exception occurred.", e);
    }
}
```

### 2.3.3.6 Updating Index Information

#### Function

**Update.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/update` directory is used to update the index.

```
/*
 * Update index
 */
public static void update(RestHighLevelClient highLevelClient, String index, String type, String id) {
    try {
        XContentBuilder builder = XContentFactory.jsonBuilder();
        builder.startObject();
        { // update information
            builder.field("postDate", new Date());
            builder.field("reason", "update again");
        }
        builder.endObject();
        UpdateRequest request = new UpdateRequest(index, type, id).doc(builder);
        UpdateResponse updateResponse = highLevelClient.update(request, RequestOptions.DEFAULT);

        LOG.info("Update response is {}", updateResponse.toString());
    } catch (Exception e) {
        LOG.error("Update is failed,exception occurred.", e);
    }
}
```

### 2.3.3.7 Querying Index Information

#### Function

**GetIndex.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/search` directory is used to query information about a document with specified **index**, **type**, and **id**.

```
/*
 * Get index information
 */
private static void getIndex(RestHighLevelClient highLevelClient, String index, String type, String id) {
    try {
        GetRequest getRequest = new GetRequest(index, type, id);
        String[] includes = new String[] { "message", "test*" };
        String[] excludes = Strings.EMPTY_ARRAY;
        FetchSourceContext fetchSourceContext = new FetchSourceContext(true, includes, excludes);
        getRequest.fetchSourceContext(fetchSourceContext);
        getRequest.storedFields("message");
        GetResponse getResponse = highLevelClient.get(getRequest, RequestOptions.DEFAULT);

        LOG.info("GetIndex response is {}", getResponse.toString());
    } catch (Exception e) {
        LOG.error("GetIndex is failed,exception occurred.", e);
    }
}
```

### 2.3.3.8 Searching for Document Information

#### Function

**Search.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/search` directory is used to query related document information in a specified index. You can customize

specified sorting, filtering, highlighting, feedback data range, timeout interval, and the like.

```
/*
 * Search some information in index
 */
public static void search(RestHighLevelClient highLevelClient, String index) {
    try {
        SearchRequest searchRequest = new SearchRequest(index);
        SearchSourceBuilder searchSourceBuilder = new SearchSourceBuilder();
        searchSourceBuilder.query(QueryBuilders.termQuery("user", "kimchy1"));

        //Specifying Sorting
        searchSourceBuilder.sort(new FieldSortBuilder("_doc").order(SortOrder.ASC));

        // Source filter
        String[] includeFields = new String[] { "message", "user", "innerObject" };
        String[] excludeFields = new String[] { "postDate" };
        searchSourceBuilder.fetchSource(includeFields, excludeFields);

        // Control which fields get included or
        // excluded
        // Request Highlighting
        HighlightBuilder highlightBuilder = new HighlightBuilder();
        HighlightBuilder.Field highlightUser = new HighlightBuilder.Field("user");
        // Create a field highlighter for the user field
        highlightBuilder.field(highlightUser);
        searchSourceBuilder.highlighter(highlightBuilder);
        searchSourceBuilder.from(0);
        searchSourceBuilder.size(2);
        searchSourceBuilder.timeout(new TimeValue(60, TimeUnit.SECONDS));
        searchRequest.source(searchSourceBuilder);
        SearchResponse searchResponse = highLevelClient.search(searchRequest, RequestOptions.DEFAULT);

        LOG.info("Search response is {}.", searchResponse.toString());
    } catch (Exception e) {
        LOG.error("Search is failed, exception occurred.", e);
    }
}
```

### 2.3.3.3.9 Searching for Document Information by Using a Cursor

#### Function

**SearchScroll.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/searchscroll** directory is used to query related document information in a specified index by using a cursor. The method returns a **scrollId**. You can use the **scrollId** to clear the cursor. For details about the clearing method, see [Clearing a Cursor](#).

```
/*
 * Send a search scroll request
 */
public static String searchScroll(RestHighLevelClient highLevelClient, String index) {
    String scrollId = null;
    try {
        final Scroll scroll = new Scroll(TimeValue.timeValueMinutes(1L));
        SearchRequest searchRequest = new SearchRequest(index);
        searchRequest.scroll(scroll);
        SearchSourceBuilder searchSourceBuilder = new SearchSourceBuilder();
        searchSourceBuilder.query(QueryBuilders.matchQuery("title", "Elasticsearch"));
        searchRequest.source(searchSourceBuilder);

        SearchResponse searchResponse = highLevelClient.search(searchRequest, RequestOptions.DEFAULT);
        scrollId = searchResponse.getScrollId();
    }
```

```
SearchHit[] searchHits = searchResponse.getHits().getHits();
LOG.info("SearchHits is {}", searchResponse.toString());

while (searchHits != null && searchHits.length > 0) {
    SearchScrollRequest scrollRequest = new SearchScrollRequest(scrollId);
    scrollRequest.scroll(scroll);
    searchResponse = highLevelClient.searchScroll(scrollRequest, RequestOptions.DEFAULT);
    scrollId = searchResponse.getScrollId();
    searchHits = searchResponse.getHits().getHits();
    LOG.info("SearchHits is {}", searchResponse.toString());
}
} catch (Exception e) {
    LOG.error("SearchScroll is failed,exception occurred.", e);
    return null;
}
return scrollId;
}
```

### 2.3.3.3.10 Clearing a Cursor

#### Function

**SearchScroll.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/searchscroll** directory includes the method **clearScroll(highLevelClient,scrollId)**, which is used to clear a cursor specified by **scrollId**.

```
/**
 * Clear a search scroll
 */
public static void clearScroll(RestHighLevelClient highLevelClient, String scrollId) {
    ClearScrollRequest clearScrollRequest = new ClearScrollRequest();
    clearScrollRequest.addScrollId(scrollId);
    ClearScrollResponse clearScrollResponse;
    try {
        clearScrollResponse = highLevelClient.clearScroll(clearScrollRequest, RequestOptions.DEFAULT);
        if (clearScrollResponse.isSucceeded()) {
            LOG.info("ClearScroll is successful.");
        } else {
            LOG.error("ClearScroll is failed.");
        }
    } catch (IOException e) {
        LOG.error("ClearScroll is failed,exception occurred.", e);
    }
}
```

### 2.3.3.3.11 Deleting an Index

#### Function

**DeleteIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/delete** directory is used to delete a specified index.

```
/**
 * Delete the index

*/
public static void deleteIndex(RestHighLevelClient highLevelClient, String index) {
    try {
        DeleteIndexRequest request = new DeleteIndexRequest(index);
        DeleteIndexResponse deleteResponse = highLevelClient.indices().deleteIndex(request,
RequestOptions.DEFAULT);
```

```
        if (deleteResponse.isAcknowledged()) {
            LOG.info("Delete index is successful");
        } else {
            LOG.info("Delete index is failed");
        }
    } catch (Exception e) {
        LOG.error("Delete index : {} is failed, exception occurred.", index, e);
    }
}
```

### 2.3.3.12 Multi-Thread Request

#### Function

**MultithreadRequest.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/multithread` directory is used to create a thread class `sendRequestThread`, rewrite a `run` method, implement a **bulk** request, and write data in batches.

```
/*
 * The thread that send a bulk request
 */
public static class sendRequestThread implements Runnable {

    private RestHighLevelClient highLevelClientTh;
    @Override
    public void run() {
        LOG.info("Thread begin.");

        HwRestClient hwRestClient = new HwRestClient();
        try {
            highLevelClientTh = new RestHighLevelClient(hwRestClient.getRestClientBuilder());
            LOG.info("Thread name: " + Thread.currentThread().getName());
            bulk(highLevelClientTh, "huawei1", "type1");
        } catch (Exception e) {
            LOG.error("SendRequestThread had exception.", e);
        } finally {
            if (highLevelClientTh != null) {
                try {
                    highLevelClientTh.close();
                    LOG.info("Close the highLevelClient successful in thread : " +
Thread.currentThread().getName());
                } catch (IOException e) {
                    LOG.error("Close the highLevelClient failed.", e);
                }
            }
        }
    }
}
```

In the main method, the **fixedThreadPool** thread pool is created. By specifying **threadPoolSize** and **jobNumber**, multiple threads are supported to send bulk requests and data can be concurrently written in batches.

```
public static void main(String[] args) throws Exception {
    LOG.info("Start to do bulk request !");

    ExecutorService fixedThreadPool;
    int threadPoolSize = 2;
    int jobNumber = 5;
    if (HighLevelUtils.getConfig()) {
        try {
            fixedThreadPool = Executors.newFixedThreadPool(threadPoolSize);
        }
```

```
        for (int i = 0; i < jobNumber; i++) {
            fixedThreadPool.execute(new sendRequestThread());
        }
        fixedThreadPool.shutdown();
    } catch (Exception e) {
        LOG.error("SendRequestThread is failed,exception occurred.", e);
    }
} else {
    LOG.error("Failed to get configuration!");
}
}
```

### 2.3.3.13 BulkProcessor Batch Import Example

#### Description

The **BulkProcessorSample.java** file in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/bulk** directory is used to instruct users to use BulkProcessor to import data to the database in batches.

BulkProcessor initialization:

```
private static BulkProcessor getBulkProcessor(RestHighLevelClient highLevelClient) {
    BulkProcessor.Listener listener = new BulkProcessor.Listener() {
        @Override
        public void beforeBulk(long executionId, BulkRequest bulkRequest) {
            int numberOfActions = bulkRequest.numberOfActions();
            LOG.info("Executing bulk {} with {} requests.", executionId, numberOfActions);
        }

        @Override
        public void afterBulk(long executionId, BulkRequest bulkRequest, BulkResponse bulkResponse) {
            if (bulkResponse.hasFailures()) {
                LOG.warn("Bulk {} executed with failures.", executionId);
            } else {
                LOG.info("Bulk {} completed in {} milliseconds.", executionId,
bulkResponse.getTook().getMillis());
            }
        }

        @Override
        public void afterBulk(long executionId, BulkRequest bulkRequest, Throwable throwable) {
            LOG.error("Failed to execute bulk.", throwable);
        }
    };

    BiConsumer<BulkRequest, ActionListener<BulkResponse>> bulkConsumer =
        (request, bulkListener) -> highLevelClient.bulkAsync(request, RequestOptions.DEFAULT,
bulkListener);

    BulkProcessor bulkProcessor = BulkProcessor.builder(bulkConsumer, listener)
        .setBulkActions(onceBulkMaxNum)
        .setBulkSize(new ByteSizeValue(onceBulkMaxSize, ByteSizeUnit.MB))
        .setConcurrentRequests(concurrentRequestsNum)
        .setFlushInterval(TimeValue.timeValueSeconds(flushTime))
        .setBackoffPolicy(BackoffPolicy.constantBackoff(TimeValue.timeValueSeconds(1L), maxRetry))
        .build();

    LOG.info("Init bulkProcess successfully.");
    return bulkProcessor;
}
```

BulkProcessor import example:

```
private void singleThreadBulk() {
    //single thread
```

```

int bulkTime = 0;
while (bulkTime++ < totalNumberForThread) {
    Map<String, Object> dataMap = new HashMap<>();
    dataMap.put("date", "2019/12/9");
    dataMap.put("text", "the test text");
    dataMap.put("title", "the title");
    bulkProcessor.add(new IndexRequest(indexName, indexType).source(dataMap));
}
LOG.info("This thread bulks successfully, the thread name is {}.", Thread.currentThread().getName());
}

```

### 2.3.3.14 Pre-sorting Indices

#### Function Description

The **IndexSorting.java** file in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/index** directory is used to configure the fields to be sorted when an index is created, implement the **bulk** request, write data in batches, and query the top N documents.

During index creation, specify the fields to be sorted and specify whether each field is sorted in descending or ascending order.

```

private static void createIndexWithSorting(RestHighLevelClient highLevelClient, String index) {
    try {
        CreateIndexRequest indexRequest = new CreateIndexRequest(index);
        indexRequest.settings(
            Settings.builder().put("index.number_of_shards", 3)
                .put("index.number_of_replicas", 1)
                .putList("index.sort.field", "height", "weight")
                .putList("index.sort.order", SortOrder.DESC.toString(), SortOrder.ASC.toString()));
        indexRequest.mapping("{\"properties\": {\"height\": {\"type\": \"float\"},"
            + "\"weight\": {\"type\": \"float\"}}}", XContentType.JSON);
        CreateIndexResponse response = highLevelClient.indices().create(indexRequest,
RequestOptions.DEFAULT);
        if (response.isAcknowledged() || response.isShardsAcknowledged()) {
            LOG.info("Create index with sorting successfully.");
        }
    } catch (IOException e) {
        LOG.error("Failed to create index with sorting, exception occurred.", e);
    }
}

```

Then, write data in batches.

```

public static void bulk(RestHighLevelClient highLevelClient, String index) {
    try {
        Map<String, Object> jsonMap = new HashMap<>();
        for (int i = 1; i <= 10; i++) {
            BulkRequest request = new BulkRequest();
            for (int j = 1; j <= 1000; j++) {
                jsonMap.clear();
                jsonMap.put("user", "Linda");
                jsonMap.put("age", ThreadLocalRandom.current().nextInt(18, 100));
                jsonMap.put("postDate", "2020-01-01");
                jsonMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
                jsonMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
                request.add(new IndexRequest(index).source(jsonMap));
            }
            BulkResponse bulkResponse = highLevelClient.bulk(request, RequestOptions.DEFAULT);

            if (RestStatus.OK.equals((bulkResponse.status()))) {
                LOG.info("Bulk is successful");
            } else {
                LOG.info("Bulk is failed");
            }
        }
    }
}

```

```
        }
    }
} catch (IOException e) {
    LOG.error("Bulk is failed,exception occurred.", e);
}
}
```

Perform the refresh operation so that the data can be queried after being written in batches.

```
private static void refresh(RestHighLevelClient highLevelClient, String index) {
    try {
        RefreshRequest refRequest = new RefreshRequest(index);
        highLevelClient.indices().refresh(refRequest, RequestOptions.DEFAULT);
        LOG.info("Refresh sorting index successfully.");
    } catch (IOException e) {
        LOG.error("Failed to refresh sorting index, exception occurred.", e);
    }
}
```

Then, you can query the sorting field. By default, the top 10 documents are obtained.

```
private static void queryData(RestHighLevelClient highLevelClient, String index) {
    try {
        SearchSourceBuilder searchSourceBuilder = new SearchSourceBuilder();
        searchSourceBuilder.sort(new FieldSortBuilder("height").order(SortOrder.DESC));
        searchSourceBuilder.sort(new FieldSortBuilder("weight").order(SortOrder.ASC));
        // Source filter
        String[] includeFields = new String[]{"weight", "height", "age"};
        String[] excludeFields = new String[]{};
        searchSourceBuilder.fetchSource(includeFields, excludeFields);
        // Control which fields get included or excluded
        // Request Highlighting
        HighlightBuilder highlightBuilder = new HighlightBuilder();
        HighlightBuilder.Field highlightUser = new HighlightBuilder.Field("height");
        highlightBuilder.field(highlightUser);
        searchSourceBuilder.highlighter(highlightBuilder);
        searchSourceBuilder.timeout(new TimeValue(1, TimeUnit.SECONDS));
        SearchRequest searchRequest = new SearchRequest(index);
        searchRequest.source(searchSourceBuilder);
        SearchResponse searchResponse = highLevelClient.search(searchRequest, RequestOptions.DEFAULT);
        LOG.info("Search response is {}", searchResponse.toString());
    } catch (IOException e) {
        LOG.error("Failed to query sorting index, exception occurred.", e);
    }
}
```

## 2.3.4 Commissioning Process

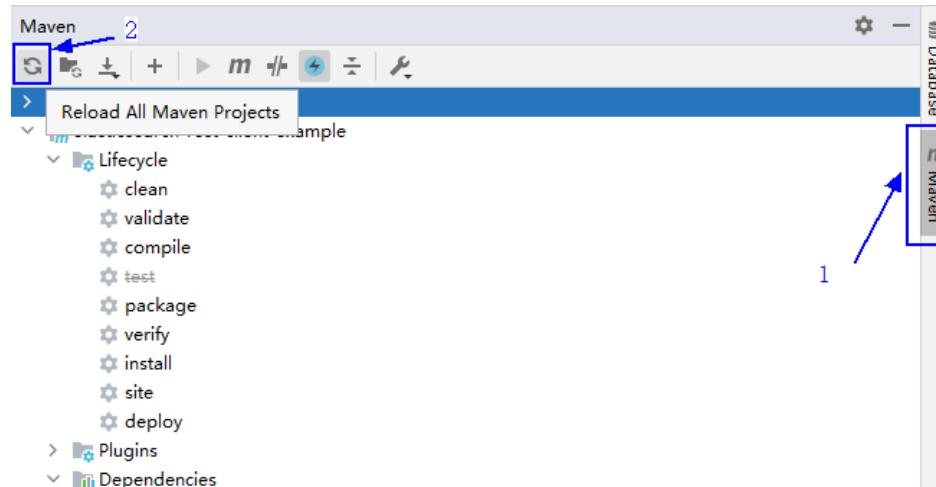

### 2.3.4.1 Commissioning Applications on Windows

#### 2.3.4.1.1 Commissioning a RestClient Application

#### Compiling and Running Applications

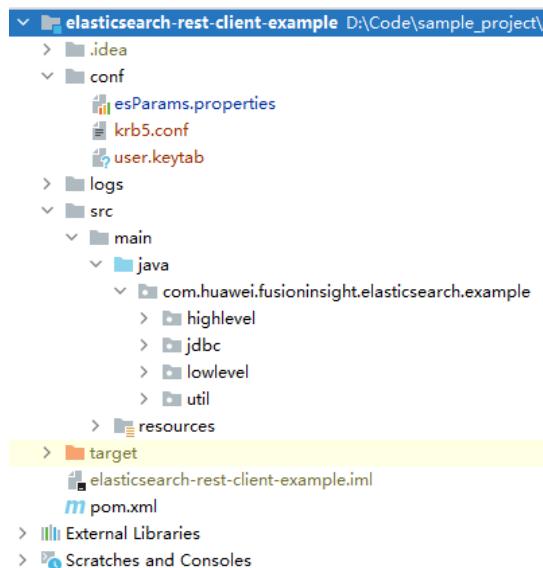

You can run an application on Windows after code development is complete. If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

1. Click **Reimport All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

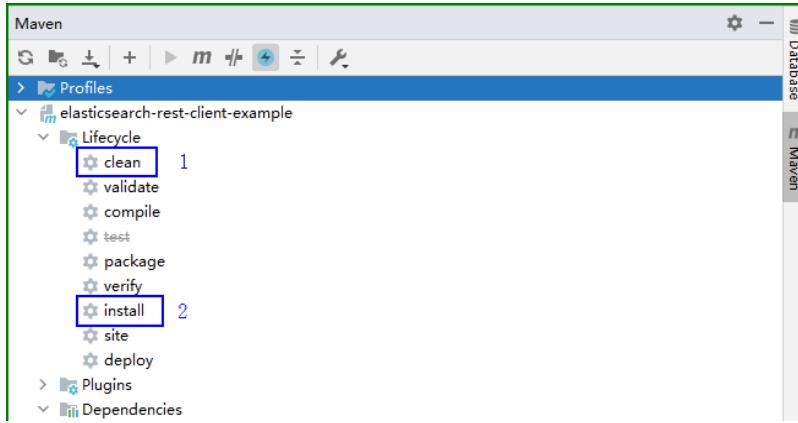

2. Compile and run an application.

- The following figure shows the file list after the configuration file has been placed and the code has been modified to match the login user. (The authentication files krb5 and keytab are not required in common mode.)

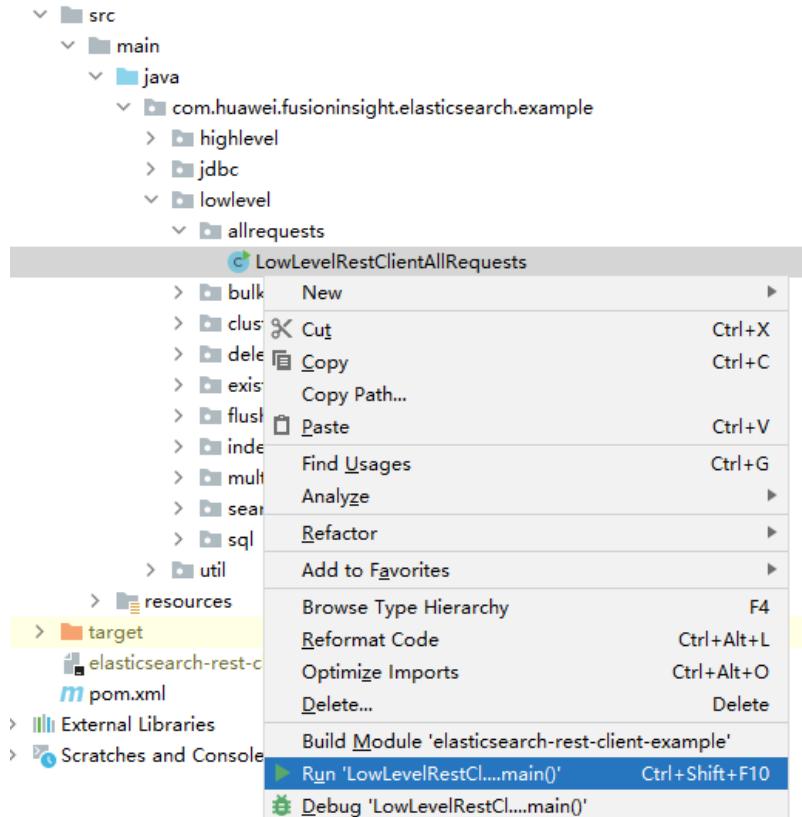

- Compile an application.

Double-click **clean** and **install** to run the **maven clean** and **maven install** commands. After the compilation is complete, the message "Build Success" is displayed.

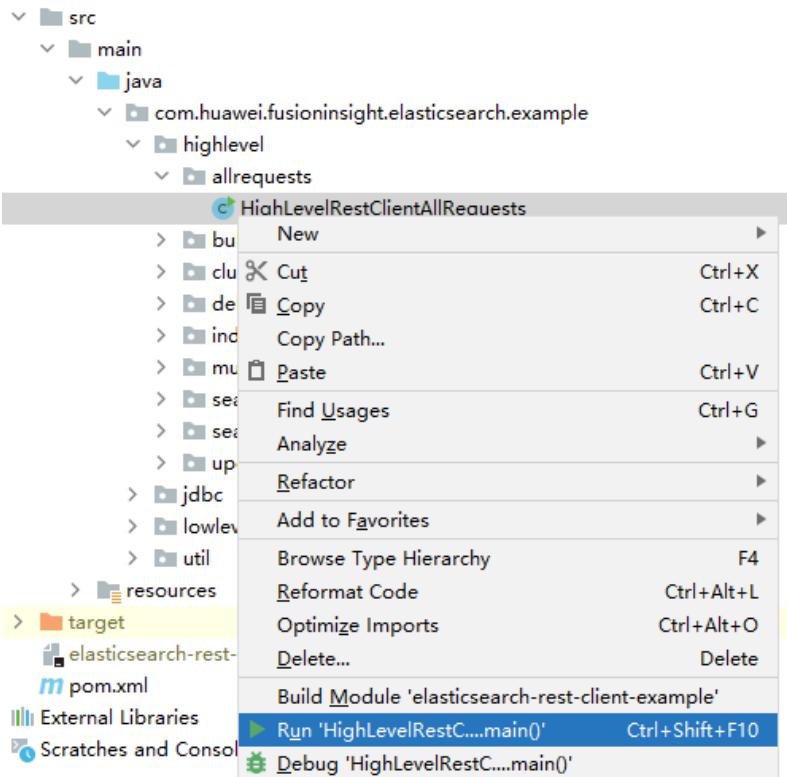

- c. Run the program.

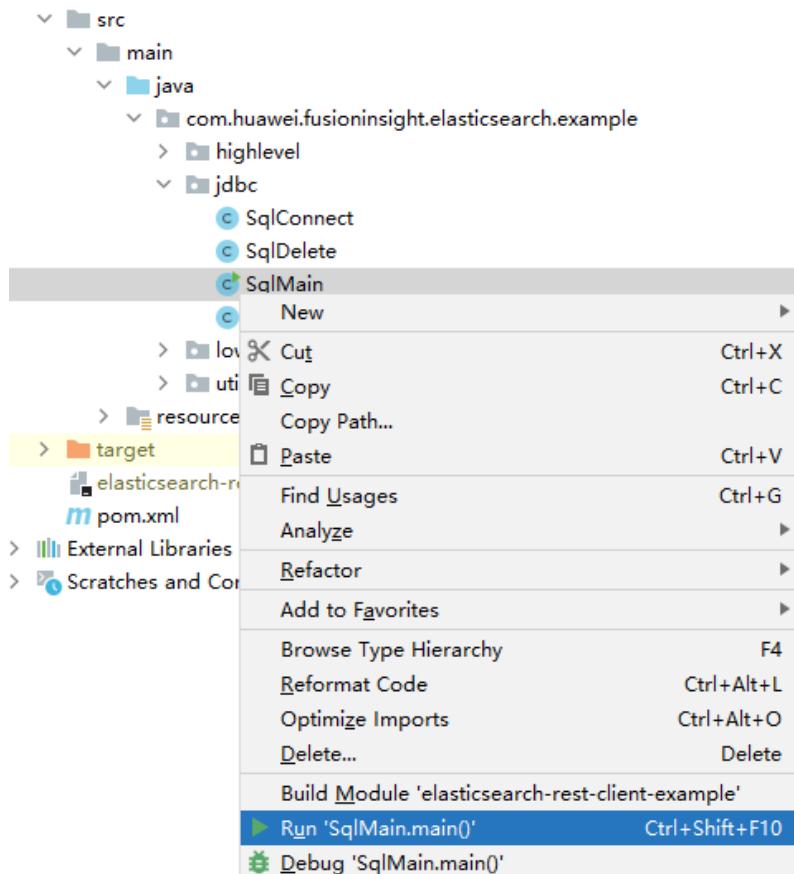

Right-click the **LowLevelRestClientAllRequests** file and choose **Run 'Low....main()'** from the shortcut menu to run all samples of the Low Level Rest Client.

Right-click the **HighLevelRestClientAllRequests** file and choose **Run 'High....main()'** from the shortcut menu to run all samples of the High Level Rest Client.

Right-click the **SqlMain** file and choose **Run 'SqlMain.main()'** from the shortcut menu to run all samples of the JDBC Rest Client.

## Viewing Commissioning Results

After you run an Elasticsearch application, you can use either of the following methods to view the running status:

- View the running result.
- View Elasticsearch logs, that is, the **elasticsearch-rest-client-example/logs/es-example.log** log file in the **logs** directory.

After a complete sample of the Low Level RestClient is run, some operation results are displayed on the console:

```

## Log Description

The log level is **INFO** by default. You can view more detailed information by changing the log level (**TRACE**, **DEBUG**, **INFO**, **WARN**, and **ERROR**). You can modify the **log4j.properties** file to change log levels, for example:

```
# This sets the global logging level and specifies the appenders
log4j.rootLogger=INFO,theConsoleAppender,R

# settings for the console appender
log4j.appender.theConsoleAppender=org.apache.log4j.ConsoleAppender
log4j.appender.theConsoleAppender.Threshold=INFO
log4j.appender.theConsoleAppender.layout=org.apache.log4j.PatternLayout
log4j.appender.theConsoleAppender.layout.ConversionPattern=%d{yyyy-MM-dd HH:mm:ss,SSS} | %-5p | %t | %m | %l%n

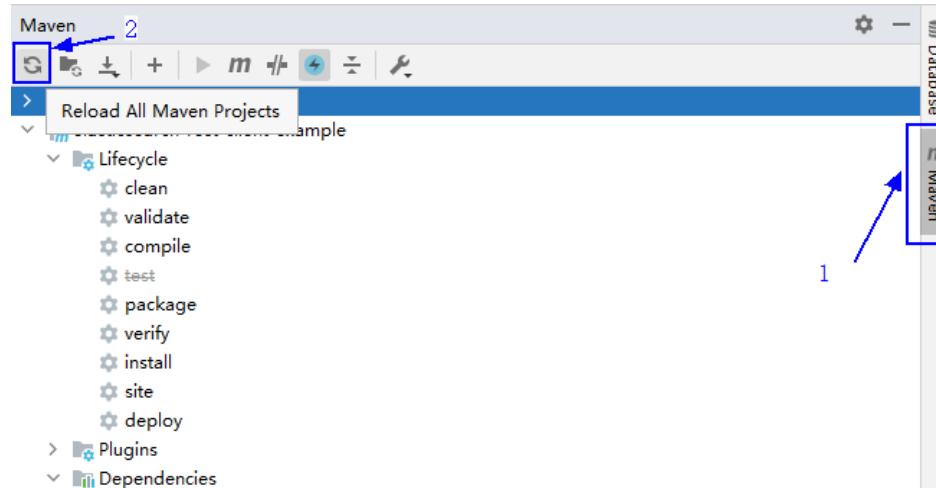

# R is set to be a File appender using a PatternLayout.
log4j.appender.R=org.apache.log4j.RollingFileAppender
log4j.appender.R.Append=true
log4j.appender.R.Threshold=debug
log4j.appender.R.MaxFileSize=10240KB
log4j.appender.R.MaxBackupIndex=10
log4j.appender.R.File=logs/es-example.log
log4j.appender.R.layout=org.apache.log4j.PatternLayout
log4j.appender.R.layout.ConversionPattern=%d{yyyy-MM-dd HH:mm:ss,SSS} | %-5p | %t | %m | %l%n
```

### 2.3.4.1.2 Commissioning a SpringBoot Program

#### Compiling and Running Applications

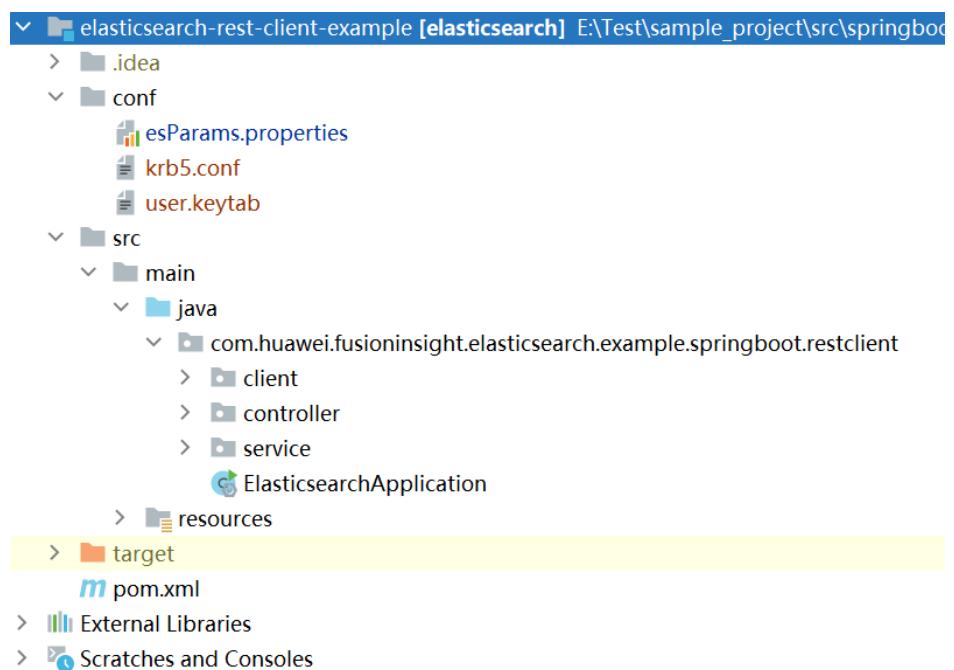

You can run applications in the Windows environment after application code development is complete. If the local and cluster service planes can communicate with each other, you can perform the commissioning on the local host.

1. Click **Reload All Maven Projects** in the Maven window on the right of IDEA to import Maven project dependency.

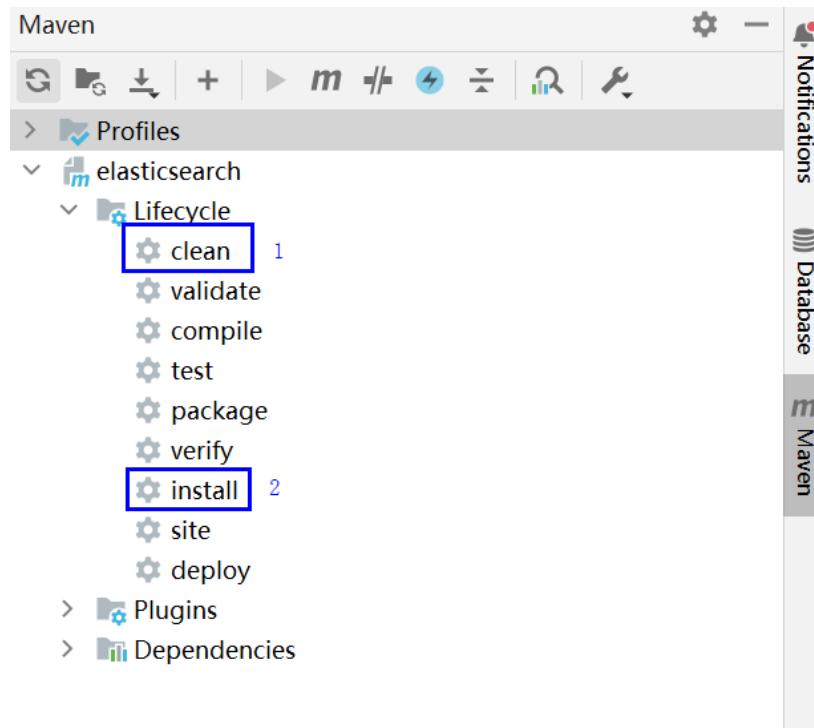

2. Compile and run an application.

- a. The following figure shows the file list after the configuration file has been placed and the code has been modified to match the login user. (Authentication files **krb5** and **keytab** are not required in normal clusters.)

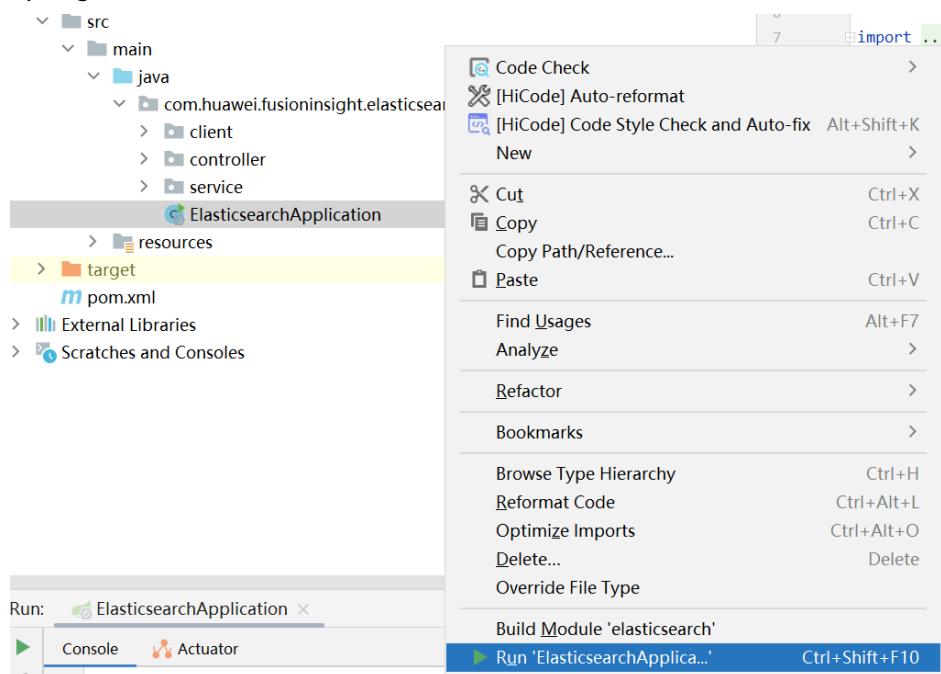

- b. Compile an application.

Double-click **clean** and **install** to run the **maven clean** and **maven install** commands. After the compilation is complete, "Build Success" is displayed.

c. Run the program.

Right-click **ElasticsearchApplication** and choose **Run'ElasticsearchApplication...'** from the shortcut menu to start the SpringBoot service.

3. Call the SpringBoot sample API of Elasticsearch to trigger the running of the sample code.

After the SpringBoot service is started, enter the link of the specific operation to be performed in the address box of the browser. For example, to query the cluster health status, enter **http://localhost:8080/elasticsearch/cluster/health** in the address box of the browser. The following result is returned:

```
{"cluster_name":"elasticsearch_cluster","status":"green","timed_out":false,"number_of_nodes":6,"number_of_data_nodes":3,"active_primary_shards":11,"active_shards":22,"relocating_shards":0,"initializing_shards":0,"unassigned_shards":0,"delayed_unassigned_shards":0,"number_of_pending_tasks":0,"number_of_in_flight_fetch":0,"task_max_waiting_in_queue_millis":0,"active_shards_percent_as_number":100.0}
```

**Table 2-12** lists the operations that can be performed when Elasticsearch interconnects with SpringBoot.

**Table 2-12** Operations for interconnecting Elasticsearch with SpringBoot

| Method                 | Browser Link   | Description  |
|------------------------|--|--|
| getElasticsearch       | http://localhost:8080/elasticsearch/   | Obtain cluster information such as clusterName, clusterUuid, and nodeName. |
| clusterHealth          | http://localhost:8080/elasticsearch/cluster/health   | Obtain the cluster health status.  |
| indexByJson            | http://localhost:8080/elasticsearch/indexByJson?index= <i>Index name</i>                   | Write data in JSON format.   |
| indexByMap             | http://localhost:8080/elasticsearch/indexByMap?index= <i>Index name</i>                    | Write data in the Map format.  |
| indexByXContentBuilder | http://localhost:8080/elasticsearch/indexByXContentBuilder?index= <i>Index name</i>        | Write data in the XContentBuilder format.                                  |
| update                 | http://localhost:8080/elasticsearch/update?index= <i>Index name</i> &id= <i>ID value</i>   | Update index data.   |
| bulk                   | http://localhost:8080/elasticsearch/bulk?index= <i>Index name</i>                          | Write data in batches.   |
| getIndex               | http://localhost:8080/elasticsearch/getIndex?index= <i>Index name</i> &id= <i>ID value</i> | Query index information.   |
| search                 | http://localhost:8080/elasticsearch/search?index= <i>Index name</i>                        | Search for related document information under a specified index.           |

| Method      | Browser Link   | Description   |
|-------------|--|---|
| scroll      | <code>http://localhost:8080/elasticsearch/scroll?index=/index name</code>      | Search for document information under a specified index using a cursor. You can disable the cursor by modifying <b>scrollId</b> . |
| deleteIndex | <code>http://localhost:8080/elasticsearch/deleteIndex?index=/index name</code> | Delete an index.  |

## 2.3.4.2 Commissioning Applications in Linux

### 2.3.4.2.1 Commissioning a RestClient Application

Elasticsearch application programs can run in a Linux environment. After the code development is complete, you can upload a .jar package to the prepared Linux running environment, to run the applications.

#### Prerequisites

JDK is installed in the Linux environment. The version must be the same as that of the JDK used to export the .jar package from IntelliJ IDEA, and Java environment variables have been set.

### Compiling and Running the Program

#### Step 1 Export a JAR package.

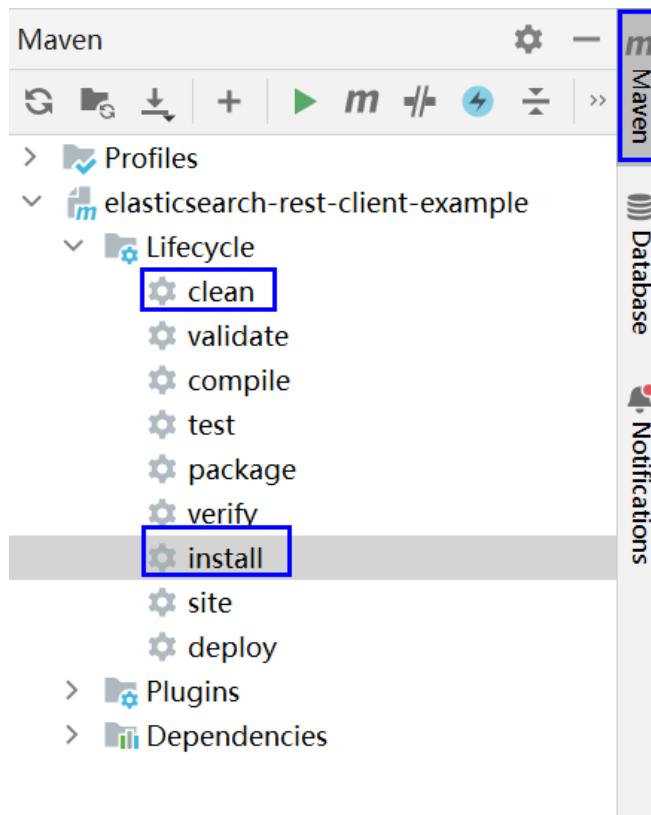

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven** > *Sample projectname* > **Lifecycle** > **clean**, double click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **install**, double click **install** to run the **install** command of Maven.

Figure 2-32 Maven tools: clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean install** command to compile the **pom.xml** file.

Figure 2-33 Enter mvn clean compile in the IDEA Terminal text box.

After the compilation is completed, the message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

### Step 2 Generate the **libs** on which the running depends.

Go to the local root directory of the project and run the following command in the Windows command prompt window to generate the **libs** on which the running depends:

**mvn dependency:copy-dependencies -DoutputDirectory=libs**

### Step 3 Run the .jar package

- Copy the directories **libs** and **conf** required for the development environment to any directory (For example, /opt/elasticsearch-example) in the Linux

operating environment. Then, copy the **.jar** package generated in the application environment to **/opt/elasticsearch-rest-client-example/libs/**.

 NOTE

Modify the **esParams.properties** file in the **conf** directory based on the site requirements. For details, see [Table 2-10](#).

2. Switch to the code directory cd /opt/elasticsearch-rest-client-example.

3. Run the following Java command:

- Run Low Level RestClient code

```
java -cp /opt/elasticsearch-rest-client-example/conf/*:/opt/
elasticsearch-rest-client-example/libs/*
com.huawei.fusioninsight.elasticsearch.example.lowlevel.allrequests.LowLevelRestClientAllRequests
```

- Run High Level RestClient code

```
java -cp /opt/elasticsearch-rest-client-example/conf/*:/opt/
elasticsearch-rest-client-example/libs/*
com.huawei.fusioninsight.elasticsearch.example.highlevel.allrequests.HighLevelRestClientAllRequests
```

- Run JDBC Rest Client code

```
java -cp /opt/elasticsearch-rest-client-example/conf/*:/opt/
elasticsearch-rest-client-example/libs/*
com.huawei.fusioninsight.elasticsearch.example.jdbc.SqlMain
```

----End

## Viewing the Commissioning Result

After the Elasticsearch ends running, you can view the running status using either of the following methods:

- View the running result.
- View Elasticsearch logs, that is, the **/opt/elasticsearch-rest-client-example/logs/es-example.log** log file in the **logs** directory.

After a complete sample of the Low Level RestClient is run, operation results are as follows:

```
2019-01-10 22:05:44,091 | INFO | main | Start to do low level rest client request ! |

### 2.3.4.2.2 Commissioning a SpringBoot Program

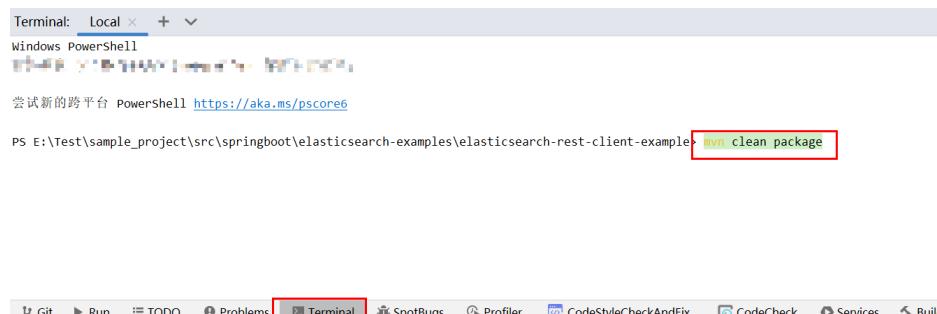

Applications that interconnect Elasticsearch with SpringBoot can run in the Linux environment. After the application code is developed, you can upload the JAR file to the prepared Linux environment.

## Prerequisites

JDK has been installed on Linux. The version must be the same as JDK version of the JAR file exported from IntelliJ IDEA. Java environment variables have been set.

## Compiling and Running Applications

**Step 1** Click Terminal in the lower left corner of the IDEA page to access the terminal. Run the **mvn clean package** command to compile the package.

If the command output contains "Build Success", the compilation is successful, as shown in the following figure. After the compilation is successful, the es-springboot.jar file is generated in the target directory of the sample project.

```
[INFO] -- maven-jar-plugin:3.2.2:jar (default-jar) @ elasticsearch ...
[INFO] Building jar: E:\Test\sample_project\src\springboot\elasticsearch-examples\elasticsearch-rest-client-example\target\es-springboot.jar
[INFO]
[INFO] -- spring-boot-maven-plugin:1.3.2.RELEASE:repackage (repackage) @ elasticsearch ...
[INFO]
[INFO] -- spring-boot-maven-plugin:1.3.2.RELEASE:repackage (default) @ elasticsearch ...
[INFO]
[INFO] -----
[INFO] BUILD SUCCESS
[INFO]
[INFO] Total time: 4.836 s
[INFO] Finished at: 2023-02-27T10:34:23+08:00
[INFO]
PS E:\Test\sample_project\src\springboot\elasticsearch-examples\elasticsearch-rest-client-example>
```

**Step 2** Create a directory on Linux as the running directory, for example, /opt/es-springboot, and save the es-springboot.jar and conf folders in the target directory to the directory. Modify the esParams.properties file in the conf directory and save the user credential files krb5.conf and user.keytab of Elasticsearch to the conf directory.

#### NOTE

Modify the esParams.properties configuration file in the conf directory based on the site requirements. For details, see [Table 2-10](#).

**Step 3** Run the JAR file.

1. Switch to the code function directory.

**cd /opt/es-springboot**

2. Run the java command to start the SpringBoot service.

**java -jar es-springboot.jar conf/**

3. Start another terminal on the current node to access the Elasticsearch client.

**cd Client installation directory**

**source bigdata\_env**

**kinit esuser**

4. Perform the curl operation of Elasticsearch. For example, if you run the **curl http://localhost:8080/elasticsearch/cluster/health** command to query the cluster health status, the following information is displayed:

```
{"cluster_name":"elasticsearch_cluster","status":"green","timed_out":false,"number_of_nodes":6,"number_of_data_nodes":3,"active_primary_shards":11,"active_shards":22,"relocating_shards":0,"initializing_shards":0,"unassigned_shards":0,"delayed_unassigned_shards":0,"number_of_pending_tasks":0,"number_of_in_flight_fetch":0,"task_max_waiting_in_queue_millis":0,"active_shards_percent_as_number":100.0}
```

For details about other operations, see [Table 2-13](#).

**Table 2-13** Curl operations for interconnecting Elasticsearch with SpringBoot

| Method           | Curl Commands on the Linux Client                         | Description  |
|------------------|---|--|
| getElasticsearch | curl 'http://localhost:8080/elasticsearch/'               | Obtain cluster information such as clusterName, clusterUuid, and nodeName. |
| clusterHealth    | curl 'http://localhost:8080/elasticsearch/cluster/health' | Obtain the cluster health status.  |

| Method                 | Curl Commands on the Linux Client   | Description   |
|------------------------|---|---|
| indexByJson            | curl 'http://localhost:8080/elasticsearch/indexByJson?index=/Index name'            | Write data in JSON format.  |
| indexByMap             | curl 'http://localhost:8080/elasticsearch/indexByMap?index=/Index name'             | Write data in the Map format.   |
| indexByXcontentBuilder | curl 'http://localhost:8080/elasticsearch/indexByXContentBuilder?index=/Index name' | Write data in the XContentBuilder format.   |
| update                 | curl 'http://localhost:8080/elasticsearch/update?index=/Index name&id=/D value'     | Update index data.  |
| bulk                   | curl 'http://localhost:8080/elasticsearch/bulk?index=/Index name'                   | Write data in batches.  |
| getIndex               | curl 'http://localhost:8080/elasticsearch/getIndex?index=/Index name&id=/D value'   | Query index information.  |
| search                 | curl 'http://localhost:8080/elasticsearch/search?index=/Index name'                 | Search for related document information under a specified index.  |
| scroll                 | curl 'http://localhost:8080/elasticsearch/scroll?index=/Index name'                 | Search for document information under a specified index using a cursor. You can disable the cursor by modifying <b>scrollId</b> . |
| deleteIndex            | curl 'http://localhost:8080/elasticsearch/deleteIndex?index=/Index name'            | Delete an index.  |

----End

## 2.4 Flink Development Guide

### 2.4.1 Overview

## 2.4.1.1 Application Development

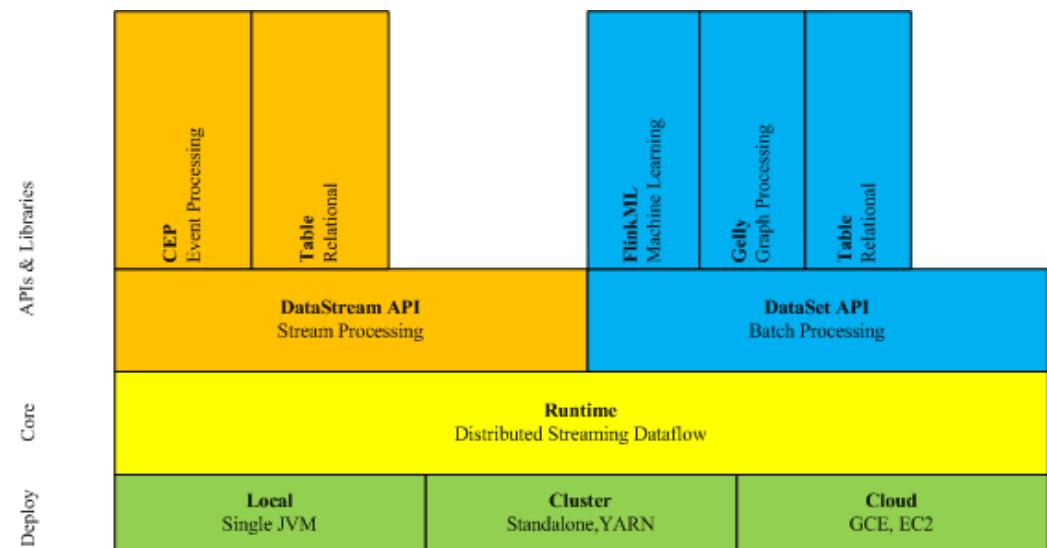

### Overview

Flink is a unified computing framework that supports both batch processing and stream processing. It provides a stream data processing engine that supports data distribution and parallel computing. Flink features stream processing and is a top open-source stream processing engine in the industry.

Flink provides high-concurrency pipeline data processing, millisecond-level latency, and high reliability, making it suitable for low-latency data processing.

[Figure 2-34](#) shows the technology stack of Flink.

**Figure 2-34** Technology stack of Flink

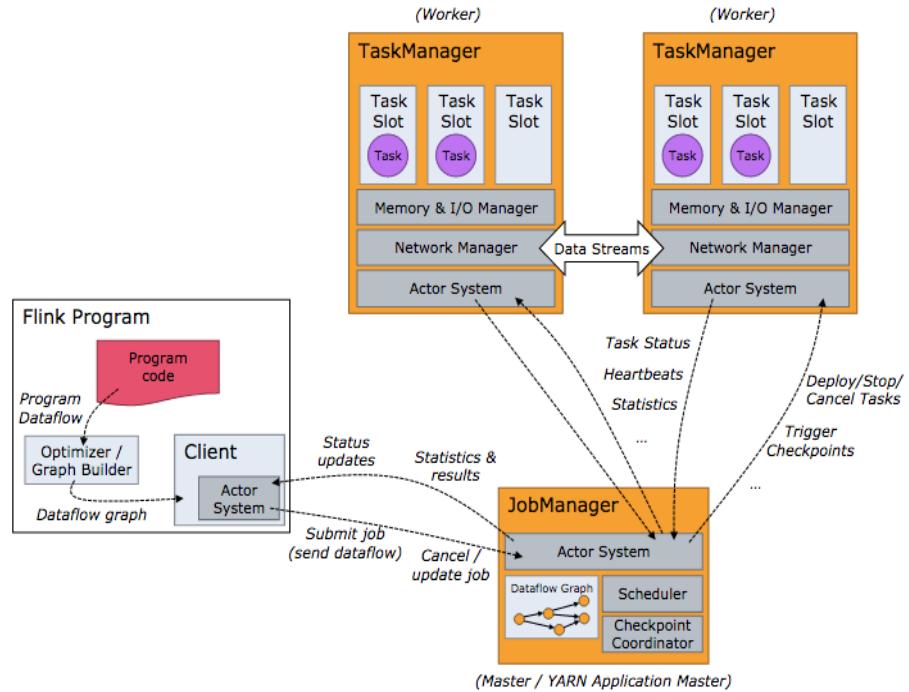

The following lists the key features of Flink in the current version:

- DataStream
- Checkpoint
- Window
- Job Pipeline
- Configuration Table

### Architecture

[Figure 2-35](#) shows the architecture of Flink.

**Figure 2-35 Flink architecture**

As shown in [Figure 2-35](#), the entire Flink system consists of three parts:

- **Client**  
Flink client is used to submit jobs (streaming jobs) to Flink.
- **TaskManager**  
TaskManager (also called worker) is a service execution node of Flink. It executes specific tasks. A Flink system could have multiple TaskManagers. These TaskManagers are equivalent to each other.
- **JobManager**  
JobManager (also called master) is a management node of Flink. It manages all TaskManagers and schedules tasks submitted by users to specific TaskManagers. In high-availability (HA) mode, multiple JobManagers are deployed. Among these JobManagers, one of which is selected as the leader, and the others are standby.

Flink provides the following features:

- **Low latency**  
Millisecond-level processing capability.
- **Exactly once**  
Asynchronous snapshot mechanism, ensuring that all data is processed only once.
- **High availability**  
Leader/Standy JobManagers, preventing single point of failure (SPOF).
- **Scale out**

Manual scale out supported by TaskManagers.

## Flink Development APIs

Flink DataStream API can be developed using Scala and Java languages, as shown in [Table 2-14](#).

**Table 2-14** Flink DataStream API

| Function  | Description  |
|-----------|--|
| Scala API | API in Scala, which can be used for data processing, such as filtering, joining, windowing, and aggregation. The Scala API is recommended for development because Scala is concise and easy to understand. |
| Java API  | API in Java, which can be used for data processing, such as filtering, joining, windowing, and aggregation.  |

### 2.4.1.2 Basic Concepts

#### Basic Concepts

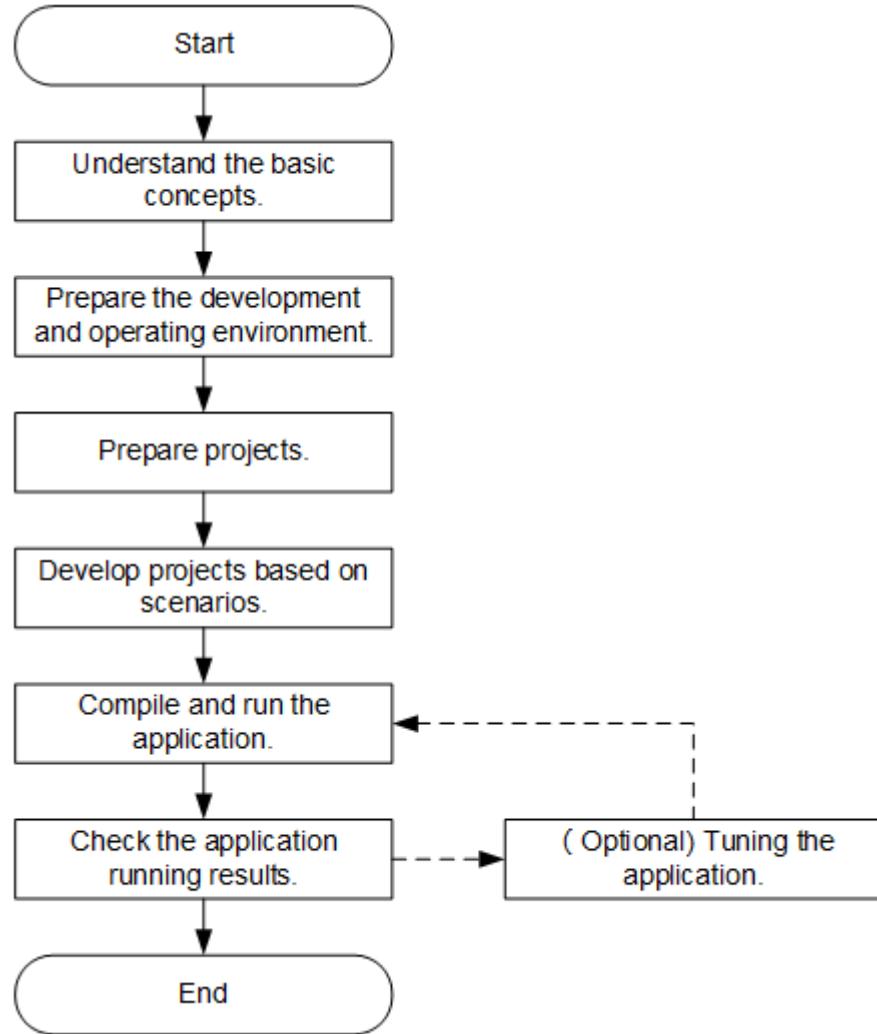

- **DataStream**  
DataStream is the minimum unit of Flink processing and is one of core concepts of Flink. DataStreams are initially imported from external systems in formats of socket, Kafka, and files. After being processed by Flink, DataStreams are exported to external systems in formats of socket, Kafka, and files.
- **Data Transformation**  
A data transformation is a data processing unit that transforms one or multiple DataStreams into a new DataStream.  
Data transformation can be classified as follows:
  - One-to-one transformation, for example, map.
  - One-to-zero, one-to-one, or one-to-multiple transformation, for example, flatMap.
  - One-to-zero or one-to-one transformation, for example, filter.
  - Multiple-to-one transformation, for example, union.
  - Transformation of multiple aggregations, for example, window and keyby.
- **Checkpoint**  
Checkpoint is the most important Flink mechanism to ensure reliable data processing. Checkpoints ensure that all application statuses can be recovered from a checkpoint in case of failure occurs and data is processed exactly once.
- **Savepoint**  
Savepoints are externally stored checkpoints that you can use to stop-and-resume or update your Flink programs. After the upgrade, you can set the task status to the savepoint storage status and start the restoration, ensuring data continuity.

### 2.4.1.3 Development Process

#### Development Process of a Flink Application

[Figure 2-36](#) shows the Flink development process:

**Figure 2-36** Development process of a Flink application

**Table 2-15** Description of the development process

| Phase                          | Description   | Reference                      |
|--------------------------------|---|--------------------------------|
| Understand the basic concepts. | Before the development process, you are advised to gain a basic understanding of Flink. | <a href="#">Basic Concepts</a> |

| Phase  | Description   | Reference  |
|--|---|--|
| Prepare the development and operating environment. | Flink applications can be developed using Scala or Java. You are advised to use IntelliJ IDEA tool to configure the development environment as instructed, based on your development language.<br><br>The running environment of Flink is the Flink client. Install and configure the client as instructed. | <a href="#">Preparing the Development and Operating Environment</a>  |
| Prepare projects.                                  | Flink provides sample projects for you to import and learn. Alternatively, you can create a Flink project as instructed.  | <a href="#">Configuring and Importing Sample Projects</a><br><a href="#">Creating a Project (Optional)</a> |
| Develop the project.                               | Sample projects in Scala and Java are provided to help you quickly understand programming interfaces of Flink components.   | <a href="#">Developing an Application</a>  |
| Compile and run the application.                   | Guidance is provided for you to compile and run a developed application.  | <a href="#">Compiling and Running Applications</a>   |
| Check running results.                             | Application running results are stored in a path specified by you. You can also view application running status through Apache Flink Dashboard.   | <a href="#">Viewing the Debugging Result</a>   |
| Tune the application.                              | Tune the application to meet certain service requirements.<br><br>After the tuning is complete, the application needs to be compiled and run again.   | "Flink Performance Tuning" in the Component Operation Guide  |

## 2.4.2 Environment Preparation

### 2.4.2.1 Preparing the Development and Operating Environment

#### Preparing the Development Environment

[Table 2-16](#) describes the environment required for secondary development.

**Table 2-16** Development environment

| Item                                | Description   |
|-------------------------------------|---|
| OS                                  | <ul style="list-style-type: none"><li>• Development environment: Windows OS</li><li>• Operating environment: Linux OS<br/>If the program needs to be commissioned locally, the operating environment must be able to communicate with the cluster service plane.</li></ul>  |
| JDK installation                    | <p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– Oracle JDK 1.8</li><li>– IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>– BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul> |
| IDEA installation and configuration | Used for developing Flink applications. The required version is 14.1.7.   |
| Scala installation                  | Basic configuration for the Scala development environment. The required version is 2.11.7.  |
| Scala plug-in installation          | Basic configuration for the Scala development environment. The required version is 1.5.4.   |
| Maven installation                  | Basic configuration for the development environment. Maven is used for project management throughout the lifecycle of software development.   |

| Item    | Description  |
|---------|--|
| 7-zip   | Used to decompress *.zip and *.rar files. <b>7-Zip 16.04</b> is supported. |
| Python3 | Used to run Flink Python jobs. Python 3.7 or later is required.            |

## Preparing the Operating Environment

During application development, prepare the code running and commissioning environment to verify that the application is running properly.

If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.

1. Install the client in a directory, for example, **/opt/hadoopclient**, on the node. Ensure that the difference between the client time and the cluster time is less than 5 minutes.  
For details about how to install a cluster client, see [Installing a Client](#).
2. Log in to FusionInsight Manager. Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Flink\config** directory to the **conf** directory where the compiled JAR file is stored for subsequent commissioning, for example, **/opt/hadoopclient/conf**.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following commands:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Flink/config/* root@IP address of the client node:/opt/hadoopclient/conf
```

[Table 2-17](#) describes the main configuration files.

**Table 2-17** Configuration files

| File            | Function                         |
|-----------------|----------------------------------|
| core-site.xml   | Configures Flink parameters.     |
| hdfs-site.xml   | Configures HDFS parameters.      |
| yarn-site.xml   | Configures YARN parameters.      |
| flink-conf.yaml | Flink client configuration file. |

3. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client is located, to ensure that the local host can communicate with each host in the cluster.

4. (Optional) To run a Python job, perform the following additional configurations:

- a. Log in to the node where the Flink client is installed as the **root** user and run the following command to check whether Python 3.7 or a later has been installed:

```
python3 -V
```

- b. Go to the python 3 installation path, for example, **/srv/pyflink-example**, and install the **virtualenv**:

```
cd /srv/pyflink-example
```

```
virtualenv venv --python=python3.x
```

```
source venv/bin/activate
```

- c. Copy the **Flink/flink/opt/python/apache-flink-\*.tar.gz** file from the client installation directory to **/srv/pyflink-example**:

```
cp /Client installation directory/Flink/flink/opt/python/apache-flink-*.tar.gz /srv/pyflink-example
```

- d. Install the dependency package. If the following command output is displayed, the installation is successful:

```
python -m pip install apache-flink-libraries-*.tar.gz
```

```
python -m pip install apache-flink- Version number.tar.gz
```

```
...
```

```
Successfully built apache-flink  
Installing collected packages: apache-flink  
Attempting uninstall: apache-flink  
    Found existing installation: apache-flink x.xx.x  
    Uninstalling apache-flink-x.xx.x:  
        Successfully uninstalled apache-flink-x.xx.x  
Successfully installed apache-flink-x.xx.x
```

#### 2.4.2.2 Configuring and Importing Sample Projects

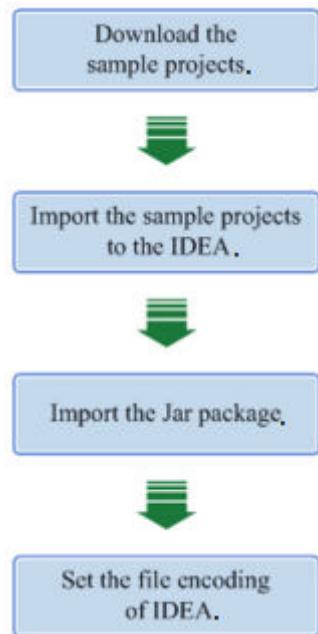

##### Scenario

Flink provides sample projects for multiple scenarios, including Java and Scala sample projects, to help you quickly learn Flink projects.

Methods to import Java and Scala projects are the same.

The following example describes how to import Java sample code. [Figure 2-37](#) shows the operation process.

Figure 2-37 Process of importing sample projects

## Procedure

**Step 1** Obtain the sample project folder **flink-examples-normal** in the **src\flink-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

 NOTE

- In security mode, obtain the sample project **flink-examples-security** from the **src\flink-examples** folder.
- In normal mode, obtain the sample project **flink-examples-normal** from the **src\flink-examples** folder.

**Step 2** Before importing the sample project, configure JDK for IntelliJ IDEA.

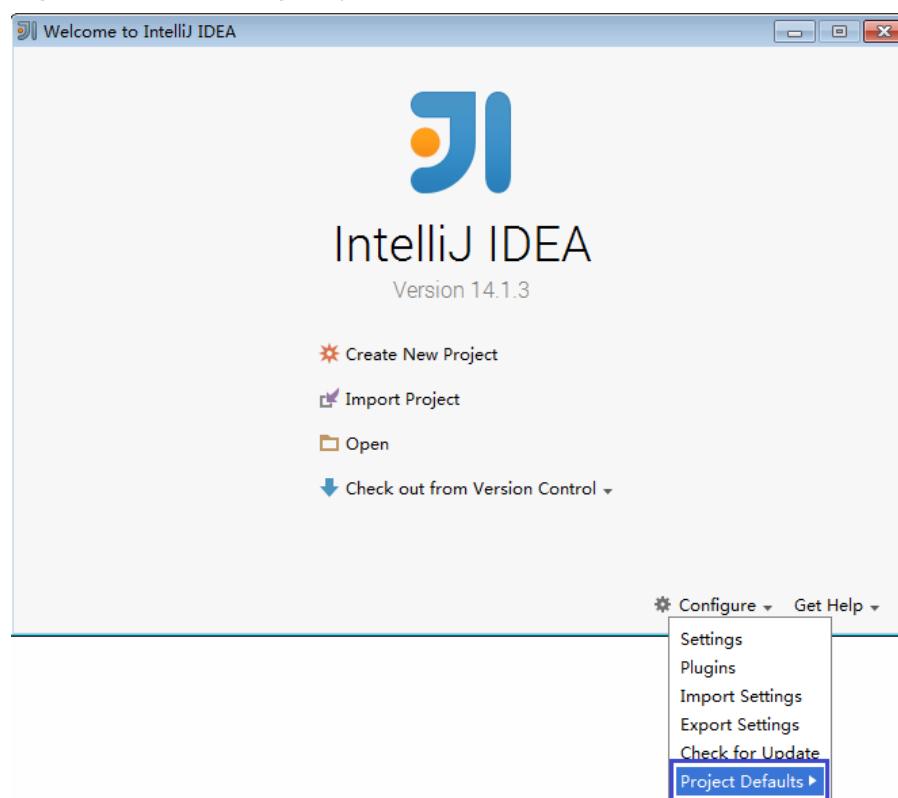

1. Start IntelliJ IDEA and click **Configure**.

Figure 2-38 Choosing Configure

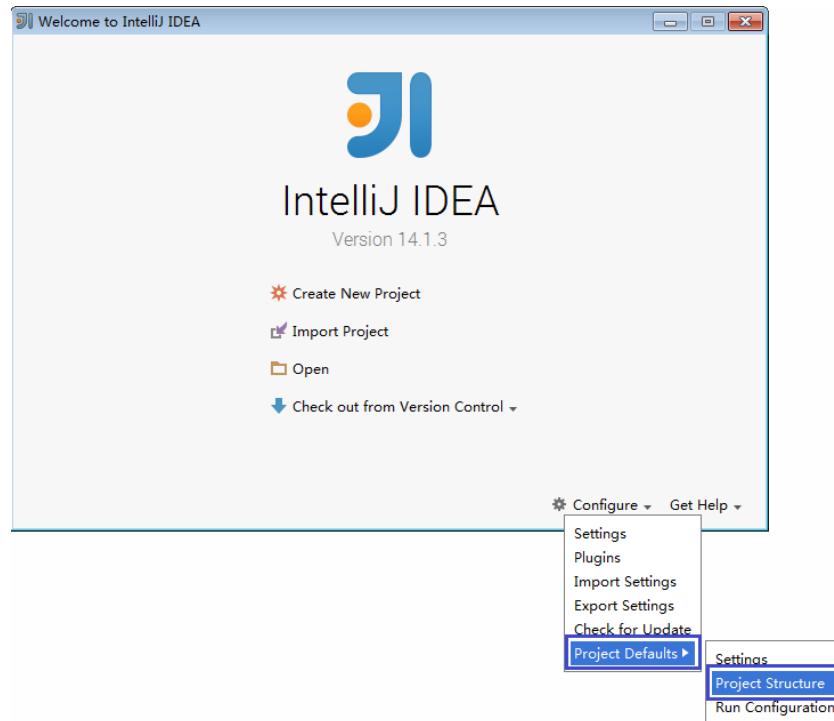

2. Choose **Project Defaults** from the **Configure** drop-down list.

Figure 2-39 Choosing Project Defaults

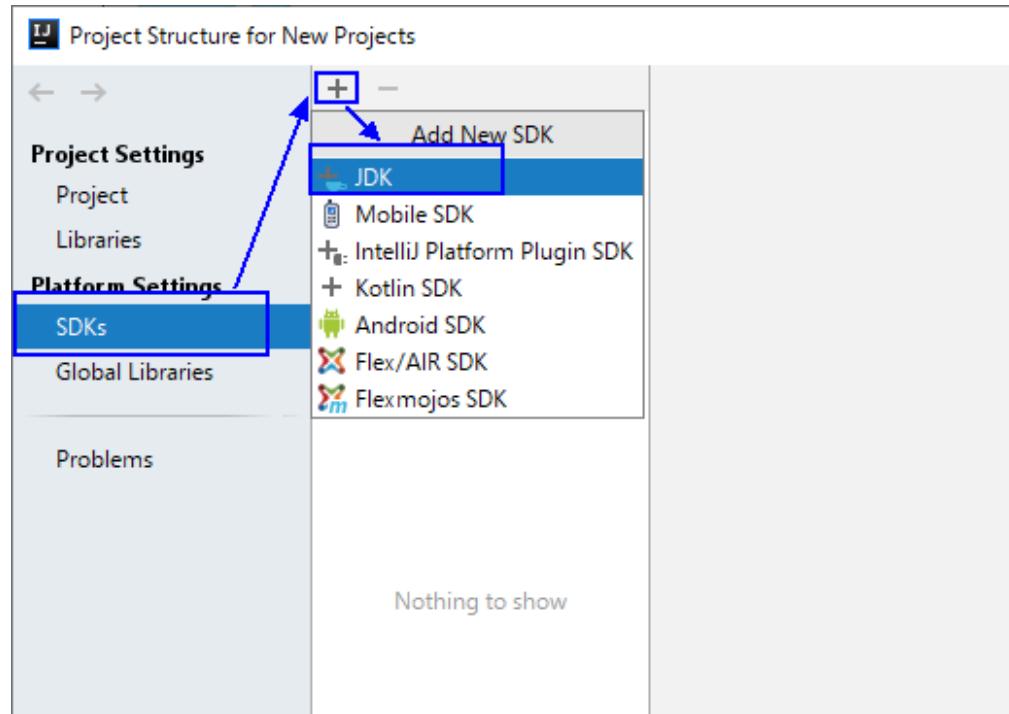

3. Choose **Project Structure** from the **Project Defaults** submenu.

Figure 2-40 Project Defaults

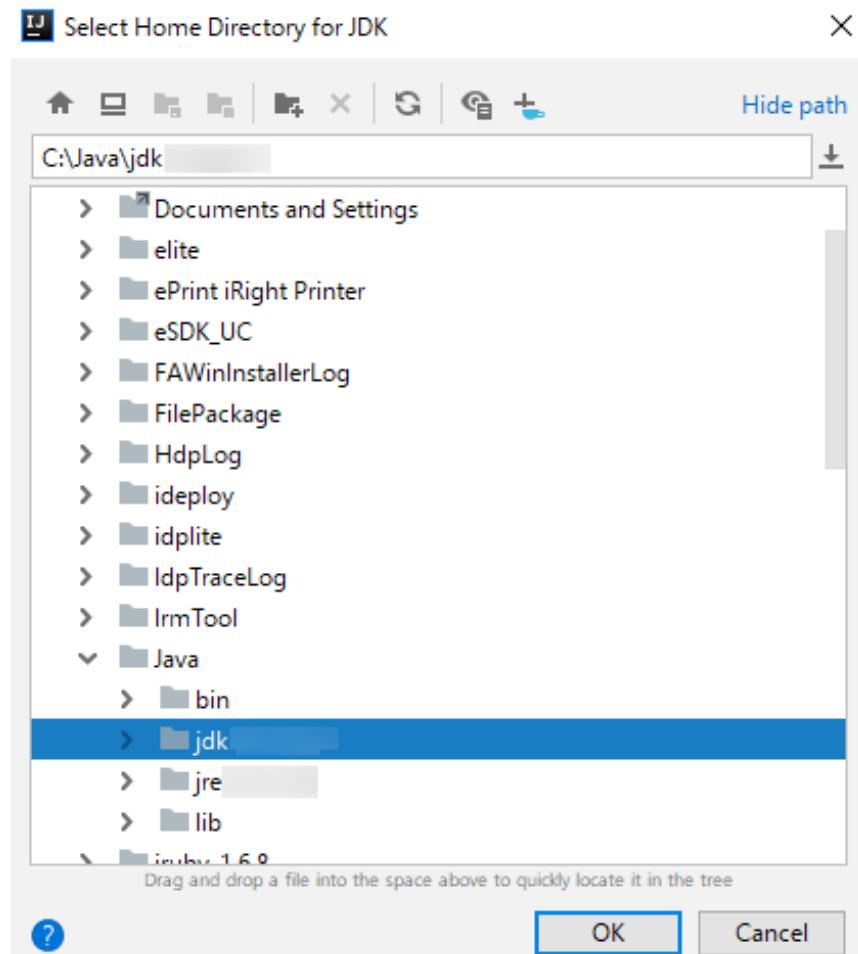

4. On the **Project Structure** page, select **SDKs** and click the plus sign to add the JDK.

Figure 2-41 Adding the JDK

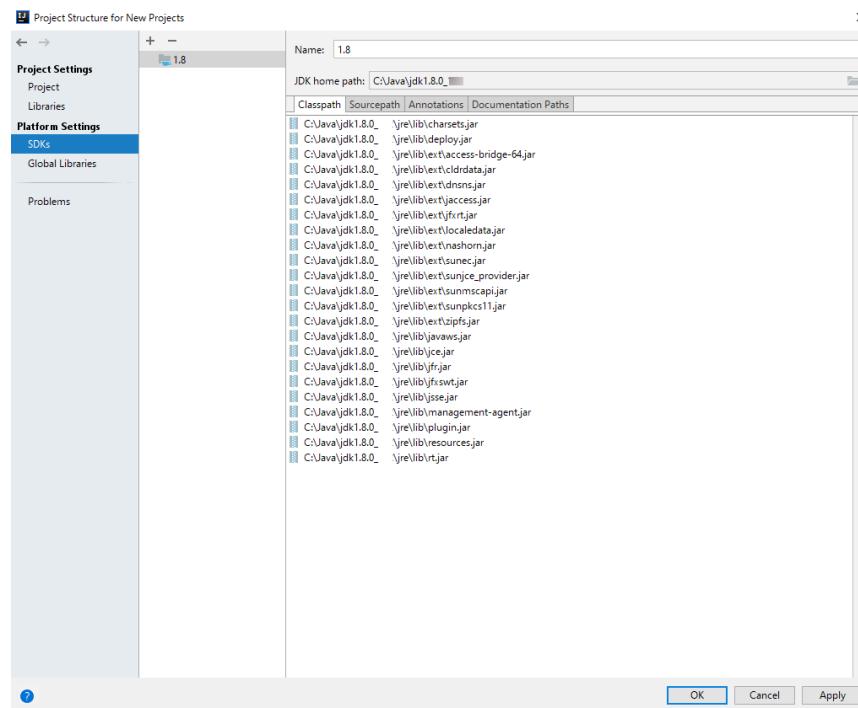

5. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.

Figure 2-42 Selecting the JDK directory

6. After the JDK is selected, click **OK** to complete the configuration.

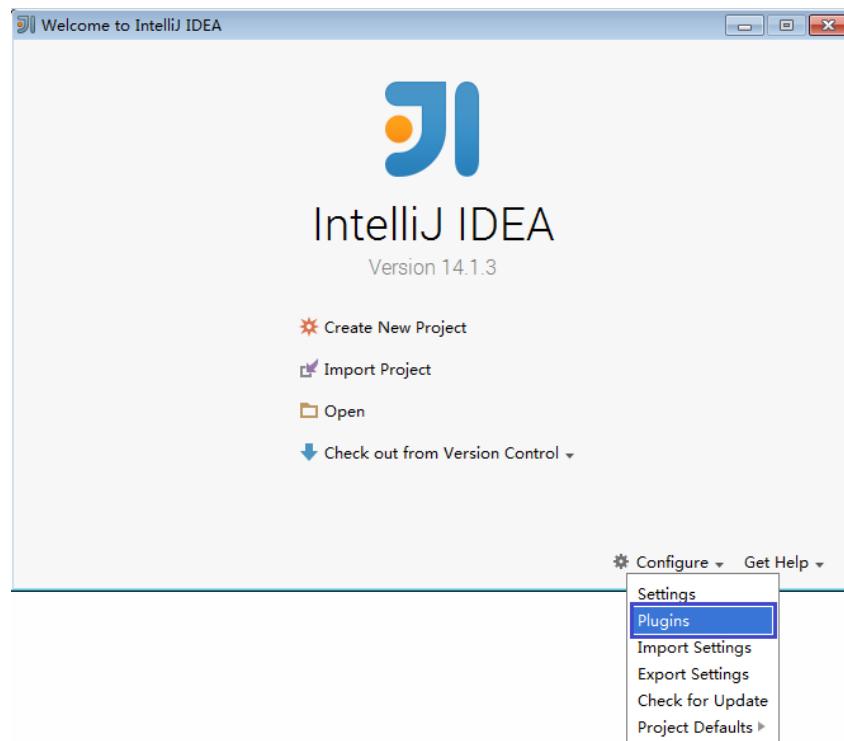

Figure 2-43 Completing the JDK configuration

**Step 3** (Optional) If a Scala sample project is imported, install Scala plug-ins in IntelliJ IDEA.

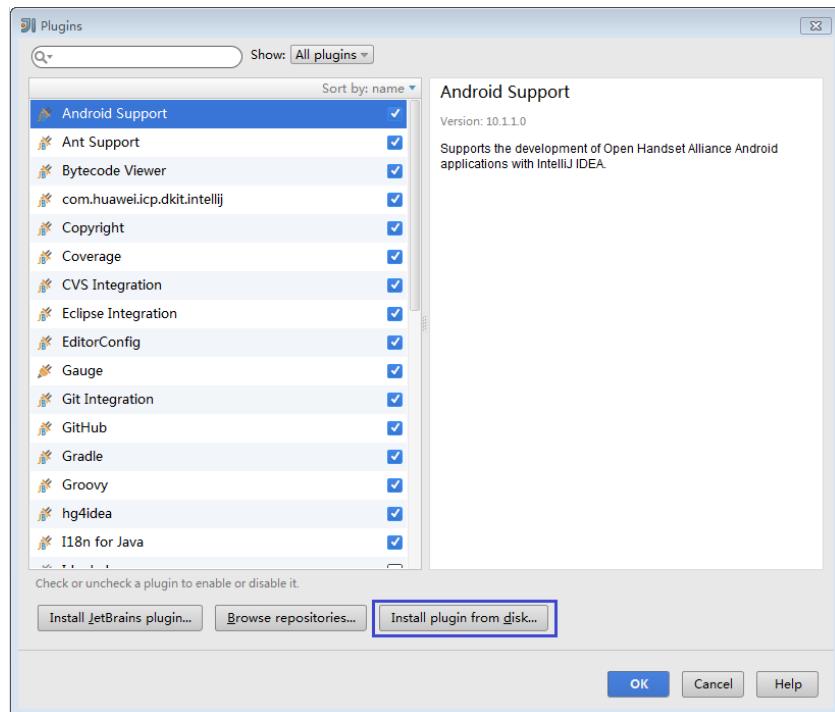

1. Choose **Plugins** from the **Configure** drop-down list.

Figure 2-44 Plugins

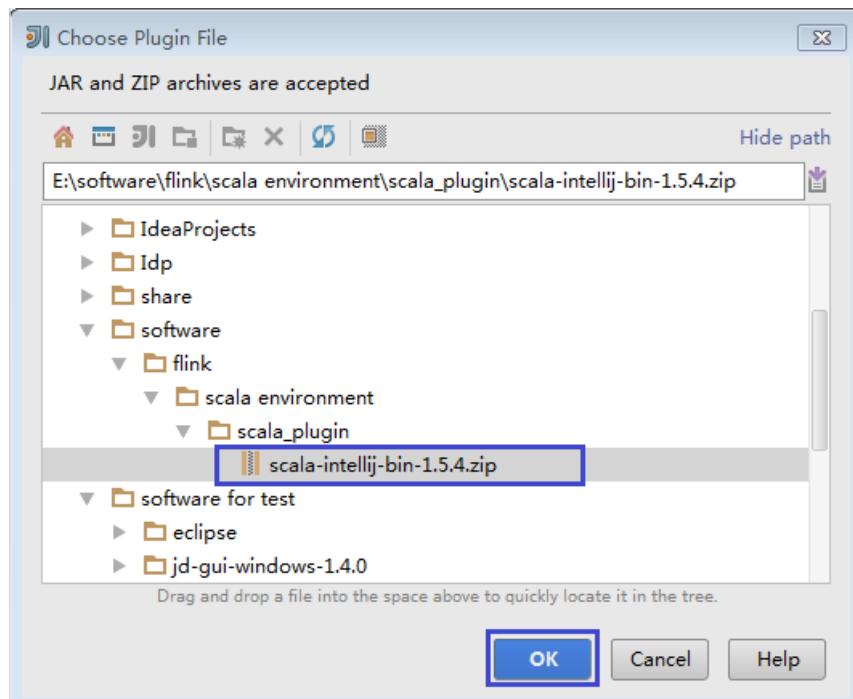

2. On the **Plugins** page, click **Install plugin from disk**.

Figure 2-45 Installing plugins from disk

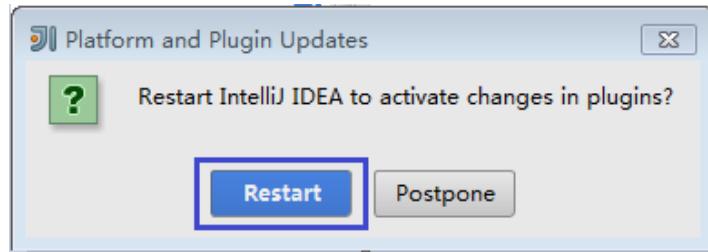

3. On the **Choose Plugin File** page, select the Scala plugin file of the corresponding version and click **OK**.

Figure 2-46 Choose Plugin File

4. On the **Plugins** page, click **Apply** to install the Scala plugins.
5. On the **Platform and Plugin Updates** page that is displayed, click **Restart** to make the configurations take effect.

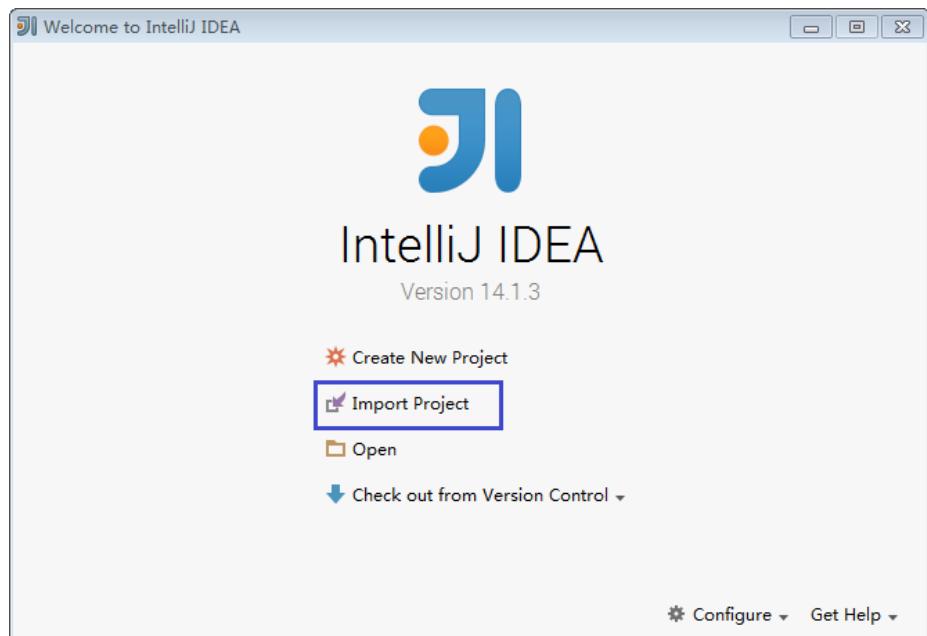

Figure 2-47 Platform and Plugin Updates

**Step 4** Import the Java sample project to IDEA.

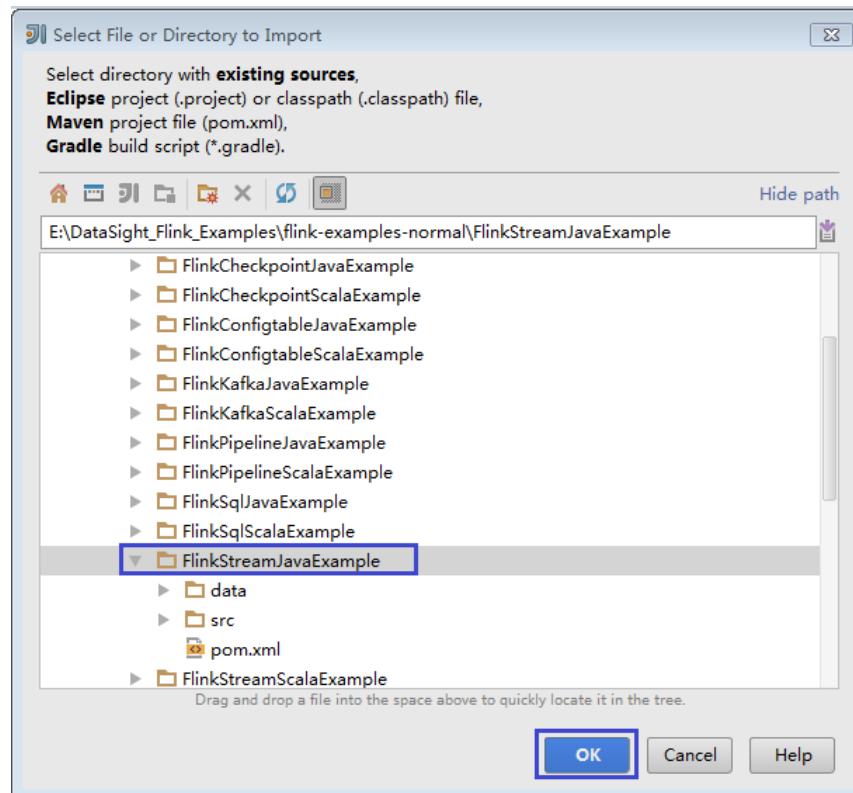

1. Start IntelliJ IDEA. On the **Quick Start** page, select **Import Project**. Alternatively, for the used IDEA tool, add the project directly from the IDEA home page. Choose **File > Import project...** to import a project.

Figure 2-48 Importing a project (on the Quick Start page)

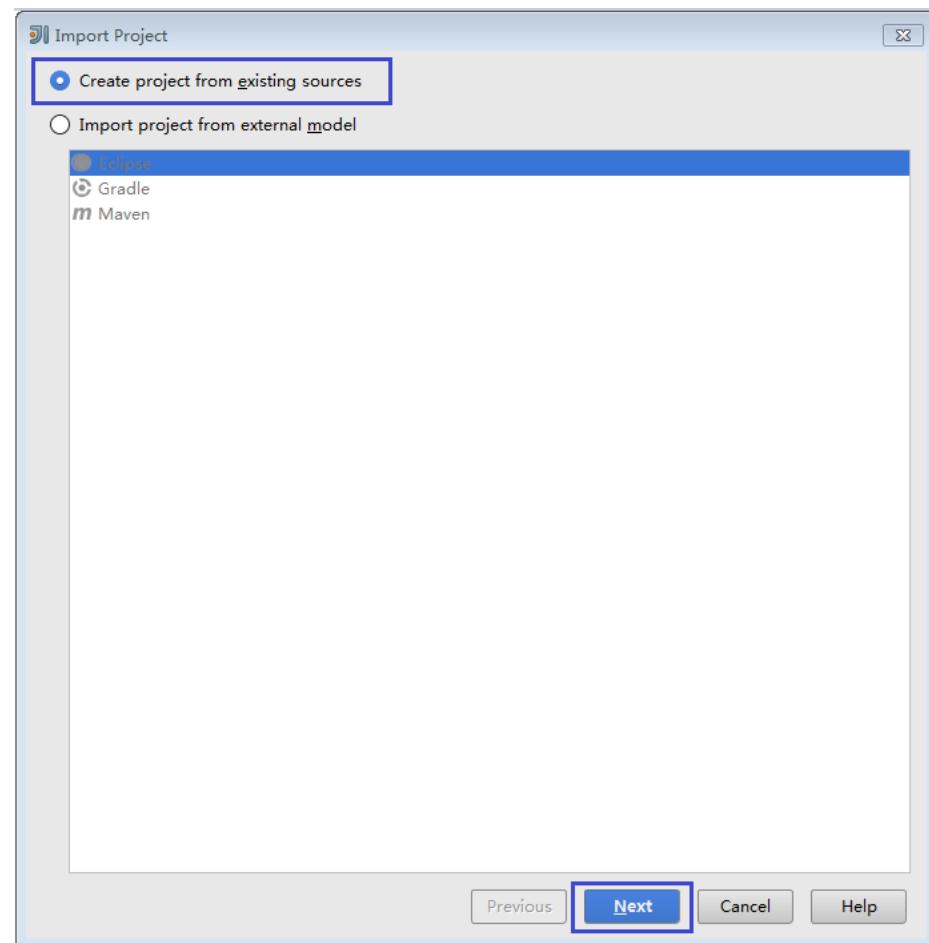

2. Select the directory for storing the imported projects and click **OK**.

Figure 2-49 Select File or Directory to Import

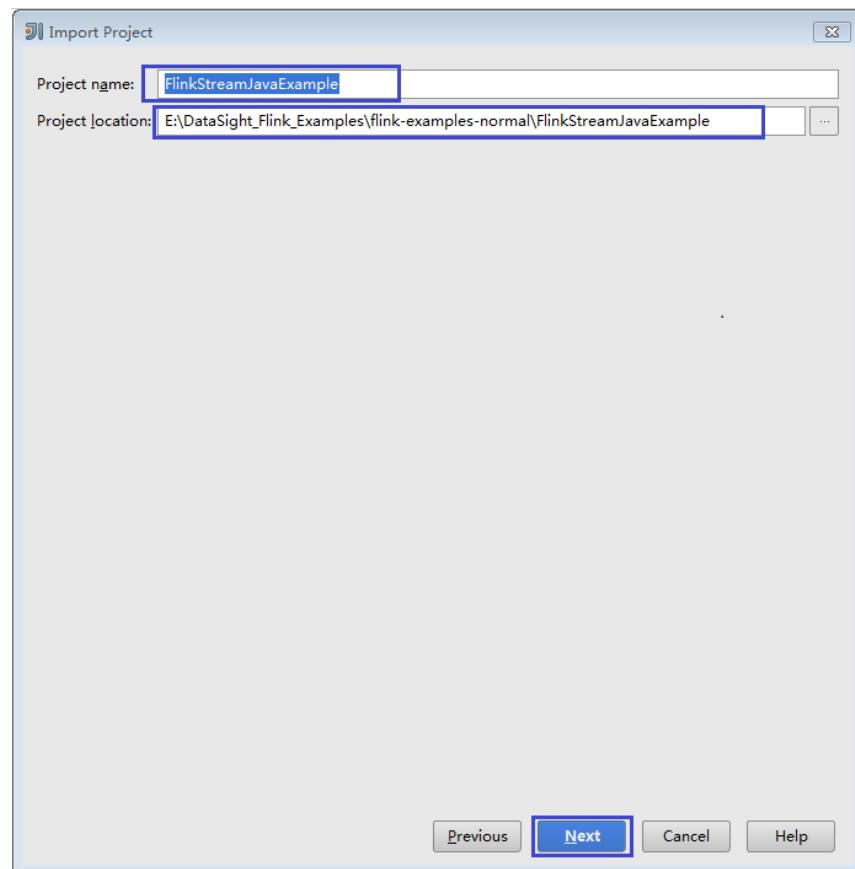

3. Select **Create project from existing sources** and click **Next**.

Figure 2-50 Create project from existing sources

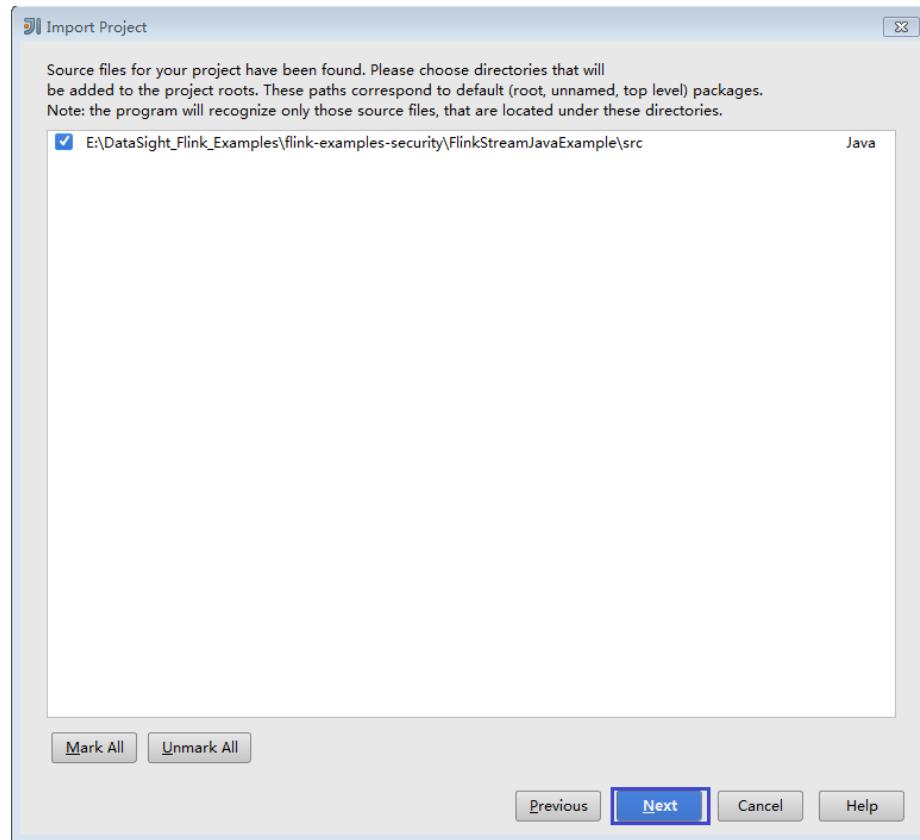

4. Confirm the project location and project name, and click **Next**.

Figure 2-51 Import Project

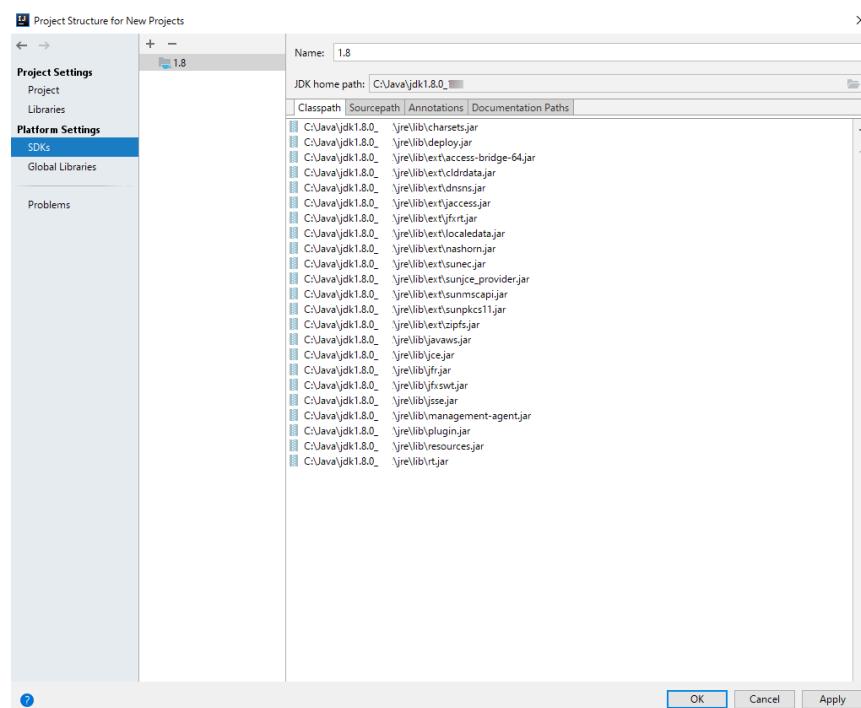

5. Retain the default value of the **root** directory for the project to be imported and click **Next**.

Figure 2-52 Import Project

6. Retain the default dependency library that is automatically recognized by IDEA and the suggested module structure, and click **Next**.
7. Confirm the JDK to be used by the project and click **Next**.

Figure 2-53 Select project SDK

8. After the import is complete, click **Finish**. The imported sample project is displayed on the IDEA home page.

**Figure 2-54** Completing the import

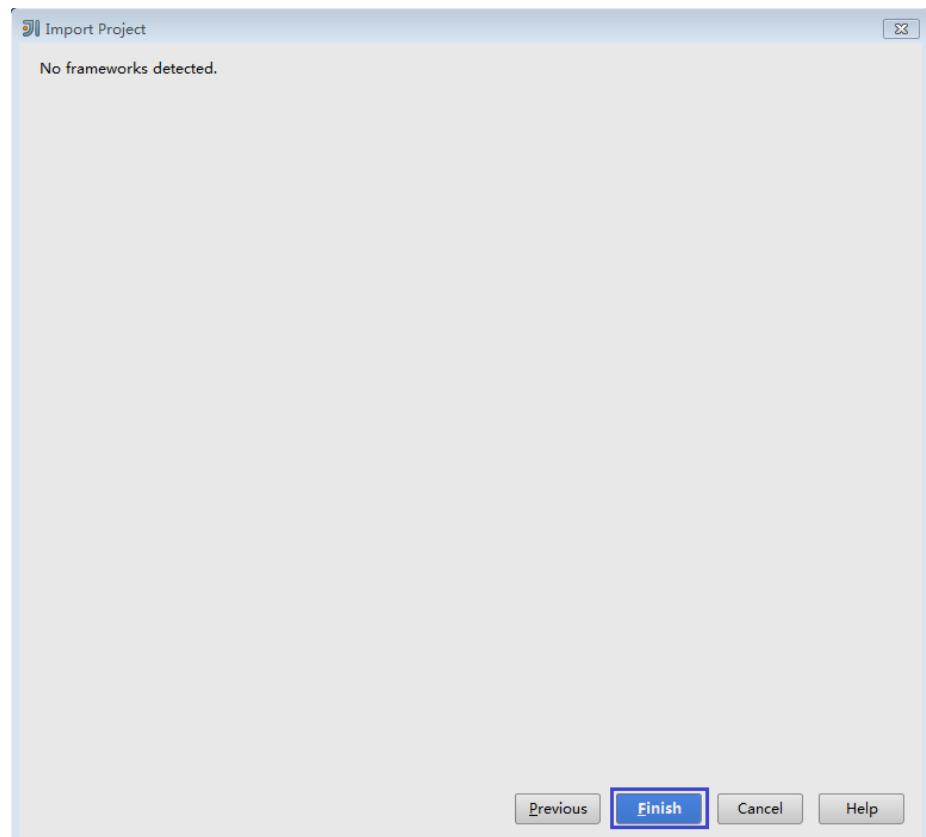

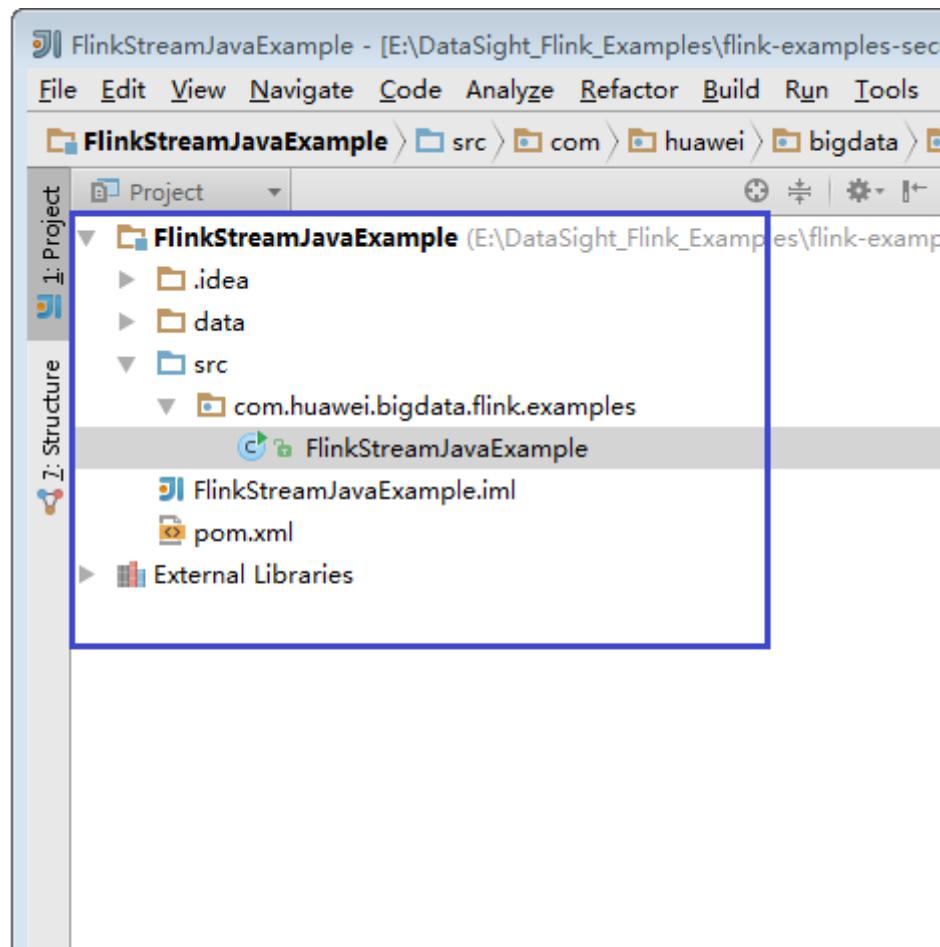

Figure 2-55 Imported project

**Step 5** Import the dependency JAR file for the sample project.

If the sample project code is obtained from an open-source image site, dependency JAR files are automatically downloaded after Maven is configured.

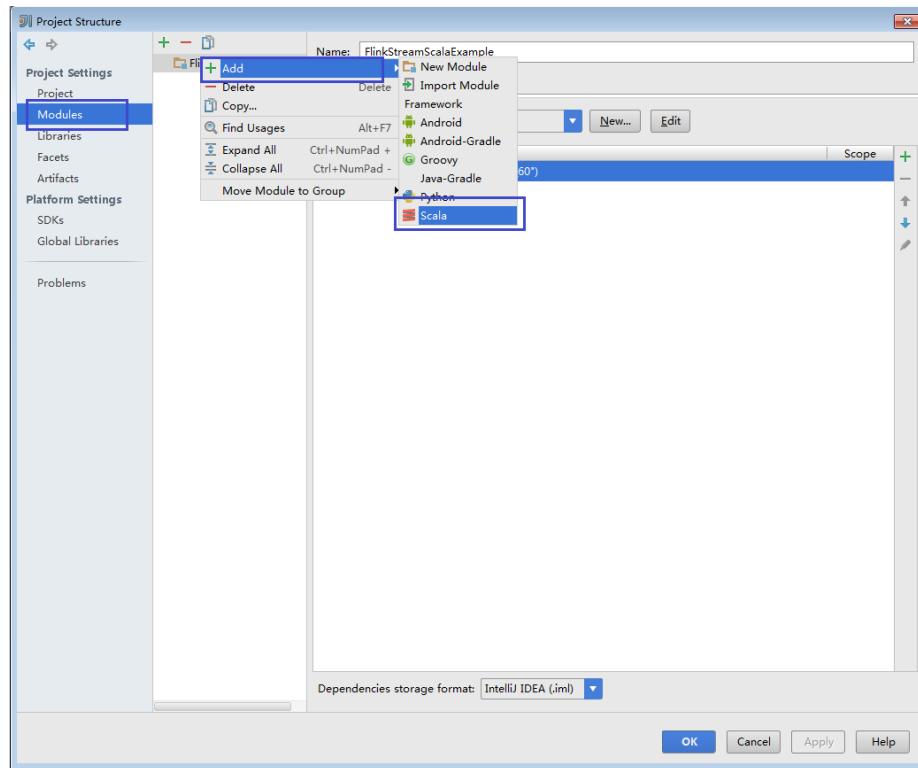

**NOTE**

If other FusionInsight components such as Kafka and Redis are used in the sample code, obtain them from the installation directory of these FusionInsight components. For details about dependency packages of sample projects, see [Reference information about the dependency package for running the sample project](#).

**Step 6** (Optional) If a Scala sample application is imported, configure a language for the project.

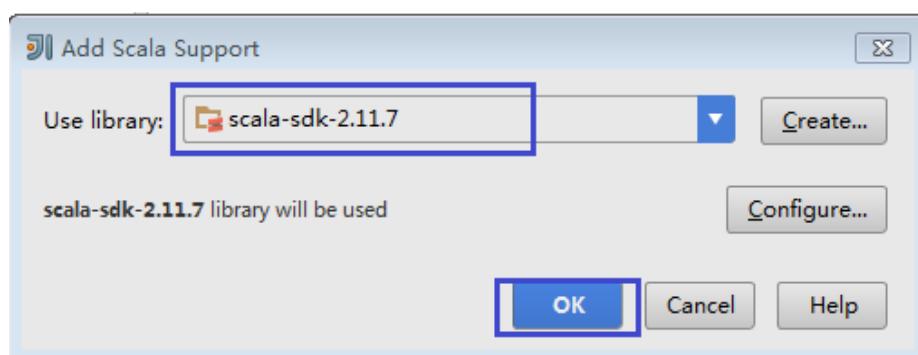

1. On the IDEA home page, choose **File > Project Structures...** to go to the **Project Structure** page.
2. Choose **Modules**, right-click a project name, and choose **Add > Scala**.

Figure 2-56 Selecting Scala

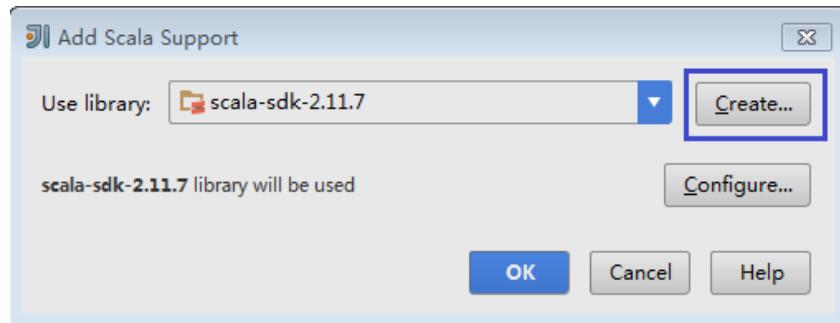

3. Wait until IDEA identifies Scala SDK, select the dependency JAR files in the **Add Scala Support** dialog box, and then click **OK**.

Figure 2-57 Add Scala Support

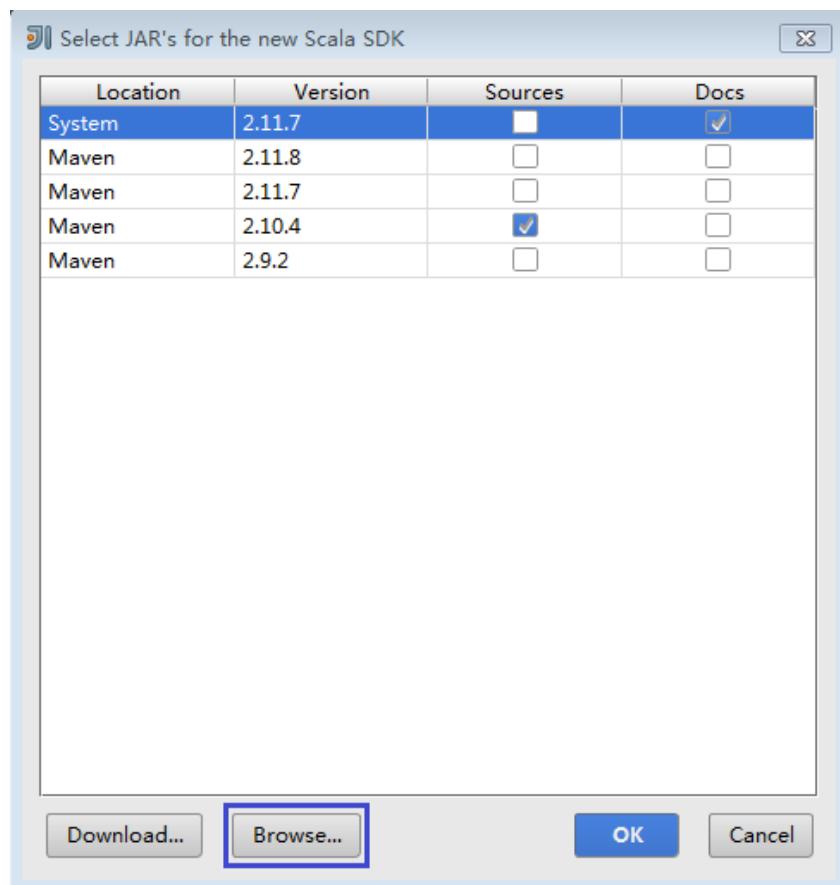

4. If IDEA fails to identify Scala SDK, create a Scala SDK.
  - a. Click **Create....**

**Figure 2-58 Create...**

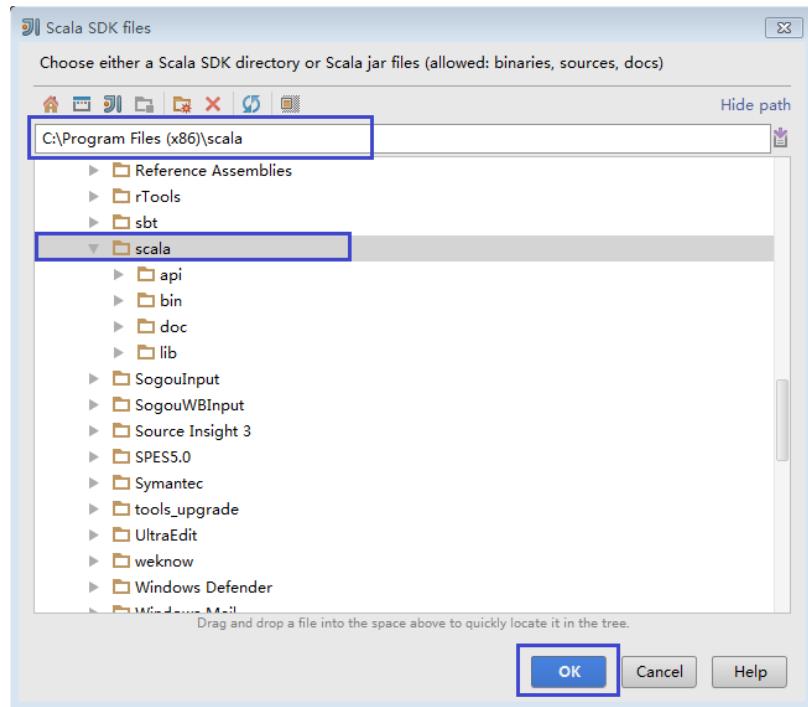

- b. On the **Select JAR's for the new Scala SDK** page, click **Browse....**

**Figure 2-59 Select JAR's for the new Scala SDK**

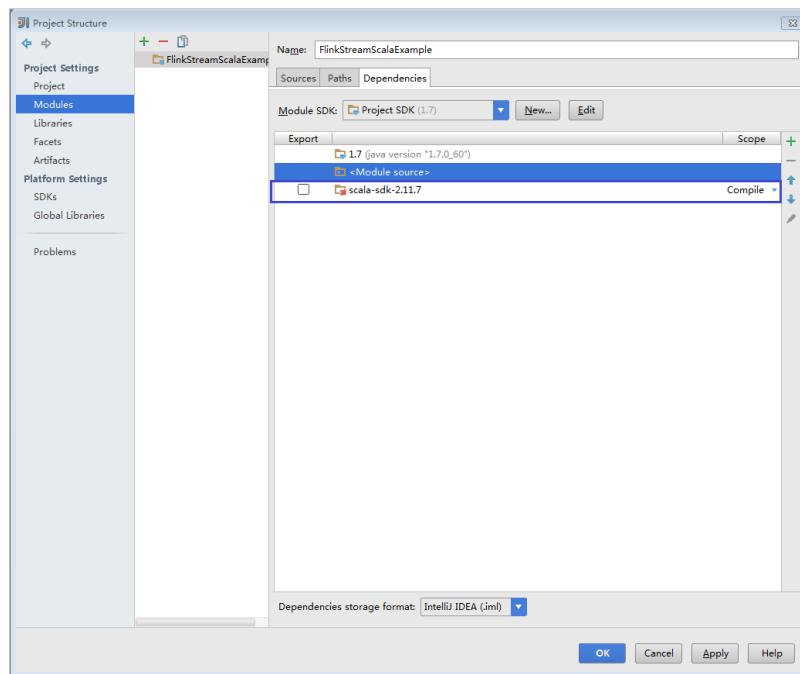

- c. On the **Scala SDK files** page, select the **scala sdk** directory and click **OK**.

Figure 2-60 Scala SDK files

5. Click OK.

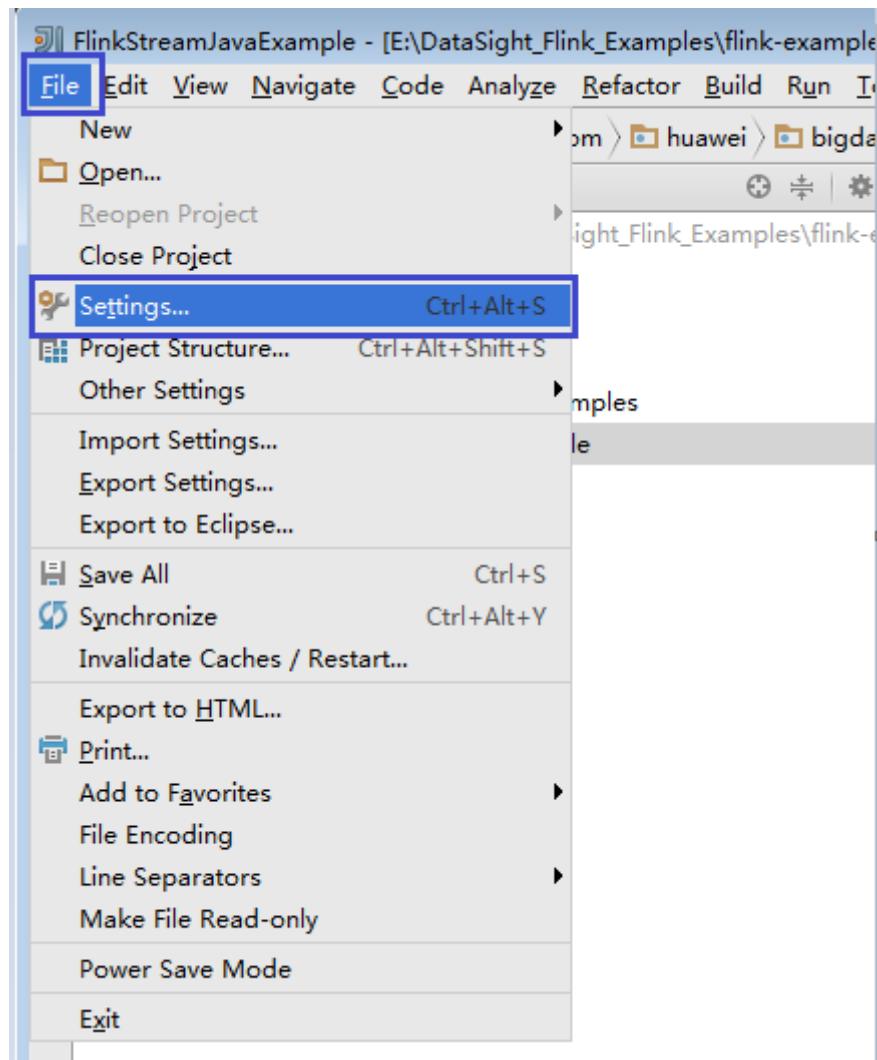

Figure 2-61 Configuration successful

**Step 7** Configure the text file encoding format of IDEA to prevent garbled characters.

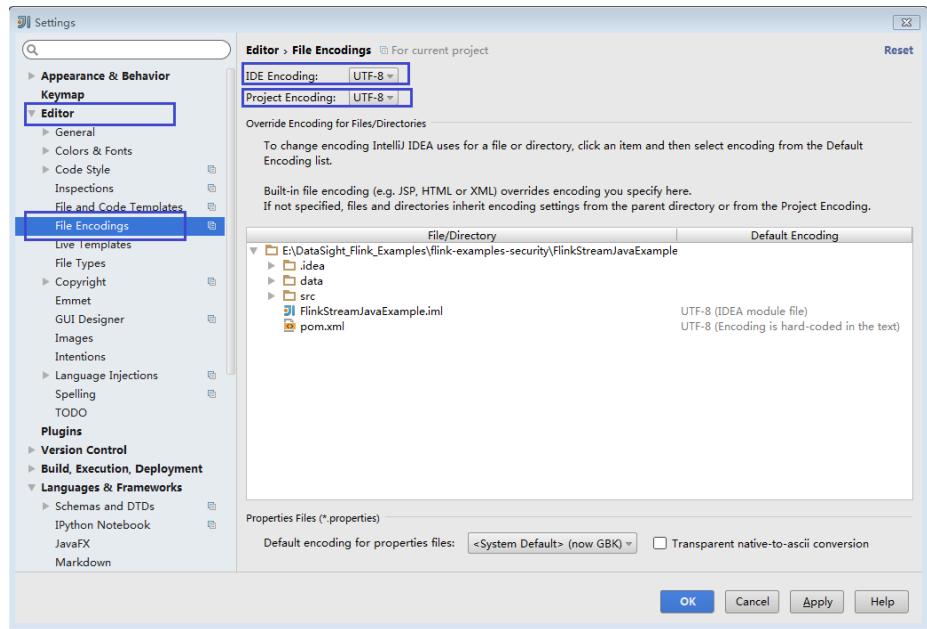

1. On the IDEA home page, choose **File > Settings....**

Figure 2-62 Choosing Settings

2. Configure encoding.
  - a. On the **Settings** page, unfold **Editor**, and choose **File Encodings**.
  - b. Select **UTF-8** from the **IDE Encoding** and **Project Encoding** drop-down lists on the right.
  - c. Click **Apply**.
  - d. Click **OK** to complete the encoding settings.

Figure 2-63 Settings

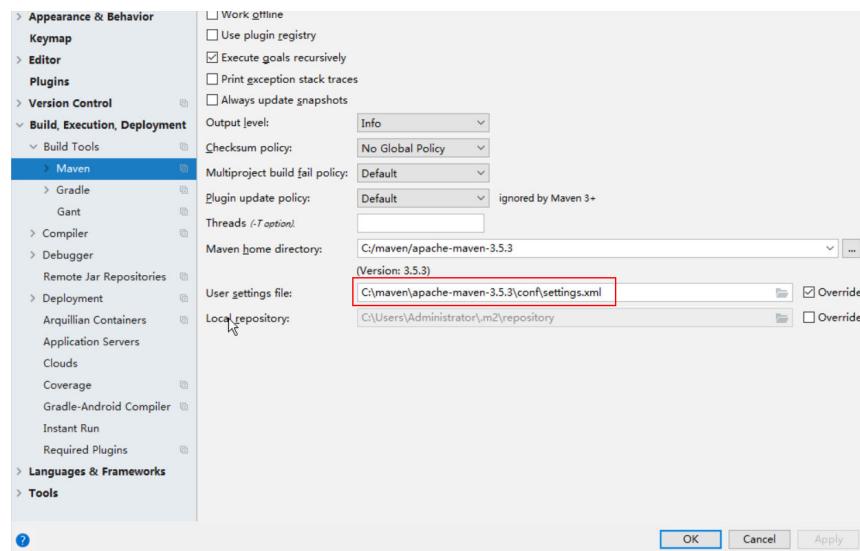

NOTE

- Obtain related dependency packages from the Flink server installation directory.
- Obtain Kafka dependency packages from the Kafka environment.
- Obtain Redis dependency packages from the Redis environment.
- For details about the dependency packages, see [Reference information about the dependency package for running the sample project](#).

**Step 8** Configure Maven.

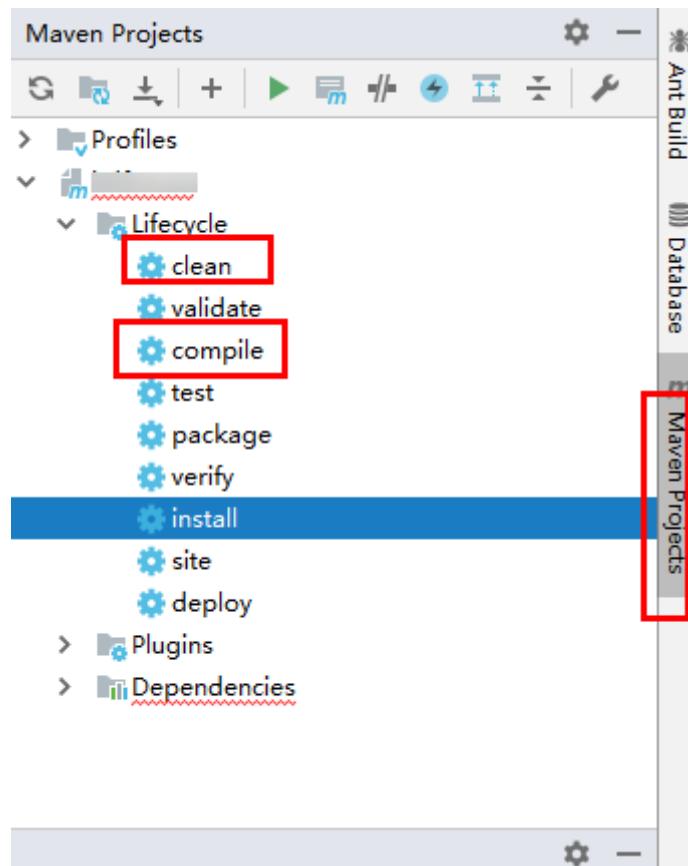

1. Add the configuration information such as the address of the open-source image repository to the `setting.xml` configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, select **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the `settings.xml` file is stored. Ensure that the directory is `<Local Maven installation directory>\conf\settings.xml`.

Figure 2-64 Directory for storing the settings.xml file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply**, and then click **OK**.
5. On the right of the IntelliJ IDEA home page, click **Maven Projects**. On the **Maven Projects** page, choose *Project name* > **Lifecycle** and run the **clean** and **compile** scripts.

Figure 2-65 Maven Projects page

----End

## Reference information about the dependency package for running the sample project

The **lib** and **opt** directories of the Flink client contain Flink JAR files. By default, the **lib** directory contains the Flink core JAR file, and the **opt** directory contains the JAR file (for example, **flink-connector-kafka\*.jar**) for connecting to external components. If it is required during application development, manually copy the related JAR files to the **lib** directory.

The dependency packages of the sample projects provided by Flink are as follows:

**Table 2-18** Dependency package for running the sample project

| Sample project   | Dependency package  | Obtaining Dependency Packages  |
|--|---|--|
| <ul style="list-style-type: none"><li>• Sample project of the DataStream application</li><li>• Sample project of the asynchronous checkpoint mechanism application</li></ul> | flink-dist_*.jar  | Can be obtained from <b>lib</b> in the installation directory of the Flink client or server.   |
| <ul style="list-style-type: none"><li>• Sample projects of Submitting SQL Jobs Using Flink Jar</li><li>• Sample projects of FlinkServer REST API</li></ul>                   | <ul style="list-style-type: none"><li>• flink-dist_*.jar</li><li>• flink-table_*.jar</li></ul>              | Can be obtained from <b>lib</b> in the installation directory of the Flink client or server.   |
| Sample projects of the application for producing and consuming data in Kafka   | <ul style="list-style-type: none"><li>• kafka-clients-*.jar</li><li>• flink-connector-kafka_*.jar</li></ul> | <ul style="list-style-type: none"><li>• <b>kafka-clients-*.jar</b> is provided by Kafka and can be obtained from the <b>lib</b> directory in the installation directory of the Kafka client or server.</li><li>• <b>flink-connector-kafka_*.jar</b> can be obtained from <b>opt</b> in the installation directory of the Flink client or server.</li></ul> |
| Sample projects of pipeline  | <ul style="list-style-type: none"><li>• flink-connector-netty_*.jar</li><li>• flink-dist_*.jar</li></ul>    | <ul style="list-style-type: none"><li>• <b>flink-connector-netty_*.jar</b> can be obtained from the <b>lib</b> folder generated after the secondary development sample code is compiled.</li><li>• <b>flink-dist_*.jar</b> can be obtained from <b>lib</b> in the installation directory of the Flink client or server.</li></ul>                          |

| Sample project   | Dependency package   | Obtaining Dependency Packages   |
|--|--|---|
| Sample projects of JOIN between configuration tables and streams | <ul style="list-style-type: none"> <li>commons-pool2-*jar</li> <li>flink-dist-*jar</li> <li>jredisclient-*jar</li> <li>super-csv-2.4.0.jar</li> <li>wcc_krb5-*jar</li> </ul> | <ul style="list-style-type: none"> <li><b>commons-pool2-*jar, jredisclient-*jar, and wcc_krb5-*jar</b> are provided by Redis and can be obtained from the <b>lib</b> directory in the installation directory of Redis server.</li> <li>flink-dist-*jar can be obtained from <b>lib</b> in the installation directory of the Flink client or server.</li> <li>You can obtain <b>super-csv-2.4.0.jar</b> from the <b>lib</b> directory of the configuration table sample code or download it from <a href="https://github.com/super-csv/super-csv/releases/download/v2.4.0/super-csv-distribution-2.4.0-bin.zip">https://github.com/super-csv/super-csv/releases/download/v2.4.0/super-csv-distribution-2.4.0-bin.zip</a>.</li> </ul> |
| Sample projects of Stream SQL JOIN                               | <ul style="list-style-type: none"> <li>kafka-clients-*jar</li> <li>flink-connector-kafka-*jar</li> <li>flink-dist-*jar</li> <li>flink-table-*jar</li> </ul>                  | <ul style="list-style-type: none"> <li><b>kafka-clients-*jar</b> is provided by Kafka and can be obtained from the <b>lib</b> directory in the installation directory of the Kafka client or server.</li> <li>flink-connector-kafka-*jar can be obtained from <b>opt</b> in the installation directory of the Flink client or server.</li> <li>flink-dist-*jar, flink-table-*jar can be obtained from <b>lib</b> in the installation directory of the Flink client or server.</li> </ul>  |
| Sample projects of HBase   | <ul style="list-style-type: none"> <li>flink-connector-hbase-*jar</li> <li>flink-dist-*jar</li> <li>flink-table-*jar</li> <li>hbase-clients-*jar</li> </ul>                  | <ul style="list-style-type: none"> <li>flink-connector-hbase-*jar can be obtained from <b>opt</b> in the installation directory of the Flink client or server.</li> <li>flink-dist-*jar, flink-table-*jar can be obtained from <b>lib</b> in the installation directory of the Flink client or server.</li> <li><b>hbase-clients-*jar</b> is provided by HBase and can be obtained from the <b>lib</b> directory in the installation directory of the HBase client or server.</li> </ul>  |
| Sample projects of Hudi  | hbase-unsafe-*jar  | Can be obtained from the <b>lib</b> folder generated after the secondary development sample code is compiled.   |

### 2.4.2.3 Creating a Project (Optional)

#### Scenarios

IntelliJ IDEA can be used to create a Flink project. A Scala project is used as an example to illustrate how to create a Flink project.

## Procedure

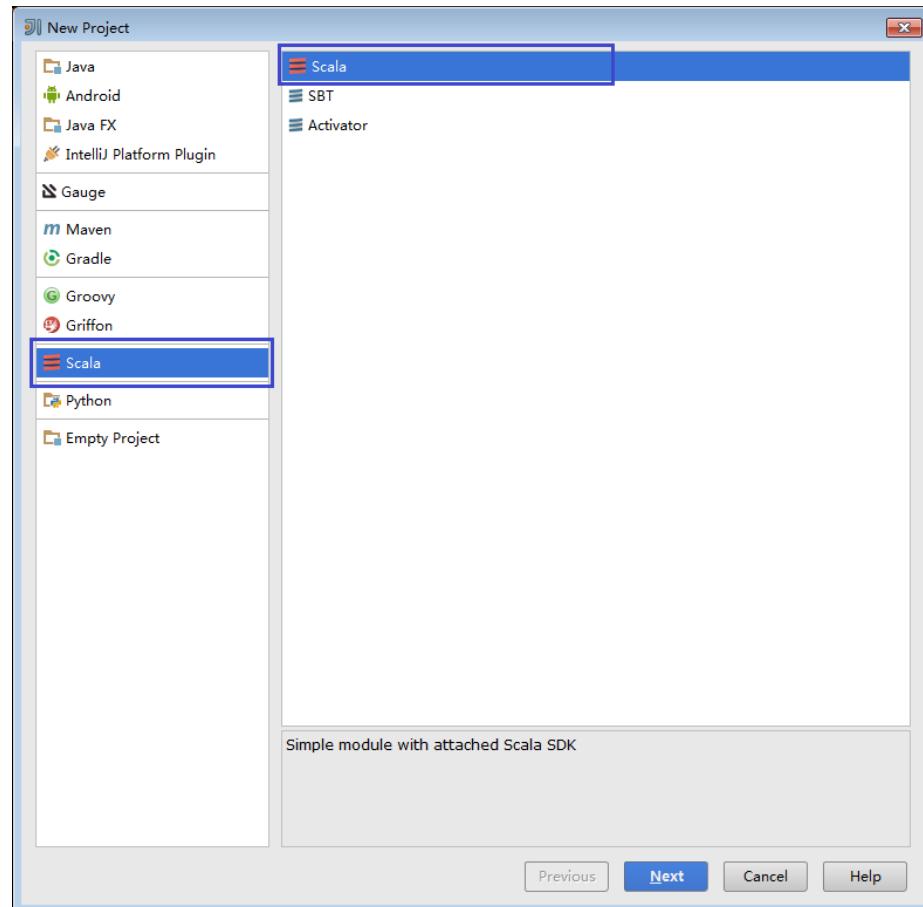

**Step 1** Start the IDEA and choose **Create New Project**.

**Figure 2-66** Creating a project

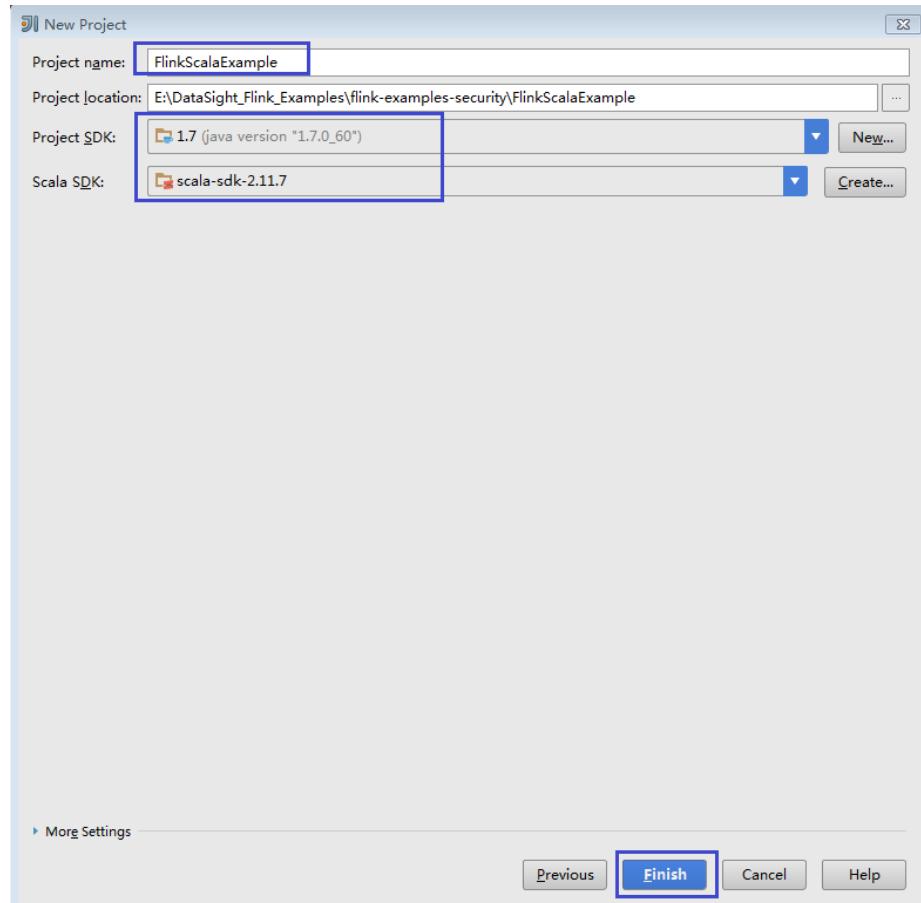

**Step 2** On the **New Project** page, choose a Scala development environment, choose **Scala Module**, and then click **Next**. If you want to create a Java project, choose corresponding parameters of Java.

Figure 2-67 Selecting a development environment

**Step 3** On the New Project page, enter the project name and project location, select the JDK version and Scala SDK, and then click **Finish**.

Figure 2-68 Filling in project information

----End

#### 2.4.2.4 Configuring a Spring Boot Sample Project

##### Scenarios

Run the sample code of the Spring Boot interface in FusionInsight MRS Hive. Currently, GaussDB(DWS) and Elasticsearch SpringBoot sample projects are supported.

In the following example, an application is developed in Linux to connect GaussDB(DWS) to Flink using Spring Boot.

##### NOTE

Before running the GaussDB(DWS) sample, log in to the node where GaussDB(DWS) is deployed to create an empty table **test\_lzh1** for receiving data. The creation command is as follows:

```
create table test_lzh1 (id integer not null);
```

##### Procedure

**Step 1** Install a client that contains only the Flink service.

The following example shows how to install the Flink client on a node in the cluster:

1. Log in to FusionInsight Manager. Choose **Cluster > Services > Flink > More > Download Client**.
2. In the dialog box that is displayed, select **Complete Client** for **Select Client Type**, select the platform type that matches the architecture of the node where the client is to install, Select **Server** from the **Select Download Location**, and click **OK**.

The generated file is stored in the **/tmp/FusionInsight-Client** directory on the active management node by default.

The name of the client software package is in the following format:  
**FusionInsight\_Cluster\_<Cluster ID>\_Flink\_Client.tar**. The following content uses the cluster ID **1** as an example.

3. Log in to the server where the client is to be installed as the client installation user.
4. Go to the directory where the installation package is stored and run the following commands to decompress the package:

```
cd /tmp/FusionInsight-Client
```

```
tar -xvf FusionInsight_Cluster_1_Flink_Client.tar
```

5. Run the following command to verify the decompressed file and check whether the command output is consistent with the information in the **sha256** file:

```
sha256sum -c FusionInsight_Cluster_1_Flink_ClientConfig.tar.sha256
```

6. Decompress the obtained installation file.

```
tar -xvf FusionInsight_Cluster_1_Flink_ClientConfig.tar
```

7. Go to the directory where the installation package is stored, and run the following command to install the client to a specified directory (absolute path), for example, **/opt/hadoopclient**:

```
cd /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Flink_ClientConfig  
.install.sh /opt/hadoopclient
```

8. Configure security authentication and encryption. For details, see "Using Flink from Scratch" in the *Component Operation Guide*.

**Step 2** Obtain the sample project folder **flink-dws-sink-example** from **src\springboot\flink-examples** in the directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

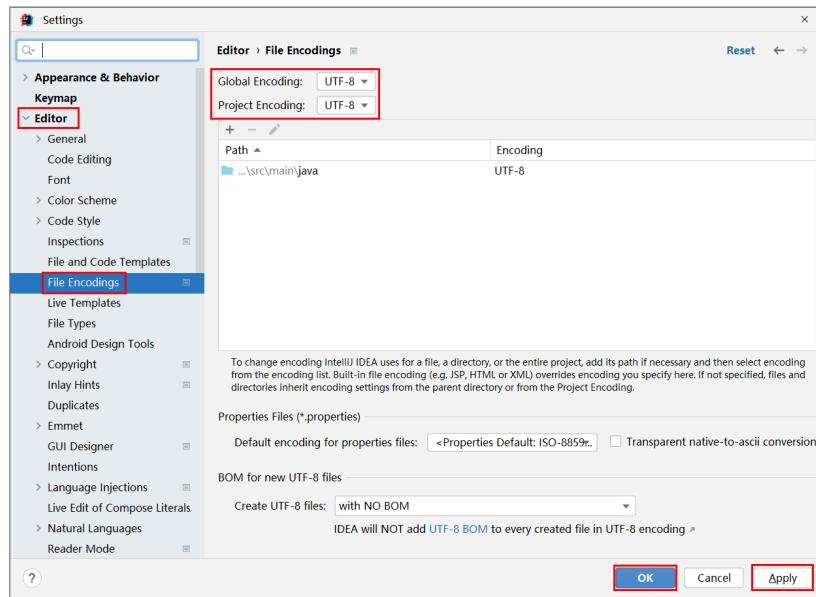

**Step 3** Import the sample project to the IntelliJ IDEA development environment.

1. On the menu bar of IntelliJ IDEA, choose **File > Open....**
2. In the **Open File or Project** dialog box that is displayed, select the **flink-dws-sink-example** folder and click **OK**.

**Step 4** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

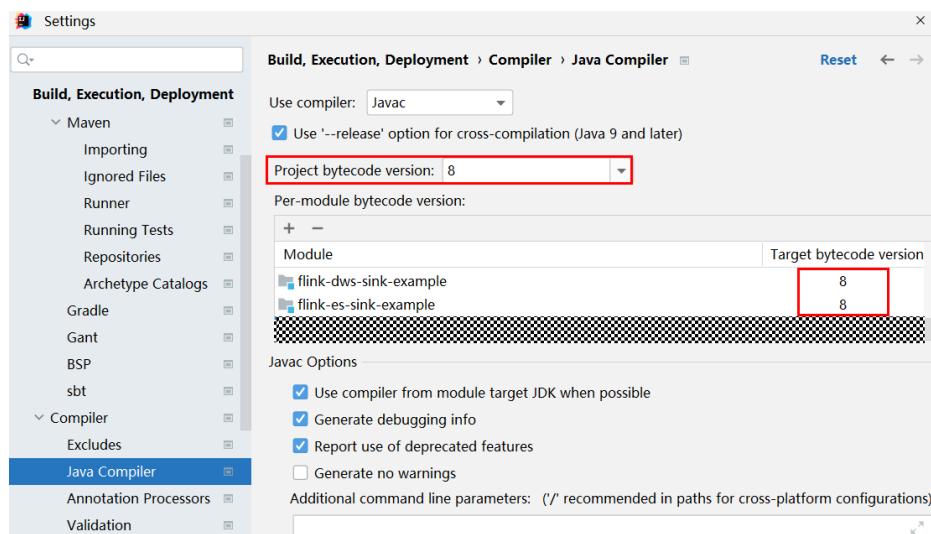

1. On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
2. In the left navigation pane, choose **Editor > File Encodings**. In the **Project Encoding** and **Global Encoding** areas, set the parameter to **UTF-8**. Click **Apply** and **OK**.

**Figure 2-69** Setting the IntelliJ IDEA coding format

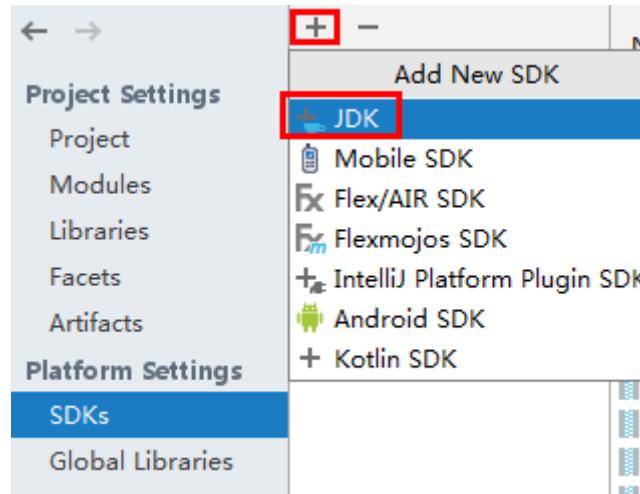

### Step 5 Set the JDK of the project.

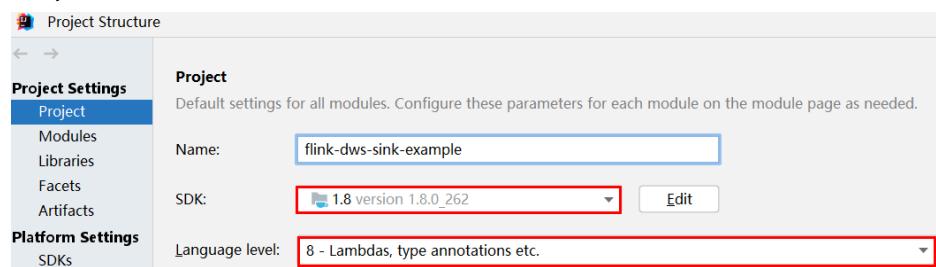

1. On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler** and select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** in **flink-dws-sink-example** to **8**.

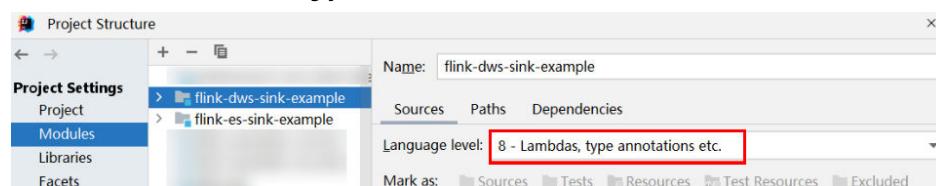

3. Click **Apply** then **OK**.
4. On the menu bar of IntelliJ IDEA, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Choose **SDKs**, click the plus sign (+), and select **JDK**.

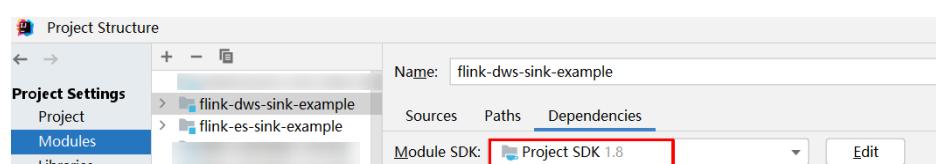

6. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.
7. Click **Apply**.
8. Select **Project**, select the JDK added in **SDKs** from the **SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Sources** tab page, change the value of **Language level** to **8 - Lambdas, type annotations etc..**

On the **Dependencies** tab page, change the value of **Module SDK** to the JDK added in **SDKs**.

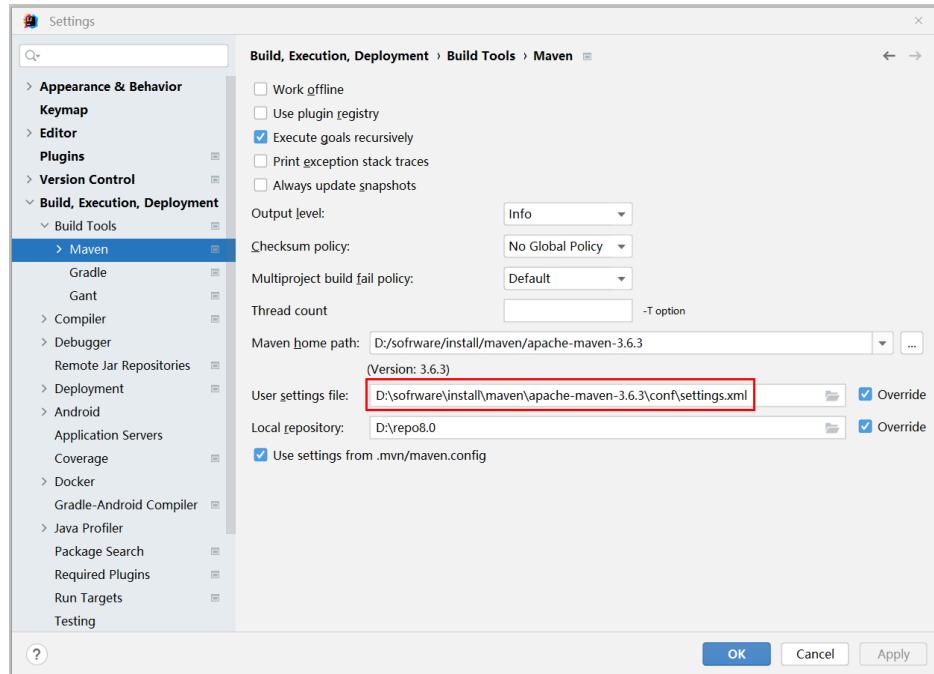

11. Click **Apply** and then **OK**.

#### Step 6 Configure Maven.

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).

2. On the IntelliJ IDEA page, choose **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is **<Local Maven installation directory>\conf\settings.xml**.

**Figure 2-70** Directory for storing the settings.xml file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply** and then **OK**.

**Step 7** Find the **application.properties** file in **src\main\resources** and add the following content to the file:

- Run the GaussDB(DWS) sample

```
spring.datasource.dws.url=jdbc:postgresql://IP address of the GaussDB(DWS) node:8000/postgres
spring.datasource.dws.username=dbadmin
spring.datasource.dws.password=Password of dbadmin
spring.datasource.dws.driver=org.postgresql.Driver
```
- Run the Elasticsearch sample

```
spring.datasource.es.host=Service IP address of Elasticsearch EsNode
spring.datasource.es.port=Elasticsearch EsNode Port
spring.datasource.es.scheme=http
```

#### NOTE

- log in to FusionInsight Manager and choose **Cluster > Services > Elasticsearch**. On the page that is displayed, click **Instance** and view the service IP addresses of all EsNode instances in the Elasticsearch cluster.
- Log in to FusionInsight Manager, choose **Cluster > Services > Elasticsearch > Configuration > All Configurations**, search for **SERVER\_PORT**, and view the EsNode port.

----End

## 2.4.3 Developing an Application

### 2.4.3.1 DataStream Application

#### 2.4.3.1.1 Scenarios

##### Scenarios

Develop a DataStream application of Flink to perform the following operations on logs about dwell durations of netizens for shopping online.

The DataStream application can run in both the Windows environment and the Linux environment.

- Collect statistics on female netizens who dwell on online shopping for more than 2 hours in total in a real time manner.
- The first column in the log file records names, the second column records genders, and the third column records the dwell duration in the unit of minute. Three attributes are separated by commas (,).

log1.txt: logs collected on Saturday. The log file can be obtained from the **data** directory of the sample project.

```
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,5
CaiXuyu,female,50
Liyuan,male,20
FangBo,female,50
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,50
CaiXuyu,female,50
FangBo,female,60
```

log2.txt: logs collected on Sunday. The log file can be obtained from the **data** directory of the sample project.

```
LiuYang,female,20
YuanJing,male,10
CaiXuyu,female,50
FangBo,female,50
GuoYijun,male,5
CaiXuyu,female,50
Liyuan,male,20
CaiXuyu,female,50
FangBo,female,50
LiuYang,female,20
YuanJing,male,10
FangBo,female,50
GuoYijun,male,50
CaiXuyu,female,50
FangBo,female,60
```

##### Data Planning

Data of DataStream sample project is stored in a **.txt** file.

Place the **log1.txt** and **log2.txt** in two directories, for example, **/opt/log1.txt** and **/opt/log2.txt**.

### NOTE

- If the data file is stored in the local file system, the data file must be stored in the specified directory on all nodes where Yarn NodeManager is deployed, and the running user access permission must be set.
- Alternatively, store the data file on HDFS and set the file read path in the program to the HDFS path, for example, `hdfs://hacluster/path/to/file`.

## Development Approach

Collect the information about female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

The process includes:

1. Read text data, generate DataStreams, and parse data to generate UserRecord information.
2. Filter the data about the time that female netizens spend online.
3. Perform keyby operation based on the name and gender, and collect the time that female netizens spend online within a time window.
4. Filter data about users whose consecutive online duration exceeds the threshold, and obtain the result.

### 2.4.3.1.2 Java Sample Code

## Function Description

Collect the information about female netizens who continuously spend more than 2 hour in online shopping and print the result.

## DataStream FlinkStreamJavaExample Sample Code

The following code segment is an example. For details, see `com.huawei.bigdata.flink.examples.FlinkStreamJavaExample`.

```
//Parameter description:  
//<filePath> indicates paths where text is read. Paths are separated by commas (,).  
//<windowTime> indicates the period covered by statistics window. The unit is minute.  
public class FlinkStreamJavaExample {  
    public static void main(String[] args) throws Exception {  
        //Print reference command for executing flink run.  
        System.out.println("use command as: ");  
        System.out.println("./bin/flink run --class  
com.huawei.bigdata.flink.examples.FlinkStreamJavaExample /opt/test.jar --filePath /opt/log1.txt,/opt/  
log2.txt --windowTime 2");  
        System.out.println("*****");  
        System.out.println("<filePath> is for text file to read data, use comma to separate");  
        System.out.println("<windowTime> is the width of the window, time as minutes");  
        System.out.println("*****");  
  
        //Paths where text is read. Paths are separated by commas (,)  
        final String[] filePaths = ParameterTool.fromArgs(args).get("filePath", "/opt/log1.txt,/opt/  
log2.txt").split(",");  
        assert filePaths.length > 0;  
  
        //windowTime specifies the size of the time window. By default, a window with 2 minutes as the size  
        can read all data in a text file.  
        final int windowTime = ParameterTool.fromArgs(args).getInt("windowTime", 2);  
    }  
}
```

```
//Build the execution environment and run eventTime to process window data.  
final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();  
env.setStreamTimeCharacteristic(TimeCharacteristic.EventTime);  
env.setParallelism(1);  
  
//Read DataStream of the text.  
DataStream<String> unionStream = env.readTextFile(filePaths[0]);  
if (filePaths.length > 1) {  
    for (int i = 1; i < filePaths.length; i++) {  
        unionStream = unionStream.union(env.readTextFile(filePaths[i]));  
    }  
}  
  
//Convert data, build the logic for the entire data process, calculate, and print results.  
unionStream.map(new MapFunction<String, UserRecord>() {  
    @Override  
    public UserRecord map(String value) throws Exception {  
        return getRecord(value);  
    }  
}).assignTimestampsAndWatermarks(  
    new Record2TimestampExtractor()  
).filter(new FilterFunction<UserRecord>() {  
    @Override  
    public boolean filter(UserRecord value) throws Exception {  
        return value.sex.equals("female");  
    }  
}).keyBy(  
    new UserRecordSelector()  
).window(  
    TumblingEventTimeWindows.of(Time.minutes(windowTime))  
).reduce(new ReduceFunction<UserRecord>() {  
    @Override  
    public UserRecord reduce(UserRecord value1, UserRecord value2)  
        throws Exception {  
        value1.shoppingTime += value2.shoppingTime;  
        return value1;  
    }  
}).filter(new FilterFunction<UserRecord>() {  
    @Override  
    public boolean filter(UserRecord value) throws Exception {  
        return value.shoppingTime > 120;  
    }  
}).print();  
  
//Call execute to trigger the execution.  
env.execute("FemaleInfoCollectionPrint java");  
}  
  
//Build the keyword of keyBy as the grouping basis.  
private static class UserRecordSelector implements KeySelector<UserRecord, Tuple2<String, String>> {  
    @Override  
    public Tuple2<String, String> getKey(UserRecord value) throws Exception {  
        return Tuple2.of(value.name, value.sex);  
    }  
}  
  
//Parse the row data of the text and build UserRecord data structure.  
private static UserRecord getRecord(String line) {  
    String[] elems = line.split(",");  
    assert elems.length == 3;  
    return new UserRecord(elems[0], elems[1], Integer.parseInt(elems[2]));  
}  
  
//Defines UserRecord data structure and rewrite toString printing method.  
public static class UserRecord {  
    private String name;  
    private String sex;  
    private int shoppingTime;
```

```

public UserRecord(String n, String s, int t) {
    name = n;
    sexy = s;
    shoppingTime = t;
}

public String toString() {
    return "name: " + name + " sexy: " + sexy + " shoppingTime: " + shoppingTime;
}

//Build class that inherits AssignerWithPunctuatedWatermarks to configure eventTime and watermark.
private static class Record2TimestampExtractor implements
AssignerWithPunctuatedWatermarks<UserRecord> {

    //add tag in the data of datastream elements
    @Override
    public long extractTimestamp(UserRecord element, long previousTimestamp) {
        return System.currentTimeMillis();
    }

    //give the watermark to trigger the window to execute, and use the value to check if the window
    elements are ready
    @Override
    public Watermark checkAndGetNextWatermark(UserRecord element, long extractedTimestamp) {
        return new Watermark(extractedTimestamp - 1);
    }
}
}

```

The following is the command output:

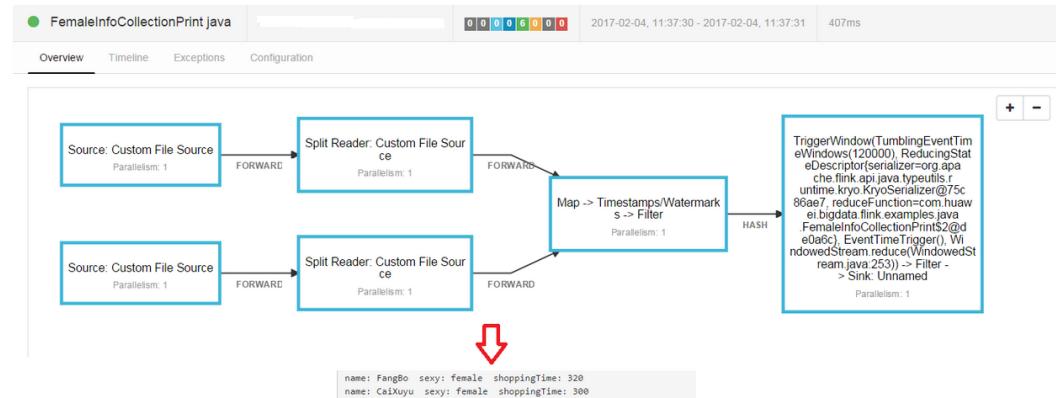

```

name: FangBo sexy: female shoppingTime: 320
name: CaiXuyu sexy: female shoppingTime: 300

```

**Figure 2-71** shows the process of execution.

**Figure 2-71** Process of execution

### 2.4.3.1.3 Scala Sample Code

#### Function Description

Collect the information about female netizens who continuously spend more than 2 hour in online shopping and print the result.

## DataStream FlinkStreamScalaExample Sample Code

The following code is an example. For details, see  
[com.huawei.bigdata.flink.examples.FlinkStreamScalaExample](#).

```
//Parameter description
//filePath indicates paths where text is read. Paths are separated by commas (,).
//windowTime indicates the period covered by statistics window. The unit is minute.
object FlinkStreamScalaExample {
def main(args: Array[String]) {
    //Print the reference command used to execute flink run.
    System.out.println("use command as:")
    System.out.println("./bin/flink run --class")
    com.huawei.bigdata.flink.examples.FlinkStreamScalaExample /opt/test.jar --filePath /opt/log1.txt,/opt/
log2.txt --windowTime 2")
    System.out.println("*****")
    System.out.println("<filePath> is for text file to read data, use comma to separate")
    System.out.println("<windowTime> is the width of the window, time as minutes")
    System.out.println("*****")

    //Paths where text is read. Paths are separated by commas (,)
    val filePaths = ParameterTool.fromArgs(args).get("filePath",
        "/opt/log1.txt,/opt/log2.txt").split(",").map(_.trim)
    assert(filePaths.length > 0)

    //windowTime specifies the size of the time window. By default, a window with 2 minutes as the size can
    read all data in a text file.
    val windowTime = ParameterTool.fromArgs(args).getInt("windowTime", 2)

    //Build the execution environment and run eventTime to process window data.
    val env = StreamExecutionEnvironment.getExecutionEnvironment
    env.setStreamTimeCharacteristic(TimeCharacteristic.EventTime)
    env.setParallelism(1)
    //Read DataStream of the text.
    val unionStream = if (filePaths.length > 1) {
        val firstStream = env.readTextFile(filePaths.apply(0))
        firstStream.union(filePaths.drop(1).map(it => env.readTextFile(it)): _*)
    } else {
        env.readTextFile(filePaths.apply(0))
    }

    //Convert data, build the logic for the entire data process, calculate, and print results.
    unionStream.map(getRecord(_))
        .assignTimestampsAndWatermarks(new Record2TimestampExtractor)
        .filter(_.sexy == "female")
        .keyBy("name", "sexy")
        .window(TumblingEventTimeWindows.of(Time.minutes(windowTime)))
        .reduce((e1, e2) => UserRecord(e1.name, e1.sex, e1.shoppingTime + e2.shoppingTime))
        .filter(_shoppingTime > 120).print()

    //Call execute to trigger the execution
    env.execute("FemaleInfoCollectionPrint scala")
}

//Parse the row data of the text and build UserRecord data structure.
def getRecord(line: String): UserRecord = {
    val elems = line.split(",")
    assert(elems.length == 3)
    val name = elems(0)
    val sexy = elems(1)
    val time = elems(2).toInt
    UserRecord(name, sexy, time)
}

//Defines UserRecord data structure.
case class UserRecord(name: String, sexy: String, shoppingTime: Int)

//Build class that inherits AssignerWithPunctuatedWatermarks to configure eventTime and waterMark.
```

```
private class Record2TimestampExtractor extends AssignerWithPunctuatedWatermarks[UserRecord] {

    //add tag in the data of datastream elements
    override def extractTimestamp(element: UserRecord, previousTimestamp: Long): Long = {
        System.currentTimeMillis()
    }

    //give the watermark to trigger the window to execute, and use the value to check if the window
    //elements are ready
    def checkAndGetNextWatermark(lastElement: UserRecord,
                                  extractedTimestamp: Long): Watermark = {
        new Watermark(extractedTimestamp - 1)
    }
}
```

The following is the command output:

```
UserRecord(FangBo,female,320)
UserRecord(CaiXuyu,female,300)
```

[Figure 2-72](#) shows the process of execution.

**Figure 2-72** Process of execution

### 2.4.3.2 Interconnecting with Kafka

#### 2.4.3.2.1 Scenarios

##### Scenarios

Assume that a Flink service receives one word record every 1 second.

Develop a Flink application that can generate output of prefixed message contents.

##### Data Planning

Sample project data of Flink is stored in Kafka. A user with Kafka permission can send data to Kafka and receive data from it.

1. Ensure that clusters, including HDFS, YARN, Flink, and Kafka are successfully installed.

## 2. Create a topic.

The format of the command is following:

```
bin/kafka-topics.sh --create --bootstrap-server <Kafka cluster IP address:21005> --command-config config/client.properties --partitions {partitionNum} --replication-factor {replicationNum} --topic {Topic}
```

**Table 2-19**

| parameter                  | Description   |
|----------------------------|---|
| {Kafka cluster IP address} | Service IP address of the Broker node in the Kafka cluster. |
| {PartitionNum}             | The number of partitions for the topic.                     |
| {ReplicationNum}           | The number of copies of each partition for the topic.       |
| {Topic}                    | The topic name.   |

For example, run the following command on the Kafka client, and the topic name is **topic1**.

```
bin/kafka-topics.sh --create --bootstrap-server  
10.96.101.32:21005,10.96.101.251:21005,10.96.101.177:21005 --partitions 5 --replication-factor 1 --topic topic1
```

## Development Approach

1. Start the Flink Kafka Producer to send data to Kafka.
2. Start Flink Kafka Consumer to receive data from Kafka. Ensure that topics of Kafka Consumer are consistent with that of Kafka Producer.
3. Add prefix to the data content and print the result.

### 2.4.3.2.2 Java Sample Code

#### Function Description

In a Flink application, call API of the **flink-connector-kafka** module to produce and consume data.

#### Sample Code

Following is the main logic code of Kafka Consumer and Kafka Producer.

For the complete code, see `com.huawei.bigdata.flink.examples.WriteIntoKafka` and `com.huawei.bigdata.flink.examples.ReadFromKafka`.

```
//producer code  
public class WriteIntoKafka {  
    public static void main(String[] args) throws Exception {  
        //Print the reference command of flink run.  
        System.out.println("use command as: ");  
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +
```

```
" /opt/test.jar --topic topic-test --bootstrap.servers 10.91.8.218:21005");
System.out.println("*****");
System.out.println("<topic> is the kafka topic name");
System.out.println("<bootstrap.servers> is the ip:port list of brokers");
System.out.println("*****");

//Build the execution environment.
StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
//Configure the parallelism.
env.setParallelism(1);
//Parse the execution parameter.
ParameterTool paraTool = ParameterTool.fromArgs(args);
//Build the StreamGraph and write data generated by customized source into Kafka.
DataStream<String> messageStream = env.addSource(new SimpleStringGenerator());
messageStream.addSink(new FlinkKafkaProducer<>(paraTool.get("topic"),
    new SimpleStringSchema(),
    paraTool.getProperties()));
//Call execute to trigger the execution.
env.execute();
}

//Customize source to continuously generate messages every one second.
public static class SimpleStringGenerator implements SourceFunction<String> {
    private static final long serialVersionUID = 2174904787118597072L;
    boolean running = true;
    long i = 0;

    @Override
    public void run(SourceContext<String> ctx) throws Exception {
        while (running) {
            ctx.collect("element-" + (i++));
            Thread.sleep(1000);
        }
    }

    @Override
    public void cancel() {
        running = false;
    }
}

//consumer code
public class ReadFromKafka {
    public static void main(String[] args) throws Exception {
        //Print the reference command of flink run.
        System.out.println("use command as: ");
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21005");
        System.out.println("*****");
        System.out.println("<topic> is the kafka topic name");
        System.out.println("<bootstrap.servers> is the ip:port list of brokers");
        System.out.println("*****");

        //Build the execution environment.
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        //Configure the parallelism.
        env.setParallelism(1);
        //Parse the execution parameter.
        ParameterTool paraTool = ParameterTool.fromArgs(args);
        //Build the StreamGraph, read data from Kafka and print the result in another row.
        DataStream<String> messageStream = env.addSource(new FlinkKafkaConsumer<>(paraTool.get("topic"),
            new SimpleStringSchema(),
            paraTool.getProperties()));
        messageStream.rebalance().map(new MapFunction<String, String>() {
            @Override
            public String map(String s) throws Exception {
                return "Flink says " + s + System.getProperty("line.separator");
            }
        });
    }
}
```

```
}).print();
//Call execute to trigger the execution.
env.execute();
}
```

### 2.4.3.2.3 Scala Sample Code

#### Function Description

In a Flink application, call API of the **flink-connector-kafka** module to produce and consume data.

#### Sample Code

Following is the main logic code of Kafka Consumer and Kafka Producer.

For the complete code, see `com.huawei.bigdata.flink.examples.WriteIntoKafka` and `com.huawei.bigdata.flink.examples.ReadFromKafka`.

```
//Code of producer
object WriteIntoKafka {
  def main(args: Array[String]) {
    //Print the reference command of flink run.
    System.out.println("use command as:")
    System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +
      " /opt/test.jar --topic topic-test --bootstrap.servers 10.91.8.218:21005")
    System.out.println("*****")
    System.out.println("<topic> is the kafka topic name")
    System.out.println("<bootstrap.servers> is the ip:port list of brokers")
    System.out.println("*****")

    //Build the execution environment.
    val env = StreamExecutionEnvironment.getExecutionEnvironment
    //Configure the parallelism.
    env.setParallelism(1)
    //Parse the execution parameter.
    val paraTool = ParameterTool.fromArgs(args)
    //Build the StreamGraph and write data generated by customized source into Kafka.
    val messageStream: DataStream[String] = env.addSource(new SimpleStringGenerator)
    messageStream.addSink(new FlinkKafkaProducer(
      paraTool.get("topic"), new SimpleStringSchema, paraTool.getProperties()))
    //Call execute to trigger the execution.
    env.execute
  }
}

//Customize source to continuously generate messages every one second.
class SimpleStringGenerator extends SourceFunction[String] {
  var running = true
  var i = 0

  override def run(ctx: SourceContext[String]) {
    while (running) {
      ctx.collect("element-" + i)
      i += 1
      Thread.sleep(1000)
    }
  }

  override def cancel() {
    running = false
  }
}

//consumer code
```

```
object ReadFromKafka {
    def main(args: Array[String]) {
        //Print the reference command of flink run.
        System.out.println("use command as:")
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21005")
        System.out.println("*****")
        System.out.println("<topic> is the kafka topic name")
        System.out.println("<bootstrap.servers> is the ip:port list of brokers")
        System.out.println("*****")

        //Build the execution environment
        val env = StreamExecutionEnvironment.getExecutionEnvironment
        //Configure the parallelism.
        env.setParallelism(1)
        //Parse the execution parameter.
        val paraTool = ParameterTool.fromArgs(args)
        //Build the StreamGraph, read data from Kafka and print the result in another row.
        val messageStream = env.addSource(new FlinkKafkaConsumer(
            paraTool.get("topic"), new SimpleStringSchema, paraTool.getProperties))
        messageStream
            .map(s => "Flink says " + s + System.getProperty("line.separator")).print()
        //Call execute to trigger the execution
        env.execute()
    }
}
```

### 2.4.3.3 Asynchronous Checkpoint Mechanism

#### 2.4.3.3.1 Scenarios

##### Scenarios

Assume that you want to collect data volume in the window covering preceding 4 seconds at the interval of one second, and achieve strict consistency of status. In this case, when the application is recovered from failure, all operator statuses are the same.

##### Data Planning

1. Customized operators generate about 10000 pieces of data per second.
2. Generated data is of four tuples (Long, String, String, Integer).
3. Statistic results are printed on the devices.
4. Printed data is of the long type.

##### Development Approach

1. The source operator sends 10000 pieces of data and injects the data to the window operator every second.
2. The window operator calculates the data volume of preceding 4 seconds at the interval of one second.
3. The statistics is printed to the device at the interval of one second. Please refer to the specific [Viewing the Debugging Result](#)
4. The checkpoint is triggered at the interval of 6 seconds and the checkpoint result is stored in HDFS.

### 2.4.3.3.2 Java Sample Code

#### Function Description

Assume that you want to collect data volume in the window covering preceding 4 seconds at the interval of one second, and achieve strict consistency of status.

#### Sample Code

##### 1. Snapshot data

The snapshot data is used to store number of data pieces recorded by operators during creation of snapshots.

```
import java.io.Serializable;

//The class is a part of the snapshot and is used to store user-defined statuses.
public class UDFState implements Serializable {
    private long count;

    //Initialize user-defined statuses.
    public UDFState() {
        count = 0L;
    }

    //Configure self-defined statuses.
    public void setState(long count) {
        this.count = count;
    }

    //Obtain user-defined statuses.
    public long getState() {
        return this.count;
    }
}
```

##### 2. Data source with checkpoints

Code of the source operator. The code can be used to send 10000 pieces after each pause of one second. When a snapshot is created, number of sent data pieces is recorded in UDFState. When the snapshot is used for restoration, the number of sent data pieces recorded in UDFState is read and assigned to the count variable.

```
import org.apache.flink.api.java.tuple.Tuple4;
import org.apache.flink.streaming.api.checkpoint.ListCheckpointed;
import org.apache.flink.streaming.api.functions.source.RichSourceFunction;

import java.util.ArrayList;
import java.util.List;
import java.util.Random;

//The class is the source operator with checkpoint.
public class SEventSourceWithChk extends RichSourceFunction<Tuple4<Long, String, String, Integer>>
implements ListCheckpointed<UDFState> {
    private Long count = 0L;
    private boolean isRunning = true;
    private String alphabet =
"abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789abcdefghijklmnpqrstuvwxyz
wxyzABCDEFGHIJKLMNPQRSTUVWXYZ0987654321";

    //The main logic of the operator is to inject 10000 tuples to the StreamGraph.
    public void run(SourceContext<Tuple4<Long, String, String, Integer>> ctx) throws Exception {
        Random random = new Random();
        while(isRunning) {
            for (int i = 0; i < 10000; i++) {
                ctx.collect(Tuple4.of(random.nextLong(), "hello-" + count, alphabet, 1))
            }
        }
    }
}
```

```
        count++;
    }
    Thread.sleep(1000);
}
}

//Call this when the task is canceled.
public void cancel() {
    isRunning = false;
}

//Customize a snapshot.
public List<UDFState> snapshotState(long l, long ll) throws Exception {
    UDFState udfState = new UDFState();
    List<UDFState> listState = new ArrayList<UDFState>();
    udfState.setState(count);
    listState.add(udfState);
    return listState;
}

//Restore data from customized snapshots.
public void restoreState(List<UDFState> list) throws Exception {
    UDFState udfState = list.get(0);
    count = udfState.getState();
}
}
```

### 3. Definition of window with checkpoint.

This code is about the window operator and is used to calculate number or tuples in the window.

```
import org.apache.flink.api.java.tuple.Tuple;
import org.apache.flink.api.java.tuple.Tuple4;
import org.apache.flink.streaming.api.checkpoint.ListCheckpointed;
import org.apache.flink.streaming.api.functions.windowing.WindowFunction;
import org.apache.flink.streaming.api.windowing.windows.TimeWindow;
import org.apache.flink.util.Collector;

import java.util.ArrayList;
import java.util.List;

//The class is the window operator with checkpoint.
public class WindowStatisticWithChk implements WindowFunction<Tuple4<Long, String, String, Integer>, Long, Tuple, TimeWindow>, ListCheckpointed<UDFState> {
    private Long total = 0L;

    //The implementation logic of the window operator, which is used to calculate the number of tuples in a window.
    void apply(Tuple key, TimeWindow window, Iterable<Tuple4<Long, String, String, Integer>> input,
               Collector<Long> out) throws Exception {
        long count = 0L;
        for (Tuple4<Long, String, String, Integer> event : input) {
            count++;
        }
        total += count;
        out.collect(count);
    }

    //Customize snapshot.
    public List<UDFState> snapshotState(Long l, Long ll) {
        List<UDFState> listState = new ArrayList<UDFState>();
        UDFState udfState = new UDFState();
        udfState.setState(total);
        listState.add(udfState);
        return listState;
    }

    //Restore data from customized snapshots.
    public void restoreState(List<UDFState> list) throws Exception {
        UDFState udfState = list.get(0);
    }
}
```

```
        total = udfState.getState();
    }
}
```

#### 4. Application code

The code is about the definition of StreamGraph and is used to implement services. The processing time is used as the timestamp for triggering the window.

```
import org.apache.flink.runtime.state.filesystem.FsStateBackend;
import org.apache.flink.streaming.api.CheckpointingMode;
import org.apache.flink.streaming.api.environment.StreamExecutionEnvironment;
import org.apache.flink.streaming.api.windowing.assigners.SlidingProcessingTimeWindows;
import org.apache.flink.streaming.api.windowing.time.Time;

public class FlinkProcessingTimeAPIChkMain {
    public static void main(String[] args) throws Exception{
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();

        //Set configurations and enable checkpoint.
        env.setStateBackend(new FsStateBackend("hdfs://hacluster/flink/checkpoint/"));
        env.getCheckpointConfig.setCheckpointingMode(CheckpointingMode.EXACTLY_ONCE);
        env.getCheckpointConfig.setCheckpointInterval(6000);

        //Application logic.
        env.addSource(new SEventSourceWithChk()
            .keyBy(0)
            .window(SlidingProcessingTimeWindows.of(Time.seconds(4), Time.seconds(1)))
            .apply(new WindowStatisticWithChk())
            .print()

        env.execute();
    }
}
```

### 2.4.3.3.3 Scala Sample Code

#### Function Description

Assume that you want to collect data volume in the window covering preceding 4 seconds at the interval of one second, and achieve strict consistency of status.

#### Sample Code

##### 1. Formats of sent data.

```
case class SEvent(id: Long, name: String, info: String, count: Int)
```

##### 2. Snapshot data

The snapshot data is used to store number of data pieces recorded by operators during creation of snapshots.

```
//User-defined statuses.

class UDFState extends Serializable{
    private var count = 0L

    //Configure user-defined statuses.
    def setState(s: Long) = count = s

    //Obtain user-defined statuses.
    def getState = count
}
```

##### 3. Data source with checkpoints

Code of the source operator. The code can be used to send 10000 pieces after each pause of one second. When a snapshot is created, number of sent data pieces is recorded in UDFState. When the snapshot is used for restoration, the number of sent data pieces recorded in UDFState is read and assigned to the *count* variable.

```

import java.util
import org.apache.flink.streaming.api.checkpoint.ListCheckpointed
import org.apache.flink.streaming.api.functions.source.RichSourceFunction
import org.apache.flink.streaming.api.functions.source.SourceFunction.SourceContext

//The class is the source operator with checkpoint.
class SEventSourceWithChk extends RichSourceFunction[SEvent] with ListCheckpointed[UDFState]{
    private var count = 0L
    private var isRunning = true
    private val alphabet =
"abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789abcdefghijklmnpqrstuvwxyz
wxyzABCDEFGHIJKLMNPQRSTUWZYX0987654321"

    //The logic of the operator is to inject 10000 tuples to the StreamGraph.
    override def run(sourceContext: SourceContext[SEvent]): Unit = {
        while(isRunning) {
            for (i <- 0 until 10000) {
                sourceContext.collect(SEvent(1, "hello-"+count, alphabet,1))
                count += 1L
            }
            Thread.sleep(1000)
        }
    }

    //Call this when the task is canceled.
    override def cancel(): Unit = {
        isRunning = false;
    }

    override def close(): Unit = super.close()

    //Create a snapshot.
    override def snapshotState(l: Long, l1: Long): util.List[UDFState] = {
        val udfList: util.ArrayList[UDFState] = new util.ArrayList[UDFState]
        val udfState = new UDFState
        udfState.setState(count)
        udfList.add(udfState)
        udfList
    }

    //Obtain status from the snapshot.
    override def restoreState(list: util.List[UDFState]): Unit = {
        val udfState = list.get(0)
        count = udfState.getState
    }
}

```

#### 4. Definition of window with checkpoint.

This code is about the window operator and is used to calculate number or tuples in the window.

```
import java.util
import org.apache.flink.api.java.tuple.Tuple
import org.apache.flink.streaming.api.checkpoint.ListCheckpointed
import org.apache.flink.streaming.api.scala.function.WindowFunction
import org.apache.flink.streaming.api.windowing.windows.TimeWindow
import org.apache.flink.util.Collector

//The class is the window operator with checkpoint.
class WindowStatisticWithChk extends WindowFunction[SEvent, Long, Tuple, TimeWindow] with
ListCheckpointed[UDFState]{
    private var total = 0L
```

```

//The implementation logic of the window operator, which is used to calculate the number of
//tuples in a window.
override def apply(key: Tuple, window: TimeWindow, input: Iterable[SEvent], out: Collector[Long]): Unit = {
    var count = 0L
    for (event <- input) {
        count += 1L
    }
    total += count
    out.collect(count)
}

//Customize a snapshot.
override def snapshotState(l: Long, l1: Long): util.List[UDFState] = {
    val udfList: util.ArrayList[UDFState] = new util.ArrayList[UDFState]
    val udfState = new UDFState
    udfState.setState(total)
    udfList.add(udfState)
    udfList
}

//Restore data from customized snapshots.
override def restoreState(list: util.List[UDFState]): Unit = {
    val udfState = list.get(0)
    total = udfState.getState
}
}

```

## 5. Application code

The code is about the definition of StreamGraph and is used to implement services. The **event time** is used as the timestamp for triggering the window.

```

import com.huawei.rt.flink.core.{SEvent, SEventSourceWithChk, WindowStatisticWithChk}
import org.apache.flink.contrib.streaming.state.RocksDBStateBackend
import org.apache.flink.streaming.api.functions.AssignerWithPeriodicWatermarks
import org.apache.flink.streaming.api.{CheckpointingMode, TimeCharacteristic}
import org.apache.flink.streaming.api.scala.StreamExecutionEnvironment
import org.apache.flink.streaming.api.watermark.Watermark
import org.apache.flink.streaming.api.windowing.assigners.SlidingEventTimeWindows
import org.apache.flink.streaming.api.windowing.time.Time
import org.apache.flink.api.scala._
import org.apache.flink.runtime.state.filesystem.FsStateBackend
import org.apache.flink.streaming.api.environment.CheckpointConfig.ExternalizedCheckpointCleanup

object FlinkEventTimeAPIChkMain {
    def main(args: Array[String]): Unit ={
        val env = StreamExecutionEnvironment.getExecutionEnvironment
        env.setStateBackend(new FsStateBackend("hdfs://hacluster/flink/checkpoint/"))
        env.setStreamTimeCharacteristic(TimeCharacteristic.EventTime)
        env.getConfig.setAutoWatermarkInterval(2000)
        env.getCheckpointConfig.setCheckpointingMode(CheckpointingMode.EXACTLY_ONCE)
        env.getCheckpointConfig.setCheckpointInterval(6000)

        //Application logic.
        env.addSource(new SEventSourceWithChk)
            .assignTimestampsAndWatermarks(new AssignerWithPeriodicWatermarks[SEvent] {
                //Configure watermark.
                override def getCurrentWatermark: Watermark = {
                    new Watermark(System.currentTimeMillis())
                }
                //Add timestamp for each tuple.
                override def extractTimestamp(t: SEvent, l: Long): Long = {
                    System.currentTimeMillis()
                }
            })
            .keyBy(0)
            .window(SlidingEventTimeWindows.of(Time.seconds(4), Time.seconds(1)))
            .apply(new WindowStatisticWithChk)
            .print()
        env.execute()
    }
}

```

```
}
```

## 2.4.3.4 Job Pipeline Program

### 2.4.3.4.1 Scenario

The concurrency of NettySource and the concurrency NettySink must be the same. Otherwise, the connection cannot be created.

#### Scenario

Assume that there are three jobs, a publisher and two subscribers. The publisher generates 10000 pieces of data each second. Data is sent by the NettySink operator from the publisher job to downstream subscribers which subscribe a same piece of data.

#### Data Planning

1. The publisher uses customized operators to generate about 10000 pieces of data per second.
2. The data contains two attributes, which are of integer and string types.
3. Configuration file
  - nettyconnector.registerserver.topic.storage: (Mandatory) Configures the path (on a third-party server) to information about IP address, port numbers, and concurrency of NettySink. For example:  
nettyconnector.registerserver.topic.storage: /flink/nettyconnector
  - nettyconnector.sinkserver.port.range: (Mandatory) Configures the range of port numbers of NettySink. For example:  
nettyconnector.sinkserver.port.range: 28444-28943
  - nettyconnector.sinkserver.subnet: Configure the network domain. For example:  
nettyconnector.sinkserver.subnet: 10.162.0.0/16

#### 4. Description of APIs

- RegisterServer API

RegisterServerHandler stores information such as IP address, port number, and concurrency of NettySink for the connection with NettySource. Following APIs are provided for users:

```
public interface RegisterServerHandler {  
  
    /**
     * Start the RegisterServer
     * @param The configuration indicates the configuration type of Flink.  

     */  
    void start(Configuration configuration) throws Exception;  
    /**
     * Create a topic node (directory) on the RegisterServer
     * @param The topic indicates the name of the topic node
     */  
    void createTopicNode(String topic) throw Exception;  
}
```

```
*Register the information to a topic node (directory)
* @param topic @param The topic indicates the directory to be registered with
* @param The registerRecord indicates the information to be registered
*/
void register(String topic, RegisterRecord registerRecord) throws Exception;
/**
     *Delete the topic node.
     *@param The topic indicates the topic to be deleted.
     */
void deleteTopicNode(String topic) throws Exception;
/**
     * Deregister the registration inDeregister the registration information formation
     * @param The topic indicates the topic where the registration information locates.
     * @param The recordId indicates the ID of the registration information to be deregistered
     */
void unregister(String topic, int recordId) throws Exception;
/**
     * Query information
     * @param Topic where the query information locates
     * @param The recordId indicates the ID of the query information
     */
RegisterRecord query(String topic, int recordId) throws Exception;
/**
     * Query whether a topic exist.
     * @param topic
     */
Boolean isExist(String topic) throws Exception;
/**
     *Disable RegisterServerHandler.
     */
void shutdown() throws Exception;
```

In addition to the preceding APIs, Flink provides ZookeeperRegisterHandler.

- NettySink operator

```
Class NettySink(String name,
String topic,
RegisterServerHandler registerServerHandler,
int numberOfSubscribedJobs)
```

- name: Name of a current NettySink.
- topic: The topic that generates data for the current NettySink. Different NettySinks must use different topics. Otherwise, the subscription may be disordered and data transmission may be abnormal.
- registerServerHandler: Handler of the registration server.
- numberOfSubscribedJobs: Specific number of jobs that subscribe the current NettySink. NettySink sends data only when all subscribers are connected to NettySink.

- NettySource operator

```
Class NettySource(String name,
String topic,
RegisterServerHandler registerServerHandler)
```

- name: name of the NettySource. The NettySource must be unique (concurrency excluded). Otherwise, connection with NettySink may be conflicted.

- topic: topic of subscribed NettySink.
- registerServerHandler: Handler of the registration server.

 NOTE

The concurrency of NettySource and the concurrency NettySink must be the same. Otherwise, the connection cannot be created.

## Development Approach

1. There are three jobs, one publisher and two subscribers.
2. The publisher transforms generated data into byte[] and send them to the subscribers.
3. After receiving the byte[], subscribers transform data into the string type and print sampled data.

### 2.4.3.4.2 Java Sample Code

Following is the main logic code for demonstration.

For details about the complete code, see the following:

- com.huawei.bigdata.flink.examples.UserSource.
- com.huawei.bigdata.flink.examples.TestPipelineNettySink.
- com.huawei.bigdata.flink.examples.TestPipelineNettySource1.
- com.huawei.bigdata.flink.examples.TestPipelineNettySource2.

1. The publisher customizes source operators to generate data.

```
package com.huawei.bigdata.flink.examples;

import org.apache.flink.api.java.tuple.Tuple2;
import org.apache.flink.configuration.Configuration;
import org.apache.flink.streaming.api.functions.source.RichParallelSourceFunction;

import java.io.Serializable;

public class UserSource extends RichParallelSourceFunction<Tuple2<Integer, String>> implements Serializable {

    private boolean isRunning = true;

    public void open(Configuration configuration) throws Exception {
        super.open(configuration);
    }

    /**
     * Data generation function, which is used to generate 10000 pieces of data each second.
     */
    public void run(SourceContext<Tuple2<Integer, String>> ctx) throws Exception {

        while(isRunning) {
            for (int i = 0; i < 10000; i++) {
                ctx.collect(Tuple2.of(i, "hello-" + i));
            }
            Thread.sleep(1000);
        }
    }

    public void close() {
```

```
        isRunning = false;
    }

    public void cancel() {
        isRunning = false;
    }
}
```

## 2. Code for the publisher:

```
package com.huawei.bigdata.flink.examples;

import org.apache.flink.api.common.functions.MapFunction;
import org.apache.flink.api.java.tuple.Tuple2;
import org.apache.flink.streaming.api.environment.StreamExecutionEnvironment;
import org.apache.flink.streaming.connectors.netty.sink.NettySink;
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler;

public class TestPipelineNettySink {

    public static void main(String[] args) throws Exception{

        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        //Set the concurrency of job to 2.
        env.setBufferTimeout(2);

        //Create a ZookeeperRegisterServerHandler.
        ZookeeperRegisterServerHandler zkRegisterServerHandler = new ZookeeperRegisterServerHandler();
        // Add a customized source operator.
        env.addSource(new UserSource()
            .keyBy(0)
            .map(new MapFunction<Tuple2<Integer,String>, byte[]>() {
                //Transform the to-be-sent data into a byte array.

@Override
        public byte[] map(Tuple2<Integer, String> integerStringTuple2) throws Exception {
            return integerStringTuple2.f1.getBytes();
        }
    }).addSink(new NettySink("NettySink-1", "TOPIC-2", zkRegisterServerHandler, 2));//NettySink
transmits the data.

        env.execute();
    }
}
```

## 3. Code for the first subscriber.

```
package com.huawei.bigdata.flink.examples;

import org.apache.flink.api.common.functions.MapFunction;
import org.apache.flink.streaming.api.environment.StreamExecutionEnvironment;
import org.apache.flink.streaming.connectors.netty.source.NettySource;
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler;

import java.nio.charset.Charset;

public class TestPipelineNettySource1 {

    public static void main(String[] args) throws Exception{

        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        // Set the concurrency of job to 2.
        env.setParallelism(2);

        // Create a ZookeeperRegisterServerHandler.
        ZookeeperRegisterServerHandler zkRegisterServerHandler = new ZookeeperRegisterServerHandler();
        //Add a NettySource operator to receive messages from the publisher.
        env.addSource(new NettySource("NettySource-1", "TOPIC-2", zkRegisterServerHandler))
            .map(new MapFunction<byte[], String>()
```

```
// Transform the received byte stream into character strings
@Override
    public String map(byte[] bytes) {
        return new String(bytes, Charset.forName("UTF-8"));
    }
}).print();

env.execute();
}
}
```

#### 4. Code for the second subscriber.

```
package com.huawei.bigdata.flink.examples;

import org.apache.flink.api.common.functions.MapFunction;
import org.apache.flink.streaming.api.environment.StreamExecutionEnvironment;
import org.apache.flink.streaming.connectors.netty.source.NettySource;
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler;

import java.nio.charset.Charset;

public class TestPipelineNettySource2 {

    public static void main(String[] args) throws Exception {

        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        // Set the concurrency of job to 2.
        env.setParallelism(2);

        //Create a ZookeeperRegisterServerHandler.
        ZookeeperRegisterServerHandler zkRegisterServerHandler = new ZookeeperRegisterServerHandler();
        //Add a NettySource operator to receive messages from the publisher.
        env.addSource(new NettySource("NettySource-2", "TOPIC-2", zkRegisterServerHandler))
            .map(new MapFunction<byte[], String>() {
                //Transform the received byte array into character strings.
                @Override
                public String map(byte[] bytes) {
                    return new String(bytes, Charset.forName("UTF-8"));
                }
            }).print();

        env.execute();
    }
}
```

#### 2.4.3.4.3 Scala Sample Code

Following is the main logic code for demonstration.

For details about the complete code, see the following:

- com.huawei.bigdata.flink.examples.UserSource.
- com.huawei.bigdata.flink.examples.TestPipeline\_NettySink.
- com.huawei.bigdata.flink.examples.TestPipeline\_NettySource1.
- com.huawei.bigdata.flink.examples.TestPipeline\_NettySource2.

##### 1. Code for sending messages:

```
package com.huawei.bigdata.flink.examples

case class Inforamtion(index: Int, content: String) {

    def this() = this(0, "")
}
```

##### 2. The publisher customizes source operators to generate data.

```
package com.huawei.bigdata.flink.examples

import org.apache.flink.configuration.Configuration
import org.apache.flink.streaming.api.functions.source.RichParallelSourceFunction
import org.apache.flink.streaming.api.functions.source.SourceFunction.SourceContext

class UserSource extends RichParallelSourceFunction[Inforamtion] with Serializable{

    var isRunning = true

    override def open(parameters: Configuration): Unit = {
        super.open(parameters)
    }

    // Generate 10000 pieces of data each second.
    override def run(sourceContext: SourceContext[Inforamtion]) = {

        while (isRunning) {
            for (i <- 0 until 10000) {
                sourceContext.collect(Inforamtion(i, "hello-" + i));
            }
            Thread.sleep(1000)
        }
    }

    override def close(): Unit = super.close()

    override def cancel() = {
        isRunning = false
    }
}
```

### 3. Code for the publisher:

```
package com.huawei.bigdata.flink.examples

import org.apache.flink.streaming.api.scala.StreamExecutionEnvironment
import org.apache.flink.streaming.connectors.netty.sink.NettySink
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler
import org.apache.flink.streaming.api.scala._

object TestPipeline_NettySink {

    def main(args: Array[String]): Unit = {

        val env = StreamExecutionEnvironment.getExecutionEnvironment
        // Set the concurrency of job to 2.
        env.setParallelism(2)
        //Set Zookeeper as the registration server
        val zkRegisterServerHandler = new ZookeeperRegisterServerHandler
        //Add a user-defined operator to generate data.
        env.addSource(new UserSource) .keyBy(0).map(x=>x.content.getBytes)//Transform the to-be-sent data
        into a byte array.
        .addSink(new NettySink("NettySink-1", "TOPIC-2", zkRegisterServerHandler, 2))//Add NettySink
        operator to send data.
        env.execute()
    }
}
```

### 4. Code for the first subscriber

```
package com.huawei.bigdata.flink.examples

import org.apache.flink.streaming.api.scala.StreamExecutionEnvironment
import org.apache.flink.streaming.connectors.netty.source.NettySource
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler
import org.apache.flink.streaming.api.scala._

import scala.util.Random
```

```
object TestPipeline_NettySource1 {  
    def main(args: Array[String]): Unit = {  
        val env = StreamExecutionEnvironment.getExecutionEnvironment  
        // Set the concurrency of job to 2.  
        env.setParallelism(2)  
        //Set ZooKeeper as the registration server  
        val zkRegisterServerHandler = new ZookeeperRegisterServerHandler  
        //Add a NettySource operator to receive messages from the publisher.  
        env.addSource(new NettySource("NettySource-1", "TOPIC-2", zkRegisterServerHandler))  
            .map(x => (1, new String(x)))//Add a NettySource operator to receive messages from the publisher.  
            .filter(x => {  
                Random.nextInt(50000) == 10  
            })  
            .print  
  
        env.execute()  
    }  
}
```

## 5. Code for the second subscriber.

```
package com.huawei.bigdata.flink.examples  
  
import org.apache.flink.streaming.api.scala.StreamExecutionEnvironment  
import org.apache.flink.streaming.connectors.netty.source.NettySource  
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler  
import org.apache.flink.streaming.api.scala._  
  
import scala.util.Random  
  
object TestPipeline_NettySource2 {  
    def main(args: Array[String]): Unit = {  
        val env = StreamExecutionEnvironment.getExecutionEnvironment  
        //Set the concurrency of job to 2.  
        env.setParallelism(2)  
        //Set the concurrency of job to 2.  
        val zkRegisterServerHandler = new ZookeeperRegisterServerHandler  
        //Add NettySource operator and receive data.  
  
        env.addSource(new NettySource("NettySource-2", "TOPIC-2", zkRegisterServerHandler))  
            .map(x=>(2, new String(x)))//Transform the received byte array into character strings.  
  
            .filter(x=>{  
                Random.nextInt(50000) == 10  
            })  
            .print()  
  
        env.execute()  
    }  
}
```

## 2.4.3.5 JOIN Operation between Configuration Tables and Streams

### 2.4.3.5.1 Scenario Description

#### Scenario

Assume that there is a log text file about dwell durations of netizens for shopping online and a CSV table about netizen information. Develop a Flink application that achieves following functions:

- Collects statistics on female netizens who spend more than 2 hours in total for online shopping during the weekend in real time.  
The name fields in the log file and the CSV table can be used as keywords, based on which the two files are joined.
- The first column in the log file records names, the second column records gender, and the third column records the dwell duration (in minutes). Three columns are separated by commas (,).

**data.txt:** logs of netizen dwell duration on weekends

```
LA,female,20
YA,male,10
GA,male,5
CA,female,50
LAA,male,20
FA,female,50
LA,female,20
YA,male,10
GA,male,50
CA,female,50
FA,female,60
LA,female,20
YA,male,10
CA,female,50
FA,female,50
GA,male,5
CA,female,50
LB,male,20
CA,female,50
FA,female,50
LA,female,20
YA,male,10
FA,female,50
GA,male,50
CA,female,50
FA,female,60
NotExist,female,200
```

- **configtable.csv:** contains netizens' personal information. Fields starting from the first column to the ninth column are the name, age, company name, work place, academic degree, years of working, mobile number, domicile place, and school of graduation. These columns are separated by commas (,).

```
username,age,company,workLocation,educational,workYear,phone,nativeLocation,school
LA,25,C1,W1,college,5,1312345678,N1,S1 university
YA,26,C2,W2,master,6,1312345679,N2,S2 university
GA,27,C3,W3,college,7,1312345680,N3,S3 university
CA,28,C4,W4,master,8,1312345681,N4,S4 university
LB,29,C5,W5,doctor,9,1312345682,N5,S5 university
FA,30,C6,W6,doctor,10,1312345683,N6,S6 university
```

## Data Preparation

The stream data of the example project is saved in a TXT file, and the configuration table is in CSV format.

1. Ensure that clusters, including HDFS, YARN, non-secure Redis, and Flink are successfully installed.
2. Create a Redis cluster. For details about Redis, see "Component Operation Guide" > "Using Redis" in MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1) in the MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1).
3. Modify the **import.properties** and **read.properties** files, which are in the **config** directory specified in the sample code.

#### NOTE

In the Scala sample code, the IP addresses and port numbers of all the instances in the logical cluster must be configured for the **Redis\_IP\_Port** parameter.

The formula for calculating the port number of the Redis instance is:  $22400 + \text{Instance ID} - 1$ .

To obtain the instance ID, choose **Cluster > Name of the desired cluster > Service > Redis > Redis Manager** on FusionInsight Manager and click the target Redis cluster name. For example, the port numbers of the Redis instances corresponding to the role R1 and role R2 are 22400 ( $22400 + 1 - 1 = 22400$ ) and 22401 ( $22400 + 2 - 1 = 22401$ ), respectively.

- The following is an example of configurations in the **import.properties** file:

```
#path to read csv files, it can be file or directory  
CsvPath=config/configtable.csv  
  
#csv file headers exist in file first line or not  
CsvHeaderExist=true  
#csv file headers, also the redis field names  
#Notice: if CsvHeaderExist false, you must set it, if CsvHeaderExist true, it read from csv file  
ColumnNames=username,age,company,workLocation,educational,workYear,phone,nativeLocation,school  
#redis hostname/ip and port when you need to connect to redis  
Redis_IP_Port=SZV1000064084:22400,SZV1000064082:22400,SZV1000064085:22400  
# redis ssl on  
Redis_ssl_on=false
```

- The following is an example of configurations in the **read.properties** file:

```
#the redis field names, configure which fields you need to read, Notice you need English field  
names  
ReadFields=username,age,company,workLocation,educational,workYear,phone,nativeLocation,sch  
ool  
#redis hostname/ip and port when you need to connect to redis  
Redis_IP_Port=SZV1000064084:22400,SZV1000064082:22400,SZV1000064085:22400  
# redis ssl on  
Redis_ssl_on=false
```

4. Create the **config** directory on the Flink client and save the **data.txt**, **configtable.csv**, **import.properties** and **read.properties** files to the **config** directory, for example, `/opt/hadoopclient/Flink/flink/config/configtable.csv`.

#### NOTE

The **data.txt** and **configtable.csv** files are in the **data** directory specified in the sample code.

## Development Guideline

Collect the detailed information about female netizens who continuously spend more than 2 hours on online shopping on the current weekend.

To achieve the objective, the process is as follows:

- Modify the configuration of **import.properties** and **read.properties**, configure fields in the CSV file, fields read by Redis, and information about Redis nodes.
- Import the **configtable.csv** table to Redis for storage.
- Read text data, generate DataStreams, and parse data to generate OriginalRecord information.

- Call the function of asynchronous I/O, use the OriginalRecord username field as the keyword to query personal information in Redis, and transform the information into UserRecord.
- Filter the data about the time that female netizens spend online.
- Perform keyby operation based on names, and collect the time that female netizens spend online within a time window.
- Filter data about netizens whose consecutive online duration exceeds the threshold, and obtain the results.

#### 2.4.3.5.2 Java Sample Code

##### Description

Collect the information from the log file about female netizens who continuously spend more than 2 hours in online shopping, collect personal information from the CSV table, and use the names of netizens as the keywords for joining the log file and the CSV table.

##### Sample Code

The following code snippet is used as an example for importing the **configtable.csv** file to Redis clusters in normal mode. For the complete code, see [com.huawei.bigdata.flink.examples.RedisDataImport](#).

```
package com.huawei.bigdata.flink.examples;

import org.apache.flink.api.java.utils.ParameterTool;

import org.supercsv.cellprocessor.constraint.NotNull;
import org.supercsv.cellprocessor.ift.CellProcessor;
import org.supercsv.io.CsvBeanReader;
import org.supercsv.io.ICsvBeanReader;
import org.supercsv.prefs.CsvPreference;
import redis.clients.jedis.HostAndPort;
import redis.clients.jedis.JedisCluster;

import java.io.File;
import java.io.FileReader;
import java.util.*;

/**
 * Read data from csv file and import to redis.
 */
public class RedisDataImport {

    private static final int MAX_ATTEMPTS = 2;

    private static final int TIMEOUT = 60000;

    public static void main(String[] args) throws Exception {
        // print comment for command to use run flink
        System.out.println("use command as: \n" +
            "java -cp /opt/hadoopclient/Flink/flink/lib/*:/opt/FlinkConfigtableJavaExample.jar" +
            " com.huawei.bigdata.flink.examples.RedisDataImport --configPath <config filePath>" +
            "*****\n" +
            "<config filePath> is for configure file to load\n" +
            "you may write following content into config filePath: \n" +
            "CsvPath=config/configtable.csv\n" +
            "CsvHeaderExist=true\n" +
            "\n" +
            "ColumnNames=username,age,company,workLocation,educational,workYear,phone,nativeLocation,school\n"
    }
}
```

```
+        "Redis_IP_Port=SZV1000064084:22400,SZV1000064082:22400,SZV1000064085:22400\n" +
+*****");
+

#### 2.4.3.5.3 Scala Sample Code

##### Description

Collect the information from the log file about female netizens who continuously spend more than 2 hours in online shopping, collect personal information from the CSV table, and use the names of netizens as the keywords for joining the log file and the CSV table.

##### Sample Code

The following code snippet is used as an example for importing the **configurable.csv** file to Redis clusters in normal mode. For the complete code, see [com.huawei.bigdata.flink.examples.RedisDataImport](#).

```
package com.huawei.bigdata.flink.examples;

import org.apache.flink.api.java.utils.ParameterTool;

import org.supercsv.cellprocessor.constraint.NotNull;
import org.supercsv.cellprocessor.ift.CellProcessor;
import org.supercsv.io.CsvBeanReader;
import org.supercsv.io.ICsvBeanReader;
import org.supercsv.prefs.CsvPreference;
import redis.clients.jedis.HostAndPort;
import redis.clients.jedis.JedisCluster;

import java.io.File;
import java.io.FileReader;
import java.util.*;

/**
 * Read data from csv file and import to redis.
 */

case class OriginalRecord(name: String, sexy: String, shoppingTime: Int)

case class UserRecord(name: String, age: Int, company: String, workLocation: String, educational: String,
workYear: Int,
    phone: String, nativeLocation: String, school: String, sexy: String, shoppingTime: Int)

// class to set watermark and timestamp
private class Record2TimestampExtractor extends AssignerWithPunctuatedWatermarks[OriginalRecord] {

    // add tag in the data of datastream elements
    override def extractTimestamp(element: OriginalRecord, previousTimestamp: Long): Long = {
        System.currentTimeMillis()
    }

    // Give the watermark to trigger the window to start execution, and use the value to check if the window
    // elements are ready.
    def checkAndGetNextWatermark(lastElement: OriginalRecord,
                                extractedTimestamp: Long): Watermark = {
        new Watermark(extractedTimestamp - 1)
    }
}
```

### 2.4.3.6 Stream SQL Join Program

#### 2.4.3.6.1 Scenario

##### Scenario

Assume that a Flink service (service 1) receives a message every second. The message records the basic information about a user, including the name, gender, and age. Another Flink service (service 2) receives a message irregularly, and the message records the name and career information about the user.

To meet the requirements of some services, the Flink application is developed to achieve the following function: uses the username recorded in the message received by service 2 as the keyword to jointly query two pieces of service data.

##### Data Planning

- The data of service 1 is stored in the Kafka component. Service 1 sends data (requiring Kafka user rights) to and receives data from the Kafka component. For details about how to configure Kafka, see the data planning section of [Data Planning](#).
- Service 2 receives messages using the socket. You can run the **netcat** command to input the analog data source.
  - Run the **netcat -l -p <port>** command to start a simple text server.
  - After starting the application to connect to the port monitored by **netcat**, enter the data information to the netcat terminal.

## Development Approach

1. Start the Flink Kafka Producer application to send data to Kafka.
2. Start the Flink Kafka Consumer application to receive data from Kafka, construct **Table1**, and ensure that the Topic is the same as that of Producer.
3. Read data from the socket and construct **Table2**.
4. Use Flink SQL to query and print **Table1** and **Table2**.

### 2.4.3.6.2 Java Sample Code

#### Function

In the Flink application, this code invokes the flink-connector-kafka module's API to generate and consume data.

#### Sample Code

If the user needs to use FusionInsight Kafka interconnected with the security mode before the development, obtain the **kafka-client-\*jar** JAR file from the FusionInsight client directory.

The following lists Producer, Consumer, and the main logic code used by Flink Stream SQL Join.

For the complete code, see  
[com.huawei.bigdata.flink.examples.WriteIntoKafka](#) and  
[com.huawei.bigdata.flink.examples.SqlJoinWithSocket](#).

1. A piece of user information is generated in Kafka every second. The user information includes the name, age, and gender.

```
//Producer code
public class WriteIntoKafka {
    public static void main(String[] args) throws Exception {
        //Print the command reference for flink run.
        System.out.println("use command as: ");
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21005");
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21007 --security.protocol
        SASL_PLAINTEXT --sasl.kerberos.service.name kafka");
        System.out.println("*****");
        System.out.println("<topic> is the kafka topic name");
        System.out.println("<bootstrap.servers> is the ip:port list of brokers");
        System.out.println("*****");

        //Construct the execution environment.
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        //Set the concurrency.
        env.setParallelism(1);
        //Parse the running parameters.
        ParameterTool paraTool = ParameterTool.fromArgs(args);
        //Construct a flow diagram and write the data generated from self-defined sources to Kafka.
        DataStream<String> messageStream = env.addSource(new SimpleStringGenerator());
        FlinkKafkaProducer<String> producer = new FlinkKafkaProducer<>(paraTool.get("topic"),
            new SimpleStringSchema(),
            paraTool.getProperties());
        producer.setWriteTimestampToKafka(true);
        messageStream.addSink(producer);
        //Invoke execute to trigger the execution.
        env.execute();
    }
}
```

```
//Customize the sources and generate a message every second.
public static class SimpleStringGenerator implements SourceFunction<String> {
    static final String[] NAME = {"Carry", "Alen", "Mike", "Ian", "John", "Kobe", "James"};
    static final String[] SEX = {"MALE", "FEMALE"};
    static final int COUNT = NAME.length;
    boolean running = true;
    Random rand = new Random(47);
    @Override
    //Use rand to randomly generate a combination of the name, gender, and age.
    public void run(SourceContext<String> ctx) throws Exception {
        while (running) {
            int i = rand.nextInt(COUNT);
            int age = rand.nextInt(70);
            String sexy = SEX[rand.nextInt(2)];
            ctx.collect(NAME[i] + "," + age + "," + sexy);
            thread.sleep(1000);
        }
    }
    @Override
    public void cancel() {
        running = false;
    }
}
```

2. Generate **Table1** and **Table2**, use Join to jointly query **Table1** and **Table2**, and print the output result.

```
public class SqJoinWithSocket {
    public static void main(String[] args) throws Exception{
        final String hostname;
        final int port;
        System.out.println("use command as: ");
        System.out.println("flink run --class com.huawei.bigdata.flink.examples.SqJoinWithSocket" +
                " /opt/test.jar --topic topic-test -bootstrap.servers xxxx.xxx.xxx.xxx:21005 --hostname
xxxx.xxx.xxx.xxx --port xxx");
        System.out.println("flink run --class com.huawei.bigdata.flink.examples.SqJoinWithSocket" +
                " /opt/test.jar --topic topic-test -bootstrap.servers xxxx.xxx.xxx.xxx:21007 --security.protocol
SASL_PLAINTEXT --sasl.kerberos.service.name kafka"
                + "--hostname xxx.xxx.xxx.xxx --port xxx");
        System.out.println("*****");
        System.out.println("<topic> is the kafka topic name");
        System.out.println("<bootstrap.servers> is the ip:port list of brokers");
        System.out.println("*****");
        try {
            final ParameterTool params = ParameterTool.fromArgs(args);
            hostname = params.has("hostname") ? params.get("hostname") : "localhost";
            port = params.getInt("port");
        } catch (Exception e) {
            System.err.println("No port specified. Please run 'FlinkStreamSqJoinExample " +
                    "--hostname <hostname> --port <port>', where hostname (localhost by default) " +
                    "and port is the address of the text server");
            System.err.println("To start a simple text server, run 'netcat -l -p <port>' and " +
                    "type the input text into the command line");
            return;
        }
        EnvironmentSettings fsSettings =
EnvironmentSettings.newInstance().useOldPlanner().inStreamingMode().build();
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        StreamTableEnvironment tableEnv = StreamTableEnvironment.create(env, fsSettings);
        //Perform processing based on EventTime.
        env.setStreamTimeCharacteristic(TimeCharacteristic.EventTime);
        env.setParallelism(1);
        ParameterTool paraTool = ParameterTool.fromArgs(args);
        //Use Stream1 to read data from Kafka.
        DataStream<Tuple3<String, String, String>> kafkaStream = env.addSource(new
FlinkKafkaConsumer<>(paraTool.get("topic"),
        new SimpleStringSchema(),
        paraTool.getProperties()).map(new MapFunction<String, Tuple3<String, String, String>>()
{
```

```

@Override
public Tuple3<String, String, String> map(String s) throws Exception {
    String[] word = s.split(",");
    return new Tuple3<>(word[0], word[1], word[2]);
}
});
//Register Stream1 as Table1.
tableEnv.registerDataStream("Table1", kafkaStream, "name, age, sexy, proctime.proctime");
//Use Stream2 to read data from the socket.
DataStream<Tuple2<String, String>> socketStream = env.socketTextStream(hostname, port,
"\n").
map(new MapFunction<String, Tuple2<String, String>>() {
    @Override
    public Tuple2<String, String> map(String s) throws Exception {
        String[] words = s.split("\s");
        if (words.length < 2) {
            return new Tuple2<>();
        }
        return new Tuple2<>(words[0], words[1]);
    }
});
//Register Stream2 as Table2.
tableEnv.registerDataStream("Table2", socketStream, "name, job, proctime.proctime");
//Run SQL Join to perform a combined query.
Table result = tableEnv.sqlQuery("SELECT t1.name, t1.age, t1.sex, t2.job, t2.proctime as shiptime
\n" +
    "FROM Table1 AS t1\n" +
    "JOIN Table2 AS t2\n" +
    "ON t1.name = t2.name\n" +
    "AND t1.proctime BETWEEN t2.proctime - INTERVAL '1' SECOND AND t2.proctime +
INTERVAL '1' SECOND");
//Convert the query result into the stream and print the output.
tableEnv.toAppendStream(result, Row.class).print();
env.execute();
}
}

```

#### 2.4.3.6.3 Scala Sample Code

##### Function

In a Flink application, call the API of the flink-connector-kafka module to produce and consume data.

##### Sample Code

If you need to interconnect with Kafka in security mode before application development, **kafka-clients-\*jar** of FusionInsight is required. You can obtain the JAR file from the Kafka client directory.

The following example provides the main code logic of Producer, Consumer, and Flink Stream SQL Join.

Complete code is provided in **com.huawei.bigdata.flink.examples.WriteIntoKafka** and **com.huawei.bigdata.flink.examples.SqlJoinWithSocket**.

1. Produce a piece of user information in Kafka every second. The user information includes the name, age, and gender.

```

//Producer

object WriteIntoKafka {
    def main(args: Array[String]): Unit = {

```

```

System.out.println("use command as: ")
System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +
" /opt/test.jar --topic topic-test -bootstrap.servers xxx.xxx.xxx:21005")
System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka /opt/
test.jar --topic" + " topic-test -bootstrap.servers xxx.xxx.xxx:21007 --security.protocol
SASL_PLAINTEXT" + " --sasl.kerberos.service.name kafka")

System.out.println("*****")
System.out.println("<topic> is the kafka topic name")
System.out.println("<bootstrap.servers> is the ip:port list of brokers")
System.out.println("*****")
val env = StreamExecutionEnvironment.getExecutionEnvironment
env.setParallelism(1)

val paraTool = ParameterTool.fromArgs(args)

val messageStream = env.addSource(new WriteIntoKafka.SimpleStringGenerator)
val producer = new FlinkKafkaProducer[String](paraTool.get("topic"), new SimpleStringSchema,
paraTool.getProperties)

producer.setWriteTimestampToKafka(true)

messageStream.addSink(producer)
env.execute
}

/**
 * String source class
 *
 */
object SimpleStringGenerator {
  private[examples] val NAME = Array("Carry", "Alen", "Mike", "Ian", "John", "Kobe", "James")
  private[examples] val SEX = Array("MALE", "FEMALE")
  private[examples] val COUNT = NAME.length
}

class SimpleStringGenerator extends SourceFunction[String] {
  private[examples] var running = true
  private[examples] val rand = new Random(47)

  @throws[Exception]
  override def run(ctx: SourceFunction.SourceContext[String]): Unit = {
    while (running) {
      val i = rand.nextInt(SimpleStringGenerator.COUNT)
      val age = rand.nextInt(70)
      val sexy = SimpleStringGenerator.SEX(rand.nextInt(2))
      ctx.collect(SimpleStringGenerator.NAME(i) + "," + age + "," + sexy)
      Thread.sleep(1000)
    }
  }

  override def cancel(): Unit = {
    running = false
  }
}

```

2. Generate Table1 and Table2, use **Join** to query both Table1 and Table2, and print the output.

```

object SqJoinWithSocket {
  def main(args: Array[String]): Unit = {
    var hostname: String = null
    var port = 0
    System.out.println("use command as: ")
    System.out.println("flink run --class com.huawei.bigdata.flink.examples.SqJoinWithSocket /opt/
test.jar --topic" + " topic-test -bootstrap.servers xxxx.xxx.xxx:21005 --hostname xxx.xxx.xxx --port
xxx")
    System.out.println("flink run --class com.huawei.bigdata.flink.examples.SqJoinWithSocket /opt/
test.jar --topic" + " topic-test -bootstrap.servers xxxx.xxx.xxx:21007 --security.protocol

```

```
SASL_PLAINTEXT" + " --sasl.kerberos.service.name kafka--hostname xxx.xxx.xxx.xxx --port xxx")  
  
System.out.println("*****  
System.out.println("<topic> is the kafka topic name")  
System.out.println("<bootstrap.servers> is the ip:port list of brokers")  
System.out.println("*****")  
try {  
    val params = ParameterTool.fromArgs(args)  
    hostname = if (params.has("hostname")) params.get("hostname")  
    else "localhost"  
    port = params.getInt("port")  
} catch {  
    case e: Exception =>  
        System.err.println("No port specified. Please run 'FlinkStreamSqlJoinExample " + "--hostname  
<hostname> --port <port>', where hostname (localhost by default) " + "and port is the address of the  
text server")  
        System.err.println("To start a simple text server, run 'netcat -l -p <port>' and " + "type the input  
text into the command line")  
        return  
}  
  
val fsSettings = EnvironmentSettings.newInstance.inStreamingMode.build  
val env = StreamExecutionEnvironment.getExecutionEnvironment  
val tableEnv = StreamTableEnvironment.create(env, fsSettings)  
  
env.getConfig.setAutoWatermarkInterval(200)  
env.setParallelism(1)  
val paraTool = ParameterTool.fromArgs(args)  
  
val kafkaStream = env.addSource(new FlinkKafkaConsumer[String](paraTool.get("topic"), new  
SimpleStringSchema, paraTool.getProperties)).map(new MapFunction[String, Tuple3[String, String,  
String]]())  
{@throws[Exception]  
override def map(str: String): Tuple3[String, String, String] = {  
    val word = str.split(",")  
    new Tuple3[String, String, String](word(0), word(1), word(2))  
}  
})  
  
tableEnv.createTemporaryView("Table1", kafkaStream, $("name"), $($("age")), $($("sexy")), $\n  
("proctime").proctime)  
  
val socketStream = env.socketTextStream(hostname, port, "\n").map(new MapFunction[String,  
Tuple2[String, String]]())  
{@throws[Exception]  
override def map(str: String): Tuple2[String, String] = {  
    val words = str.split("\\s")  
    if (words.length < 2) return new Tuple2[String, String]  
    new Tuple2[String, String](words(0), words(1))  
}  
})  
  
tableEnv.createTemporaryView("Table2", socketStream, $("name"), $($("job")), $\n  
("proctime").proctime)  
  
val result = tableEnv.sqlQuery("SELECT t1.name, t1.age, t1.sex, t2.job, t2.proctime as shiptime\n" +  
"FROM Table1 AS t1\n" + "JOIN Table2 AS t2\n" + "ON t1.name = t2.name\n" + "AND t1.proctime  
BETWEEN t2.proctime - INTERVAL '1' SECOND AND t2.proctime + INTERVAL '1' SECOND")  
  
tableEnv.toAppendStream(result, classOf[Row]).print  
env.execute  
}  
}
```

### 2.4.3.7 Submitting a SQL Job Using Flink Jar

#### 2.4.3.7.1 Scenario Description

##### Description

If SQL statements of a job are frequently modified, submit Flink SQL statements in Flink Jar mode to reduce your workload.

##### Development Guideline

Use the current sample to submit and execute specified SQL statements. Use semicolons (;) to separate multiple statements.

#### 2.4.3.7.2 Java Sample Code

The core logic for submitting SQL statements is as follows. Currently, only **CREATE** and **INSERT** statements can be submitted. For details about the complete code, see `com.huawei.bigdata.flink.examples.FlinkSQLExecutor`.

```
public class FlinkSQLExecutor {  
    public static void main(String[] args) throws IOException {  
        System.out.println("----- begin init -----");  
        final String sqlPath = ParameterTool.fromArgs(args).get("sql", "config/redisSink.sql");  
        final StreamExecutionEnvironment streamEnv =  
            StreamExecutionEnvironment.getExecutionEnvironment();  
        EnvironmentSettings bsSettings = EnvironmentSettings.newInstance().inStreamingMode().build();  
        StreamTableEnvironment tableEnv = StreamTableEnvironment.create(streamEnv, bsSettings);  
        StatementSet statementSet = tableEnv.createStatementSet();  
        String sqlStr = FileUtils.readFileToString(FileUtils.getFile(sqlPath), "utf-8");  
        String[] sqlArr = sqlStr.split(";;");  
        for (String sql : sqlArr) {  
            sql = sql.trim();  
            if (sql.toLowerCase(Locale.ROOT).startsWith("create")) {  
                System.out.println("-----\nexecuteSql=\n" + sql);  
                tableEnv.executeSql(sql);  
            } else if (sql.toLowerCase(Locale.ROOT).startsWith("insert")) {  
                System.out.println("-----\ninsert=\n" + sql);  
                statementSet.addInsertSql(sql);  
            }  
        }  
        System.out.println("----- begin exec sql -----");  
        statementSet.execute();  
    }  
}
```

##### NOTE

Copy the dependency package required by the current sample, that is, the JAR package in the **lib** file after compilation, to the **lib** folder on the client.

The following uses Kafka in a normal cluster as an example to describe how to submit SQL statements:

```
create table kafka_sink  
(  
    uuid varchar(20),  
    name varchar(10),  
    age int,  
    ts timestamp(3),  
    p varchar(20)  
) with (  
    'connector' = 'kafka',  
    'topic' = 'input2',  
    'properties.bootstrap.servers' = 'IP address of the Kafka broker instance',  
    'properties.group.id' = 'testGroup2',
```

```
'scan.startup.mode' = 'latest-offset',
'format' = 'json'
);
create TABLE datagen_source
(
    uuid varchar(20),
    name varchar(10),
    age int,
    ts timestamp(3),
    p varchar(20)
) WITH (
    'connector' = 'datagen',
    'rows-per-second' = '1'
);
INSERT INTO kafka_sink
SELECT *
FROM datagen_source;
```

## 2.4.3.8 FlinkServer REST API JavaExample

### 2.4.3.8.1 Scenario Description

#### Scenario

Call the FlinkServer RESTful API to create tenants.

#### Data Preparation

- Prepare information required for creating a tenant, for example, **tenantId** is **92**, **tenantName** is **test92**, and **remark** is **test tenant remark1**.
- If you run this sample program in Windows, add the host names and IP addresses of all nodes where FlinkServer resides to the **C:\Windows\System32\drivers\etc\hosts** file.
- To call the RESTful API for starting a job, you need to prepare the FlinkServer job, for example, whose ID is **cb4fa1b385ec4b3bb35f0d1ae3990857**.

#### Development Guideline

1. Configure user authentication information.
2. Log in as a user.
3. Send requests.

### 2.4.3.8.2 Java sample code for invoking the FlinkServer REST API to create a tenant

#### Description

Call the FlinkServer RESTful API to create tenants.

#### Sample Code

```
public class TestCreateTenants {
    public static void main(String[] args) {
        ParameterTool paraTool = ParameterTool.fromArgs(args);
        final String hostName = paraTool.get("hostName"); // Replace hostName in the hosts file with the
actual host name.

        String url = "https://"+hostName+":28943/flink/v1/tenants";
```

```
String jsonstr = "{" +  
    "\n\t\"tenantId\":\"92\"," +  
    "\n\t\"tenantName\":\"test92\"," +  
    "\n\t\"remark\":\"test tenant remark\"," +  
    "\n\t\"updateUser\":\"test_updateUser\"," +  
    "\n\t\"createUser\":\"test_createUser\\"" +  
    "\n}";  
  
try {  
    System.out.println(HttpClientUtil.doPost(url, jsonstr, "utf-8", false));  
} catch (Exception e) {  
    System.out.println(e);  
}  
}  
}
```

#### 2.4.3.8.3 Calling a FlinkServer REST API to Start a Job

### Function

This topic describes how to start a FlinkServer job by calling a FlinkServer REST API.

### Sample Code

The following example uses the job whose ID is **cb4fa1b385ec4b3bb35f0d1ae3990857** to describe how to call the API for starting a job on FlinkServer. The complete code is as follows:

```
public class TestJobsAction {  
    public static void main(String[] args) {  
        ParameterTool paraTool = ParameterTool.fromArgs(args);  
        final String hostName = paraTool.get("hostName"); // Host name  
        final String keytab = paraTool.get("keytab"); // Path for storing user.keytab  
        final String krb5 = paraTool.get("krb5"); // Path for storing krb5.conf  
        final String principal = paraTool.get("principal"); // Authentication user  
  
        System.setProperty("java.security.krb5.conf", krb5);  
        String url = "https://" + hostName + ":28943/flink/v1/1/jobs/action";  
  
        // Modify the corresponding jsonstr.  
        String jsonstr = "{" +  
            "\n\t\"jobId\":\"cb4fa1b385ec4b3bb35f0d1ae3990857\"," +  
            "\n\t\"action\":\"start\\"" +  
            "\n}";  
        try {  
            LoginClient.getInstance().setConfigure(url, principal, keytab, "");  
            LoginClient.getInstance().login();  
            System.out.println(HttpClientUtil.doPost(url, jsonstr, "utf-8", false));  
        } catch (Exception e) {  
            System.out.println(e);  
        }  
    }  
}
```

#### 2.4.3.8.4 Accessing Flinkserver RESTful API as a Proxy User

### Function

Call the FlinkServer RESTful API as a proxy user. Use a proxy to access the API as a FlinkServer administrator to obtain common user permissions.

## Sample Code

Assume that the tenant user is **test92**, the tenant ID is **92**, and the user name is **flinkserveradmin** with FlinkServer administrator permissions. The following code is a complete example.

```
public class TestCreateTenants {  
    public static void main(String[] args) {  
        ParameterTool paraTool = ParameterTool.fromArgs(args);  
        final String hostName = paraTool.get("hostName"); // Replace hostName in the hosts file with the  
actual host name.  
        final String keytab = paraTool.get("keytab"); // Path for storing user.keytab

### 2.4.3.9 Flink Reading Data from and Writing Data to HBase

#### 2.4.3.9.1 Scenario Description

#### Typical Scenario Description

Use Flink API jobs to read data from and write data to HBase.

#### Data Preparation

Prepare the HBase configuration file and download the cluster configuration on FusionInsight Manager to obtain the **hbase-site.xml** file.

## Development Guideline

1. Writes data to HBase:
  - a. Specify the parent directory of the **hbase-site.xml** file. Flink Sink can obtain the HBase connection.
  - b. Use the connection to determine whether a table exists. If it does not, create one.
  - c. Convert received data into Put objects and writes the Put objects to HBase.
2. Reads data from HBase:
  - a. Specify the parent directory of the **hbase-site.xml** file. Flink Source can obtain the HBase connection.
  - b. Use the connection to determine whether a table exists. If it does not, the job fails. In this case, you need to create a table in HBase shell or an upstream job.
  - c. Read data from HBase, converts result data into Row objects, and sends the Row objects to downstream operators.

### 2.4.3.9.2 Java Sample Code

#### Description

Call Flink APIs to read data from and write data to HBase.

#### Sample Code

The following example shows the main logic code of WriteHBase and ReadHBase.

For details about the complete code, see  
[com.huawei.bigdata.flink.examples.WriteHBase](#) and  
[com.huawei.bigdata.flink.examples.ReadHBase](#).

- Main logic code of WriteHBase

```
public static void main(String[] args) throws Exception {
    System.out.println("use command as: ");
    System.out.println(
        "./bin/flink run --class com.huawei.bigdata.flink.examples.WriteHBase"
        + " /opt/test.jar --tableName t1 --confDir /tmp/hbaseConf");
    System.out.println(
        "*****");
    System.out.println("<tableName> hbase tableName");
    System.out.println("<confDir> hbase conf dir");
    System.out.println(
        "*****");
    StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
    env.setParallelism(1);
    ParameterTool paraTool = ParameterTool.fromArgs(args);
    DataStream<Row> messageStream = env.addSource(new SimpleStringGenerator());
    messageStream.addSink(
        new HBaseWriteSink(paraTool.get("tableName"), createConf(paraTool.get("confDir"))));
    env.execute("WriteHBase");
}

private static org.apache.hadoop.conf.Configuration createConf(String confDir) {
    LOG.info("Create HBase configuration.");
    org.apache.hadoop.conf.Configuration hbaseConf =
        HBaseConfigurationUtil.getHBaseConfiguration();
```

```

### 2.4.3.10 Flink Reading Data from and Writing Data to Hudi

#### 2.4.3.10.1 Scenario Description

#### Typical Scenario Description

In this example, the job generates one data record per second, writes the data to the Hudi table, and reads and prints the data in the Hudi table.

#### Development Guideline

1. Write data to Hudi:
  - a. Generate data through a random data generation class.
  - b. Convert the generated data into **DataStream<RowData>**.
  - c. Write data to the Hudi table.
2. Read data from Hudi:
  - a. Read data from the Hudi table.
  - b. Combine the read data into the JSON format and print the data.

#### 2.4.3.10.2 Java Sample Code

#### Description

Call Flink APIs to read data from and write data to Hudi.

#### Sample Code

The following example shows the main logic code of **WriteIntoHudi** and **ReadFromHudi**.

For details about the complete code, see  
**com.huawei.bigdata.flink.examples.WriteIntoHudi** and  
**com.huawei.bigdata.flink.examples.ReadFromHudi**.

- Main logic code of WriteIntoHudi

```

public class WriteIntoHudi {
    public static void main(String[] args) throws Exception {
        System.out.println("use command as: ");
        System.out.println(
            "./bin/flink run -m yarn-cluster --class com.huawei.bigdata.flink.examples.WriteIntoHudi"
            + " /opt/test.jar --hudiTableName hudiSinkTable --hudiPath hdfs://hacluster/tmp/"
            + "flinkHudi/hudiTable");
        System.out.println(
            "*****");
        System.out.println("<hudiTableName> is the hudi table name. (Default value is hudiSinkTable)");
        System.out.println("<hudiPath> Base path for the target hoodie table. (Default value is hdfs://"
            + "hacluster/tmp/flinkHudi/hudiTable)");
        System.out.println(
            "*****");
        System.out.println(
            "*****");

        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        env.setParallelism(1);
        env.getCheckpointConfig().setCheckpointInterval(10000);
        ParameterTool paraTool = ParameterTool.fromArgs(args);
        DataStream<RowData> stringDataStreamSource = env.addSource(new SimpleStringGenerator()

            sb.append("}");
        }
    });
}

```

```
        return sb.toString();
    }
}).print();
env.execute("Hudi_Source");
}
}
```

### 2.4.3.11 Python Development Examples

#### 2.4.3.11.1 Submitting a Regular Job Using Python

##### Description

Assume that you need to submit a Flink task to an MRS cluster. The main language used by the service platform is Python. The following content uses an example Python program to read and write Kafka jobs.

##### Python Sample Code

##### Function

Submit Flink Kafka read and write jobs to Yarn through Python APIs.

##### Sample Code

The main logic code in **pyflink-kafka.py** is provided. Before submitting the code, ensure that **file\_path** is the path where the SQL statement to be executed. You are advised to use a full path.

For details about the complete code, see **pyflink-kafka.py** in **flink-examples/pyflink-example/pyflink-kafka**.

```
import os
import logging
import sys
from pyflink.common import JsonRowDeserializationSchema, JsonRowSerializationSchema
from pyflink.common.typeinfo import Types
from pyflink.datastream.connectors import FlinkKafkaProducer, FlinkKafkaConsumer
from pyflink.datastream import StreamExecutionEnvironment
from pyflink.table import TableEnvironment, EnvironmentSettings
def read_sql(file_path):
    if not os.path.isfile(file_path):
        raise TypeError(file_path + " does not exist")
    all_the_text = open(file_path).read()
    return all_the_text
def exec_sql():
    # Change the SQL path before job submission.
    # file_path = "/opt/client/Flink/flink/insertData2kafka.sql"
    # file_path = os.getcwd() + "/../../../../../yarnship/insertData2kafka.sql"
    # file_path = "/opt/client/Flink/flink/conf/ssl/insertData2kafka.sql"
    file_path = "insertData2kafka.sql"
    sql = read_sql(file_path)
    t_env = TableEnvironment.create(EnvironmentSettings.in_streaming_mode())
    statement_set = t_env.create_statement_set()
    sqlArr = sql.split(";")
    for sqlStr in sqlArr:
        sqlStr = sqlStr.strip()
        if sqlStr.lower().startswith("create"):
            print("-----create-----")
            print(sqlStr)
            t_env.execute_sql(sqlStr)
        if sqlStr.lower().startswith("insert"):
```

```

print("-----insert-----")
print(sqlStr)
statement_set.add_insert_sql(sqlStr)
statement_set.execute()
def read_write_kafka():
    # find kafka connector jars
    env = StreamExecutionEnvironment.get_execution_environment()
    env.set_parallelism(1)
    specific_jars = "file:///opt/client/Flink/flink/lib/flink-connector-kafka-xxx.jar"
    # specific_jars = "file://" + os.getcwd() + "/../../yarnship/flink-connector-kafka-xxx.jar"
    # specific_jars = "file:///opt/client/Flink/flink/conf/ssl/flink-connector-kafka-xxx.jar"
    # the sql connector for kafka is used here as it's a fat jar and could avoid dependency issues
    env.add_jars(specific_jars)
    kafka_properties = {'bootstrap.servers': '192.168.20.162:21005', 'group.id': 'test_group'}
    deserialization_schema = JsonRowDeserializationSchema.builder() \
        .type_info(type_info=Types.ROW([Types.INT(), Types.STRING()])).build()
    kafka_consumer = FlinkKafkaConsumer(
        topics='test_source_topic',
        deserialization_schema=deserialization_schema,
        properties=kafka_properties)
    print("-----read -----")
    ds = env.add_source(kafka_consumer)
    serialization_schema = JsonRowSerializationSchema.builder().with_type_info(
        type_info=Types.ROW([Types.INT(), Types.STRING()])).build()
    kafka_producer = FlinkKafkaProducer(
        topic='test_sink_topic',
        serialization_schema=serialization_schema,
        producer_config=kafka_properties)
    print("-----write-----")
    ds.add_sink(kafka_producer)
    env.execute("pyflink kafka test")
if __name__ == '__main__':
    logging.basicConfig(stream=sys.stdout, level=logging.INFO, format"%(message)s")
    print("-----insert data to kafka-----")
    exec_sql()
    print("-----read_write_kafka-----")
    read_write_kafka()

```

**Table 2-20** Parameters for submitting a regular job using Python

| Parameter         | Description  | Example  |
|-------------------|--|--|
| bootstrap.servers | Service IP address and port number of the Broker instance of Kafka   | 192.168.12.25:21005  |
| specific_jars     | <p>Package path: <i>Client installation directory/Flink/flink/lib/flink-connector-kafka-*.jar</i>. You are advised to use a full path.</p> <p><b>NOTE</b><br/>If a job needs to be submitted as yarn-application, replace the following path. Replace the JAR package version with the actual one.</p> <pre>specific_jars="file://" + os.getcwd() + "/../../yarnship/flink-connector-kafka-xxx-h0.cbu.mrs.xxx.jar"</pre> | specific_jars = file:///Client installation directory/Flink/flink/lib/flink-connector-kafka-xxx-h0.cbu.mrs.xxx.jar |

| Parameter | Description  | Example   |
|-----------|--|---|
| file_path | <p>Path of the <b>insertData2kafka.sql</b> file. You are advised to use a full path. Obtain the package from the secondary development sample code and upload it to the specified directory on the client.</p> <p><b>NOTE</b><br/>If a job needs to be submitted as yarn-application, replace the following path:<br/><code>file_path = os.getcwd() + "/../../../../../yarnship/insertData2kafka.sql"</code></p> | file_path = /Client installation directory/Flink/flink/insertData2kafka.sql |

The following is an example SQL statement:

```
create table kafka_sink_table (
    age int,
    name varchar(10)
) with (
    'connector' = 'kafka',
    'topic' = 'test_source_topic', --Name of the topic written to Kafka. Ensure that the topic name is the same as that in the Python file.
    'properties.bootstrap.servers' = 'IP address of the Kafka broker instance.Kafka port number',
    'properties.group.id' = 'test_group',
    'format' = 'json'
);
create TABLE datagen_source_table (
    age int,
    name varchar(10)
) WITH (
    'connector' = 'datagen',
    'rows-per-second' = '1'
);
INSERT INTO
    kafka_sink_table
SELECT
    *
FROM
    datagen_source_table;
```

## Running the Program

**Step 1** Obtain **pyflink-kafka.py** and **insertData2kafka.sql** from the sample project **flink-examples/pyflink-example/pyflink-kafka**.

**Step 2** Package the prepared Python virtual environment by referring to [Preparing Development and Operating Environment](#) and obtain the **venv.zip** file.

```
zip -q -r venv.zip venv/
```

**Step 3** Log in to the active management node as the **root** user and upload **venv.zip**, **pyflink-kafka.py**, and **insertData2kafka.sql** files obtained in [Step 1](#) and [Step 2](#) to the client environment.

- Per-job: Upload the preceding files to *Client installation directory/Flink/flink*.
- yarn-application: Upload the preceding files and the **flink-connector-kafka-Actual version number.jar** package to *Client installation directory/Flink/flink/yarnship*.

**Step 4** Change the `specific_jars` path in `pyflink-kafka.py`.

- per-job: Change the path to the actual path of the SQL file, for example, `file:///Client installation directory/Flink/flink/lib/flink-connector-kafka-Actual version number.jar`.
  - yarn-application: Change to `file://" + os.getcwd() + "/../../..../yarnship/flink-connector-kafka-Actual version number.jar`.

## **Step 5 Change file\_path in pyflink-kafka.py.**

- per-job: Change the path to the actual path of the SQL file. For example:  
*Client installation directory/Flink/flink/insertData2kafka.sql*
  - yarn-application: Change the path to **os.getcwd () + "/../../../../yarnship/insertData2kafka.sql"**

**Step 6** Run the following command to specify the running environment:

```
export PYFLINK_CLIENT_EXECUTABLE=venv.zip/venv/bin/python3
```

**Step 7** Run the following command to run the program:

- **Per-job:**  
./bin/flink run --detached -t yarn-per-job -Dyarn.application.name=py\_kafka -pyarch venv.zip -pyexec venv.zip/venv/bin/python3 -py pyflink-kafka.py

## Execution result:

- **yarn-application**  
./bin/flink run-application --detached -t yarn-application -Dyarn.application.name=py\_kafka -Dyarn.ship-files=/opt/client/Flink/flink/yarnship/ -pyarch yarnship/venv.zip -pyexec venv.zip/venv/bin/python3 -pyclientexec venv.zip/venv/bin/python3 -pyfs yarnship -pym pyflink-kafka

## Execution result:

-----End

### 2.4.3.11.2 Submitting a SQL Job Using Python

## Description

Assume that you need to submit Flink tasks to the MRS cluster, the main language used by the service platform is Python, and core service processing requires SQL. The following content provides an example to describe how to submit a SQL job using Python.

## Python Sample Code

### Function

Submit a Flink SQL job to Yarn through Python APIs.

### Sample Code

The main logic code in **pyflink-sql.py** is provided. Before submitting the code, ensure that **file\_path** is the path where the SQL statement to be executed. You are advised to use a full path.

For details about the complete code, see **pyflink-sql.py** in **flink-examples/pyflink-example/pyflink-sql**.

```
import logging
import sys
import os
from pyflink.table import (EnvironmentSettings, TableEnvironment)
def read_sql(file_path):
    if not os.path.isfile(file_path):
        raise TypeError(file_path + " does not exist")
    all_the_text = open(file_path).read()
    return all_the_text
def exec_sql():
    # Change the SQL path before job submission.
    file_path = "datagen2kafka.sql"
    sql = read_sql(file_path)
    t_env = TableEnvironment.create(EnvironmentSettings.in_streaming_mode())
    statement_set = t_env.create_statement_set()
    sqlArr = sql.split(";\n")
    for sqlStr in sqlArr:
        sqlStr = sqlStr.strip()
        if sqlStr.lower().startswith("create"):
            print("-----create-----")
            print(sqlStr)
            t_env.execute_sql(sqlStr)
        if sqlStr.lower().startswith("insert"):
            print("-----insert-----")
            print(sqlStr)
            statement_set.add_insert_sql(sqlStr)
    statement_set.execute()
if __name__ == '__main__':
    logging.basicConfig(stream=sys.stdout, level=logging.INFO, format"%(message)s")
    exec_sql()
```

**Table 2-21** Parameters for submitting a SQL job using Python

| Parameter | Description   | Example   |
|-----------|---|---|
| file_path | <p>Path of the <b>datagen2kafka.sql</b> file. You are advised to use a full path. Obtain the package from the secondary development sample code and upload it to the specified directory on the client.</p> <p><b>NOTE</b><br/>If a job needs to be submitted as <b>yarn-application</b>, replace the following path:<br/><code>file_path = os.getcwd() + "/../../../../../yarnship/datagen2kafka.sql"</code></p> | <code>file_path = /Client<br/>installation directory/<br/>Flink/flink/<br/>datagen2kafka.sql</code> |

The following is an example SQL statement:

```
create table kafka_sink (
    uuid varchar(20),
    name varchar(10),
    age int,
    ts timestamp(3),
    p varchar(20)
) with (
    'connector' = 'kafka',
    'topic' = 'input2',
    'properties.bootstrap.servers' = 'IP address of the Kafka broker instance.Kafka port number',
    'properties.group.id' = 'testGroup2',
    'scan.startup.mode' = 'latest-offset',
    'format' = 'json'
);
create TABLE datagen_source (
    uuid varchar(20),
    name varchar(10),
    age int,
    ts timestamp(3),
    p varchar(20)
) WITH (
    'connector' = 'datagen',
    'rows-per-second' = '1'
);
INSERT INTO
    kafka_sink
SELECT
    *
FROM
    datagen_source;
```

## Running the Program

**Step 1** Obtain **pyflink-sql.py** and **datagen2kafka.sql** from the sample project **flink-examples/pyflink-example/pyflink-sql**.

**Step 2** Package the prepared Python virtual environment by referring to [Preparing Development and Operating Environment](#) and obtain the **venv.zip** file.

```
zip -q -r venv.zip venv/
```

**Step 3** Log in to the active management node as the **root** user and upload **venv.zip**, **pyflink-sql.py**, and **datagen2kafka.sql** files obtained in **Step 1** and **Step 2** to the client environment.

- Per-job: Upload the preceding files to *Client installation directory/Flink/flink*.
- yarn-application: Upload the preceding files to *Client installation directory/Flink/flink/yarnship*.
- yarn-session: Upload the preceding files to *Client installation directory/Flink/flink/conf/ssl*.

**Step 4** Change **file\_path** in **pyflink-sql.py**.

- per-job: Change the path to the actual path of the SQL file. For example: *Client installation directory/Flink/flink/datagen2kafka.sql*
- yarn-application: Change the path to **os.getcwd() + "/../../../../../yarnship/datagen2kafka.sql"**
- yarn-session: Change the path to the actual path of the SQL file. For example: *Client installation directory/Flink/flink/conf/ssl//datagen2kafka.sql*

**Step 5** Run the following command to specify the running environment:

```
export PYFLINK_CLIENT_EXECUTABLE=venv.zip/venv/bin/python3
```

**Step 6** Run the following command to run the program:

- Per-job:

```
./bin/flink run --detached -t yarn-per-job -Dyarn.application.name=py_sql -pyarch venv.zip -pyexec venv.zip/venv/bin/python3 -py pyflink-sql.py
```

## Execution result:

```
bin/yarn-session.sh -jm 1024 -tm 4096 -t conf/ssl/ -d
```

Run the following command to submit the job:

```
./bin/flink run --detached -t yarn-session -Dyarn.application.name=py_sql -Dyarn.application.id=application_1685505909197_0285 -pyarch conf/ssl/venv.zip -pyexec conf/ssl/venv.zip/venv/bin/python3 -py conf/ssl/pyflink-sql.py
```

## Execution result:

----End

## 2.4.4 Debugging the Application

### 2.4.4.1 Compiling and Running Applications

#### Scenario

After application code is developed, upload it to the Linux client to run applications. The procedures for running applications developed using Scala or Java are the same on the Flink client.

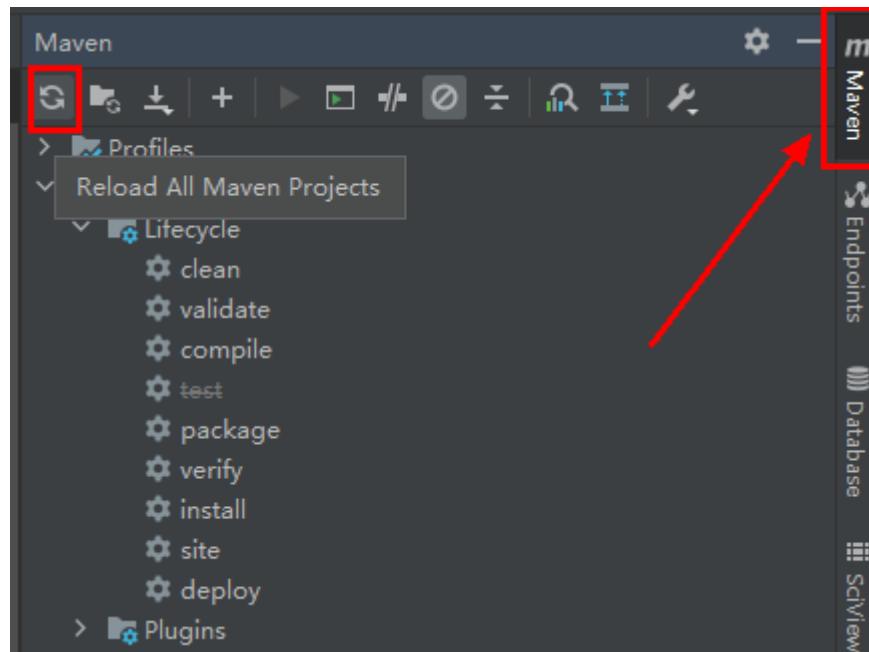

Flink applications of a YARN cluster can run only on Linux.

#### Procedure

- Step 1** In IntelliJ IDEA, click **Reload All Maven Projects** in the Maven window on the right of IDEA to import Maven project dependencies.

**Figure 2-73** Reload projects

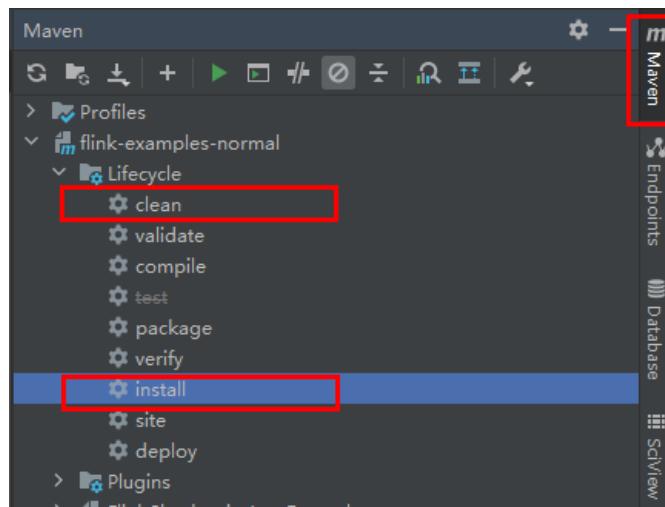

- Step 2** Compile and run the application.

Use either of the following two methods:

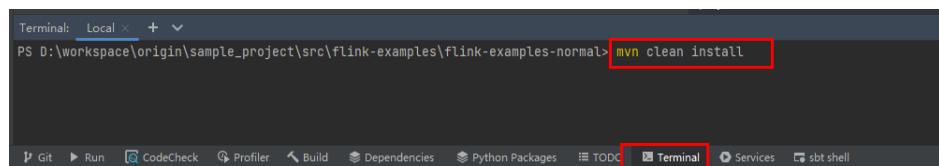

- Method 1:
  - a. Choose **Maven**, locate the target project name, and double-click **clean** under **Lifecycle** to run the **clean** command of Maven.
  - b. Choose **Maven**, locate the target project name, and double-click **install** under **Lifecycle** to run the **install** command of Maven.

Figure 2-74 Maven clean and install

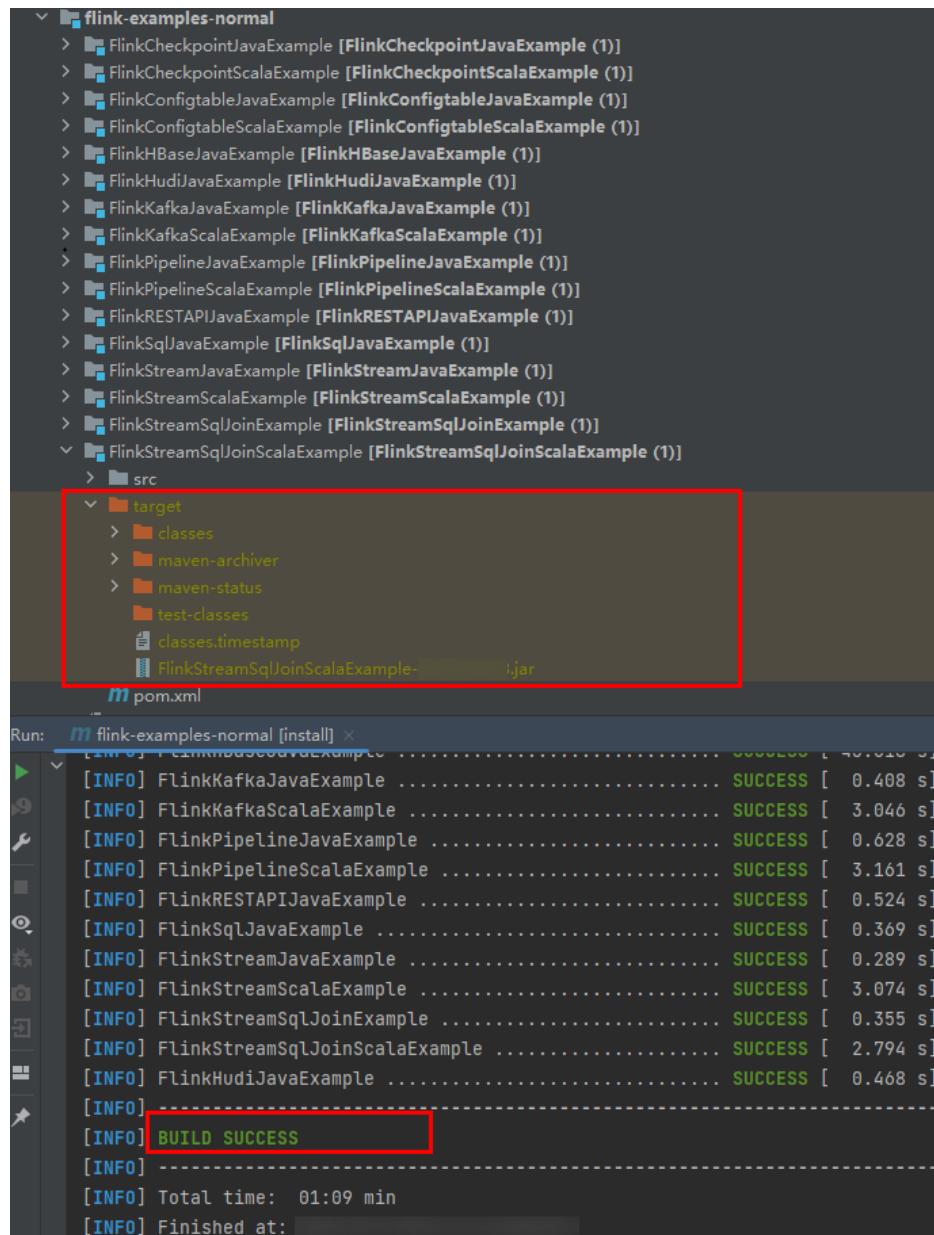

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window of IDEA, and run the **mvn clean install** command to build the file.

Figure 2-75 Entering **mvn clean install** in the IDEA Terminal text box

**Step 3** After the compilation is complete, the message "BUILD SUCCESS" is printed and the **target** directory is generated. Obtain the JAR package in the directory.

Figure 2-76 Compilation completed

**Step 4** Copy the JAR file generated in **Step 3** (for example, **FlinkStreamJavaExample.jar**) to the Flink runtime environment on Linux (that is, the Flink client), for example, **/opt/hadoopclient**. Create the **conf** directory in the directory and copy the required configuration file to **conf**. For details, see [Preparing the Operating Environment](#). Then, run the Flink application.

Start the Flink cluster before running the Flink applications on Linux. Run the yarn session command on the Flink client to start the Flink cluster. An example command is as follows:

```
bin/yarn-session.sh -jm 1024 -tm 4096
```

 NOTE

- Before running the **yarn-session.sh** command, copy the dependency package of the Flink application to the client directory **{client\_install\_home}/Flink/flink/lib**. For details about the dependency packages of the application, see [Reference information about the dependency package for running the sample project](#).
- The dependencies of different sample projects may conflict. When running a new sample project, you need to remove the dependencies copied from the old sample project to the **{client\_install\_home}/Flink/flink/lib** directory on the client.
- Run the **source bingdata\_env** command in the client installation directory before running the **yarn-session.sh** command.
- The **yarn-session.sh** command must be run in the */Flink client installation directory/Flink/flink* directory, for example, **/opt/hadoopclient/Flink/flink**.
- Do not restart the HDFS service or all DataNode instances during Flink job running. Otherwise, the job may fail and some temporary application data cannot be cleared.
- Ensure that the user permissions on the JAR file and configuration file are the same as those on the Flink client. For example, the user is **omm** and the permission is **755**.
- The memory size of TaskManagers specified by using the **-tm** command must be at least 4,096 MB.

• Running the DataStream sample application (in Scala or Java)

Open another window on the terminal. Go to the Flink client directory and invoke the **bin.flink run** script to run code.

– Java

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkStreamJavaExample /opt/hadoopclient/FlinkStreamJavaExample.jar --filePath /opt/log1.txt,/opt/log2.txt --windowTime 2
```

– Scala

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkStreamScalaExample /opt/hadoopclient/FlinkStreamScalaExample.jar --filePath /opt/log1.txt,/opt/log2.txt --windowTime 2
```

 NOTE

The **log1.txt** and **log2.txt** files must be stored on each node where NodeManager instances are deployed, and the permission is **755**.

**Table 2-22 Parameters**

| Parameter     | Description   |
|---------------|---|
| <filePath>    | File path in the local file system. The <b>/opt/log1.txt</b> and <b>/opt/log2.txt</b> files must be stored on every node. The default value can be retained or changed. |
| <>windowTime> | Duration of a time window, in minutes. The default value can be retained or changed.  |

- Running the sample application for producing and consuming data in Kafka (in Java or Scala)

Command for starting the application to produce data

```
bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka /opt/hadoopclient/FlinkKafkaJavaExample.jar <topic> <bootstrap.servers> [security.protocol] [sasl.kerberos.service.name] [ssl.truststore.location] [ssl.truststore.password]
```

**Command for starting the application to consume data**

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/  
FlinkKafkaJavaExample.jar <topic> <bootstrap.servers> [security.protocol] [sasl.kerberos.service.name]  
[ssl.truststore.location] [ssl.truststore.password]
```

**Table 2-23 Parameters**

| Parameter         | Description   | Mandatory  |
|-------------------|---|--|
| topic             | Kafka topic name  | Yes  |
| bootstrap.server  | List of IP addresses or ports of broker clusters  | Yes  |
| security.protocol | The parameter can be set to <b>PLAINTEXT</b> (optional), <b>SASL_PLAINTEXT</b> , <b>SSL</b> , or <b>SASL_SSL</b> , corresponding to port <b>21005</b> , <b>21007</b> , <b>21008</b> , or <b>21009</b> of the FusionInsight Kafka cluster, respectively.<br>- If SASL is configured, <b>sasl.kerberos.service.name</b> must be set to <b>kafka</b> and the configuration items related to <b>security.kerberos.login</b> in <b>conf/flink-conf.yaml</b> must be configured.<br>- If SSL is configured, <b>ssl.truststore.location</b> (path of <b>truststore</b> ) and <b>ssl.truststore.password</b> (password of <b>truststore</b> ) must be configured. | No<br><b>NOTE</b><br>- If this parameter is not configured, Kafka is in non-security mode.<br>- If SSL needs to be configured, find more information about how to generate the <b>truststore.jks</b> file in <b>More Information &gt; External Interfaces &gt; SSL Encryption Function Used by a Client of Kafka Development Guide</b> . |

The following commands use ReadFromKafka as an example and the cluster domain name is **HADOOP.COM**:

- **Command 1:**  
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/  
FlinkKafkaJavaExample.jar --topic topic1 --bootstrap.servers 10.96.101.32:21005
- **Command 2:**  
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/  
FlinkKafkaJavaExample.jar --topic topic1 --bootstrap.servers 10.96.101.32:21005 --

- ```
security.protocol PLAINTEXT --sasl.kerberos.service.name kafka --kerberos.domain.name
hadoop.hadoop.com
```
- Command 3:  

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/
FlinkKafkaJavaExample.jar --topic topic1 --bootstrap.servers 10.96.101.32:21008 --
security.protocol SSL --ssl.truststore.location /home/truststore.jks --ssl.truststore.password xxx
```
- Command 4:  

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/
FlinkKafkaJavaExample.jar --topic topic1 --bootstrap.servers 10.96.101.32:21005 --
security.protocol PLAINTEXT --sasl.kerberos.service.name kafka --ssl.truststore.location config/
truststore.jks --ssl.truststore.password xxx --kerberos.domain.name hadoop.hadoop.com
```
- Running the sample application of the asynchronous checkpoint mechanism (in Scala or Java)  

To diversify sample code, the processing time is used as a timestamp for data stream in Java, and the event time is used as a timestamp for data stream in Scala. The command reference is as follows:

Saving checkpoint snapshot information to HDFS

  - Java  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkProcessingTimeAPIMain /opt/
hadoopclient/FlinkCheckpointJavaExample.jar --chkPath hdfs://hacluster/flink/checkpoint/
```
  - Scala  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkEventTimeAPIChkMain /opt/
hadoopclient/FlinkCheckpointScalaExample.jar --chkPath hdfs://hacluster/flink/checkpoint/
```

 NOTE

  - Checkpoint source file path: **flink/checkpoint/fd5f5b3d08628d83038a30302b611/chk-X/4f854bf4-ea54-4595-a9d9-9b9080779ffe**  
**flink/checkpoint**: specified root directory  
**fd5f5b3d08628d83038a30302b611**: level-2 directory named after jobID  
**chk-X**: "X" indicates the checkpoint number, which is the level-3 directory  
**4f854bf4-ea54-4595-a9d9-9b9080779ffe**: a checkpoint source file
  - If Flink is in cluster mode, checkpoints store the file in HDFS. A local path can be used only when Flink is in local mode, facilitating commissioning.- Running the Pipeline sample application
  - Java
    - i. Start the publisher job.  

```
bin/flink run -p 2 --class com.huawei.bigdata.flink.examples.TestPipelineNettySink /opt/
hadoopclient/FlinkPipelineJavaExample.jar
```
    - ii. Start the subscriber Job1.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.TestPipelineNettySource1 /opt/
hadoopclient/FlinkPipelineJavaExample.jar
```
    - iii. Start the subscriber Job2.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.TestPipelineNettySource2 /opt/
hadoopclient/FlinkPipelineJavaExample.jar
```
  - Scala
    - i. Start the publisher job.  

```
bin/flink run -p 2 --class com.huawei.bigdata.flink.examples.TestPipeline_NettySink /opt/
hadoopclient/FlinkPipelineScalaExample.jar
```
    - ii. Start the subscriber Job1.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.TestPipeline_NettySource1 /opt/
hadoopclient/FlinkPipelineScalaExample.jar
```

- iii. Start the subscriber Job2.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.TestPipeline_NettySource2 /opt/hadoopclient/FlinkPipelineScalaExample.jar
```
- Running the sample application for configuring JOIN between tables and streams (for example, FlinkConfigtableJavaExample and FlinkConfigtableScalaExample)

The execution modes of Java are as follows:

- yarn-session mode

- i. Import **configtable.csv** to the Redis cluster.  

```
java -cp /opt/hadoopclient/Flink/flink/lib/*:/opt/hadoopclient/FlinkConfigtableJavaExample.jar com.huawei.bigdata.flink.examples.RedisDataImport --configPath config/import.properties
```

- ii. Start the Flink cluster.

```
bin/yarn-session.sh -t config -jm 1024 -tm 4096
```

- iii. Stream data reads personal information from Redis using netizen names as keywords, joins the information, and generates the output.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkConfigtableJavaExample /opt/hadoopclient/FlinkConfigtableJavaExample.jar --dataPath config/data.txt
```

- yarn-cluster mode

- i. Import **configtable.csv** to the Redis cluster.

```
java -cp /opt/hadoopclient/Flink/flink/lib/*:/opt/hadoopclient/FlinkConfigtableJavaExample.jar com.huawei.bigdata.flink.examples.RedisDataImport --configPath config/import.properties
```

- ii. Start the Flink cluster. Stream data reads personal information from Redis using netizen names as keywords, joins the information, and generates the output.

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkConfigtableJavaExample -m yarn-cluster -yt config -yjm 1024 -ytm 4096 /opt/hadoopclient/FlinkConfigtableJavaExample.jar --dataPath config/data.txt
```

The execution modes of Scala are as follows:

- yarn-session mode

- i. Import **configtable.csv** to the Redis cluster.

```
java -cp /opt/hadoopclient/Flink/flink/lib/*:/opt/hadoopclient/FlinkConfigtableScalaExample.jar com.huawei.bigdata.flink.examples.RedisDataImport --configPath config/import.properties
```

- ii. Start the Flink cluster.

```
bin/yarn-session.sh -t config -jm 1024 -tm 4096
```

- iii. Stream data reads personal information from Redis using netizen names as keywords, joins the information, and generates the output.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkConfigtableScalaExample /opt/hadoopclient/FlinkConfigtableScalaExample.jar --dataPath config/data.txt
```

- yarn-cluster mode

- i. Import **configtable.csv** to the Redis cluster.

```
java -cp /opt/hadoopclient/Flink/flink/lib/*:/opt/hadoopclient/FlinkConfigtableScalaExample.jar com.huawei.bigdata.flink.examples.RedisDataImport --configPath config/import.properties
```

- ii. Start the Flink cluster. Stream data reads personal information from Redis using netizen names as keywords, joins the information, and generates the output.

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkConfigtableScalaExample -m yarn-cluster -yt config -yjm 1024 -ytm 4096 /opt/hadoopclient/FlinkConfigtableScalaExample.jar --dataPath config/data.txt
```

- Running the Stream SQL Join sample application

- Java

- i. Start the application to generate data for Kafka. For details about Kafka configuration, see [Running the sample application for producing and consuming data in Kafka \(in Java or Scala\)](#).

```
bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka /opt/hadoopclient/FlinkStreamSqlJoinExample.jar --topic topic-test --bootstrap.servers xxx.xxx.xxx.21005
```

- ii. Run the **netcat** command on any node in the cluster to wait for an application connection.

```
netcat -l -p 9000
```

 NOTE

If "command not found" is displayed, install NetCat and run the command again.

- iii. Start the application to receive socket data and perform a joint query.

```
bin/flink run --class com.huawei.bigdata.flink.examples.SqlJoinWithSocket /opt/hadoopclient/FlinkStreamSqlJoinExample.jar --topic topic-test --bootstrap.servers xxx.xxx.xxx.21005 --hostname xxx.xxx.xxx.21005 --port 9000
```

- Scala

- i. Start the application to produce data in Kafka. For details about how to configure Kafka, see [Running the sample application for producing and consuming data in Kafka \(in Java or Scala\)](#).

```
bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka /opt/hadoopclient/FlinkStreamSqlJoinScalaExample.jar --topic topic-test --bootstrap.servers xxx.xxx.xxx.21005
```

- ii. Run the **netcat** command on any node in the cluster to wait for an application connection.

```
netcat -l -p 9000
```

- iii. Start the application to receive socket data and perform a joint query.

```
bin/flink run --class com.huawei.bigdata.flink.examples.SqlJoinWithSocket /opt/hadoopclient/FlinkStreamSqlJoinScalaExample.jar --topic topic-test --bootstrap.servers xxx.xxx.xxx.21005 --hostname xxx.xxx.xxx.21005 --port 9000
```

● Running the Flink HBase sample application

- yarn-session mode

- i. Start the Flink cluster.

```
./bin/yarn-session.sh -jm 1024 -tm 4096
```

- ii. Run the Flink application and enter parameters.

```
bin/flink run --class com.huawei.bigdata.flink.examples.WriteHBase /opt/client1/Flink/flink/FlinkHBaseJavaExample-xxx.jar --tableName xxx --confDir xxx
```

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadHBase /opt/client1/Flink/flink/FlinkHBaseJavaExample-xxx.jar --tableName xxx --confDir xxx
```

- yarn-cluster mode

```
bin/flink run -m yarn-cluster --class com.huawei.bigdata.flink.examples.WriteHBase /opt/client1/Flink/flink/FlinkHBaseJavaExample-xxx.jar --tableName xxx --confDir xxx
```

```
bin/flink run -m yarn-cluster --class com.huawei.bigdata.flink.examples.ReadHBase /opt/client1/Flink/flink/FlinkHBaseJavaExample-xxx.jar --tableName xxx --confDir xxx
```

● Running the Flink Hudi sample application

- yarn-session mode

- i. Start the Flink cluster.

```
./bin/yarn-session.sh -jm 1024 -tm 4096
```

ii. Run the Flink application and enter parameters.

```
./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoHudi /opt/test.jar --  
hudiTableName hudiSinkTable --hudiPath hdfs://hacluster/tmp/flinkHudi/hudiTable
```

```
./bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromHudi /opt/test.jar --  
hudiTableName hudiSourceTable --hudiPath hdfs://hacluster/tmp/flinkHudi/hudiTable --  
read.start-commit xxx
```

- yarn-cluster mode

```
./bin/flink run -m yarn-cluster --class com.huawei.bigdata.flink.examples.WriteIntoHudi /opt/  
test.jar --hudiTableName hudiSinkTable --hudiPath hdfs://hacluster/tmp/flinkHudi/hudiTable
```

```
./bin/flink run -m yarn-cluster --class com.huawei.bigdata.flink.examples.ReadFromHudi /opt/  
test.jar --hudiTableName hudiSourceTable --hudiPath hdfs://hacluster/tmp/flinkHudi/hudiTable  
--read.start-commit xxx
```

- Run the REST APIs to create a tenant sample application. The TestCreateTenants application is used as an example.

- yarn-session mode

i. Start the Flink cluster.

```
./bin/yarn-session.sh -jm 1024 -tm 4096
```

ii. Run the Flink application and enter parameters.

```
./bin/flink run --class com.huawei.bigdata.flink.examples.TestCreateTenants /opt/  
hadoopclient/FlinkRESTAPIJavaExample-xxx.jar --hostName xx-xx-xx-xx
```

- yarn-cluster mode

```
./bin/flink run -m yarn-cluster -yjm 1024 -ytm 4096 --class  
com.huawei.bigdata.flink.examples.TestCreateTenants /opt/hadoopclient/  
FlinkRESTAPIJavaExample-xxx.jar --hostName xx-xx-xx-xx
```

- Run a SQL task to submit Flink JAR jobs.

- yarn-session mode

i. Start the Flink cluster.

```
./bin/yarn-session.sh -jm 1024 -tm 4096
```

ii. Run the Flink application and enter parameters.

```
bin/flink run -d --class com.huawei.mrs.FlinkSQLExecutor /opt/flink-sql-xxx.jar --sql ./sql/  
datagen2kafka.sql
```

- yarn-cluster mode

```
bin/flink run -m yarn-cluster -yjm 1024 -ytm 4096 -d --class  
com.huawei.mrs.FlinkSQLExecutor /opt/flink-sql-xxx.jar --sql ./sql/datagen2kafka.sql
```

----End

#### 2.4.4.2 Viewing the Debugging Result

##### Scenarios

After a Flink application completes running, you can view the running result, or use Apache Flink Dashboard to view application running status.

##### Procedure

- **View the running result of the Flink application.**

If you want to check the execution result, view the Stdout log of Task Manager on the Apache Flink Dashboard.

If the execution result is exported to a file or a location specified by Flink, view the result from the exported file or the location. The checkpoint, pipeline, and join between configuration tables and streams are used as examples.

- View checkpoint results and files

- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Checkpoints** to view the submitted jobs as shown in [Figure 2-77](#). Choose **Task Managers > Stdout** to view the running result, as shown in [Figure 2-78](#).

**Figure 2-77** Submitted jobs

```

- Run the `hdfs dfs -ls hdfs://hacluster/flink/checkpoint/` command to view the checkpoint snapshot information in the HDFS.

- View pipeline results

- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Running Jobs** to view the running jobs as shown in [Figure 2-79](#). Choose **Task Managers**. You can see two tasks, as shown in [Figure 2-80](#). Click any task, choose **Stdout** to view the output of the task, as shown in [Figure 2-81](#) and [Figure 2-82](#).

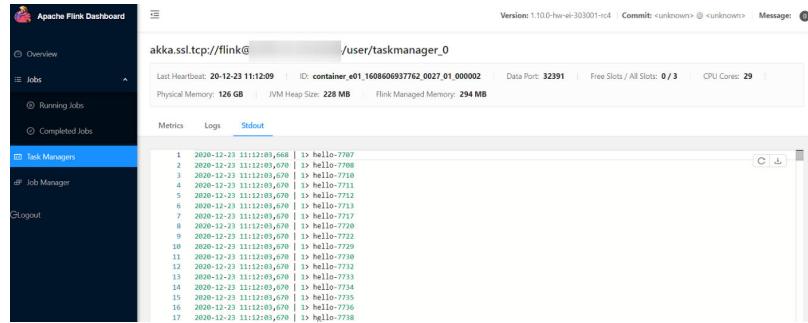

**Figure 2-79** Running jobs

Job Name	Start Time	Duration	End Time	Tasks	Status
Flink Streaming Job	2020-12-23 11:07:44	0m 0s	-	2	RUNNING
Flink Streaming Job	2020-12-23 11:07:58	4m 24s	-	2	RUNNING
Flink Streaming Job	2020-12-23 11:06:35	5m 8s	-	4	RUNNING

com.flink.e01.160.80.69.37.7742.0021.01.000002	32391	20-12-23 11:11:49	3	0	29	124 GB	238 MB	294 MB

**Figure 2-81** Output of task1

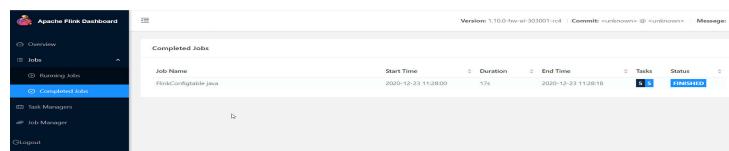

**Figure 2-82** Output of task2

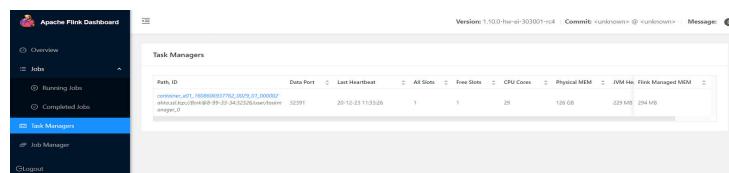

- View the JOIN result of configuration table and streams

- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Completed Jobs** to view the completed job as shown in [Figure 2-83](#). Choose **Task Managers**, you can see submitted task, as shown in [Figure 2-84](#). Choose **Stdout** to view the running result, as shown in [Figure 2-85](#).

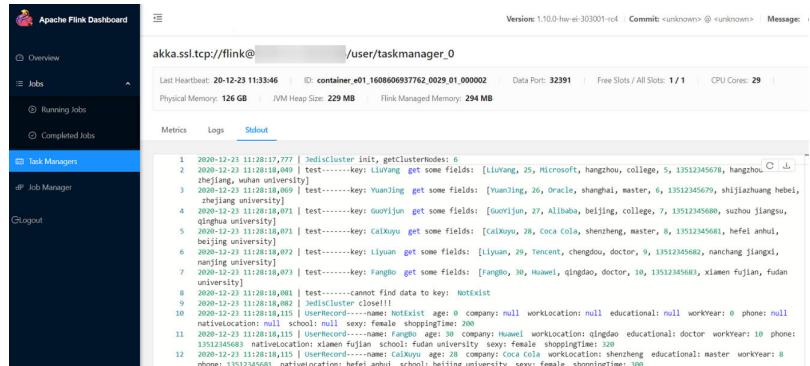

**Figure 2-83** Completed job

## **Figure 2-84 Submitted task**

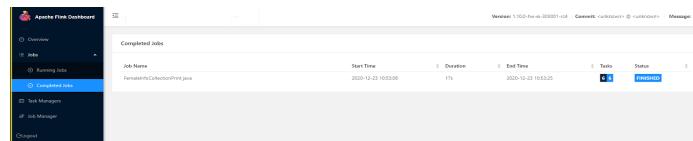

**Figure 2-85** Execution result

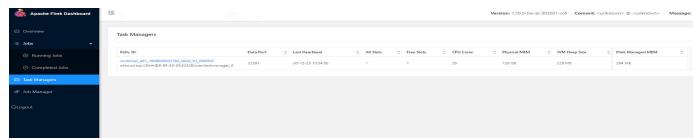

- View the result of DataStream

- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Completed Jobs** to view the completed job as shown in [Figure 2-86](#). Choose **Task Managers**, you can see submitted task, as shown in [Figure 2-87](#). Choose **Stdout** to view the running result, as shown in [Figure 2-88](#).

**Figure 2-86** Completed job

## **Figure 2-87 Submitted task**

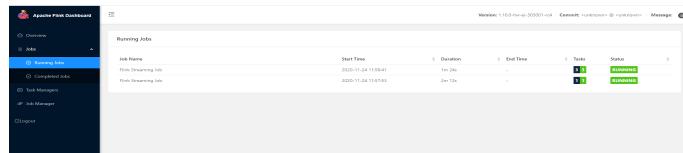

**Figure 2-88** Execution result

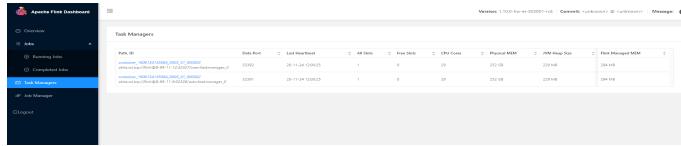

- View the result of stream sql join

- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Running Jobs** to view the running jobs as shown in [Figure 2-89](#). Choose **Task Managers**, you can see submitted task, as shown in [Figure 2-90](#). Choose **Stdout** to view the running result, as shown in [Figure 2-91](#).

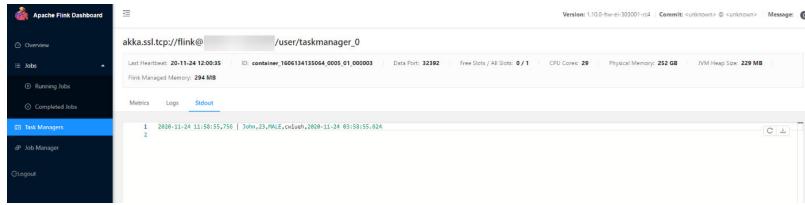

**Figure 2-89** Running jobs

**Figure 2-90 Submitted task**

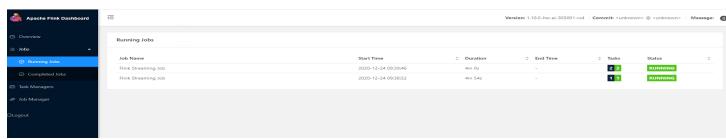

**Figure 2-91 Execution result**

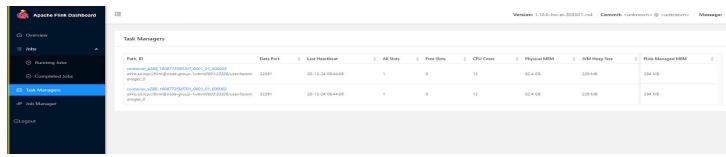

- **View the result of produce and consume data in Kafka**
  - The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Running Jobs** to view the running jobs as shown in **Figure 2-92**. Choose **Task Managers**, you can see submitted task, as shown in **Figure 2-93**. Choose **Stdout** to view the running result, as shown in **Figure 2-94**.

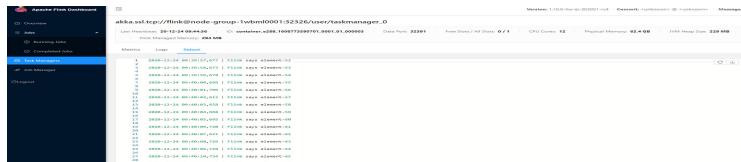

**Figure 2-92 Running jobs**

**Figure 2-93 Submitted task**

**Figure 2-94 Execution result**

- **Use Apache Flink Dashboard to view the running status of the Flink application.**

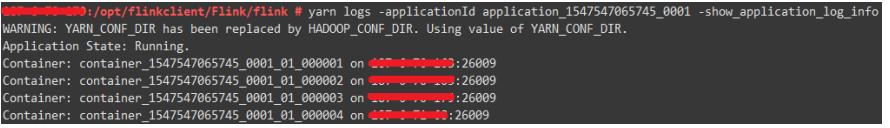

The Apache Flink Dashboard mainly includes Overview, Running Jobs, Completed Jobs, Task Managers, Job Manager and Logout and so on.

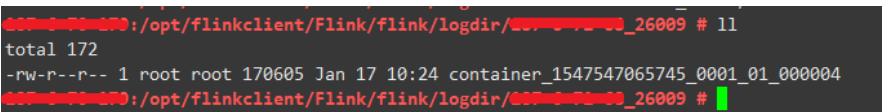

On In the YARN web UI, find the desired Flink application. Click the **ApplicationMaster** at the last column of the application to switch to the Apache Flink Dashboard.

View the print results of the program execution: find the corresponding **Task Manager** to see the corresponding **Stdout** tag log information.

- **View Flink logs.**

Three methods can be used to obtain Flink logs:

- Log in to the Apache Flink Dashboard and view logs of TaskManagers and JobManager.
- Log in to the YARN web UI to view logs about JobManager and GC. On the YARN web UI wind, find the desired Flink application. Click the **ID** of the application. On the switched page, click **Logs** in the Logs column.
- On the Yarn client, obtain or view logs of Task Managers and Job Manager.
  - i. Download and install the Yarn client, for example, in the /opt/hadoopclient directory.
  - ii. Use PuTTY to log in to the node where the client is installed as the client installation user.
  - iii. Run the following command to switch to the client installation directory:  
**cd /opt/hadoopclient**
  - iv. Run the following command to configure environment variables:  
**source bigdata\_env**
  - v. If the cluster employs the security mode, run the following command to authenticate the user. If the normal mode is used, skip this step.  
**kinit component service user**
  - vi. Run the following commands to obtain container information of the Flink cluster:  
**yarn logs -applicationId application\_\* -show\_application\_log\_info**  

```
[root@node01:~/opt/flinkclient/Flink/flink # yarn logs -applicationId application_1547547065745_0001 -show_application_log_info
WARNING: YARN_CONF_DIR has been replaced by HADOOP_CONF_DIR. Using value of YARN_CONF_DIR.
Application State: Running.
Container: container_1547547065745_0001_01_000001 on [REDACTED]:26009
Container: container_1547547065745_0001_01_000002 on [REDACTED]:26009
Container: container_1547547065745_0001_01_000003 on [REDACTED]:26009
Container: container_1547547065745_0001_01_000004 on [REDACTED]:26009
```
  - vii. Run the following command to obtain run logs of the specified container. Generally, container\_\*\_000001 is the container where the Job Manager is running.  
**yarn logs -applicationId application\_\* --containerId container\_1547547065745\_0001\_01\_000004 -out logdir**  

```
[root@node01:~/opt/flinkclient/Flink/flink/logdir/container_1547547065745_0001_01_000004_26009 # ll
total 172
-rw-r--r-- 1 root root 170605 Jan 17 10:24 container_1547547065745_0001_01_000004
[root@node01:~/opt/flinkclient/Flink/flink/logdir/container_1547547065745_0001_01_000004_26009 #
```

After the command is executed, container run logs, including run logs of the Task Manager and Job Manager and GC logs, are downloaded to the local host.

- viii. You can also run a command to obtain the log with the specified name:

The following command is used to obtain the container log list.

**yarn logs -applicationId application\_\* -show\_container\_log\_info --containerId container\_1547547065745\_0001\_01\_000004**

LogFile	LogLength	LastModificationTime	LogAggregationType
container-localizer-syslog	184	Wed Jan 16 17:49:27 +0800 2019	LOCAL
taskmanager.log	131430	Wed Jan 16 17:49:35 +0800 2019	LOCAL
gc.log.0.current	17952	Thu Jan 17 10:22:26 +0800 2019	LOCAL
taskmanager.out	0	Wed Jan 16 17:49:31 +0800 2019	LOCAL
launch_container.sh	12232	Wed Jan 16 17:49:31 +0800 2019	LOCAL
directory.info	3661	Wed Jan 16 17:49:31 +0800 2019	LOCAL
taskmanager.err	1060	Wed Jan 16 17:49:31 +0800 2019	LOCAL
prelaunch.out	160	Wed Jan 16 17:49:31 +0800 2019	LOCAL
prelaunch.err	0	Wed Jan 16 17:49:31 +0800 2019	LOCAL

Download **taskmanager.log** to the local host.

```
yarn logs -applicationId application_* --containerId
container_1547547065745_0001_01_000004 -log_files
taskmanager.log -out localpath
```

#### 2.4.4.3 Running a Spring Boot Sample Project and Viewing Results

##### Running the Spring Boot Sample in CLI

**Step 1** Use Maven to run **install** on the IDEA.

If "BUILD SUCCESS" is displayed, the compilation is successful. A JAR file containing the **flink-dws-sink-example-1.0.0-SNAPSHOT** field is generated in the **target** directory of the sample project.

```
[INFO] Dependency-reduced POM written at: D:\code\spring\sample_project\src\springboot\flink-examples\flink-dws-sink-example\dependency-reduced-pom.xml
[INFO]
[INFO] --- maven-install-plugin:2.5.2:install (default-install) @ flink-dws-sink-example ---
[INFO] Installing D:\code\spring\sample_project\src\springboot\flink-examples\flink-dws-sink-example\target\flink-dws-sink-example.jar to D:\soft\maven\local\org\springframework\boot\flink-dws-sink-example\flink-dws-sink-example-1.0.0-SNAPSHOT.jar
[INFO] Installing D:\code\spring\sample_project\src\springboot\flink-examples\flink-dws-sink-example\dependency-reduced-pom.xml to D:\soft\maven\local\org\springframework\boot\flink-dws-sink-example\dependency-reduced-pom.xml
[INFO]
[INFO] BUILD SUCCESS
[INFO]
[INFO] -----
[INFO] Total time: 15.581 s
[INFO] Finished at: 2023-08-18T11:39:01+08:00
[INFO]
[INFO] Process finished with exit code 0
```

**Step 2** On Linux, go to the client installation directory, for example, **/opt/client/Flink/flink/conf**, and save the JAR packages whose names contain **flink-dws-sink-example-1.0.0-SNAPSHOT** in the **target** directory generated in to this directory.

The Flink client running the Spring Boot sample must contain only the Flink service.

**Step 3** Run the following command to create a Yarn session:

```
yarn-session.sh -t ssl/ -nm "session-spring11" -d
```

```
[root@host1 conf]#
[root@host1 conf]#
[root@host1 conf]# yarn-session.sh -t ssl/ -nm "session-spring11" -d
SLF4J: Class path contains multiple SLF4J bindings.
SLF4J: Found binding in [jar:file:/opt/client123/Flink/flink/lib/log4j-slf4j-impl-2.17.1.jar!/org/slf4j/impl/StaticLoggerBinder.class]

- Run the Elasticsearch sample

**flink run flink-es-sink-example.jar**

-----End

## 2.4.5 More Information

### 2.4.5.1 Introduction to Common APIs

#### **2.4.5.1.1 Java**

To avoid API compatibility or reliability issues after updates to the open-source Flink, recommended that APIs of the matching version are recommended. For details about APIs, see MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1).

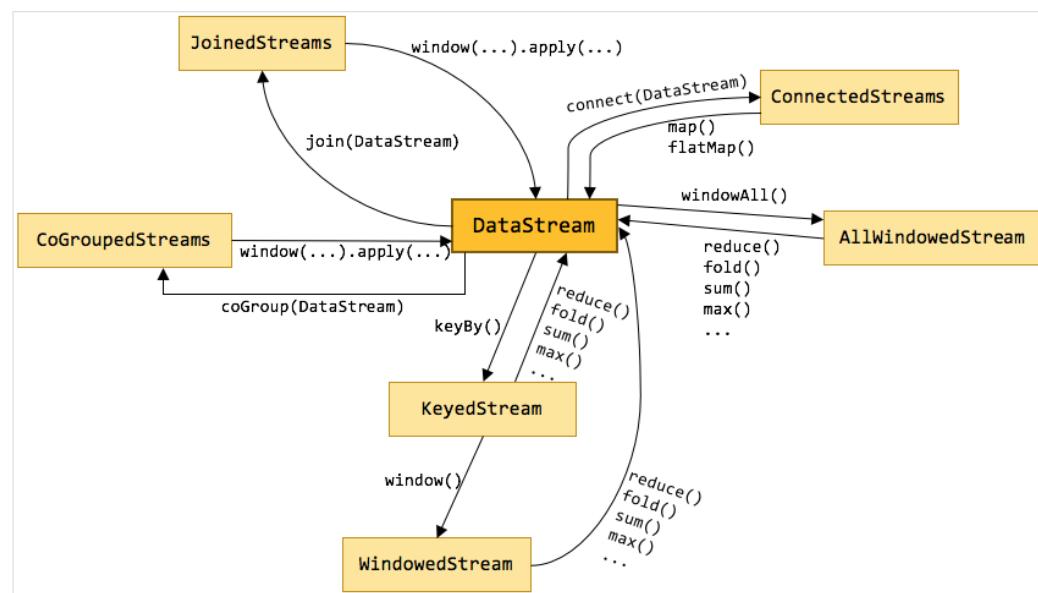

## Common APIs of Flink

Flink mainly uses the following APIs:

- StreamExecutionEnvironment: provides the execution environment, which is the basis of Flink stream processing.
  - DataStream: represents streaming data. DataStream can be regarded as unmodifiable collection that contains duplicate data. The number of elements in DataStream are unlimited.
  - KeyedStream: generates the stream by performing keyBy grouping operations on DataStream. Data is grouped based on the specified key value.
  - WindowedStream: generates the stream by performing the window function on KeyedStream, sets the window type, and defines window triggering conditions.

- AllWindowedStream: generates streams by performing the window function on DataStream, sets the window type, defines window triggering conditions, and performs operations on the window data.
- ConnectedStreams: generates streams by connecting the two DataStreams and retaining the original data type, and performs the map or flatMap operation.
- JoinedStreams: performs equijoin (which is performed when two values are equal, for example, a.id = b.id) operation to data in the window. The join operation is a special scenario of coGroup operation.
- CoGroupedStreams: performs the coGroup operation on data in the window. CoGroupedStreams can perform various types of join operations.

**Figure 2-95** Conversion of Flink stream types

## Data Stream Source

**Table 2-24** APIs about data stream source

API	Description
<pre>public final &lt;OUT&gt; DataStreamSource&lt;OUT&gt; fromElements(OUT... data)</pre>	Obtain user-defined data of multiple elements as the data stream source. <ul style="list-style-type: none"> <li>• <b>type</b> indicates the data type of an element.</li> <li>• <b>data</b> indicates the data of multiple elements.</li> </ul>
<pre>public final &lt;OUT&gt; DataStreamSource&lt;OUT&gt; fromElements(Class&lt;OUT&gt; type, OUT... data)</pre>	

API	Description
public <OUT> DataStreamSource<OUT> fromCollection(Collection<OUT> data)	Obtain the user-defined data collection as the data stream source. <ul style="list-style-type: none"> <li>• <b>type</b> indicates the data type of elements in the collection.</li> </ul>
public <OUT> DataStreamSource<OUT> fromCollection(Collection<OUT> data, TypeInformation<OUT> typeInfo)	<ul style="list-style-type: none"> <li>• <b>typeInfo</b> indicates the type information obtained based on the element data type in the collection.</li> </ul>
public <OUT> DataStreamSource<OUT> fromCollection(Iterator<OUT> data, Class<OUT> type)	<ul style="list-style-type: none"> <li>• <b>data</b> indicates the iterator.</li> </ul>
public <OUT> DataStreamSource<OUT> fromCollection(Iterator<OUT> data, TypeInformation<OUT> typeInfo)	
public <OUT> DataStreamSource<OUT> fromParallelCollection(SplittableIterator<OUT> iterator, Class<OUT> type)	Obtain the user-defined data collection as parallel data stream source. <ul style="list-style-type: none"> <li>• <b>type</b> indicates the data type of elements in the collection.</li> </ul>
public <OUT> DataStreamSource<OUT> fromParallelCollection(SplittableIterator<OUT> iterator, TypeInformation<OUT> typeInfo)	<ul style="list-style-type: none"> <li>• <b>typeInfo</b> indicates the type information obtained based on the element data type in the collection.</li> </ul>
private <OUT> DataStreamSource<OUT> fromParallelCollection(SplittableIterator<OUT> iterator, TypeInformation<OUT> typeInfo, String operatorName)	<ul style="list-style-type: none"> <li>• <b>iterator</b> indicates the iterator that can be divided into multiple partitions.</li> </ul>
public DataStreamSource<Long> generate Sequence(long from, long to)	Obtain a sequence of user-defined data as the data stream source. <ul style="list-style-type: none"> <li>• <b>from</b> indicates the starting point of numbers.</li> <li>• <b>to</b> indicates the end point of numbers.</li> </ul>
public DataStreamSource<String> readTextFile(String filePath)	Obtain the user-defined text file from a specific path as the data stream source.
public DataStreamSource<String> readTextFile(String filePath, String charsetName)	<ul style="list-style-type: none"> <li>• <b>filePath</b> indicates the path of the text file.</li> <li>• <b>charsetName</b> indicates the encoding format.</li> </ul>

API	Description
public <OUT> DataStreamSource<OUT> readFile(FileInputformat<OUT> inputformat, String filePath)	Obtain the user-defined file from a specific path as the data stream source. <ul style="list-style-type: none"><li>• <b>filePath</b> indicates the file path.</li></ul>
public <OUT> DataStreamSource<OUT> readFile(FileInputformat<OUT> inputformat, String filePath, FileProcessingMode watchType, long interval)	<ul style="list-style-type: none"><li>• <b>inputformat</b> indicates the format of the file.</li><li>• <b>watchType</b> indicates the file processing mode, which can be <b>PROCESS_ONCE</b> or <b>PROCESS_CONTINUOUSLY</b>.</li><li>• <b>interval</b> indicates the interval for processing directories or files.</li></ul>
public <OUT> DataStreamSource<OUT> readFile(FileInputformat<OUT> inputformat, String filePath, FileProcessingMode watchType, long interval, TypeInformation<OUT> typeInformation)	
public DataStreamSource<String> socketTextStream(String hostname, int port, String delimiter, long maxRetry)	Obtain user-defined socket data as the data stream source. <ul style="list-style-type: none"><li>• <b>hostname</b> indicates the host name of the socket server.</li></ul>
public DataStreamSource<String> socketTextStream(String hostname, int port, String delimiter)	<ul style="list-style-type: none"><li>• <b>port</b> indicates the listening port of the server.</li><li>• <b>delimiter</b> indicates the separator of messages.</li></ul>
public DataStreamSource<String> socketTextStream(String hostname, int port)	<ul style="list-style-type: none"><li>• <b>maxRetry</b> refers to the maximum retry times that can be triggered by abnormal connections.</li></ul>
public <OUT> DataStreamSource<OUT> addSource(SourceFunction<OUT> function)	Customize the <b>SourceFunction</b> and <b>addSource</b> methods to add data sources such as Kafka. The implementation method is the run method of SourceFunction. <ul style="list-style-type: none"><li>• <b>function</b> indicates the user-defined <b>SourceFunction</b> function.</li></ul>
public <OUT> DataStreamSource<OUT> addSource(SourceFunction<OUT> function, String sourceName)	<ul style="list-style-type: none"><li>• <b>sourceName</b> indicates the name of data source.</li></ul>
public <OUT> DataStreamSource<OUT> addSource(SourceFunction<OUT> function, TypeInformation<OUT> typeInfo)	<ul style="list-style-type: none"><li>• <b>typeInfo</b> indicates the type information obtained based on the element data type.</li></ul>

API	Description
<pre>public &lt;OUT&gt; DataStreamSource&lt;OUT&gt; addSource(SourceFunction&lt;OUT&gt; function, String sourceName, TypeInformation&lt;OUT&gt; typeInfo)</pre>	

## Data Output

Table 2-25 APIs about data output

API	Description
<code>public DataStreamSink&lt;T&gt; print()</code>	Print data as the standard output stream.
<code>public DataStreamSink&lt;T&gt; printToErr()</code>	Print data as the standard error output stream.
<code>public DataStreamSink&lt;T&gt; writeAsText(String path)</code>	Write data to a specific text file. <ul style="list-style-type: none"> <li>• <b>path</b> indicates the path of the text file.</li> </ul>
<code>public DataStreamSink&lt;T&gt; writeAsText(String path, WriteMode writeMode)</code>	<ul style="list-style-type: none"> <li>• <b>writeMode</b> indicates the writing mode, which can be <b>OVERWRITE</b> or <b>NO_OVERWRITE</b>.</li> </ul>
<code>public DataStreamSink&lt;T&gt; writeAsCsv(String path)</code>	Writhe data to a specific .csv file. <ul style="list-style-type: none"> <li>• <b>path</b> indicates the path of the text file.</li> </ul>
<code>public DataStreamSink&lt;T&gt; writeAsCsv(String path, WriteMode writeMode)</code>	<ul style="list-style-type: none"> <li>• <b>writeMode</b> indicates the writing mode, which can be <b>OVERWRITE</b> or <b>NO_OVERWRITE</b>.</li> </ul>
<code>public &lt;X extends Tuple&gt; DataStreamSink&lt;T&gt; writeAsCsv(String path, WriteMode writeMode, String rowDelimiter, String fieldDelimiter)</code>	<ul style="list-style-type: none"> <li>• <b>rowDelimiter</b> indicates the row separator.</li> <li>• <b>fieldDelimiter</b> indicates the column separator.</li> </ul>
<code>public DataStreamSink&lt;T&gt; writeToSocket(String hostName, int port, SerializationSchema&lt;T&gt; schema)</code>	Write data to the socket connection. <ul style="list-style-type: none"> <li>• <b>hostName</b> indicates the host name.</li> <li>• <b>port</b> indicates the port number.</li> </ul>
<code>public DataStreamSink&lt;T&gt; writeUsingOutputformat(Outputformat&lt;T&gt; format)</code>	Write data to a file, for example, a binary file.

API	Description
public DataStreamSink<T> addSink(SinkFunction<T> sinkFunction)	Export data in a user-defined manner. The flink-connectors allows the addSink method to support exporting data to Kafka. The implementation method is the invoke method of SinkFunction.

## Filtering and Mapping

**Table 2-26** APIs about filtering and mapping

API	Description
public <R> SingleOutputStreamOperator<R> map(MapFunction<T, R> mapper)	Transform an element into another element of the same type.
public <R> SingleOutputStreamOperator<R> flatMap(FlatMapFunction<T, R> flatMapMapper)	Transform an element into zero, one, or multiple elements.
public SingleOutputStreamOperator<T> filter(FilterFunction<T> filter)	Run a Boolean function on each element and retain elements that return <b>true</b> .

## Aggregation

**Table 2-27** APIs about aggregation

API	Description
public KeyedStream<T, Tuple> keyBy(int... fields)	Logically divide a stream into multiple partitions, each containing elements with the same key. The partitioning is internally implemented using hash partition. A KeyedStream is returned.
public KeyedStream<T, Tuple> keyBy(String... fields)	Return the KeyedStream after the KeyBy operation, and call the KeyedStream function, such as reduce, fold, min, minby, max, maxby, sum, and sumby.
public <K> KeyedStream<T, K> keyBy(KeySelector<T, K> key)	<ul style="list-style-type: none"> <li>• <b>fields</b> indicates the numbers of columns or names of member variables.</li> <li>• <b>key</b> indicates the user-defined basis for partitioning.</li> </ul>

API	Description
public SingleOutputStreamOperator<T> reduce(ReduceFunction<T> reducer)	Perform reduce on KeyedStream in a rolling manner. Aggregate the current element and the last reduced value into a new value. The types of the three values are the same.
public <R> SingleOutputStreamOperator<R> fold(R initialValue, FoldFunction<T, R> folder)	Perform fold operation on KeyedStream based on an initial value in a rolling manner. Aggregate the current element and the last folded value into a new value. The input and returned values of Fold can be different.
public SingleOutputStreamOperator<T> sum(int positionToSum)	Calculate the sum in a KeyedStream in a rolling manner.
public SingleOutputStreamOperator<T> sum(String field)	<b>positionToSum</b> and <b>field</b> indicate calculating the sum of a specific column.
public SingleOutputStreamOperator<T> min(int positionToMin)	Calculate the minimum value in a KeyedStream in a rolling manner. <b>min</b> returns the minimum value, without guarantee of the correctness of columns of non-minimum values.
public SingleOutputStreamOperator<T> min(String field)	<b>positionToMin</b> and <b>field</b> indicate calculating the minimum value of a specific column.
public SingleOutputStreamOperator<T> max(int positionToMax)	Calculate the maximum value in KeyedStream in a rolling manner. <b>max</b> returns the maximum value, without guarantee of the correctness of columns of non-maximum values.
public SingleOutputStreamOperator<T> max(String field)	<b>positionToMax</b> and <b>field</b> indicate calculating the maximum value of a specific column.
public SingleOutputStreamOperator<T> minBy(int positionToMinBy)	Obtain the row where the minimum value of a column locates in a KeyedStream. <b>minBy</b> returns all elements of that row.
public SingleOutputStreamOperator<T> minBy(String positionToMinBy)	
public SingleOutputStreamOperator<T> minBy(int positionToMinBy, boolean first)	<ul style="list-style-type: none"><li>• <b>positionToMinBy</b> indicates the column on which the minBy operation is performed.</li><li>• <b>first</b> indicates whether to return the first or last minimum value.</li></ul>
public SingleOutputStreamOperator<T> minBy(String field, boolean first)	

API	Description
public SingleOutputStreamOperator<T> maxBy(int positionToMaxBy)	Obtain the row where the maximum value of a column locates in a KeyedStream. maxBy returns all elements of that row.
public SingleOutputStreamOperator<T> maxBy(String positionToMaxBy)	
public SingleOutputStreamOperator<T> maxBy(int positionToMaxBy, boolean first)	
public SingleOutputStreamOperator<T> maxBy(String field, boolean first)	<ul style="list-style-type: none"><li>• <b>positionToMaxBy</b> indicates the column on which the maxBy operation is performed.</li><li>• <b>first</b> indicates whether to return the first or last maximum value.</li></ul>

## DataStream Distribution

**Table 2-28** APIs about DataStream distribution

API	Description
public <K> DataStream<T> partitionCustom(Partitioner<K> partitioner, int field)	Use a user-defined partitioner to select target task for each element. <ul style="list-style-type: none"><li>• <b>partitioner</b> indicates the user-defined method for repartitioning.</li><li>• <b>field</b> indicates the input parameters of partitioner.</li><li>• <b>keySelector</b> indicates the user-defined input parameters of partitioner.</li></ul>
public <K> DataStream<T> partitionCustom(Partitioner<K> partitioner, String field)	
public <K> DataStream<T> partitionCustom(Partitioner<K> partitioner, KeySelector<T, K> keySelector)	
public DataStream<T> shuffle()	Randomly and evenly partition elements.
public DataStream<T> rebalance()	Partition elements in round-robin manner, ensuring load balance of each partition. This partitioning is helpful to data with skewness.
public DataStream<T> rescale()	Distribute elements into downstream subset in round-robin manner.

API	Description
public DataStream<T> broadcast()	Broadcast each element to all partitions.

## Project Capabilities

**Table 2-29** APIs about projecting

API	Description
public <R extends Tuple> SingleOutputStreamOperator<R> project(int... fieldIndexes)	Select some field subset from the tuple. <b>fieldIndexes</b> indicates some sequences of the tuple. <b>NOTE</b> Only tuple data type is supported by the project API.

## Configuring the eventtime Attribute

**Table 2-30** APIs about configuring the eventtime attribute

API	Description
public SingleOutputStreamOperator<T> assignTimestampsAndWatermarks(AssignerWithPeriodicWatermarks<T> timestampAndWatermarkAssigner)	Extract timestamp from records, enabling event time window to trigger computing.
public SingleOutputStreamOperator<T> assignTimestampsAndWatermarks(AssignerWithPunctuatedWatermarks<T> timestampAndWatermarkAssigner)	

**Table 2-31** lists differences of AssignerWithPeriodicWatermarks and AssignerWithPunctuatedWatermarks APIs.

**Table 2-31** Difference of AssignerWithPeriodicWatermarks and AssignerWithPunctuatedWatermarks APIs

Parameter	Description
AssignerWithPeriodicWatermarks	Generate Watermark based on the getConfig().setAutoWatermarkInterval(200L) timestamp of StreamExecutionEnvironment class.
AssignerWithPunctuatedWatermarks	Generate a Watermark each time an element is received. Watermarks can be different based on received elements.

## Iteration

**Table 2-32** APIs about iteration

API	Description
public IterativeStream<T> iterate()	In the flow, create in a feedback loop to redirect the output of an operator to a preceding operator. <b>NOTE</b> <ul style="list-style-type: none"><li>This API is helpful to algorithms that require constant update of models.</li><li>long maxWaitTimeMillis: The timeout period of each round of iteration.</li></ul>
public IterativeStream<T> iterate(long maxWaitTimeMillis)	

## Stream Splitting

**Table 2-33** APIs about stream splitting

API	Description
public SplitStream<T> split(OutputSelector<T> outputSelector)	Use OutputSelector to rewrite select method, specify stream splitting basis (by tagging), and construct SplitStream streams. That is, a string is tagged for each element, so that a stream of a specific tag can be selected or created.
public DataStream<OUT> select(String... outputNames)	Select one or multiple streams from a SplitStream. outputNames indicates the sequence of string tags created for each element using the split method.

## Window

Windows can be classified as tumbling windows and sliding windows.

- APIs such as Window, TimeWindow, CountWindow, WindowAll, TimeWindowAll, and CountWindowAll can be used to generate windows.
- APIs such as Window Apply, Window Reduce, Window Fold, and Aggregations on windows can be used to operate windows.
- Multiple Window Assigners are supported, including TumblingEventTimeWindows, TumblingProcessingTimeWindows, SlidingEventTimeWindows, SlidingProcessingTimeWindows, EventTimeSessionWindows, ProcessingTimeSessionWindows, and GlobalWindows.
- ProcessingTime, EventTime, and IngestionTime are supported.
- Timestamp modes EventTime: AssignerWithPeriodicWatermarks and AssignerWithPunctuatedWatermarks are supported.

**Table 2-34** lists APIs for generating windows.

**Table 2-34** APIs for generating windows

API	Description
public <W extends Window> WindowedStream<T, KEY, W> window(WindowAssigner<? super T, W> assigner)	Define windows in partitioned KeyedStreams. A window groups each key according to some characteristics (for example, data received within the latest 5 seconds).
public <W extends Window> AllWindowedStream<T, W> windowAll(WindowAssigner<? super T, W> assigner)	Define windows in DataStreams.
public WindowedStream<T, KEY, TimeWindow> timeWindow(Time size)	Define time windows in partitioned KeyedStreams, select ProcessingTime or EventTime based on the environment.getStreamTimeCharacteristic() parameter, and determine whether the window is TumblingWindow or SlidingWindow depends on the number of parameters. <ul style="list-style-type: none"><li>• <b>size</b> indicates the duration of the window.</li><li>• <b>slide</b> indicates the sliding time of window.</li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• WindowedStream and AllWindowedStream indicates two types of streams.</li><li>• If the API contains only one parameter, the window is TumblingWindow. If the API contains two or more parameters, the window is SlidingWindow.</li></ul>
public WindowedStream<T, KEY, TimeWindow> timeWindow(Time size, Time slide)	

API	Description
public AllWindowedStream<T, TimeWindow> timeWindowAll(Time size)	Define time windows in partitioned DataStream, select ProcessingTime or EventTime based on the environment.getStreamTimeCharacteristic() parameter, and determine whether the window is TumblingWindow or SlidingWindow depends on the number of parameters.
public AllWindowedStream<T, TimeWindow> timeWindowAll(Time size, Time slide)	<ul style="list-style-type: none"> <li>• <b>size</b> indicates the duration of the window.</li> <li>• <b>slide</b> indicates the sliding time of window.</li> </ul>
public WindowedStream<T, KEY, GlobalWindow> countWindow(long size)	Divide windows according to the number of elements and define windows in partitioned KeyedStreams.
public WindowedStream<T, KEY, GlobalWindow> countWindow(long size, long slide)	<ul style="list-style-type: none"> <li>• <b>size</b> indicates the duration of the window.</li> <li>• <b>slide</b> indicates the sliding time of window.</li> </ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"> <li>• WindowedStream and AllWindowedStream indicates two types of streams.</li> <li>• If the API contains only one parameter, the window is TumblingWindow. If the API contains two or more parameters, the window is SlidingWindow.</li> </ul>
public AllWindowedStream<T, GlobalWindow> countWindowAll(Time size)	Divide windows according to the number of elements and define windows in DataStreams.
public AllWindowedStream<T, GlobalWindow> countWindowAll(Time size, Time slide)	<ul style="list-style-type: none"> <li>• <b>size</b> indicates the duration of the window.</li> <li>• <b>slide</b> indicates the sliding time of window.</li> </ul>

**Table 2-35** lists APIs for operating windows.**Table 2-35** APIs for operating windows

Method	API	Description
Window	public <R> SingleOutputStrea- mOperator<R> apply(WindowFunction<T, R, K, W> function)	<p>Apply a general function to a window. The data in the window is calculated as a whole.</p> <ul style="list-style-type: none"> <li>• <b>function</b> indicates the window function to be executed.</li> <li>• <b>resultType</b> indicates the type of returned data.</li> </ul>

Method	API	Description
	public <R> SingleOutputStreamOperator<R> apply(WindowFunction<T, R, K, W> function, TypeInformation<R> resultType)	
	public SingleOutputStreamOperator<T> reduce(ReduceFunction<T> function)	Apply a reduce function to the window and return the result. <ul style="list-style-type: none"><li>• <b>reduceFunction</b> indicates the reduce function to be executed.</li></ul>
	public <R> SingleOutputStreamOperator<R> reduce(ReduceFunction<T> reduceFunction, WindowFunction<T, R, K, W> function)	<ul style="list-style-type: none"><li>• <b>function of WindowFunction</b> indicates triggering an operation to the window after a reduce operation.</li></ul>
	public <R> SingleOutputStreamOperator<R> reduce(ReduceFunction<T> reduceFunction, WindowFunction<T, R, K, W> function, TypeInformation<R> resultType)	<ul style="list-style-type: none"><li>• <b>resultType</b> indicates the type of returned data.</li></ul>
	public <R> SingleOutputStreamOperator<R> fold(R initialValue, FoldFunction<T, R> function)	Apply a fold function to the window and return the result. <ul style="list-style-type: none"><li>• <b>initialValue</b> indicates the initial value.</li></ul>
	public <R> SingleOutputStreamOperator<R> fold(R initialValue, FoldFunction<T, R> function, TypeInformation<R> resultType)	<ul style="list-style-type: none"><li>• <b>foldFunction</b> indicates the fold function.</li><li>• <b>function of WindowFunction</b> indicates triggering an operation to the window after a fold operation.</li></ul>
	public <ACC, R> SingleOutputStreamOperator<R> fold(ACC initialValue, FoldFunction<T, ACC> foldFunction, WindowFunction<ACC, R, K, W> function)	<ul style="list-style-type: none"><li>• <b>resultType</b> indicates the type of returned data.</li></ul>

Method	API	Description
	public <ACC, R> SingleOutputStreamOperator<R> fold(ACC initialValue, FoldFunction<T, ACC> foldFunction, WindowFunction<ACC, R, K, W> function, TypeInformation<ACC> foldAccumulatorType, TypeInformation<R> resultType)	
Window All	public <R> SingleOutputStreamOperator<R> apply(AllWindowFunction<T, R, W> function)	Apply a general function to a window. The data in the window is calculated as a whole.
	public <R> SingleOutputStreamOperator<R> apply(AllWindowFunction<T, R, W> function, TypeInformation<R> resultType)	
	public SingleOutputStreamOperator<T> reduce(ReduceFunction<T> function)	Apply a reduce function to the window and return the result. <ul style="list-style-type: none"> <li>• <b>reduceFunction</b> indicates the reduce function to be executed.</li> </ul>
	public <R> SingleOutputStreamOperator<R> reduce(ReduceFunction<T> reduceFunction, AllWindowFunction<T, R, W> function)	<ul style="list-style-type: none"> <li>• <b>AllWindowFunction</b> indicates triggering an operation to the window after a reduce operation.</li> </ul>
	public <R> SingleOutputStreamOperator<R> reduce(ReduceFunction<T> reduceFunction, AllWindowFunction<T, R, W> function, TypeInformation<R> resultType)	<ul style="list-style-type: none"> <li>• <b>resultType</b> indicates the type of returned data.</li> </ul>

Method	API	Description
	<pre>public &lt;R&gt; SingleOutputStreamOperator&lt;R&gt; fold(R initialValue, FoldFunction&lt;T, R&gt; function)</pre>	Apply a fold function to the window and return the result. <ul style="list-style-type: none"><li>• <b>initialValue</b> indicates the initial value.</li><li>• <b>foldFunction</b> indicates the fold function.</li><li>• <b>function of WindowFunction</b> indicates triggering an operation to the window after a fold operation.</li><li>• <b>resultType</b> indicates the type of returned data.</li></ul>
	<pre>public &lt;R&gt; SingleOutputStreamOperator&lt;R&gt; fold(R initialValue, FoldFunction&lt;T, R&gt; function, TypeInformation&lt;R&gt; resultType)</pre>	
	<pre>public &lt;ACC, R&gt; SingleOutputStreamOperator&lt;R&gt; fold(ACC initialValue, FoldFunction&lt;T, ACC&gt; foldFunction, AllWindowFunction&lt;ACC, R, W&gt; function)</pre>	
	<pre>public &lt;ACC, R&gt; SingleOutputStreamOperator&lt;R&gt; fold(ACC initialValue, FoldFunction&lt;T, ACC&gt; foldFunction, AllWindowFunction&lt;ACC, R, W&gt; function, TypeInformation&lt;ACC&gt; foldAccumulatorType, TypeInformation&lt;R&gt; resultType)</pre>	
Window and Window All	<pre>public SingleOutputStreamOperator&lt;T&gt; sum(int positionToSum)</pre>	Sum a specified column of the window data. <b>field</b> and <b>positionToSum</b> indicate a specific column of the data.
	<pre>public SingleOutputStreamOperator&lt;T&gt; sum(String field)</pre>	
	<pre>public SingleOutputStreamOperator&lt;T&gt; min(int positionToMin)</pre>	Calculate the minimum value of a specified column of the window data. <b>min</b> returns the minimum value, without guarantee of the correctness of columns of non-minimum values.
	<pre>public SingleOutputStreamOperator&lt;T&gt; min(String field)</pre>	<b>positionToMin</b> and <b>field</b> indicate calculating the minimum value of a specific column.

Method	API	Description
	public SingleOutputStreamOperator<T> minBy(int positionToMinBy)	Obtain the row where the minimum value of a column locates in the window data. <b>minBy</b> returns all elements of that row.
	public SingleOutputStreamOperator<T> minBy(String positionToMinBy)	<ul style="list-style-type: none"> <li>• <b>positionToMinBy</b> indicates the column on which the <b>minBy</b> operation is performed.</li> </ul>
	public SingleOutputStreamOperator<T> minBy(int positionToMinBy, boolean first)	<ul style="list-style-type: none"> <li>• <b>first</b> indicates whether to return the first or last minimum value.</li> </ul>
	public SingleOutputStreamOperator<T> minBy(String field, boolean first)	
	public SingleOutputStreamOperator<T> max(int positionToMax)	Calculate the maximum value of a specified column of the window data. <b>max</b> returns the maximum value, without guarantee of the correctness of columns of non-maximum values.
	public SingleOutputStreamOperator<T> max(String field)	<b>positionToMax</b> and <b>field</b> indicate calculating the maximum value of a specific column.
	The default public SingleOutputStreamOperator<T> maxBy(int positionToMaxBy)//true	Obtain the row where the maximum value of a column locates in the window data. <b>maxBy</b> returns all elements of that row.
	The default public SingleOutputStreamOperator<T> maxBy(String positionToMaxBy)//true	<ul style="list-style-type: none"> <li>• <b>positionToMaxBy</b> indicates the column on which the <b>maxBy</b> operation is performed.</li> </ul>
	public SingleOutputStreamOperator<T> maxBy(int positionToMaxBy, boolean first)	<ul style="list-style-type: none"> <li>• <b>first</b> indicates whether to return the first or last maximum value.</li> </ul>
	public SingleOutputStreamOperator<T> maxBy(String field, boolean first)	

## Combining Multiple DataStreams

**Table 2-36** APIs about combining multiple DataStreams

API	Description
<pre>public final DataStream&lt;T&gt; union(DataStream&lt;T&gt;.. . streams)</pre>	<p>Perform union operation on multiple DataStreams to generate a new data stream containing all data from original DataStreams.</p> <p><b>NOTE</b> If you perform union operation on a piece of data with itself, there are two copies of the same data.</p>
<pre>public &lt;R&gt; ConnectedStreams&lt;T, R&gt; connect(DataStream&lt;R &gt; dataStream)</pre>	Connect two DataStreams and retain the original type. The connect API method allows two DataStreams to share statuses. After ConnectedStreams is generated, map or flatMap operation can be called.
<pre>public &lt;R&gt; SingleOutputStreamOperator&lt;R&gt; map(CoMapFunction&lt;I N1, IN2, R&gt; coMapper)</pre>	Perform mapping operation, which is similar to map and flatMap operation in a ConnectedStreams, on elements. After the operation, the type of the new DataStreams is string.
<pre>public &lt;R&gt; SingleOutputStreamOperator&lt;R&gt; flatMap(CoFlatMapFun ction&lt;IN1, IN2, R&gt; coFlatMapper)</pre>	Perform mapping operation, which is similar to flatMap operation in DataStream, on elements.

## Join Operation

**Table 2-37** APIs about join operation

API	Description
<pre>public &lt;T2&gt; JoinedStreams&lt;T, T2&gt; join(DataStream&lt;T2&gt; otherStream)</pre>	Join two DataStreams using a given key in a specified window.
<pre>public &lt;T2&gt; CoGroupedStreams&lt;T, T2&gt; coGroup(DataStream&lt; T2&gt; otherStream)</pre>	Co-group two DataStreams using a given key in a specified window.

### 2.4.5.1.2 Scala

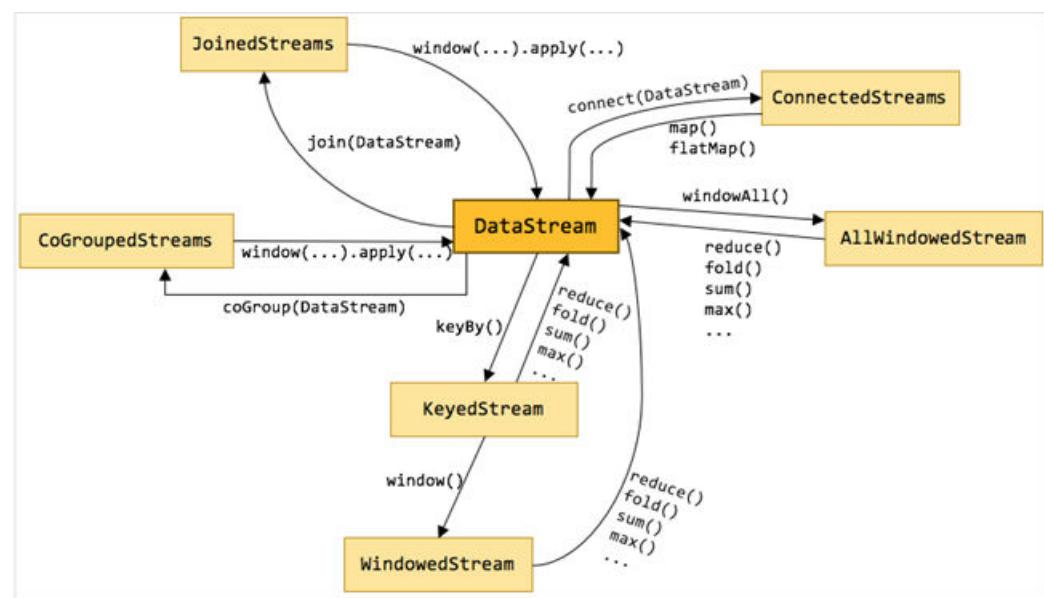

To avoid API compatibility or reliability issues after updates to the open-source Flink, recommended that APIs of the matching version are recommended. For details about APIs, see MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)

## Common APIs of Flink

Flink mainly uses the following APIs:

- StreamExecutionEnvironment: provides the execution environment, which is the basis of Flink stream processing.
- DataStream: represents streaming data. DataStream can be regarded as unmodifiable collection that contains duplicate data. The number of elements in DataStream are unlimited.
- KeyedStream: generates the stream by performing keyBy grouping operations on DataStream. Data is grouped based on the specified key value.
- WindowedStream: generates the stream by performing the window function on KeyedStream, sets the window type, and defines window triggering conditions.
- AllWindowedStream: generates streams by performing the window function on DataStream, sets the window type, defines window triggering conditions, and performs operations on the window data.
- ConnectedStreams: generates streams by connecting the two DataStreams and retaining the original data type, and performs the map or flatMap operation.
- JoinedStreams: performs equijoin operation to data in the window. The join operation is a special scenario of coGroup operation.
- CoGroupedStreams: performs the coGroup operation on data in the window. CoGroupedStreams can perform various types of join operations.

Figure 2-96 Conversion of Flink stream types

## Data Stream Source

**Table 2-38** APIs about data stream source

API	Description
def fromElements[T: TypeInformation] (data: T*): DataStream[T]	Obtain user-defined data of multiple elements as the data stream source. <b>data</b> is the specific data of multiple elements.
def fromCollection[T: TypeInformation] (data: Seq[T]): DataStream[T]	Obtain the user-defined data collection as input data stream.
def fromCollection[T: TypeInformation] (data: Iterator[T]): DataStream[T]	<b>data</b> can be a data collection or a data body that can be iterated.
def fromParallelCollection[T: TypeInformation] (data: SplittableIterator[T]): DataStream[T]	Obtain the user-defined data collection as parallel data stream source. <b>data</b> indicates the iterator that can be divided into multiple partitions.
def generateSequence(from: Long, to: Long): DataStream[Long]	Obtain a sequence of user-defined data as the data stream source. <ul style="list-style-type: none"><li>• <b>from</b> indicates the starting point of numbers.</li><li>• <b>to</b> indicates the end point of numbers.</li></ul>
def readTextFile(filePath: String): DataStream[String]	Obtain the user-defined text file from a specific path as the data stream source.
def readTextFile(filePath: String, charsetName: String): DataStream[String]	<ul style="list-style-type: none"><li>• <b>filePath</b> indicates the path of the text file.</li><li>• <b>charsetName</b> indicates the encoding format.</li></ul>
def readFile[T: TypeInformation] (inputFormat: FileInputFormat[T], filePath: String)	Obtain the user-defined file from a specific path as the data stream source.
def readFile[T: TypeInformation] (inputFormat: FileInputFormat[T], filePath: String, watchType: FileProcessingMode, interval: Long): DataStream[T]	<ul style="list-style-type: none"><li>• <b>filePath</b> indicates the file path.</li><li>• <b>inputFormat</b> indicates the format of the file.</li><li>• <b>watchType</b> indicates the file processing mode, which can be <b>PROCESS_ONCE</b> or <b>PROCESS_CONTINUOUSLY</b>.</li><li>• <b>interval</b> indicates the interval for processing directories or files.</li></ul>

API	Description
<pre>def socketTextStream(hostname: String, port: Int, delimiter: Char = '\n', maxRetry: Long = 0): DataStream[String]</pre>	<p>Obtain user-defined socket data as the data stream source.</p> <ul style="list-style-type: none"><li>• <b>hostname</b> indicates the host name of the socket server.</li><li>• <b>port</b> indicates the listening port of the server.</li><li>• <b>delimiter</b> and <b>maxRetry</b> are not supported by Scala APIs.</li></ul>
<pre>def addSource[T: TypeInformation](function: SourceFunction[T]): DataStream[T]</pre>	<p>Customize the <b>SourceFunction</b> and <b>addSource</b> methods to add data sources such as Kafka. The implementation method is the run method of SourceFunction.</p> <ul style="list-style-type: none"><li>• <b>function</b> indicates the user-defined <b>SourceFunction</b> function.</li><li>• Simplified format is supported by Scala.</li></ul>
<pre>def addSource[T: TypeInformation](function: SourceContext[T] =&gt; Unit): DataStream[T]</pre>	

## Data Output

Table 2-39 APIs about data output

API	Description
<pre>def print(): DataStreamSink[T]</pre>	Print data as the standard output stream.
<pre>def printToErr()</pre>	Print data as the standard error output stream.
<pre>def writeAsText(path: String): DataStreamSink[T]</pre>	Write data to a specific text file.
<pre>def writeAsText(path: String, writeMode: FileSystem.WriteMode): DataStreamSink[T]</pre>	<ul style="list-style-type: none"><li>• <b>path</b> indicates the path of the text file.</li><li>• <b>writeMode</b> indicates the writing mode, which can be <b>OVERWRITE</b> or <b>NO_OVERWRITE</b>.</li></ul>

API	Description
def writeAsCsv(path: String): DataStreamSink[T]	Writhe data to a specific .csv file. • <b>path</b> indicates the path of the text file.
def writeAsCsv(path: String, writeMode: FileSystem.WriteMode): DataStreamSink[T]	• <b>writeMode</b> indicates the writing mode, which can be <b>OVERWRITE</b> or <b>NO_OVERWRITE</b> .
def writeAsCsv(path: String, writeMode: FileSystem.WriteMode, rowDelimiter: String, fieldDelimiter: String): DataStreamSink[T]	• <b>rowDelimiter</b> indicates the row separator. • <b>fieldDelimiter</b> indicates the column separator.
def writeUsingOutputFormat(format: OutputFormat[T]): DataStreamSink[T]	Write data to a file, for example, a binary file.
def writeToSocket(hostname: String, port: Integer, schema: SerializationSchema[T]): DataStreamSink[T]	Write data to the socket connection. • <b>hostName</b> indicates the host name. • <b>port</b> indicates the port number.
def addSink(sinkFunction: SinkFunction[T]): DataStreamSink[T]	Export data in a user-defined manner. The flink-connectors allows addSink method to support exporting data to Kafka. The implementation method is the invoke method of SinkFunction.
def addSink(fun: T => Unit): DataStreamSink[T]	

## Filtering and Mapping

Table 2-40 APIs about filtering and mapping

API	Description
def map[R: TypeInformation](fun: T => R): DataStream[R]	Transform an element into another element of the same type.
def map[R: TypeInformation](mapper: MapFunction[T, R]): DataStream[R]	
def flatMap[R: TypeInformation](flatMapMapper: FlatMapFunction[T, R]): DataStream[R]	Transform an element into zero, one, or multiple elements.
def flatMap[R: TypeInformation](fun: (T, Collector[R]) => Unit): DataStream[R]	
def flatMap[R: TypeInformation](fun: T => TraversableOnce[R]): DataStream[R]	

API	Description
def filter(filter: FilterFunction[T]): DataStream[T]	Run a Boolean function on each element and retain elements that return <b>true</b> .
def filter(fun: T => Boolean): DataStream[T]	

## Aggregation

**Table 2-41** APIs about aggregation

API	Description
def keyBy(fields: Int*): KeyedStream[T, JavaTuple]	Logically divide a stream into multiple partitions, each containing elements with the same key. The partitioning is internally implemented using hash partition. A KeyedStream is returned.
def keyBy(firstField: String, otherFields: String*): KeyedStream[T, JavaTuple]	
def keyBy[K: TypeInformation](fun: T => K): KeyedStream[T, K]	Return the KeyedStream after the KeyBy operation, and call the KeyedStream function, such as reduce, fold, min, minby, max, maxby, sum, and sumby. <ul style="list-style-type: none"><li>• <b>fields</b> indicates the IDs of certain columns</li><li>• <b>firstField</b> and <b>otherFields</b> are names of member variables.</li><li>• <b>key</b> indicates the user-defined basis for partitioning.</li></ul>
def reduce(fun: (T, T) => T): DataStream[T]	Perform reduce on KeyedStream in a rolling manner. Aggregate the current element and the last reduced value into a new value. The types of the three values are the same.
def reduce(reducer: ReduceFunction[T]): DataStream[T]	
def fold[R: TypeInformation] (initialValue: R)(fun: (R,T) => R): DataStream[R]	Perform fold operation on KeyedStream based on an initial value in a rolling manner. Aggregate the current element and the last folded value into a new value. The input and returned values of Fold can be different.
def fold[R: TypeInformation] (initialValue: R, folder: FoldFunction[T,R]): DataStream[R]	
def sum(position: Int): DataStream[T]	Calculate the sum in a KeyedStream in a rolling manner.
def sum(field: String): DataStream[T]	<b>position</b> and <b>field</b> indicate calculating the sum of a specific column.

API	Description
def min(position: Int): DataStream[T]	Calculate the minimum value in a KeyedStream in a rolling manner. <b>min</b> returns the minimum value, without guarantee of the correctness of columns of non-minimum values.
def min(field: String): DataStream[T]	<b>position and field</b> indicate calculating the minimum value of a specific column.
def max(position: Int): DataStream[T]	Calculate the maximum value in KeyedStream in a rolling manner. <b>max</b> returns the maximum value, without guarantee of the correctness of columns of non-maximum values.
def max(field: String): DataStream[T]	<b>position and field</b> indicate calculating the maximum value of a specific column.
def minBy(position: Int): DataStream[T]	Obtain the row where the minimum value of a column locates in a KeyedStream. <b>minBy</b> returns all elements of that row.
def minBy(field: String): DataStream[T]	<b>position and field</b> indicate the column on which the <b>minBy</b> operation is performed.
def maxBy(position: Int): DataStream[T]	Obtain the row where the maximum value of a column locates in a KeyedStream. <b>maxBy</b> returns all elements of that row.
def maxBy(field: String): DataStream[T]	<b>position and field</b> indicate the column on which the <b>maxBy</b> operation is performed.

## DataStream Distribution

**Table 2-42** APIs about DataStream distribution

API	Description
<code>def partitionCustom[K: TypeInformation](partitioner: Partitioner[K], field: Int) : DataStream[T]</code>	Use a user-defined partitioner to select target task for each element. <ul style="list-style-type: none"><li>• <b>partitioner</b> indicates the user-defined method for repartitioning.</li><li>• <b>field</b> indicates the input parameters of partitioner.</li><li>• <b>keySelector</b> indicates the user-defined input parameters of partitioner.</li></ul>
<code>def partitionCustom[K: TypeInformation](partitioner: Partitioner[K], field: String):DataStream[T]</code>	
<code>def partitionCustom[K: TypeInformation](partitioner: Partitioner[K], fun: T =&gt; K): DataStream[T]</code>	
<code>def shuffle: DataStream[T]</code>	Randomly and evenly partition elements.
<code>def rebalance: DataStream[T]</code>	Partition elements in round-robin manner, ensuring load balance of each partition. This partitioning is helpful to data with skewness.
<code>def rescale: DataStream[T]</code>	Distribute elements into downstream subset in round-robin manner. <b>NOTE</b> The method for checking the code is similar to the rebalance method.
<code>def broadcast: DataStream[T]</code>	Broadcast each element to all partitions.

## Configuring the eventtime Attribute

**Table 2-43** APIs about configuring the eventtime attribute

API	Description
<code>def assignTimestampsAndWatermarks(assigner: AssignerWithPeriodicWatermarks[T]): DataStream[T]</code>	Extract timestamp from records, enabling event time window to trigger computing.

API	Description
<code>def assignTimestampsAndWatermarks(assigner: AssignerWithPunctuatedWatermarks[T]): DataStream[T]</code>	

## Iteration

**Table 2-44** APIs about iteration

API	Description
<code>def iterate[R] (stepFunction: DataStream[T] =&gt; (DataStream[T], DataStream[R]),maxWaitTimeMillis:Long = 0,keepPartitioning: Boolean = false) : DataStream[R]</code>	<p>In the flow, create in a feedback loop to redirect the output of an operator to a preceding operator.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"> <li>• This API is helpful to algorithms that require constant update of models.</li> <li>• long maxWaitTimeMillis: The timeout period of each round of iteration.</li> </ul>
<code>def iterate[R, F: TypeInformation] (stepFunction: ConnectedStreams[T, F] =&gt; (DataStream[F], DataStream[R]),maxWaitTimeMillis:Long): DataStream[R]</code>	

## Stream Splitting

**Table 2-45** APIs about stream splitting

API	Description
<code>def split(selector: OutputSelector[T]): SplitStream[T]</code>	Use OutputSelector to rewrite select method, specify stream splitting basis (by tagging), and construct SplitStream streams. That is, a string is tagged for each element, so that a stream of a specific tag can be selected or created.
<code>def select(outputNames: String*): DataStream[T]</code>	Select one or multiple streams from a SplitStream. outputNames indicates the sequence of string tags created for each element using the split method.

## Window

Windows can be classified as tumbling windows and sliding windows.

- APIs such as Window, TimeWindow, CountWindow, WindowAll, TimeWindowAll, and CountWindowAll can be used to generate windows.
- APIs such as Window Apply, Window Reduce, Window Fold, and Aggregations on windows can be used to operate windows.
- Multiple Window Assigners are supported, including TumblingEventTimeWindows, TumblingProcessingTimeWindows, SlidingEventTimeWindows, SlidingProcessingTimeWindows, EventTimeSessionWindows, ProcessingTimeSessionWindows, and GlobalWindows.
- ProcessingTime, EventTime, and IngestionTime are supported.
- Timestamp modes EventTime: AssignerWithPeriodicWatermarks and AssignerWithPunctuatedWatermarks are supported.

**Table9 APIs for generating windows** lists APIs for generating windows.

**Table 2-46** APIs for generating windows

API	Description
<code>def window[W &lt;: Window](assigner: WindowAssigner[_ &gt;: T, W]): WindowedStream[T, K, W]</code>	Define windows in partitioned KeyedStreams. A window groups each key according to some characteristics (for example, data received within the latest 5 seconds. For details about windows, see: <a href="https://ci.apache.org/projects/flink/flink-docs-release-1.10/dev/event_time.html">https://ci.apache.org/projects/flink/flink-docs-release-1.10/dev/event_time.html</a> .
<code>def windowAll[W &lt;: Window](assigner: WindowAssigner[_ &gt;: T, W]): AllWindowedStream[T, W]</code>	Define windows in DataStreams.
<code>def timeWindow(size: time</code> <code>WindowedStream[T, K, TimeWindow]</code>	Define time windows in partitioned KeyedStreams, select ProcessingTime or EventTime based on the environment.getStreamTimeCharacteristic() parameter, and determine whether the window is TumblingWindow or SlidingWindow depends on the number of parameters. <ul style="list-style-type: none"><li>• <b>size</b> indicates the duration of the window.</li><li>• <b>slide</b> indicates the sliding time of window.</li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• WindowedStream and AllWindowedStream indicates two types of streams.</li><li>• If the API contains only one parameter, the window is TumblingWindow. If the API contains two or more parameters, the window is SlidingWindow.</li></ul>
<code>def countWindow(size: Long, slide: Long): WindowedStream[T, K, GlobalWindow]</code>	

API	Description
def timeWindowAll(size: time AllWindowedStream[T, TimeWindow]	Define time windows in partitioned DataStream, select ProcessingTime or EventTime based on the environment.getStreamTimeCharacteristic() parameter, and determine whether the window is TumblingWindow or SlidingWindow depends on the number of parameters. <ul style="list-style-type: none"> <li>• <b>size</b> indicates the duration of the window.</li> <li>• <b>slide</b> indicates the sliding time of window.</li> </ul>
def countWindow(size: Long, slide: Long): WindowedStream[T, K, GlobalWindow]	Divide windows according to the number of elements and define windows in partitioned KeyedStreams. <ul style="list-style-type: none"> <li>• <b>size</b> indicates the duration of the window.</li> <li>• <b>slide</b> indicates the sliding time of window.</li> </ul>
def countWindow(size: Long): WindowedStream[T, K, GlobalWindow]	<b>NOTE</b> <ul style="list-style-type: none"> <li>• WindowedStream and AllWindowedStream indicates two types of streams.</li> <li>• If the API contains only one parameter, the window is TumblingWindow. If the API contains two or more parameters, the window is SlidingWindow.</li> </ul>
def countWindowAll(size: Long, slide: Long): AllWindowedStream[T, GlobalWindow]	Divide windows according to the number of elements and define windows in DataStreams. <ul style="list-style-type: none"> <li>• <b>size</b> indicates the duration of the window.</li> <li>• <b>slide</b> indicates the sliding time of window.</li> </ul>
def countWindowAll(size: Long): AllWindowedStream[T, GlobalWindow]	

**Table 2-47** lists APIs for operating windows.

**Table 2-47** APIs for operating windows

Method	API	Description
Window	def apply[R: TypeInformation] (function: WindowFunction[T, R, K, W]): DataStream[R]	Apply a general function to a window. The data in the window is calculated as a whole. <b>function</b> indicates the window function to be executed.
	def apply[R: TypeInformation] (function: (K, W, Iterable[T], Collector[R]) => Unit): DataStream[R]	

Method	API	Description
	<pre>def reduce(function: ReduceFunction[T]): DataStream[T]</pre>	Apply a reduce function to the window and return the result.
	<pre>def reduce(function: (T, T) =&gt; T): DataStream[T]</pre>	<ul style="list-style-type: none"> <li>• <b>reduceFunction</b> indicates the reduce function to be executed.</li> </ul>
	<pre>def reduce[R: TypeInformation] (preAggregator: ReduceFunction[T], function: WindowFunction[T, R, K, W]): DataStream[R]</pre>	<ul style="list-style-type: none"> <li>• <b>function of WindowFunction</b> indicates triggering an operation to the window after a reduce operation.</li> </ul>
	<pre>def reduce[R: TypeInformation] (preAggregator: (T, T) =&gt; T, windowFunction: (K, W, Iterable[T], Collector[R]) =&gt; Unit): DataStream[R]</pre>	
	<pre>def fold[R: TypeInformation] (initialValue: R, function: FoldFunction[T,R]): DataStream[R]</pre>	Apply a fold function to the window and return the result.
	<pre>def fold[R: TypeInformation] (initialValue: R)(function: (R, T) =&gt; R): DataStream[R]</pre>	<ul style="list-style-type: none"> <li>• <b>initialValue</b> indicates the initial value.</li> <li>• <b>foldFunction</b> indicates the fold function.</li> </ul>
	<pre>def fold[ACC: TypeInformation, R: TypeInformation](initialValue: ACC, foldFunction: FoldFunction[T, ACC], function: WindowFunction[ACC, R, K, W]): DataStream[R]</pre>	<ul style="list-style-type: none"> <li>• <b>function of WindowFunction</b> indicates triggering an operation to the window after a fold operation.</li> </ul>
	<pre>def fold[ACC: TypeInformation, R: TypeInformation](initialValue: ACC, foldFunction: (ACC, T) =&gt; ACC, windowFunction: (K, W, Iterable[ACC], Collector[R]) =&gt; Unit): DataStream[R]</pre>	
Window All	<pre>def apply[R: TypeInformation] (function: AllWindowFunction[T, R, W]): DataStream[R]</pre>	Apply a general function to a window. The data in the window is calculated as a whole.

Method	API	Description
	def apply[R: TypeInformation] (function: (W, Iterable[T], Collector[R]) => Unit): DataStream[R]	
	def reduce(function: ReduceFunction[T]): DataStream[T]	Apply a reduce function to the window and return the result. <ul style="list-style-type: none"> <li>• <b>reduceFunction</b> indicates the reduce function to be executed.</li> </ul>
	def reduce(function: (T, T) => T): DataStream[T]	
	def reduce[R: TypeInformation] (preAggregator: ReduceFunction[T], windowFunction: AllWindowFunction[T, R, W]): DataStream[R]	
	def reduce[R: TypeInformation] (preAggregator: (T, T) => T, windowFunction: (W, Iterable[T], Collector[R]) => Unit): DataStream[R]	
	def fold[R: TypeInformation] (initialValue: R, function: FoldFunction[T,R]): DataStream[R]	Apply a fold function to the window and return the result. <ul style="list-style-type: none"> <li>• <b>initialValue</b> indicates the initial value.</li> </ul>
	def fold[R: TypeInformation] (initialValue: R)(function: (R, T) => R): DataStream[R]	
	def fold[ACC: TypeInformation, R: TypeInformation](initialValue: ACC, preAggregator: FoldFunction[T, ACC], windowFunction: AllWindowFunction[ACC, R, W]): DataStream[R]	
	def fold[ACC: TypeInformation, R: TypeInformation](initialValue: ACC, preAggregator: (ACC, T) => ACC, windowFunction: (W, Iterable[ACC], Collector[R]) => Unit): DataStream[R]	

Method	API	Description
Window and Window All	def sum(position: Int): DataStream[T]	Sum a specified column of the window data. <b>field</b> and <b>position</b> indicate a specific column of the data.
	def sum(field: String): DataStream[T]	
	def min(position: Int): DataStream[T]	Calculate the minimum value of a specified column of the window data. <b>min</b> returns the minimum value, without guarantee of the correctness of columns of non-minimum values.
	def min(field: String): DataStream[T]	<b>position</b> and <b>field</b> indicate calculating the minimum value of a specific column.
	def max(position: Int): DataStream[T]	Calculate the maximum value of a specified column of the window data. <b>max</b> returns the maximum value, without guarantee of the correctness of columns of non-maximum values.
	def max(field: String): DataStream[T]	<b>position</b> and <b>field</b> indicate calculating the maximum value of a specific column.
	def minBy(position: Int): DataStream[T]	Obtain the row where the minimum value of a column locates in the window data. <b>minBy</b> returns all elements of that row.
	def minBy(field: String): DataStream[T]	<b>position</b> and <b>field</b> indicate the column on which the <b>minBy</b> operation is performed.
	def maxBy(position: Int): DataStream[T]	Obtain the row where the maximum value of a column locates in the window data. <b>maxBy</b> returns all elements of that row.
	def maxBy(field: String): DataStream[T]	<b>position</b> and <b>field</b> indicate the column on which the <b>maxBy</b> operation is performed.

## Combining Multiple DataStreams

**Table 2-48** APIs about combining multiple DataStreams

API	Description
<code>def union(dataStreams: DataStream[T]*): DataStream[T]</code>	Perform union operation on multiple DataStreams to generate a new data stream containing all data from original DataStreams. <b>NOTE</b> If you perform union operation on a piece of data with itself, there are two copies of the same data.
<code>def connect[T2] (dataStream: DataStream[T2]): ConnectedStreams[T, T2]</code>	Connect two DataStreams and retain the original type. The connect API method allows two DataStreams to share statuses. After ConnectedStreams is generated, map or flatMap operation can be called.
<code>def map[R: TypeInformation] (coMapper: CoMapFunction[IN1, IN2, R]): DataStream[R]</code>	Perform mapping operation, which is similar to map and flatMap operation in a ConnectedStreams, on elements. After the operation, the type of the new DataStreams is string.
<code>def map[R: TypeInformation](fun1: IN1 =&gt; R, fun2: IN2 =&gt; R): DataStream[R]</code>	
<code>def flatMap[R: TypeInformation] (coFlatMapper: CoFlatMapFunction[IN1, IN2, R]): DataStream[R]</code>	Perform union operation on multiple DataStreams to generate a new data stream containing all data from original DataStreams. <b>NOTE</b> If you perform union operation on a piece of data with itself, there are two copies of the same data.
<code>def flatMap[R: TypeInformation](fun1: (IN1, Collector[R]) =&gt; Unit, fun2: (IN2, Collector[R]) =&gt; Unit): DataStream[R]</code>	
<code>def flatMap[R: TypeInformation] (fun1: IN1 =&gt; TraversableOnce[R], fun2: IN2 =&gt; TraversableOnce[R]): DataStream[R]</code>	

## Join Operation

**Table 2-49** APIs about join operation

API	Description
<code>def join[T2] (otherStream: DataStream[T2]): JoinedStreams[T, T2]</code>	Join two DataStreams using a given key in a specified window. The key value of the join operation is specified by the <b>where</b> and <b>equalTo</b> method, indicating filtering data with equivalent conditions from two DataStreams.
<code>def coGroup[T2] (otherStream: DataStream[T2]): CoGroupedStreams[T, T2]</code>	Co-group two DataStreams using a given key in a specified window. The key value of the coGroup operation is specified by the where and equalTo method, indicating partitioning two DataStreams using equivalent conditions.

### 2.4.5.2 Overview of RESTful APIs

Flink has a monitoring API that can be used to query status and statistics of running jobs, as well as recent completed jobs. This monitoring API is used by Apache Flink Dashboard.

The monitoring API is a RESTful API that accepts HTTP GET requests and responds with JSON data. RESTful API is a set of APIs used to log in to the web server. In Flink, web server is a module of JobManager and shares the same process with JobManager. By default, the listening port of web server is 8081. If you want to change the listening port, modify **jobmanager.web.port** in the **flink-conf.yaml** file.

The *Netty* and the *Netty Router* library are used to handle REST requests and analysis URLs.

RESTful APIs are executed through HTTP requests.

The format of the HTTP requests is `http://<JobManager_IP>:<JobManager_Port><Path>`

The *JobManager\_IP* indicates the IP address of JobManager, *JobManager\_Port* indicates the listening port of JobManager, and *Path* indicates the path. For details, see [Table 2-50](#). For example, `http://10.162.181.57:32261/config`.

#### NOTE

If you want to modify the configuration file **flink-conf.yaml** of the Flink Client, add to-be-visited IP addresses (separated with commas) in **jobmanager.web.allow-access-address** and **jobmanager.web.access-control-allow-origin** parameters.

[Table 2-50](#) lists all RESTful API paths supported by Flink.

**Table 2-50** Paths supported by Flink

Path	Description
/config	Some information about the monitoring API and the server setup.
/logout	Some information about the logout.
/overview	Simple summary of the Flink cluster status.
/jobs	IDs of the jobs, grouped by status <i>running</i> , <i>finished</i> , <i>failed</i> , <i>canceled</i> .
/jobmanager/config	the configuration of the jobmanager.
/joboverview	Jobs, grouped by status, each with a small summary of its status.
/joboverview/running	Jobs, grouped by status, each with a small summary of its status. The same as <a href="#">/joboverview</a> , but containing only currently running jobs.
/joboverview/completed	Jobs, grouped by status, each with a small summary of its status. The same as <a href="#">/joboverview</a> , but containing only completed (finished, canceled, or failed) jobs.
/jobs/<jobid>	Summary of one job, listing dataflow plan, status, timestamps of state transitions, aggregate information for each vertex (operator).
/jobs/<jobid>/vertices	Currently the same as <a href="#">/jobs/&lt;jobid&gt;</a> .
/jobs/<jobid>/config	The user-defined execution config used by the job.
/jobs/<jobid>/exceptions	The non-recoverable exceptions that have been observed by the job. The truncated flag defines whether more exceptions occurred, but are not listed, because the response would otherwise get too big.
/jobs/<jobid>/accumulators	The aggregated user accumulators plus job accumulators.
/jobs/<jobid>/checkpoints	checkpoint stats for a job.
/jobs/<jobid>/metrics	a job a list of all available metrics.
/jobs/<jobid>/vertices/<vertexid>	Information about one specific vertex, with a summary for each of its subtasks.

Path	Description
/jobs/<jobid>/vertices/<vertexid>/subtasktimes	This request returns the timestamps for the state transitions of all subtasks of a given vertex. These can be used, for example, to create time-line comparisons between subtasks.
/jobs/<jobid>/vertices/<vertexid>/taskmanagers	TaskManager statistics for one specific vertex. This is an aggregation of subtask statistics returned by <code>/jobs/&lt;jobid&gt;/vertices/&lt;vertexid&gt;</code> .
/jobs/<jobid>/vertices/<vertexid>/accumulators	The aggregated user-defined accumulators, for a specific vertex.
/jobs/<jobid>/vertices/<vertexid>/checkpoints	checkpoint stats for a single job vertex.
/jobs/<jobid>/vertices/<vertexid>/backpressure	back pressure stats for a single job vertex and all its sub tasks.
/jobs/<jobid>/vertices/<vertexid>/metrics	a given task of the values for a set of metrics.
/jobs/<jobid>/vertices/<vertexid>/subtasks/accumulators	Gets all user-defined accumulators for all subtasks of a given vertex. These are the individual accumulators that are returned in aggregated form by the request <code>/jobs/&lt;jobid&gt;/vertices/&lt;vertexid&gt;/accumulators</code> .
/jobs/<jobid>/vertices/<vertexid>/subtasks/<subtasknum>	Summary of the current or latest execution attempt of a specific subtask. See below for a sample.
/jobs/<jobid>/vertices/<vertexid>/subtasks/<subtasknum>/attempts/<attempt>	Summary of a specific execution attempt of a specific subtask. Multiple execution attempts happen in case of failure/recovery.
/jobs/<jobid>/vertices/<vertexid>/subtasks/<subtasknum>/attempts/<attempt>/accumulators	The accumulators collected for one specific subtask during one specific execution attempt (multiple attempts happen in case of failure/recovery).
/jobs/<jobid>/plan	The dataflow plan of a job. The plan is also included in the job summary ( <code>/jobs/&lt;jobid&gt;</code> ).
/taskmanagers	Some information of the TaskManagers.
/taskmanagers/<taskmanagerid>/metrics	the metrics information of a TaskManager.

Path	Description
/taskmanagers/<taskmanagerid>/log	the log information of a TaskManager.
/taskmanagers/<taskmanagerid>/stdout	the stdout of a TaskManager.
/jobmanager/log	the log of the jobmanager.
/jobmanager/stdout	the stdout of the jobmanager.
/jobmanager/metrics	the metrics of the jobmanager.
/*	services requests to web frontend's static files, such as HTML, CSS, or JS files.

**Table 2-51** describes variables listed in **Table 2-50**.

**Table 2-51** Description of variables

Variable	Description
jobid	ID of jobs
vertexid	Vertices ID of the flow diagram.
subtasknum	Sum of subtasks.
attempt	Times of attempts
taskmanagerid	ID of TaskManager

### 2.4.5.3 Overview of Savepoints CLI

#### Overview

Savepoints are externally stored checkpoints that you can use to stop-and-resume or update your Flink programs. They use Flink's checkpoint mechanism to create a snapshot of the state of your streaming program and write the checkpoint meta data out to an external file system.

It is highly recommended that you adjust your programs as described in this section in order to be able to upgrade your programs in the future. The main required change is to manually specify operator IDs via the **uid(String)** method. These IDs are used to scope the state of each operator.

```
DataStream<String> stream = env
//Statefulesource(e.g.Kafka)withID
.addSource(new StatefulSource())
.uid("source-id") //IDforthesourceoperator
.shuffle()
//StatefulemapperwithID
.map(new StatefulMapper())
```

```
.uid("mapper-id") //IDforthemapper  
//Statelessprintingsink  
.print(); //Auto-generatedID
```

## Savepoint Recovery

If you do not specify the IDs manually, they will be generated automatically. You can automatically restore from the savepoint if these IDs do not change. The generated IDs depend on the structure of your program and are sensitive to program changes. Therefore, it is highly recommended to assign these IDs manually. When a savepoint is triggered, a single savepoint file will be created containing the checkpoint metadata. The actual checkpoint state will be kept around in the configured checkpoint directory, for example, with a FsStateBackend or RocksDBStateBackend:

1. Trigger a savepoint.

```
$ bin/flink savepoint jobId [targetDirectory]
```

This command will trigger a savepoint for the job with ID:*jobid*. Furthermore, you can specify a target file system directory to store the savepoint. The directory must be accessible by JobManager. The targetDirectory is optional. If targetDirectory is not configured, the directory specified by **state.savepoints.dir** in the configuration file is used to store savepoint.

You can configure a default savepoint target directory via the **state.savepoints.dir** key in the **flink-conf.yaml** file.

```
# Default savepoint target directory
```

### NOTE

You are advised to configure targetDirectory to an HDFS path.

For example:

```
bin/flink savepoint 405af8c02cf6dc069a0f9b7a1f7be088 hdfs://savepoint.
```

2. Cancel a job with a savepoint.

```
$ bin/flink cancel -s [targetDirectory] jobId
```

This will atomically trigger a savepoint for the job with ID:*jobid* and cancel the job. Furthermore, you can specify a target file system directory to store the savepoint. The directory must be accessible by JobManager.

3. Resume jobs.

- Resume from a savepoint.

```
$ bin/flink run -s savepointPath [runArgs]
```

This command submits a job and specifies the savepoint path. The execution will resume from the respective savepoint state.

### NOTE

**runArgs** is a user-defined parameter with parameter format and name varying depending on users.

- Allow non-restored state.

```
$ bin/flink run -s savepointPath -n [runArgs]
```

By default the resume operation will try to map all state of the savepoint back to the program you are restoring with. If you dropped an operator, you can skip the state that cannot be mapped to the new program via -allowNonRestoredState (short: -n).

4. Dispose savepoints.

```
$ bin/flink savepoint -d savepointPath
```

This command disposes the savepoint stored in: *savepointPath*.

## Precautions

- Chained operators are identified by the ID of the first task. It is not possible to manually assign an ID to an intermediate chained task, for example, in the chain [ a -> b -> c ] only **a** can have its ID assigned manually, but not **b** or **c**. To work around this, you can manually define the task chains. To manually define chains, use the **disableChaining()** interface. See the following example:

```
env.addSource(new GetDataSource())
.keyBy(0)
.timeWindow(Time.seconds(2)).uid("window-id")
.reduce(_+_).uid("reduce-id")
.map(f->(f1)).disableChaining().uid("map-id")
.print().disableChaining().uid("print-id")
```
- During job upgrade, the data type of operators cannot be changed.

### 2.4.5.4 Introduction to Flink Client CLI

#### Common CLIs

Common Flink CLIs are as follows:

- yarn-session.sh**
  - You can run **yarn-session.sh** to start a standing Flink cluster to receive tasks submitted by clients. Run the following command to start a Flink cluster with three TaskManager instances:

```
bin/yarn-session.sh
```
  - Run the following command to obtain other parameters of **yarn-session.sh**:

```
bin/yarn-session.sh -help
```
- flink**
  - You can run Flink commands to submit a Flink job to a standing Flink cluster or to execute the job in single-server mode.
    - Run the following command to submit a Flink job to a standing Flink cluster:

```
bin/flink run ..//examples/streaming/WindowJoin.jar
```

#### NOTE

Before using the command to submit a task, you need to run **yarn-session.sh** to start the Flink cluster.

- Run the following command to execute a per-job YARN Cluster mode:

```
bin/flink run -m yarn-cluster ..//examples/streaming/WindowJoin.jar
```

#### NOTE

The **-m** **yarn-cluster** parameter is used to specify a job to independently start a Flink cluster.

- List scheduled and running jobs (including their JobIDs):

```
bin/flink list
```

- Cancel a job:  
`bin/flink cancel <jobID>`
- Stop a job (streaming jobs only):  
`bin/flink stop <jobID>`

#### NOTE

The difference between cancelling and stopping a (streaming) job is the following:

- Cancel a job: On a cancel call, the operators in a job immediately receive a cancel() method call to cancel them as soon as possible. If operators are not stopping after the cancel call, Flink will start interrupting the thread periodically until it stops.
- Stop a job: Stop is only available for jobs which use sources that implement the `StoppableFunction` interface. The job will keep running until all sources properly shut down. Stop a job is more graceful than cancel, but it may cause the job to stop failing.
- Run the following command to obtain other parameters of Flink commands:  
`bin/flink --help`

## Precautions

- If `yarn-session.sh` uses `-z` to configure the specified ZooKeeper NameSpace, you need to use `-yid` to specify the applicationID and use `-yz` to specify the ZooKeeper NameSpace when using `flink run`. The NameSpaces must the same.

Example:

```
bin/yarn-session.sh -z YARN101  
bin/flink run -yid application_****_*** -yz YARN101 examples/streaming/WindowJoin.jar
```

- If `yarn-session.sh` does not use `-z` to configure the specified ZooKeeper NameSpace, do not use `-yz` to specify the ZooKeeper NameSpace when using `flink run`.

Example:

```
bin/yarn-session.sh  
bin/flink run examples/streaming/WindowJoin.jar
```

- You can use `-yz` to specify a ZooKeeper NameSpace when using `flink run -m yarn-cluster` to start a cluster.
- A NameSpace cannot be shared by multiple clusters.
- If you use `-z` to specify a ZooKeeper NameSpace when starting a cluster or submitting a job, you need to use `-z` again to specify the NameSpace when deleting, stopping, or querying the job or triggering the savepoint.

## 2.4.5.5 FAQ

### 2.4.5.5.1 Savepoints-related Problems

1. Should I assign IDs to all operators of the job?

Strictly speaking, you can assign IDs to only operators with statuses because savepoints save only statuses of operators that have statuses and not operators without statuses.

However, in actual situations, you are advised to allocate IDs to all operators because some internal operators, such as window operators of Flink have statuses. Whether an operator has status or not is not obvious. If you are specific that an operator does not have status, you do not need to call `uid()` to allocate an ID to the operator.

2. What would be the impact if I add an operator with status while upgrading the job?

If you add an operator with status to the job, the status of the operator is not saved in the savepoint and thus the status cannot be recovered. The operator is processed as an operator without status and is executed from the start.

3. What would be the impact if I delete an operator with status while upgrading the job?

By default, savepoints attempt to recover all saved statuses. If the savepoint saves the status of the deleted operator, recovery fails.

You can run the following command and use the `-allowNonRestoredState (-n` in the following command) parameter to skip recovering the status of the deleted operator:

```
$ bin/flink run -s savepointPath -n [runArgs]
```

4. What would be the impact if I rearrange the sequence of operators with statuses?

- If you have allocated IDs to the operators, the statuses would be recovered normally.
- If you do not allocate IDs to the operators, IDs would be automatically allocated to the operators in the new sequence. Then, the status recovery would fail.

5. What would be the impact if I delete or add an operator without status or rearrange the sequence of operators without statuses?

- If you have allocated IDs to operators with statuses, operators without statuses do not affect status recovery from savepoints.
- If you do not allocate IDs to operators, operators with statuses may be allocated with new IDs due to the sequence change. This would cause status recovery failure.

6. What would be the impact if I change the operator concurrency during the status recovery?

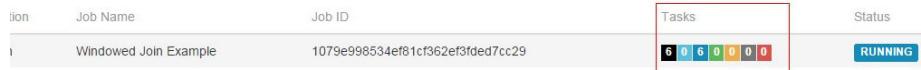

If the Flink version is higher than 1.2.0 and discarded status APIs, such as `checkpointed`, are not used, you can recover statuses from savepoints. Otherwise, statuses cannot be recovered.

#### 2.4.5.5.2 What If the Chrome Browser Cannot Display the Title

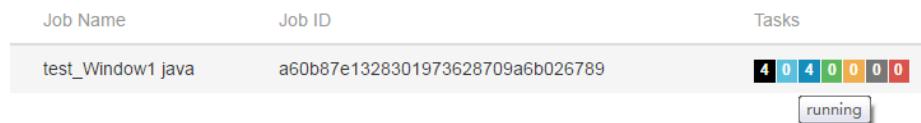

##### Question

What to do if the title is not displayed when I use Chrome browser to access the Apache Flink Dashboard? This section takes the Tasks field as an example. When the pointer is placed on a colorful box in Tasks, the title of the box is not displayed, as shown in [Figure 2-97](#). [Figure 2-98](#) shows the normal situation when the title is displayed.

**Figure 2-97 Title not displayed on the page**

**Figure 2-98 Title displayed normally**

## Answer

If the Chrome browser does not display the title, perform the following procedure:

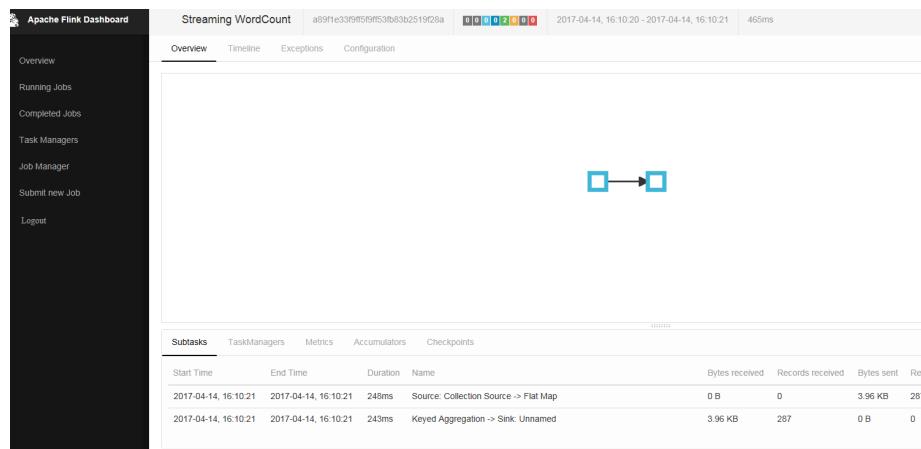

Check whether a tool that affects the tooltip display by the Chrome browser is running. If so, shut down the tool.

### 2.4.5.5.3 What If the Page Is Displayed Abnormally on Internet Explorer 10/11

## Question

What to do if Internet Explorer 10/11 does not display operator texts, as shown in [Figure 2-99](#)?

**Figure 2-99 Page displayed abnormally on Internet Explorer 10/11**

## Answer

Flink uses the `foreignObject` element to draw scalable vector graphics (SVGs) but Internet Explorer 10/11 does not support `foreignObject` and thus operators cannot be displayed normally. Google Chrome browser is supported.

#### 2.4.5.5.4 What If Checkpoint Is Executed Slowly in RocksDBStateBackend Mode When the Data Amount Is Large

##### Question

What to do if checkpoint is executed slowly in RocksDBStateBackend mode when the data amount is large?

##### Cause Analysis

Customized windows are used and the window state is ListState. There are many values under the same key. In the case of a new value, the merge operation of RocksDB is used. When calculation is triggered, all values under the key are read.

- The RocksDB mode is `merge() > merge() ... > merge() > read()`. Data reading in this mode consumes much time, as shown in [Figure 2-100](#).
- The source operator sends a large amount of data in a short period of time and the data keys are the same. The window operator fails to process data fast enough and barriers accumulate in the cache. The time consumed for snapshot preparation is too long and the window operator cannot report snapshot completion to CheckpointCoordinator in the specified time. Therefore, CheckpointCoordinator determines snapshot preparation failure, as shown in [Figure 2-101](#).

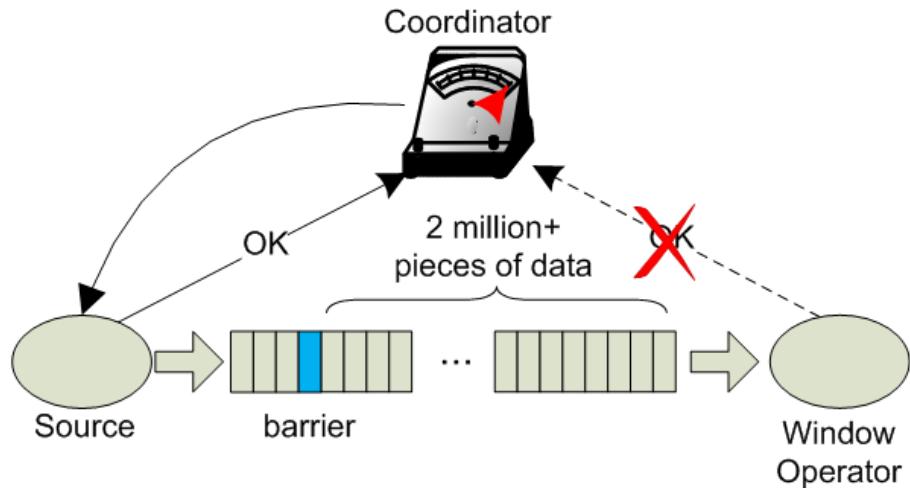

Figure 2-100 Time monitoring

```

2 million pieces of data are sent within 466 ms

40S+  
39.7s is spent on reading data from RocksDB

Figure 2-101 Relationship

## Answer

Flink introduces the third-party software package RocksDB, whose defect causes the problem. You are advised to set checkpoint to FsStateBackend mode.

Set checkpoint to FsStateBackend mode in the application code as follows:

```
env.setStateBackend(new FsStateBackend("hdfs://hacluster/flink/checkpoint/"));
```

### 2.4.5.5.5 What If yarn-session Start Fails When blob.storage.directory Is Set to /home

## Question

When **blob.storage.directory** is set to **/home**, the **blobStore-UUID** file cannot be created in **/home**. This causes yarn-session start failure

## Answer

**Step 1** It is recommended that **blob.storage.directory** be set to **/tmp** or **/opt/huawei/Bigdata/tmp**.

**Step 2** When you set **blob.storage.directory** to a customized directory, manually grant permissions to the directory. This section takes the **admin** user of FusionInsight as an example.

1. Modify **conf/flink-conf.yaml** on the Flink client and run the **blob.storage.directory: /home/testdir/testdirdir/xxx** command.
2. Create the **/home/testdir** directory (level 1 is enough) and set the directory to be managed by the **admin** user.

```
SZV1000064084:/home # id admin  
uid=20000(admin) gid=9998(ficcommon) groups=9998(ficcommon),8003(System_administrator_186)  
SZV1000064084:/home # chown admin:ficcommon testdir/ -R
```

### NOTE

The **testdirdir/xxx** directory under the **/home/testdir/** directory is automatically created on each node when Flink cluster starts.

3. Run **./bin/yarn-session.sh -jm 2048 -tm 3072** on the client to check that yarn-session is normally started and the directory is successfully created.

```
SV1000064084:/home # ll testdir/
total 4
drwxr-x--- 3 admin ficommon 4096 Mar 13 11:55 testdirdir
SV1000064084:/home # ll testdir/testdirdir/
total 4
drwxr-x--- 4 admin ficommon 4096 Mar 13 11:55 xxx
SV1000064084:/home # ll testdir/testdirdir/xxx/
total 8
drwxr-x--- 2 admin ficommon 4096 Mar 13 11:55 blobStore-6fb3f049-ecf3-49ac-9fc9-95ad0aeeffd3
drwxr-x--- 2 admin ficommon 4096 Mar 13 11:55 blobStore-ad89b118-8545-4ece-8cae-1334b01de857
```

----End

#### 2.4.5.5.6 Why Does Non-static KafkaPartitioner Class Object Fail to Construct FlinkKafkaProducer010?

##### Question

After Flink kernel is upgraded to 1.3.0 or later versions, if Kafka calls the FlinkKafkaProducer010 that contains the non-static KafkaPartitioner class object as parameter to construct functions, an error is reported.

The error message is as follows:

```
org.apache.flink.api.common.InvalidProgramException: The implementation of the FlinkKafkaPartitioner is not serializable. The object probably contains or references non serializable fields.
```

##### Answer

In the 1.3.0 version of Flink, the FlinkKafkaDelegatePartitioner class is added, so that Flink allows APIs that use KafkaPartitioner, for example, FlinkKafkaProducer010 that contains KafkaPartitioner object, to construct functions.

The FlinkKafkaDelegatePartitioner class defines the member variable kafkaPartitioner.

```
private final KafkaPartitioner<T> kafkaPartitioner;
```

When Flink input parameter KafkaPartitioner constructs FlinkKafkaProducer010, the call stack is as follows:

```
FlinkKafkaProducer010(String topicId, KeyedSerializationSchema<T> serializationSchema, Properties
producerConfig, KafkaPartitioner<T> customPartitioner)
-> FlinkKafkaProducer09(String topicId, KeyedSerializationSchema<IN> serializationSchema, Properties
producerConfig, FlinkKafkaPartitioner<IN> customPartitioner)
---> FlinkKafkaProducerBase(String defaultTopicId, KeyedSerializationSchema<IN> serializationSchema,
Properties producerConfig, FlinkKafkaPartitioner<IN> customPartitioner)
-----> ClosureCleaner::clean(Object func, boolean checkSerializable)
```

Run the KafkaPartitioner object to construct a FlinkKafkaDelegatePartitioner object, and then check whether the object can be serializable. The ClosureCleaner::clean function is a static function. If the KafkaPartitioner object in a case is non-static, the ClosureCleaner::clean function cannot access the non-static member variable kafkaPartitioner in the KafkaDelegatePartitioner class and an exception is reported.

Either of the following methods can be used to solve the problem:

- Change the KafkaPartitioner class into static class.
- Use the FlinkKafkaProducer010 that contains FlinkKafkaPartitioner as the parameter to construct functions. In this case, FlinkKafkaDelegatePartitioner is not constructed and the exception about member variable is avoided.

#### 2.4.5.5.7 When I Use a Newly Created Flink User to Submit Tasks, Why Does the Task Submission Fail and a Message Indicating Insufficient Permission on ZooKeeper Directory Is Displayed?

##### Question

When I use a newly-created Flink user to submit tasks, the task submission fails because of insufficient permission on the ZooKeeper directory. The error message in the log is as follows:

```
NoAuth for /flink_base/flink/application_1499222480199_0013
```

##### Answer

1. Check whether the permission on the /flink\_base directory in ZooKeeper is 'world,'anyone: cdrwa; If no, change the permission on the /flink\_base directory to 'world,'anyone: cdrwa and go to **step 2**. If yes, go to **step 2**.
2. In the configuration file of Flink, the default value of `high-availability.zookeeper.client.acl` is `creator`, indicating that only the creator of the directory has permission on it. The user created later has no access to the /flink\_base/flink directory in ZooKeeper because only the user created earlier has permission on it.

To solve the problem, perform the following operation as the newly-created user:

- a. Check the configuration file `conf/flink-conf.yaml` on the client.
- b. Modify the parameter `high-availability.zookeeper.path.root` to the corresponding ZooKeeper directory, for example, `/flink2`.
- c. Submit tasks again.

#### 2.4.5.5.8 Why Cannot I Access the Apache Flink Dashboard?

##### Question

Why cannot I access the Apache Flink Dashboard through the URL: `http://IP address of JobManager:port of JobManager`.

##### Answer

The IP address of the computer you used has not been added to the whitelist of Apache Flink Dashboard. To solve this problem, modify the `conf/flink-conf.yaml` configuration file as follows:

1. Check whether the value of `jobmanager.web.ssl.enabled` is `false`. If not, set it to `false`.
2. Check whether the IP address of the computer you used has been added to the values of `jobmanager.web.access-control-allow-origin` and

**jobmanager.web.allow-access-address.** If the IP address has not been added, add it to the two parameters:

jobmanager.web.access-control-allow-origin:*IP address of the computer where the browser is installed*  
jobmanager.web.allow-access-address:*IP address of the computer where the browser is installed*

### 2.4.5.5.9 How Do I View the Debugging Information Printed Using System.out.println or Export the Debugging Information to a Specified File?

#### Question

System.out.println is added to the Flink service codes for printing debugging information. How do I view the debugging log? How do I export service logs to a specified file to differentiate service logs from run logs?

#### Answer

All run logs of Flink are printed to the local directory of Yarn. By default, all logs are exported to **taskmanager.log** in the local directory of Yarn container. All logs generated by invoking System.out will be exported to the **taskmanager.out** file. You can perform as follows to view the logs:

1. Log in to the native Flink web page.
2. Choose **Task Managers > Logs** or **Task Managers > Stdout** on the left to view log information.

Configure the function of printing service logs and Task Manager run logs separately:

#### NOTE

If service logs and Task Manager run logs are separately printed, service logs are not exported to the **taskmanager.log** file and cannot be viewed on the web page.

1. Modify the configuration file **logback.xml** in the **conf** directory of the client. Add the following log configuration information to the file. Modify the information in bold according to the actual situation.

```
<appender name="TEST" class="ch.qos.logback.core.rolling.RollingFileAppender">
    <file>/path/test.log</file>
    <rollingPolicy class="ch.qos.logback.core.rolling.FixedWindowRollingPolicy">
        <fileNamePattern>/path/test.log.%i</fileNamePattern>
        <minIndex>1</minIndex>
        <maxIndex>20</maxIndex>
    </rollingPolicy>
    <triggeringPolicy class="ch.qos.logback.core.rolling.SizeBasedTriggeringPolicy">
        <maxFileSize>20MB</maxFileSize>
    </triggeringPolicy>
    <encoder>
```

```
<pattern>%d{"yyyy-MM-dd HH:mm:ss,SSS"} | %m %n</pattern>
</encoder>
</appender>

<logger name="com.huawei.bigdata.flink.examples" additivity="false">
    <level value="INFO"/>
    <appender-ref ref="TEST"/>
</logger>
```

2. Run **yarn-session.sh** to submit the task.

If the configuration file **logback.xml** contains `<file>/path/test.log</file>`, ensure that the user (configured **flink-conf.yaml**) used for running the task has the write and read permissions on the directory.

#### 2.4.5.5.10 Incorrect GLIBC Version

##### Question

When **State Backend** is set to **RocksDB** for a Flink task, the following error message is displayed:

```
Caused by: java.lang.UnsatisfiedLinkError: /srv/BigData/hadoop/data1/nm/usercache/**/appcache/application_***/rocksdb-lib-***/librocksdbjni-linux64.so: /lib64/libpthread.so.0: version `GLIBC_2.12` not found (required by /srv/BigData/hadoop/**/librocksdbjni-linux64.so)
at java.lang.ClassLoader$NativeLibrary.load(Native Method)
at java.lang.ClassLoader.loadLibrary0(ClassLoader.java:1965)
at java.lang.ClassLoader.loadLibrary(ClassLoader.java:1890)
at java.lang.Runtime.load0(Runtime.java:795)
at java.lang.System.load(System.java:1062)
at org.rocksdb.NativeLibraryLoader.loadLibraryFromJar(NativeLibraryLoader.java:78)
at org.rocksdb.NativeLibraryLoader.loadLibrary(NativeLibraryLoader.java:56)
at
org.apache.flink.contrib.streaming.state.RocksDBStateBackend.ensureRocksDBIsLoaded(RocksDBStateBackend.java:734)
... 11 more
```

##### Possible Causes

The version of the system where the task runs and the version of the system where the compilation environment locates are different, resulting in the incompatibility of GLIBC versions.

##### Troubleshooting Method

Run the **strings /lib64/libpthread.so.0 | grep GLIBC** command to check whether the GLIBC version is earlier than 2.12.

##### Procedure

If the version of the GLIBC is too early, use the file of later version (2.12) to replace **libpthread-\* .so**. (This is a link file. You need to replace only the file that is linked to this link file.)

None

## 2.5 GraphBase Development Guide

### 2.5.1 Overview

#### 2.5.1.1 Application Development Overview

##### GraphBase Introduction

FusionInsight GraphBase is a distributed graph database based on HBase and Elasticsearch. It builds a property graph model for storage and provides powerful graph query, analysis, and traversal capabilities. It has the following features:

- The HBase-based distributed storage mechanism is provided to process massive data.
- The Spark distributed memory computing technology is provided to support quick data import.
- The Elasticsearch-based index mechanism is provided to quickly query data based on indexes.

##### Interface Type Introduction

- REST API Interface

REST APIs are developed using the Java language that is simple and easy. Therefore, you are advised to use the Java language to develop upper-layer applications. For details, see **GraphBase** in *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

The following table describes the functions provided by GraphBase after REST API is invoked.

Function	Description
User login and logout	This function can be used for access authentication.
Metadata read/write	This function can be used to add, delete, modify, and query metadata.
Metadata-based operations on vertices and edges	This function can be used to add, delete, modify, and query vertices and edges.
Filtering and querying relationships for a large amount of data	This function can be used for full graph query, conditional query, line expansion query, and path query for vertices and edges.
Index management	This function can be used to create and query full graph indexes and edge indexes, and query the status of asynchronous index tasks.

- Gremlin API Interface

Gremlin is the graph traversal language of Apache TinkerPop. Gremlin is a functional, data-flow language that enables users to succinctly express complex traversals on (or queries of) their application's property graph. Every Gremlin traversal is composed of a sequence of (potentially nested) steps. A step performs an atomic operation on the data stream. For details about Gremlin, visit <http://tinkerpop.apache.org/docs/3.3.2/reference/#traversal>.

Gremlin has the following three types of basic operations:

- map-step: converts objects in a data flow.
- filter-step: filters objects in a data flow.
- sideEffect-step: calculates data flows.

### 2.5.1.2 Basic Concepts

Like most graph databases, GraphBase uses property graphs for modeling. Based on the property graph models, GraphBase has the following basic concepts:

- **Vertex**: A vertex is also called a node, which is used to specify an entity object in the real world, such as a person.
- **Vertex label**: A vertex label indicates a node type that specifies the type of an entity object in the real world. Example: person. In GraphBase, a node has only one vertex label. The default value is **vertex**.
- **Edge**: An edge, also known as a relationship that is used to specify the connections between two entity objects (vertices in a graph) in the real world. For example, the relationship between two persons is friend. Edges in GraphBase are unidirectional, which starts from a vertex and ends at another. Therefore, a bidirectional edge has an incoming and an outgoing edge.
- **Edge label**: An edge label specifies the type of a relationship in the real world. For example, the relationship is friend.
- **Property**: A property describes some attribute of either a vertex or an edge in the format of key-value pair. Property key is used to describe the key in the key-value pair, property value describes a specific value. For example, a property key is **name**, the property value is **Zhang San**.

### 2.5.1.3 Development Process

This section describes how to develop a GraphBase application based on GraphBase REST API and Gremlin API.

[Figure 2-102](#) shows the development process, and [Table 2-52](#) describes each phase.

Figure 2-102 GraphBase application development process

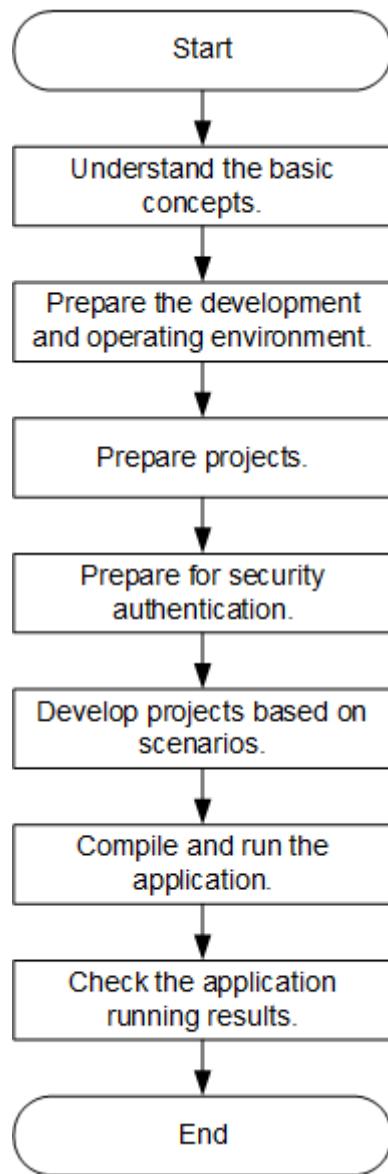

Table 2-52 GraphBase application development process

Phase	Description	Reference Document
Understand basic concepts about GraphBase.	Before application development, learn basic concepts of GraphBase, understand the scenario requirements, and design tables.	<a href="#">Basic Concepts</a>

Phase	Description	Reference Document
Prepare the development and running environment.	REST APIs and the Gremlin language are recommended for GraphBase application development. You can use the IntelliJ IDEA tool. The GraphBase running environment is the GraphBase client. Install and configure the client according to the guide.	<ul style="list-style-type: none"><li>For details about how to prepare the development environment for the REST API, see <a href="#">Preparing the Development and Operating Environment</a>.</li><li>For details about how to prepare the development environment for the Gremlin API, see <a href="#">Preparing the Development and Operating Environment</a>.</li></ul>
Prepare a project.	GraphBase provides sample projects for different scenarios. You can import a sample project to learn the application.	<ul style="list-style-type: none"><li>For details about how to prepare a project for the REST API, see <a href="#">Configuring and Importing Sample Projects</a>.</li><li>For details about how to prepare a project for the Gremlin API, see <a href="#">Configuring and Importing a Piece of Sample Code</a>.</li></ul>
Preparing for security authentication.	In normal mode of the cluster, security authentication must be performed for the REST API.	For details about how to perform security authentication for the REST API, see <a href="#">Preparing for Security Authentication</a> .

Phase	Description	Reference Document
Develop a project based on the scenario.	<ul style="list-style-type: none"><li>Sample projects for developing REST APIs are provided, including projects for creating and deleting graphs and performing full graph query, path query, and line expansion query.</li><li>The Gremlin syntax scenario is provided, including syntax scenarios for querying a specified graph object, querying one or more properties, traversing graph objects and paths.</li></ul>	<a href="#">Developing an Application</a>
Compile and run applications.	You can compile a developed application and submit it for running.	<ul style="list-style-type: none"><li><a href="#">Compiling and Running an Application</a></li><li><a href="#">Compiling and Running an Application</a></li></ul>
Check the application running results.	Application running results are exported to a path you specify. ## 2.5.2 Environment Preparation

### 2.5.2.1 REST API Development Environment Preparation

#### 2.5.2.1.1 Preparing the Development and Operating Environment

[Table 2-53](#) describes the development and running environment required for secondary development.

**Table 2-53 Environment**

Preparation Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows 7 or later</li><li>• Operating environment: Windows OS or Linux OS. If the program needs local debugging, the operating environment must be able to communicate with the cluster service plane.</li></ul>
JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– Oracle JDK 1.8</li><li>– IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>– BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA	<p>Tool used for developing GraphBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you are using an IBM JDK, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If you are using an Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If you are using an OpenJDK, ensure that the JDK configured in IntelliJ IDEA is the OpenJDK.</li></ul>
Maven	Basic configuration of the development environment. It can be used for project management throughout the lifecycle of software development.

Preparation Item	Description
JUnit plug-ins	Basic configuration of the development environment.
User development	See <a href="#">Preparing a Developer Account</a> for configuration.
7-Zip	Tool used to decompress *.zip and *.rar files. <b>7-Zip 16.04</b> is supported.

## Preparing the Operating Environment

During application development, prepare the environment for running and commissioning code to verify that the application can run properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required for commissioning; configure the network connection, and commission the application in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#) and click **Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar**. Then, decompress this file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.
  - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\GraphBase\config** and import the configuration file to the configuration file directory (usually the **conf** folder) of the GraphBase sample project.

The keytab file obtained during [Preparing a Developer Account](#) is also stored in this directory. **Table 2-54** describes the main configuration files.

**Table 2-54** Configuration files

File	Description
graphbase.properties	Parameters required for the GraphBase sample code
Person.xml	Files required by Schema

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where

the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

#### NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored, for example, in **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, install the client in the **/opt/hadoopclient** directory.

The difference between the client time and the cluster time must be less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).

- b. Log in to FusionInsight Manager. Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/GraphBase/config** directory to the **conf** directory where the compiled JAR file is stored for subsequent commissioning, for example, **/opt/hadoopclient/conf**.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active OMS node, run the following commands:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp GraphBase/config/* root@IP address of the client node:/opt/  
hadoopclient/conf
```

[Table 2-55](#) describes the main configuration files.

**Table 2-55** Configuration files

File	Description
graphbase.properties	Parameters required for the GraphBase sample code
Person.xml	Files required by Schema

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If there is

no required information, copy the content of the **hosts** file in the decompression directory to the **hosts** file on the node where the client is deployed, to ensure that the local host can communicate with each host in the cluster.

### 2.5.2.1.2 Configuring and Importing Sample Projects

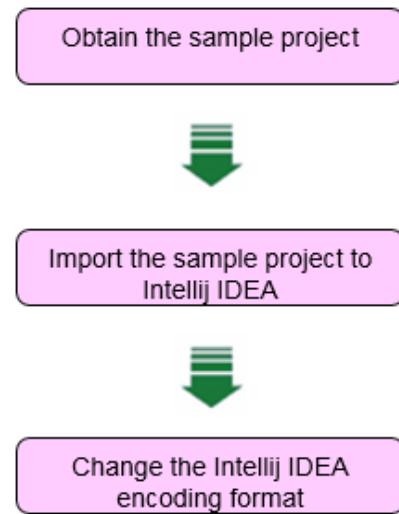

#### Prerequisites

You have installed the GraphBase client.

#### Scenarios

GraphBase provides sample projects for multiple scenarios to help customers quickly learn REST APIs. The following describes how to import the GraphBase sample code that can be imported to IntelliJ IDEA. [Figure 2-103](#) shows the importing process.

**Figure 2-103** Process of importing a sample project

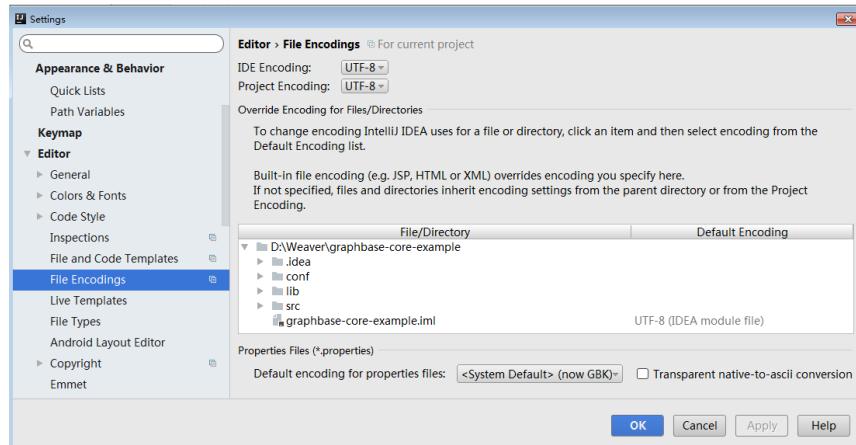

#### Procedure

- Step 1** Obtain the sample project folder **graphbase-examples** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Import the sample project to the IntelliJ IDEA development environment.
  1. Open IntelliJ IDEA and choose **File > New > Project from Existing Sources**.
  2. Select the sample project folder **graphbase-core-example** and click **OK**.
  3. In the **Import Project** dialog box, select **Create project from existing sources**.
  4. Click **Next** until **JDK** is set to **jdk1.8.0\_402**. Then, click **Next**. On the displayed dialog box, click **Finish**.
- Step 3** Configure the text file encoding format of IntelliJ IDEA to avoid garbled characters.

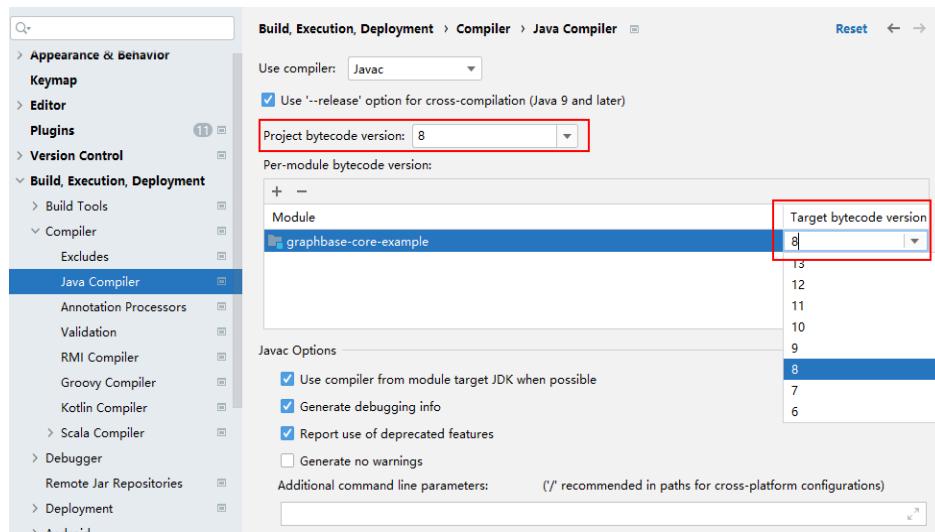

1. Choose **File > Settings...** from the main menu of IntelliJ IDEA.
2. In the displayed **Settings** page, choose **Editor > File Encoding** from the navigation pane on the left. On the displayed page, set **IDE Encoding** and **Project Encoding** to **UTF-8**, and click **Apply**. On the displayed page, click **OK**, as shown in [Figure 2-104](#).

**Figure 2-104** Setting the encoding format of IntelliJ IDEA

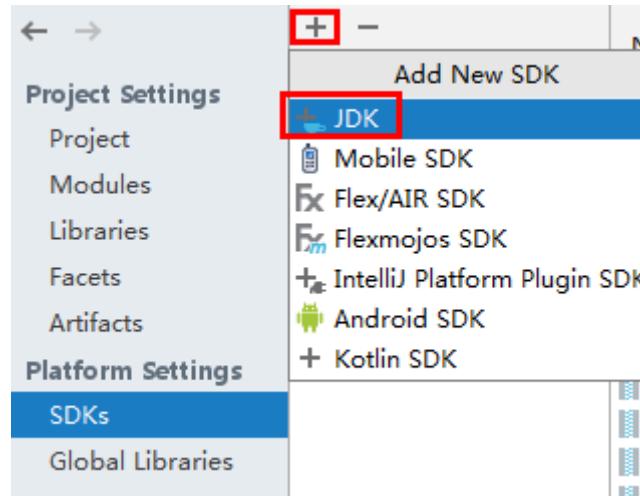

#### Step 4 Set the JDK of the project.

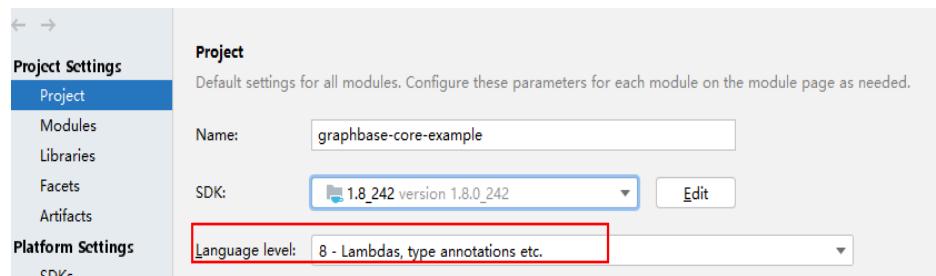

1. On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler** and select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** in **graphbase-core-example** to **8**.

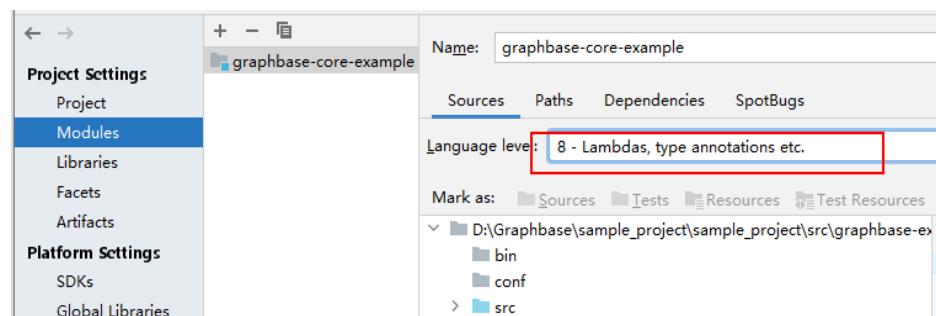

3. Click **Apply** then **OK**.
4. On the menu bar of IntelliJ IDEA, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Choose **SDKs**, click the plus sign (+), and select **JDK**.

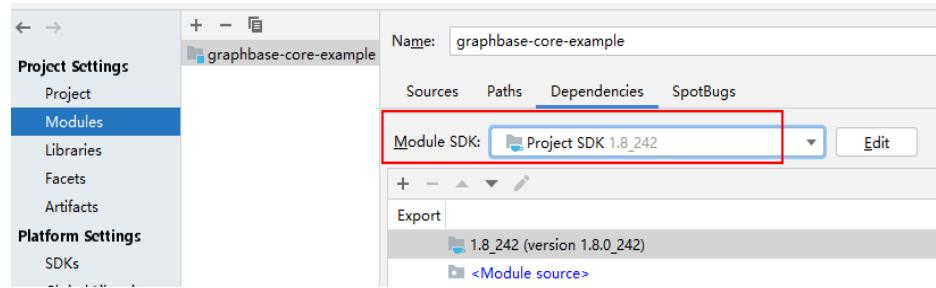

6. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.
7. Click **Apply**.
8. Select **Project**, select the JDK added in **SDKs** from the **Project SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Project language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Sources** tab page, change the value of **Language level** to **8 - Lambdas, type annotations etc..**

On the **Dependencies** tab page, change the value of **Module SDK** to the JDK added in **SDKs**.

11. Click **Apply** and then **OK**.

----End

### 2.5.2.1.3 Preparing for Security Authentication

GraphBase uses keytab authentication which never expires. You are advised to use keytab files for authentication on the client.

1. Modify the configuration data.

- In the **conf** directory of the root directory of the sample project, set the **graphbase.properties** configuration file, IP address, port number, and username as you need.

#### NOTE

The IP address and port number of the GraphBase service is the floating IP address and port number specified when the GraphBase component is installed. Log in to FusionInsight Manager, choose **Cluster** > *Name of the desired cluster* > **Services** > **GraphBase** > **Configurations** > **All Configurations**, and search for **loadbalancer.floatip**. The value of **loadbalancer.floatip** is the floating IP address, the value of **loadbalancer.https.port** is the port number.

Parameter	Value
<b>GraphBase-&gt;LoadBalancer</b>	
* <b>loadbalancer.floatip</b>	10 . 5 . 89 . 50
* <b>loadbalancer.https.port</b>	22380

**Note:** In an IPv6 network, the floating IP address must be enclosed by square brackets, for example, [IPv6 address].

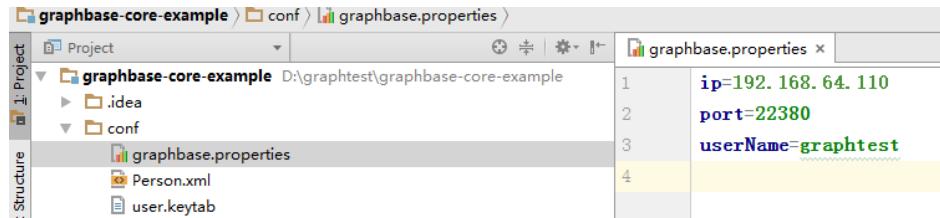

- Download the keytab file of the machine-machine user and copy it to the **conf** directory in the root directory of the sample project.

Log in to FusionInsight Manager, click **System**, and choose **Permission > User**. On the displayed page, click **More > Download Authentication Credential** to obtain the **user.keytab** authentication file.

#### NOTE

The authentication credential contains the **krb5.conf** file of Kerberos. If there are multiple clusters, select the **krb5.conf** file of the corresponding cluster.

- Modify the configuration file as follows.

## 2. Obtain Keytab authentication code.

Construct an HTTP client, log in to it with Kerberos authentication, obtain CSRF TOKEN information, and call RESTful APIs. The following code snippets are in the **GraphHttpClient** class of the **com.huawei.security** package.

```

/* step 1: create http client */
final X509TrustManager trustManager = new X509TrustManager() {
    @Override
    public final X509Certificate[] getAcceptedIssuers() {
        return null;
    }

    @Override
    public final void checkClientTrusted(X509Certificate ax509certificate[], String s) throws
CertificateException {
        // to do nothing.
    }

    @Override
    public final void checkServerTrusted(X509Certificate ax509certificate[], String s) throws
CertificateException {
        // to do nothing.
    }
};

final javax.net.ssl.SSLContext context = javax.net.ssl.SSLContext.getInstance("TLS");
context.init(null, new TrustManager[]{trustManager}, null);
final ThreadSafeClientConnManager connectionManager = new ThreadSafeClientConnManager();
connectionManager.setMaxTotal(100);
connectionManager.getSchemeRegistry().register(new Scheme("https", 443, new SSLSocketFactory(
    context, SSLSocketFactory.ALLOW_ALL_HOSTNAME_VERIFIER)));

CloseableHttpClient httpclient = new DefaultHttpClient(connectionManager);

/*
 * step 2:
 * usage: kerberos login based on username and keytab,
 * note: Password never expired
 */
HttpPost loginPost = new HttpPost(httpAuthInfo.getBaseUrl() + "/login");
MultipartEntityBuilder entityBuilder = MultipartEntityBuilder.create();
entityBuilder.addPart("username", new StringBody(httpAuthInfo.getUsername(),
ContentType.create("text/plain", Consts.UTF_8)));
entityBuilder.addBinaryBody("keytabfile", new File(httpAuthInfo.getKeytabFilePath()));
loginPost.setEntity(entityBuilder.build());
loginRsp = httpclient.execute(loginPost);
RestHelper.checkHttpRsp(loginRsp);

/* step 3: get CSRF-Token */
HttpGet httpGet = new HttpGet(httpAuthInfo.getBaseUrl() + "/graph/user/me");
CloseableHttpResponse csrfTokenRsp = httpClient.execute(httpGet);
}

```

## 2.5.2.2 Gremlin API Development Environment Preparation

### 2.5.2.2.1 Preparing the Development and Operating Environment

**Table 2-56** describes the development and running environment required for secondary development.

**Table 2-56** Environment

Preparation Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows 7 or later</li><li>• Operating environment: Windows OS or Linux OS. If the program needs local debugging, the operating environment must be able to communicate with the cluster service plane.</li></ul>
JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– Oracle JDK 1.8</li><li>– IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>– BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>

Preparation Item	Description
IntelliJ IDEA	<p>Tool used for developing GraphBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you are using an IBM JDK, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If you are using an Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If you are using an OpenJDK, ensure that the JDK configured in IntelliJ IDEA is the OpenJDK.</li></ul>
Maven	Basic configuration of the development environment. It can be used for project management throughout the lifecycle of software development.
JUnit plug-ins	Basic configuration of the development environment.
7-Zip	Tool used to decompress *.zip and *.rar files. <b>7-Zip 16.04</b> is supported.

## Preparing the Operating Environment

During application development, prepare the environment for running and commissioning code to verify that the application can run properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required for commissioning; configure the network connection, and commission the application in Windows.
    - a. **Accessing FusionInsight Manager of an MRS Cluster** and click **Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar**. Then, decompress this file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.

    - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\GraphBase\config** and import the configuration file to the configuration file directory (usually the **conf** folder) of the GraphBase sample project.
- The keytab file obtained during **Preparing a Developer Account** is also stored in this directory. **Table 2-57** describes the main configuration files.

**Table 2-57** Configuration files

File	Description
graphbase.properties	Parameters required for the GraphBase sample code
Person.xml	Files required by Schema

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 **NOTE**

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored, for example, in **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, install the client in the **/opt/hadoopclient** directory.

The difference between the client time and the cluster time must be less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).

- b. **Accessing FusionInsight Manager of an MRS Cluster**. Download the cluster client software package to the active management node and decompress it. Then log in to the active management node as user **root**. Go to the decompression directory of the cluster client, and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/GraphBase/config** directory to the client node to the **conf** directory where the compiled JAR package is stored, for example, **/opt/hadoopclient/conf**, for subsequent commissioning.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active OMS node, run the following commands:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp GraphBase/config/* root@IP address of the client node:/opt/  
hadoopclient/conf
```

**Table 2-58** describes the main configuration files.

**Table 2-58** Configuration files

File	Description
log4j.properties	Gremlin log parameters
remote-objects.yaml	Detailed parameters for Gremlin query

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If there is no required information, copy the content of the **hosts** file in the decompression directory to the **hosts** file on the node where the client is deployed, to ensure that the local host can communicate with each host in the cluster.

### 2.5.2.2 Configuring and Importing a Piece of Sample Code

1. Obtain the sample project folder **gremlin-demo4j** in the **graphbase-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
2. Import the sample code to IntelliJ IDEA. For details, see [Configuring and Importing Sample Projects](#).

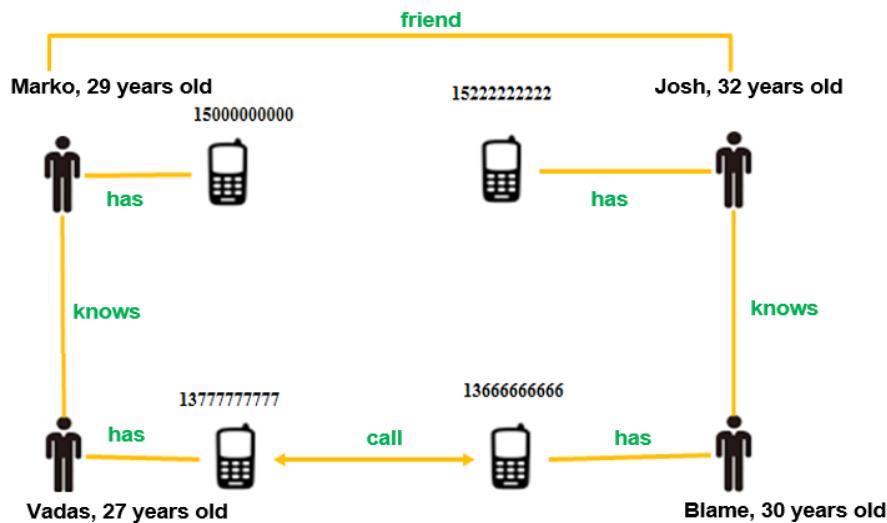

## 2.5.3 Developing an Application

### 2.5.3.1 Typical Application Scenario

You can quickly learn and master the GraphBase development process and know key interface functions in a typical application scenario.

#### Actual Scenario

Typical social relationships:

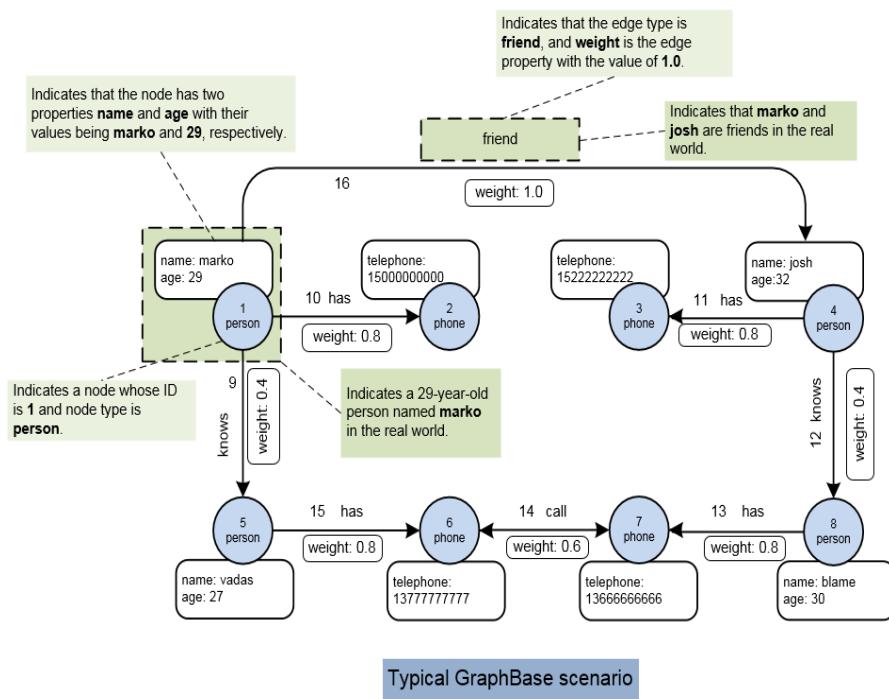

In the scenario, there are eight real world entities, four persons and four mobile phones.

There are eight relationships between the entity objects, including **friend**, **knows**, **call**, and **has**.

## Graph Modeling Scenario

The purpose of graph modeling is to map the real world relationships to GraphBase using a graph:

- **Vertex**: maps persons and mobile phones in the real world to GraphBase using vertices.
  - **Vertex label**: defines the types of persons and mobile phone in the real world in GraphBase. That is, people are labeled as **person**, and mobile phones are defined as **phone** in the graph.
  - **Edge**: maps the relationships between people and people, people and mobile phones, and mobile phones and mobile phones in the real world to GraphBase using edges.
  - **Edge label**: defines the relationships between entity objects in the real world in GraphBase. The definitions of these relationships in this scenario are as follows:
    - The friend relationship between people is defined as the edge label **friend**.
    - The acquaintance relationship is defined as the edge label **knows**.
    - The ownership between mobile phones and people is defined as **has**.
    - The communication relationship between mobile phones is defined as the edge label **call**.
  - **Property**: defines the feature information of each entity object in the real world in GraphBase. The name and age of a person is defined as the property **name** and **age**, respectively, and the mobile phone number is defined as the property **telephone**.
  - **New property**: Considering that GraphBase supports the value properties obtained by the evaluation system, the relationship weight property definition is added to indicate the importance of relationships. That is, the **weight** property is defined. It is considered that the value property has been obtained.
- The graph model is as follows.

## Development Guidelines

Based on the preceding scenario description, the basic operation process of creating a GraphBase service and querying data using the created service are as follows:

- Take **node 1 > node 2** in the scenario as an example, there are three elements included: node 1, node 2, and edge 10.
  - Create a schema using the two nodes, see instructions provided in [Creating a Schema](#).  
You need to create two vertex labels, **person** and **phone**, and an edge label, **has**.  
You need to create the properties of all nodes and edges: **name**, **age**, **telephone**, and **weight**.
  - (Optional) Create indexes for properties to improve query efficiency. For details, see [Creating an Index](#).
  - Create vertices and edges.  
Create vertex 1, vertex 2, and the edge 10. For details about how to create vertices and edges, see [Creating and Querying a Vertex or an Edge](#).
  - Query data.  
Method 1: Invoke a REST API for query.  
Invoke the full graph query interface to query vertices and edges. For details, see [Performing a Full Graph Query](#).  
Method 2: Perform data query using Gremlin statements. For details, see [Gremlin Console](#), [Gremlin Java](#) and [Gremlin Application Scenarios](#).  
You can create other nodes and edges in the same way.

- If the data volume is large, you can import the data in batches. The procedure is as follows:
  - a. Create a schema.  
Compile an XML file. For details, see [Compiling a Schema File \(XML\)](#).  
Create a schema by uploading the XML file. For details, see [Creating a Schema by Uploading an XML File](#).
  - b. Import data.  
Compile a data file (CSV), data description file (DESC), and a graph mapping rule file (.mapper). For details, see [Preparing Data Files](#).  
Import data in real time or in batches. For details, see [Importing Data](#).
  - c. Query data.  
Method 1: Invoke a REST API for query.  
Invoke the full graph query interface to query vertices and edges. For details, see [Performing a Full Graph Query](#).  
Method 2: Perform data query using Gremlin statements. For details, see [Gremlin Console](#), [Gremlin Java](#) and [Gremlin Application Scenarios](#).
- During data query, except vertex and edge query, you can query paths between vertices and perform line expansion queries. For details, see [Performing a Path Query](#) and [Performing a Line Expansion Query](#).

### 2.5.3.2 Preparing Data Files

#### 2.5.3.2.1 Compiling a Schema File (XML)

##### Defining the Schema File (XML)

In GraphBase, vertices and edges are entities. You need to create the metadata information for the entity labels, such as vertex labels, edge labels, property names, property value types. Such metadata information is the schema information of a graph.

1. Define a schema file **person.xml** based on the scenario described in [Typical Application Scenario](#) to create a schema file (containing vertexLabel, edgeLabel, and propertyKey).

The following code snippets are used as an example. For complete codes, see [GraphBase.examples.person-demo](#).

```
<?xml version="1.0" encoding="UTF-8"?>
<schema>
    <vertexLabelList>
        <vertexLabel name="person" isPartitioned="false"/>
        <vertexLabel name="phone" isPartitioned="false"/>
    </vertexLabelList>
    <edgeLabelList>
        <edgeLabel name="friend"></edgeLabel>
        <edgeLabel name="knows"></edgeLabel>
        <edgeLabel name="call"></edgeLabel>
        <edgeLabel name="has"></edgeLabel>
    </edgeLabelList>
    <propertyKeyList>
        <propertyKey name="name" dataType="STRING"/>
        <propertyKey name="age" dataType="INTEGER"/>
        <propertyKey name="telephone" dataType="STRING"/>
    </propertyKeyList>
</schema>
```

```
<propertyKey name="weight" dataType="FLOAT"/>
</propertyKeyList>
<graphIndexList>
    <graphIndex name="name_index" elementCategory="VERTEX" type="COMPOSITE" unique="false">
        <keyTextTypeList name="name" textType="" />
    </graphIndex>
    <graphIndex name="age_index" elementCategory="VERTEX" type="MIXED" unique="false">
        <keyTextTypeList name="age" textType="DEFAULT" />
    </graphIndex>
    <graphIndex name="telephone_index" elementCategory="VERTEX" type="COMPOSITE" unique="false">
        <keyTextTypeList name="telephone" textType="" />
    </graphIndex>
    <graphIndex name="weight_index" elementCategory="EDGE" type="MIXED" unique="false">
        <keyTextTypeList name="weight" textType="DEFAULT" />
    </graphIndex>
</graphIndexList>
</schema>
```

- **vertexLabelList:** indicates the vertex label set. These labels are optional in the preceding XML file, and the label content can be empty.

**vertexLabel:** indicates the vertex label. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name:** indicates the vertex label name, which is mandatory.

- **edgeLabelList:** indicates the edge label list. This parameter can be missing from the preceding XML file, and the parameter value can also be left blank.

**edgeLabel:** indicates an edge label. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name:** indicates the edge label name, which is mandatory.

**primaryKeys:** indicates the primary key to which EdgeLabel are bound with. Multiple primary keys can be specified. This parameter is optional. If there are multiple edges between two vertices and they have the same primaryKeys value, the edges can be considered as the same. For example:

```
<edgeLabel name="friend">
    <primaryKeys>p1</primaryKeys>
    <primaryKeys>p2</primaryKeys>
</edgeLabel>
```

- **propertyKeyList:** indicates the property key set. This parameter can be missing from the preceding XML file, and the parameter value can also be left blank.

**propertyKey:** indicates a property key. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name:** indicates the property name, which is mandatory.

**dataType:** indicates the property value data type, which is optional. The default value is **STRING**.

- **graphIndexList:** indicates the index set. This parameter can be missing from the preceding XML file, and the parameter value can also be left blank.

**graphIndex**: indicates the index. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name**: indicates the index name, which is mandatory.

**elementCategory**: indicates the index entity type, which is mandatory. The options are **VERTEX** and **EDGE**, which is case insensitive.

**type**: indicates the index type, which is mandatory. The options are as follows: **COMPOSITE** (Composite index: internal exact match index with index data stored in HBase) or **MIXED** (mixed index: external mixed match index with index data stored in Elasticsearch) which is case insensitive.

The analyzer cannot be configured by using COMPOSITE indexes.

- If the property key of this index does not contain any Chinese, you do not need to configure the analyzer.
- You can configure the analyzer only for data types, such as TEXT and TEXTSTRING.
- The analyzer can be set for MIXED indexes:
  - ik\_max\_word (fine-grained)
  - ik\_smart (coarse-grained, recommended)

**keyTextTypeList**: indicates the property key list in text format. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name**: indicates the property name, which is mandatory.

**textType**: indicates the index data type. The options are as follows:

- **TEXT**: indicates that the index data is of the text type.
- **TEXTSTRING**: indicates that the index data is of the text string type.
- **PREFIX\_TREE**: indicates that the index is of the geographical location type.
- **DEFAULT**: indicates the default index type. The value is case insensitive and can be empty. If this parameter is left empty, the default type is used.

## NOTICE

- GraphBase index categories:
  - Composite index: is the internal exact match index with the index data stored in HBase and does not support full-text search or splitter.
  - Mixed Index: is the external mixed match index with the index data stored in Elasticsearch and supports full-text search and splitter.
- Suggestions for using GraphBase indexes:
  - When a property is the vertex primary key, an internal index (Composite Index) must be created.
  - You are advised to create mixed indexes in common cases because the index search performance is better and the functions are and richer than the composite index.
  - The field definitions in the XML file labels are the same as those in the preceding labels. For details, see "Adding a Vertex Label", "Adding an Edge Label", "Adding a Property Key", "Adding a Graph Index", and "Vertex-centric Index Management" in "GraphBase" of the *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

## 2. Create metadata using the schema file.

REST APIs can be used to upload the schema file. For details, see [Creating a Schema by Uploading an XML File](#) in the sample project.

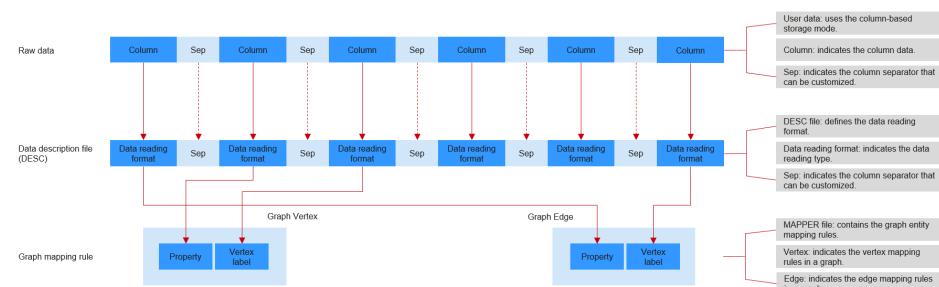

### 2.5.3.2.2 Compiling a Data File (CSV)

#### Data-Related Files

Data-related files are classified into the following types:

1. User data files, also called raw data files that are in CSV format.
2. Data description file is used to define the schema mapping relationship for data, and the file format is DESC.
3. Graph mapping rule file, which defines the mapping between raw data and entities in the graph database. The file format is MAPPER.

The following figure shows the relationship between the three types of files.

## Compiling Raw Data Files

Based on the instructions provided in [Typical Application Scenario](#), define the raw data file as follows (The following code snippets are used as an example. For complete codes, see [GraphBase.examples.person-demo](#)):

Note: The data in each column corresponds to the **index** value of properties in the graph mapping file (.mapper).

```
marko,29,,vadas,27,,knows,0.4,  
marko,29,150000000000,,,0.8,,  
josh,32,1522222222,,0.8,,  
josh,32,,blame,30,,knows,0.4,  
blame,30,136666666666,,,0.8,,  
,,136666666666,,137777777777,,0.6  
,,137777777777,,136666666666,,,0.6  
vadas,27,137777777777,,0.8,,  
marko,29,,josh,32,,friend,1.0,
```

### 2.5.3.2.3 Compiling a Data Description File (DESC)

#### Scenarios

Data description files (in DESC format) corresponding to CSV data files are required during data reading.

Based on the information provided in [Typical Application Scenario](#), design data description files as follows (The following code snippets are used as an example. For complete codes, see [GraphBase.examples.person-demo](#)):

```
{"delim":",",  
"includeRowHead":false,  
"attributes": [  
 {"name":"attr_0","type":"STRING","nominalList":[]},  
 {"name":"attr_1","type":"INTEGER","nominalList":[]},  
 {"name":"attr_2","type":"STRING","nominalList":[]},  
 {"name":"attr_3","type":"STRING","nominalList":[]},  
 {"name":"attr_4","type":"INTEGER","nominalList":[]},  
 {"name":"attr_5","type":"STRING","nominalList":[]},  
 {"name":"attr_6","type":"REAL","nominalList":[]},  
 {"name":"attr_7","type":"STRING","nominalList":[]},  
 {"name":"attr_8","type":"REAL","nominalList":[]},  
 {"name":"attr_9","type":"REAL","nominalList":[]} ]}
```

#### File Format Description

For details about the data description files (in DESC or HVDE format) corresponding to CSV data files, see [Table 2-59](#).

**Table 2-59** Data description file examples

File Format	Description
DESC	<p>The file contains <b>delim</b> and <b>attributes</b>.</p> <ul style="list-style-type: none"><li>• <b>delim</b>: defines the delimiter for data in the CSV data file. Ensure that you use the same delimiter in the CSV data file, otherwise, data fails to be imported, including commas (,), spaces, tabs, and user-defined delimiters. For example, a slash (/) or a colon (:).</li><li>• <b>includeRowHead</b>: specifies whether a header is included. If it is set to <b>false</b>, no header is included. If it is set to <b>true</b>, a header is included.</li><li>• <b>attributes</b>: includes <b>name</b>, <b>type</b>, <b>nominalList</b>, and <b>Format</b>.</li><li>• <b>type</b>: specifies the feature data type, which can be String, Integer, Real, Date, Time, or Timestamp.</li><li>• <b>name</b>: specifies the feature name.</li><li>• <b>nominalList</b>: specifies the enumerated value list.</li><li>• <b>alueFormat</b>: specifies the date format when <b>type</b> is set to <b>DateTime</b>, for example, yyyy-MM-dd HH:mm:ss.</li></ul> <p>Metadata is defined as follows:</p> <pre>{   "delim": ",",   "includeRowHead": false,   "attributes": [     {"name": "name", "type": "STRING", "nominalList": []},     {"name": "date", "type": "DATETIME", "nominalList": [], "valueFormat": "yyyy-MM-dd HH:mm:ss"} ]}</pre>

 **NOTE**

- A column name cannot contain special characters, for example, #@\*.
- The yyyyMMdd time format corresponds to year, month, and day. A complete time format is yyyyMMdd HH:mm:ss, corresponding to year, month, day, hour, minute, and second. The common time formats are yyyy/MM/dd and yyyy-MM-dd.

#### 2.5.3.2.4 Compiling a Graph Mapping Rule File (.mapper)

A graph mapping rule describes the mapping between the columns of a data set and the graph elements.

### Scenarios

Based on **Typical Application Scenario**, design the graph mapping rule file as follows (The following code snippets are used as an example. For complete codes, see **GraphBase.examples.person-demo**):

```
{  
  "entities": {  
    "entity1": {  
      "conceptIRI": "person",  
      "primaryKey": "name",  
      "label": "Person",  
      "type": "CLASS",  
      "valueFormat": "yyyy-MM-dd HH:mm:ss",  
      "valueType": "DATETIME",  
      "valueList": []  
    }  
  }  
}
```

```
"properties": {
    "name": {

## File Structure

The basic structure is as follows:

(The texts in bold are the defined property names, which are set by users.) The italic words can be entered by users based on scenarios and requirements. The underscored italic words indicate that the corresponding schemas must be created in the graph in advance.)

```
{
  "entities": {
    "entityName1": {
      "conceptIRI": "conceptName1",
      "primaryKey": "primaryKeyName1",
      "properties": {
        "propertyName1": {
          "type": "propertyValueType",
          "": ":{ }"
        },
        "propertyName2": {
          "type": "propertyValueType",
          "": ":{ }"
        }
      }
    },
    "entityName2": {
      "conceptIRIType": "constant",
      "conceptIRI": "conceptName2",
      "primaryKey": "primaryKeyName2",
      "properties": {
        "propertyName1": {
          ...
        }
      }
    }
  },
  "relationships": [
    {

        }
      }
    }
  ]
}
```

- **entities** (mandatory): specifies entity sets. Entities indicate vertices in a graph. An entity set contains multiple entities.
- **relationships** (mandatory): specifies relationship sets. Relationships indicate edges in a graph.
- **entityName** (mandatory): specifies the entity name, which identifies an entity object and is referenced when a relationship is defined. In a mapping rule, entities cannot use the same name.

---

**NOTICE**

The entity that is defined after a used name in the graph overwrites the previously defined entity with the same name.

- **conceptIRIType** (optional): specifies the conceptIRI (entity label) definition mode. The available values are **constant** and **columnLookup**. If this parameter is not defined, the default value **constant** is used.
  - **constant**  
Specifies that a constant is defined as conceptIRI.  
Parameter:  
**conceptIRI** (mandatory): specifies an entity label, that is, an entity category. For example, conceptIRI can be a person or an item. **conceptIRI** is a string.
  - **columnLookup**  
Defines a value as the **conceptIRI**.  
Parameter:  
**concept** (mandatory): specifies a label value. The definition method is the same as that used for defining a property value.
- **primaryKey** (mandatory): specifies a primary key, which is the unique identifier of an entity (vertex). For example, the ID card number of a person. The value of **primaryKey** must be a property name in properties, and the property must be of the single type or a combination of required and single. That is, the property value must be a column of values in the input data rather than a multi-condition combination value. In addition, Built-in indexes must be created for the property that is used as a primary key. Currently, only one value can be specified for **primaryKey**, and the value cannot contain multiple primary keys.
- **createIfAbsent** (optional): specifies whether to create an entity when the entity does not exist. That is, whether the entity needs to be imported again. If this parameter is not set, the default value **true** is used.
  - **true**  
If this parameter is set to **true**, the common process is used. Check whether each entity has been imported. If yes, update the properties. If no, create required entities and add corresponding properties for the entities.
  - **false**  
If this parameter is set to **false**, the entity does not need to be imported. You can skip the entity query and property update. If some entities in the

data are not imported before, the entities will not be imported, and the relationships associated with the entities are not imported. If an entity has been imported before, the relationships associated with the entity can still be imported.

Setting this parameter to **false** improves the data import speed and reduces unnecessary query verification. However, you need to set this parameter based on the actual service scenario. In the following two typical scenarios, you are advised to set this parameter to **false**.

- If an exception occurs when data is imported. After the exception is handled, you are advised to import the data again. For example, if an exception occurs when the second entity is imported after the first entity is successfully imported. In this case, you can set this parameter to **false** in the mapping rule of the first entity for the second import. After this configuration, the first entity will be skipped and the data import will start from the second entity where the exception occurred. If the last exception occurs during the relationship import, you can set this parameter to **false** in the mapping rules of all entities for this import. After this configuration, the task will skip the phase of importing entity data, and only the relationship data is imported. In this way, data import speed is greatly improved and the data integrity is not affected.
- Some entities of the data have been imported for other data before. In this case, you must ensure that the entity type IDs of the data exist in the graph and that you do not need to update the property values this time. For example, to import the data relationship table of a transaction, the card numbers in the table have been imported when the card number table is imported. In this case, the card numbers in the transaction exist in the graph, and you do not need to update other property values of the card number. You can set **createIfAbsent** to **false** in the mapping rule of the card number to speed up the import.
- **properties** (mandatory): specifies properties of entities, such as the height and gender of a person. When defining an entity, you must define at least one property as the primary key. Property names, values, and rules must be provided. **propertyName** is defined by users. Property values have multiple types which can be specified by **propertyValueType**. Currently, the following nine types are supported: **single**, **required**, **constant**, **formattedMultiColumn**, **geopoint**, and **geocircle** (mandatory), **geobox**, **mappedMultiColumn**, and **fallback**. If the type is not specified, the default value **single** is used. Multiple property types can be nested. The following uses **ColumnValue** as an example to describe how to nest a property method.
  - **single**  
A column of values in the data set is used as the property values. This is the most common scenario.  
Parameter:  
**index** (mandatory): specifies a column of subscripts corresponding to the property value.
  - **required**

If a property value is defined as **required**, the value cannot be empty. If the value is not defined as **required**, the value can be empty. This definition method needs to be nested with other definition methods.

Parameter:

**Column** (mandatory). The value is **ColumnValue**. This parameter is used to define a value that cannot be empty.

- **constant**

Specifies that the property value is a constant.

Parameter:

**value** (mandatory): The value must be a constant. The value data type can only be a basic type, for example, numeric, string, or Boolean.

- **formattedMultiColumn**

Multiple property values are combined in sequence based on the defined format.

Parameter:

**columns** (mandatory): specifies the definition of multiple values in List[*ColumnValue*] format. Note that the definition sequence is related to the combination sequence.

**format** (mandatory): specifies the combination format. Placeholders are used, for example, %s-%s, indicates that two strings are connected using a hyphen. %d indicates an integer, and %f indicates a floating point number.

- **geopoint**

Specifies the geographical location that indicates the location of a point.

Parameter:

**latitudeColumn** (mandatory): *ColumnValue* Specifies the latitude. The value must be a numeral ranging from -90 to 90.

**longitudeColumn** (mandatory): *ColumnValue* Specifies the longitude. The value must be a numeral ranging from -180 to 180.

- **geocircle**

Specifies a geographical circle, which is determined by the location of a point and its radius.

Parameter:

**latitudeColumn** (mandatory): *ColumnValue* Specifies the latitude. The value must be a numeral ranging from -90 to 90.

**longitudeColumn** (mandatory): *ColumnValue* Specifies the longitude. The value must be a numeral ranging from -180 to 180.

**radiusColumn** (mandatory): *ColumnValue* Specifies the radius. The value must be a numeral. The unit is km.

- **geobox**

Specifies a geographical frame (a trapezoid on a sphere). You can determine the scope of the trapezoid by using the latitude and longitude values in the lower left corner of the rectangle and those in the upper right corner of the trapezoid.

Parameter:

**southWestLatitudeColumn** (mandatory): *ColumnValue* Specifies the latitude of the southwest point. The value must be a numeral ranging from -90 to 90.

**southWestLongitudeColumn** (mandatory): *ColumnValue* Specifies the longitude of the southwest point. The value must be a numeral ranging from -180 to 180.

**northEastLatitudeColumn** (mandatory): *ColumnValue* Specifies the latitude of the northeast point. The value must be a numeral ranging from -90 to 90.

**northEastLongitudeColumn** (mandatory): *ColumnValue* Specifies the longitude of the northeast point. The value must be a numeral ranging from -180 to 180.

- **mappedMultiColumn**

Combines multiple values in sequence to obtain a property value. Based on the defined mapping relationship, if the property value meets the mapping relationship, obtain the mapping value based on rules described in the mapping and use the mapping value as the final property value. If the mapping relationship cannot be found, delete the last property value and then search for the mapping relationship. Repeat this operation until only the first property value is left. If no mapping relationship is found still, the default value **null** is returned.

Parameter:

**keyColumns** (mandatory): specifies the definition of multiple values in List[*ColumnValue*] format. Note that the definition sequence is related to the combination sequence.

**valueMap** (mandatory): The mapping relationship is in the following format: Map<*String*, *String*>. If a combined value does not meet the mapping requirement, the default value **null** is used. If you want to set the property value to a default value when the mapping rules are not met, you can set a null string as the key in the mapping relationship and set value to the default value.

**separator** (optional): specifies the separator. Separators are connectors between properties. **If this parameter is not specified, a colon (:) is used as the separator by default.**

If the property value is empty, the separator is also used. For example, if three values are defined for **keyColumns**, which are A, B, and C, the processing sequence is as follows:

- i. Combine the three values to obtain **A:B:C**.
- ii. Check whether there is a property whose key is **A:B:C** exists in the mapping. If the property exists, the mapping value is returned. If the property does not exist, delete the last value in the combination to obtain **A:B**.
- iii. Check whether there is a property whose key is **A:B** exists in the mapping. If the property exists, the mapping value is returned. If the property does not exist, delete the last value in the combination to obtain **A**.
- iv. Check whether the property whose key is **A** exists in the mapping. If the property does not exist, delete the last value **A**. In this case, an empty string is left.

- v. Check whether there is a null string mapping in the mapping (that is, the default value). If the mapping exists, the default value is returned. If no mapping is found, the **null** value is returned.
- **fallback**

In this definition method, two *ColumnValue* can be defined. One is active, and the other is the standby. If the active value is null or the value matches the corresponding **fallbackIf** condition, the standby value is used.

Parameter:

**Primarycolumn** (mandatory): *Columnvalue*. Specifies the first value. The property value takes precedence over the value of this parameter. Then, the system determines whether to obtain the standby value based on the condition.

**fallbackColumn** (required): *ColumnValue*. Specifies the standby value. When the primary value is empty or the value meets the **fallbackIf** condition, the value is used as the property value.

**fallbackIf** (mandatory): specifies the predicate, that is, the matching criteria. The following code uses Predicate as an example. Example:

```
"fallbackIf": {  
    "op": "stringEq",  
    "value": "unknown"  
}
```

Currently, the following nine basic conditional expression predicates are supported: **and**, **or**, **isNull**, **not**, **eq**, **stringEq**, **emptyStr**, **moreThan**, and **lessThan**.

- **and**

If multiple conditions are matched at the same time, the value is **true**.

Parameter:

**predicates** (mandatory): List[*Predicate*]: Specifies multiple conditions.

- **or**

If any condition is matched, the value is **true**.

Parameter:

**predicates** (mandatory): List[*Predicate*]: Specifies multiple conditions.

- **isNull**

If the value is empty, the value is **true**.

Specifies that no parameter is set.

- **not**

If criteria is not matched, the value is **true**.

Parameter:

**predicate** (mandatory): specifies the predicate, that is, a single condition.

- **eq**

If the values are the same, the value is **true**.

Parameter:

**value** (mandatory): specifies the value for judgment, which can be a basic type value.

- **stringEq**

If the strings are the same, the value is **true**. You can define whether the strings are case sensitive.

Parameter:

**value** (mandatory): specifies the value for judgment, which is a string.

**caseSensitive** (optional): specifies whether the value is case sensitive. The default value is **false** that is case insensitive.

- **emptyStr**

Checks whether the entered string is empty or all characters are spaces.  
Note: Empty strings are not null.

Specifies that no parameter is set.

- **moreThan**

Checks whether the entered value is greater than the specified value.

Parameter:

Value (mandatory): Specifies the value for judgment. The value must be a number, and the entered value must also be a number.

- **lessThan**

Checks whether the entered value is less than the specified value.

Parameter:

Value (mandatory): Specifies the value for judgment. The value must be a number, and the entered value must also be a number.

- **action**

A property rule is used to perform operations on the property value. The parameter is defined as an action. Currently, the following actions are supported:

**assign**: specifies that the property value is updated.

**assignIfAbsent**: specifies if the property does not exist, the property is updated. If the property does not exist, the property is not updated.

**assignIfBigger**: compares the existing value and a new value of the property to obtain the larger value and then updates the value. Only the numeric type and date type are supported.

**assignIfSmaller**: compares the existing value and a new value of the property to obtain the smaller value and then updates the value. Only the numeric type and date type are supported.

**assignSum**: sums up the existing value and a new value of the property, and then updates the value. Only the numeric type is supported.

If the property field is not set to **action**, the default value **assign** is used.

- The rules for filling in **relationships** are as follows:
  - *source* (mandatory): specifies the start entity. The value must be an entity name defined above.
  - *target* (mandatory): specifies the target entity. The value must be an entity name defined above.
  - *labelType* (optional): specifies the label (relationship) definition mode. The available values are **constant** and **columnLookup**. If this parameter is not defined, the default value **constant** is used.

- **constant**  
Specifies that a constant is defined as conceptIRI.  
Parameter:  
**label** (mandatory): specifies the edge label. The value must be an edge label defined in the graph.
  - **columnLookup**  
Defines a value as the label.  
Parameter:  
**labelColumn** (mandatory): specifies the edge label value. The definition method is the same as that for property values described in the previous content. For details, see the related information provided above.
  - **unique** (optional): specifies whether modification is required based on the original relationship. If this parameter is not set, the default value **false** is used.
    - **true**  
If this parameter is set to **true**, the system checks whether the label relationship exists between the source entity and target entity before you import the relationship. If no, add an edge. If yes, update the attribute based on the original relationship. If there are multiple label relationships between two entities, you can set the **uniqueFilter** field to update a relationship. If the field is not set, the attribute of a relationship corresponding to the label is used for update. If all relationships do not meet the condition, you need to add an edge and ignore the update. The **uniqueFilter** field contains **propertyKey** and **propertyValue**, which respectively indicate the key and value of a special attribute of the edge. Multiple attribute keys can be set in the **uniqueFilter** field. Use commas (,) to separate multiple attribute keys. You can set only **propertyKey** but not **propertyValue**.
- The query rule description is as follows:
- i. If **propertyKey** is configured but **propertyValue** is not configured, the corresponding column value in the data is used for query. If the column value is null, keys are used for query.
  - ii. If **propertyKey** and **propertyValue** are both configured but the value is not null, use the value. If the value is null, replace it with the data in the CSV file.
  - iii. If **propertyKey** and **propertyValue** are both configured but the value is null, only keys are used for query.
- The following is a configuration example of the uniqueFilter in common scenarios:
- The configuration of **uniqueFilter** in common scenarios is as follows:
- ```
"uniqueFilter" : {  
    "propertyKey" : "p1,p2"  
}
```
- **false**  
No query operation is performed before the relationship is imported. The relationship of the corresponding label is directly added, and the original relationship is not changed.

- **optimizeUniqueCheck** (optional): specifies whether to optimize the check of **unique**. This parameter is valid only when **unique** is set to **true**. If this parameter is not set, the default value **false** is used.
  - **true**  
If this parameter is set to **true**, the label relationships to be added between the entities are queried in batches, reducing the number of HBase requests and accelerating the query of **unique**.
  - **false**  
If this parameter is set to **false**, the query is performed only when a relationship is added for two entities.

### NOTICE

Note: When an entity has a large number of identical label relationships (for example, the call between a person and another), setting this parameter to **true** may lead to slow query speed because the amount of returned data is too large or even may cause query failure for insufficient memory. In practical use, estimate the number of entity edges based on the service and data. Use this parameter with caution.

- **Properties** (optional): specifies the properties corresponding to the label. The parameter setting rule is the same as that for the entity property.

## Example

Assume that the node input mapping rules are as follows. For the meanings of the mapping rules, see the comments on the right of these rules.

```
{  
    "entities": {  
        "person": { // Defines an entity and is named as person. This name is used only when relationships is defined and it does not need to be defined in the schema.  
            "conceptIRI": "person", // The entity label is person, and conceptIRIType is omitted here. The default value is constant, that is, the value of conceptIRI is directly defined. The other islabel is columnLookup. For details, see the employer entity described below.  
            "primaryKey": "UID", // The entity ID is the property value whose name is UID in properties below. You can use this ID to uniquely identify an entity in the graph.  
            "properties": { // Defines the properties of person. UID and Name are property names, and their values are property values.  
                "UID": {  
                    "type": "required", // If this parameter is set to required, the value cannot be empty. If the value is empty, an error is reported.  
                    "column": {  
                        "index": 0,  
                    }  
                },  
                "Name": {  
                    "type": "formattedMultiColumn", // formattedMultiColumn indicates that Name is composed of the values whose subscript are 1 and 2, respectively, in the format of %s-%s. For example, the values whose subscripts are 1 and 2 are zhang and san, respectively. Name is zhang-san.  
                    "columns": [  
                        {  
                            "index": 1  
                        },  
                        {  
                            "index": 2  
                        }  
                    ]  
                }  
            }  
        }  
    }  
}
```

```
        ],
        "format": "%s-%s"
    },
    "shortName": {
        "type": "mappedMultiColumn",      // mappedMultiColumn indicates that the value of shortName
is composed of the value whose subscript is 1 and the value whose subscript is 2, and the two values are
separated by a colon (:). It is used to check whether the combination result has a mapping in valueMap.
        "keyColumns": [      // If the mapping exists, use the mapping value. For example, if the value
whose subscript 1 is zhang and the value whose subscript is 2 is san, the combination is zhang:san. In
valueMap, the value of zhang:san is zs. Therefore, the value of shortName is zs.
9           {      // If the mapping does not exist, remove the last value of the combination result and then
search for the mapping. For example, if the value whose subscript is 1 is zhao, and the value whose
subscript is 2 is wu, the combination is zhao:wu.
            "index": 1      // If valueMap does not contain zhao:wu, remove wu, and only zhao is left.
valueMap still does not contain the keyword zhao. Delete zhao to obtain an empty string.
            },      // The value corresponding to an empty string in valueMap is no short name. Therefore,
the value of shortName is no short name.
            {      // If the mapping corresponding to an empty string is not defined in valueMap, the value of
shortName is null.
                "index": 2
            }
        ],
        "valueMap": {
            "": "no short name",
            "zhang:san": "zs",
            "li:si": "ls"
        },
        "separator": ":"      // This parameter is optional. If separator is not defined, the default value is a
colon(:).
    },
    "Birth Date": {
        "type": "single",      // single indicates that the value of Birth Date is the value whose subscript is
3. The property value type is single by default, which can be omitted. For example, the following property
Married, its property type is ommited.
        "index": 3
    },
    "Married": {
        "index": 4      // The type single is omitted.
    },
    "Deceased": {
        "type": "constant",      // constant indicates that all Deceased properties are set to false.
        "value": "false"
    },
    "Home Address": {
        "type": "geopoint",      // geopoint indicates that the value of Home Address is the location
corresponding to the combination of the value whose latitude is the value of subscript 5 and the value
whose longitude is the value of subscript 6.
        "latitudeColumn": {
            "index": 5
        },
        "longitudeColumn": {
            "index": 6
        }
    },
    "Home Area": {
        "type": "geocircle",      // geocircle indicates that the value of Home Area is the scope that the
latitude is subscript 7, the longitude is subscript 8, and the radius is subscript 9.
        "latitudeColumn": {
            "index": 7
        },
        "longitudeColumn": {
            "index": 8
        },
        "radiusColumn": {
            "index": 9
        }
    },
    "Country Area": {
        "type": "geobox",      // geobox indicates that the value of Country Area is a geographical area
    }
}
```

with the latitude ranges from the value of subscript 10 to that of subscript 12, the longitude ranges from the value of subscript 11 to that of subscript 13.

```

    "southWestLatitudeColumn": {
        "index": 10
    },
    "southWestLongitudeColumn": {
        "index": 11
    },
    "northEastLatitudeColumn": {
        "index": 12
    },
    "northEastLongitudeColumn": {
        "index": 13
    }
},
"employer": { // Defines an entity named employer
    "conceptIRIType": "columnLookup", // If conceptIRIType is set to columnLookup, a value is defined to indicate the conceptIRI. For example, the value of the subscript 14 is used as the conceptIRI.
        "concept": {"index": 14},
        "primaryKey": "companyName",
        "properties": {
            "companyName": {
                "index": 15
            },
            "locationAddress": {
                "type": "geopoint",
                "latitudeColumn": {
                    "index": 16
                },
                "longitudeColumn": {
                    "index": 17
                }
            },
            "locationPlace": {
                "type": "fallback", // fallback indicates that the value of primaryColumn is used preferentially as the property value. If the value of primaryColumn is empty or meets the fallbackIf condition, the value of fallbackColumn is used.
                    "primaryColumn":{ // If the value of subscript 18 is empty and the value of subscript 19 is guangdong, the value of locationPlace is guangdong.
                        "index": 18 // If the value of subscript 18 is unknown and the value of subscript 19 is guangdong, the fallbackIf condition is met. In this case, the value of locationPlace is guangdong.
                    },
                    // The value of subscript 18 is shenzhen, the value of subscript 19 is guangdong, the value shenzhen is neither empty nor meets the fallbackIf condition. In this case, the value of locationPlace is shenzhen.
                    "fallbackColumn":{
                        "index": 19
                    },

                    "index": 25
                },
                "facebook": {
                    "index": 26
                }
            }
        }
    }
]
}

```

### 2.5.3.3 Importing Data

### 2.5.3.3.1 Importing Data in Batches Using Tools

 CAUTION

Data inconsistency occurs when GraphBase imports and deletes data at the same time. If you are using a data ingestion tool on the client, ensure that no batch deletion is executed at the same time.

The system automatically checks whether there are other asynchronous tasks when tasks are submitted through a REST API. You are advised to use the REST API **graphwriter** to submit batch import tasks.

## Prerequisites

1. Install clients for all components in the cluster.
2. A graph has been created. For details about how to create a graph, see [Creating or Deleting a Graph](#).
3. A schema file (for example, an XML file) has been prepared and uploaded. For details about how to upload a schema file, see [Creating a Schema by Uploading an XML File](#).
4. You have prepared the data file (for example, a CSV file). For details about how to prepare a data file, see the example on the GraphBase client in the `/opt/hadoopclient/GraphBase/examples/person-demo/` directory.  
For details about the data description file (DESC file), see [Compiling a Data Description File \(DESC\)](#).  
The graph mapping rule file (.mapper file) has been uploaded. For details, see [Compiling a Graph Mapping Rule File \(.mapper\)](#).

## Upload related files

1. Upload data files to the HDFS.  
Switch to the `/graphwriter` directory in the installation directory of the GraphBase client.  
`cd /opt/hadoopclient/GraphBase/graphwriter`  
Run the following command to execute environment variables:  
`source /opt/hadoopclient/bigdata_env`  
Log in to the system as a GraphBase user and enter the password (specified by the user).  
`kinit graphtest`  
Create a directory storing HDFS files. (If the directory exists, skip this operation.)  
`hdfs dfs -mkdir /user/graphtest`  
Upload the data files to the `/user/graphtest` directory (for example, **person-demo**) of the HDFS.  
`hdfs dfs -put ..//examples/person-demo/Person.csv ..//examples/person-demo/Person.mapper ..//examples/person-demo/Person.desc /user/graphtest`

The details are shown in the following figure.

```
hadoopNode2:/opt/graphbaseClient/GraphBase/graphwriter # hdfs dfs -ls /user/graphtest
Found 7 items
-rw-r--r--  3 root hadoop      100 2018-08-04 14:47 /user/graphtest/Person.csv
-rw-r--r--  3 root hadoop     740 2018-08-04 14:47 /user/graphtest/Person.csv.mapper
-rw-r--r--  3 root hadoop     368 2018-08-04 14:47 /user/graphtest/Person.desc
```

## Modifying the Configuration File

Set the **RESOURCE** parameter in the **resource.properties** file under **/opt/hadoopclient/GraphBase/graphwriter/conf/**. You can modify the parameter configuration as required or add advanced parameters for Spark. For example: You can add **--conf spark.default.parallelism** and set it to **105**.

When data is imported in batches, the Yarn resource queue in Spark parameters is the default queue. To change the default resource queue, add the **--conf spark.yarn.queue** parameter and set it to the specified queue name in the **RESOURCE** parameter.

## Importing Data

Execute the following script and transfer the *graphName* parameter (*graphName* is user-defined that must exist. If it does not exist, create the graph first.)

```
./bin/graphWriter.sh graphName /user/graphtest/Person.csv /user/graphtest/Person.csv.mapper /user/graphtest/Person.desc
```

Note: The data file path must be an HDFS path that is in the following format:  
*Data file*/*Data mapping file.mapper*/*Metadata file.desc*

If no metadata file exists, the file path is: *Data file*/*Data mapping file.mapper*

After the script is executed, the following information is displayed:

```
hadoopNode2:/opt/graphbaseClient/GraphBase/graphwriter # ./bin/graphWriter.sh graphName /user/graphtest/Person.csv /user/graphtest/Person.csv.mapper /user/graphtest/Person.desc
RESOURCE= --executor-memory 5g --driver-memory 5g --num-executors 5 --executor-cores 5
SERNAME= graphtest
spark.yarn.am.memory is set but does not apply in cluster mode.
spark.yarn.am.cores is set but does not apply in cluster mode.
918-08-06 11:31:00 [WARN] [main] [ ] unable to load native-hadoop library for your platform... using builtin-java classes where applicable | org.apache.hadoop.util.NativeCodeLoader.loadNativeCodeLoader.java:62
918-08-06 11:31:00.482 [WARN] [main] [spark.varn.am.extraJavaOptions will not take effect in cluster mode] org.apache.spark.Logging$class.loogWarning(Logging.scala:71)
```

### NOTE

During data import, if the feature data type (type attribute in attributes) configured in the data description file (.desc file) is different from the data type in the data file (for example, .csv file) to be imported, the batch import tool ignores data of different data types by default and imports only the data of the same type in the data description file and data file. For example, the type of data in a column defined in the data description file is "REAL", as indicated by the following: `{"name": "Attr_0", "type": "REAL", "nominalList": []}`. In the data file to be imported, the data of the corresponding column is the character string "mary". The data type of "mary" is STRING, which is inconsistent with the "REAL" type in the description file. In this case, when the batch import tool is used to import data, the data of this error type is ignored and will not be imported.

### 2.5.3.3.2 Importing Data in Real Time Using Tool

Data import in real time is implemented by using SparkStreaming. After SparkStreaming is started, data is read from the corresponding topic based on the configuration and then imported to GraphBase.

 CAUTION

Data inconsistency occurs when GraphBase imports and deletes data at the same time. If you are using a data ingestion tool on the client, ensure that no batch deletion is executed at the same time.

## Prerequisites

1. Install clients for all components in the cluster.
2. The schema file (that is, the XML file) has been uploaded. For details, see [Creating a Schema by Uploading an XML File](#).
3. The graph mapping rule file (.mapper file) has been uploaded. For details, see [Compiling a Graph Mapping Rule File \(.mapper\)](#).

## Modifying the Configuration File

The configuration file directory is `/opt/hadoopclient/GraphBase/graphstream/conf/`.

1. Modify the **graph-streaming.properties** file.

The parameter configuration is listed in the following table.

| Parameter                            | Description  | Example  |
|--------------------------------------|--|--|
| graph.user.name                      | Specifies the name of the user to be created.  | <b>graphtest</b>                                 |
| spark.streaming.checkpoint.directory | Specifies the HDFS directory of the SparkStreaming checkpoint. If the directory does not exist, create it in advance. (It is recommended that this directory be created separately because a large number of checkpoint files are generated during the program running.) | <b>/user/graphtest/graphstreaming/checkpoint</b> |
| spark.streaming.batch.time           | Specifies the time spent by SparkStreaming on data processing in batches. The unit is s.   | 1  |

| Parameter                        | Description  | Example   |
|----------------------------------|--|---|
| spark.streaming.partition.number | Specifies the number of partitions of the node where SparkStreaming resides.   | 50  |
| kafka.topic.name                 | Specifies the name of the topic where data needs to be consumed.   | Person.csv  |
| kafka.metadata.broker.list       | Specifies the IP address of the node where Kafka metadata resides (manual configuration is not required).  | 10.3.70.133:21005,10.3.71.67:21005,10.3.71.24:21005 |
| csv.mapper.hdfs.file             | Specifies the path of the Mapper file in the HDFS.   | /user/graphtest/graphstreaming/Person.csv.mapper    |
| kafka.save.failed.message        | Specifies whether to save failure messages. The available values are <b>false</b> and <b>true</b> . <b>false</b> indicates that the failure message is not saved, and <b>true</b> indicates the reverse. | false   |
| kafka.save.failed.topic.name     | Specifies that the failure messages are saved as Kafka topic names.  | default   |
| kafka.topic.message.separator    | Specifies a separator of Kafka messages.   | ,   |

## 2. Set the **RESOURCE** parameter.

In **resource.properties**, allocate resources based on YARN resource usage. Ensure that the resources to be allocated do not exceed the total resources of YARN.

```
RESOURCE='--executor-memory 4g --driver-memory 2g --num-executors 5 --executor-cores 5'.
```

When data is imported in batches, the Yarn resource queue in Spark parameters is the default queue. To change the default resource queue, add the **--conf spark.yarn.queue** parameter and set it to the specified queue name in the **RESOURCE** parameter.

## Uploading Related Files

Upload the customized Mapper file to the HDFS.

1. Execute environment variables as user **root** (`/opt/hadoopclient/` is the installation directory of the cluster client).

```
source /opt/hadoopclient/bigdata_env
```

2. Create a directory storing HDFS files. (If the directory exists, skip this operation.)

```
hdfs dfs -mkdir /user/graphtest/graphstreaming
```

3. Upload the MAPPER data file to the `/user/graphtest/graphstreaming` directory of HDFS (Take the **person-demo** directory as an example).

```
hdfs dfs -put /opt/hadoopclient/GraphBase/examples/person-demo/  
Person.csv.mapper /user/graphtest/graphstreaming
```

## Create a topic

The APIs or scripts of Kafka can be used to create topics. For details, see "Managing Kafka Themes" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

## Importing Data

1. Go to the **graphstream** directory.

```
cd /opt/hadoopclient/GraphBase/graphstream
```

2. Execute the following script and transfer the `graphbase` parameter (`graphbase` is user-defined that must exist. If it does not exist, create the graph first. Before you create the graph, ensure that all prerequisites have been completed):

```
./bin/graphStreaming.sh graphbase
```

If you need to customize the path of the configuration file, you can specify a local absolute path for the configuration file and copy the information in **graph-streaming.properties** to the configuration file. If the path is not specified, the **graph-streaming.properties** file in the **conf**/ directory is used as the configuration file by default. Example:

```
./bin/graphStreaming.sh graphbase /opt/hadoopclient/GraphBase/  
graphstream/conf/graph-streaming.properties
```

3. (Optional) Send a message to the **Person.csv** topic.

Send the message by following the following procedure:

- a. Upload data files. If the HDFS directory does not exist, create it in advance.

```
hdfs dfs -put ..//examples/person-demo/Person.csv /user/graphtest/  
graphstreaming/data
```

Run the **vi conf/graph-producer.properties** command to configure the **graph-producer.properties** file in **conf**. The parameter configuration in this file is listed as follows.

| Parameter                  | Description   | Example   |
|----------------------------|---|---|
| graph.user.name            | Specifies the name of the user to be created.   | <b>graphtest</b>                                    |
| kafka.topic.name           | Specifies the name of the topic where data needs to be consumed.  | Person.csv  |
| kafka.metadata.broker.list | Specifies the IP address of the node where Kafka metadata resides (manual configuration is not required). | 10.3.70.133:21005,10.3.71.67:21005,10.3.71.24:21005 |
| csv.data.hdfs.directory    | Specifies the directory for storing data in the HDFS.   | /user/graphtest/graphstreaming/data                 |

- b. Run the following command to send a message to a specified Kafka topic:

**./bin/graphProducer.sh**

#### BOOK NOTE

This mode is used to test the production data. You can use other methods too.

## Monitoring Tasks

1. Click **ApplicationMaster** on the YARN task page to go to the Spark task page.

2. Click **Streaming**.

3. Check the processing progress.

| Batch Time          | Input Size     | Scheduling Delay [?] | Processing Time [?] | Total Delay [?] |
|---------------------|----------------|----------------------|---------------------|-----------------|
| 2018/07/19 11:43:40 | 3579000 events | 42 min               | 3.6 min             | 45 min          |
| 2018/07/19 11:43:30 | 3690000 events | 38 min               | 3.9 min             | 42 min          |
| 2018/07/19 11:43:20 | 3608500 events | 34 min               | 3.7 min             | 38 min          |
| 2018/07/19 11:43:10 | 3294500 events | 31 min               | 3.4 min             | 35 min          |
| 2018/07/19 11:43:00 | 3675000 events | 27 min               | 3.9 min             | 31 min          |
| 2018/07/19 11:42:50 | 3673500 events | 24 min               | 3.8 min             | 28 min          |

## Tuning Parameters

- The product of the number of executors and the number of cores of each executor determines the task concurrency capability. The value of **spark.streaming.partition.number** determines the total number of tasks that can be started. If the resources are sufficient, you can set the executor and partition quantities to the same.
- spark.streaming.batch.time** of SparkStreaming and the data traffic of Kafka messages determine the amount of data that can be processed by

SparkStreaming at a certain time. The data is distributed on each partition. The data traffic value is negatively correlated with the batchtime value. If the data traffic is small, set **batchtime** to a larger value. Otherwise, set **batchtime** to a small value. In this way, the amount of data to be processed can be ensured moderate.

## Stopping a Job

After a SparkStreaming task is submitted, it keeps running and reads messages from Kafka. To stop the task, perform the following operations: Obtain the submitted task ID on the YARN web client. Run the **yarn application -kill \${appid}** command to kill the task. Example: **yarn application -kill \$Application\_1530539359099\_0053** If no data is queried after the data import, kill the task and collect logs. Search for **ERROR** in the logs, and identify the cause. Run the following command to collect logs:

```
yarn logs -applicationId ${appid} > log
```

### 2.5.3.3.3 Using the Hive Data Import Tool

---

 CAUTION

Data inconsistency occurs when GraphBase imports and deletes data at the same time. If you are using a data ingestion tool on the client, ensure that no batch deletion is executed at the same time.

---

## Prerequisites

1. Install clients for all components in the cluster.
2. Create a graph by referring to [Creating or Deleting a Graph](#).
3. Prepare and upload a schema file (for example, an XML file) by referring to [Creating a Schema by Uploading an XML File](#).
4. The Hive component has been installed in the cluster.
5. Prepare a Hive table. The field names in the figure can be different from those in the Hive table. Compile a graph mapping rule file (**.mapper** file) based on the data columns of vertices and edges in Hive. For details, see [Compiling a Graph Mapping Rule File \(.mapper\)](#).
6. For details about how to create Hive data, see section [Developing an Application](#).

## Modify the configuration file

The configuration file directory is **/opt/hadoopclient/GraphBase/graphwriter/conf/**.

1. Modify the **hiveTable.properties** file.

The parameter configuration is listed in the following table.

| Parameter        | Description   | Example       |
|------------------|---|---------------|
| table.namespace  | Indicates the namespace where the Hive table is located. Retain the <b>default</b> value.   | default       |
| table.tablename  | Indicates the Hive table name.  | table1        |
| table.columns    | Indicates the columns to be selected in the table. By default, the asterisk (*) indicates a global column. Multiple column names are separated by commas (,). | * or name,age |
| table.conditions | Indicates that you can write a condition expression to select the column that meets the condition. The format is the same as that of the WHERE clause.        | age=20        |

## 2. Set the **RESOURCE** parameter.

In **resource.properties**, allocate resources based on YARN resource usage. Ensure that the resources to be allocated do not exceed the total resources of YARN.

`RESOURCE="--executor-memory 4g --driver-memory 2g --num-executors 5 --executor-cores 5"`

When data is imported in real time, the YARN resource queue in Spark parameters is the default queue. To change the default resource queue, add the **--conf spark.yarn.queue=default** parameter and set it to the specified queue name in the **RESOURCE** parameter.

## Import data

Run the following script that contains the graph name (*graphName* is a user-defined graph name and must exist. If the graph name does not exist, create it first.) and the mapper file path (the mapper file path must be an HDFS path).

`./bin/hiveWriter.sh graphName /user/graphtest/xxx.mapper`

Example description:

```
CREATE EXTERNAL TABLE IF NOT EXISTS table1  
(
```

```
sourceld STRING,  
targetId STRING,  
attr1 STRING,  
attr2 STRING  
)  
ROW FORMAT delimited fields terminated by ','  
STORED AS TEXTFILE;
```

Create the preceding Hive table. **sourceld** corresponds to the primary key attribute of the start vertex, and **targetId** corresponds to the primary key attribute of the end vertex. If the start vertex and end vertex are not of the same type (for example, the start vertex is an ID card number and the end vertex is a mobile number), **entities** in the mapper file are defined as follows:

```
"entities": {  
  "entity1": {  
    "conceptIRI": "person",  
    "primaryKey": "idCard",  
    "properties": {  
      "name": {  
        "index": 0  
      }  
    }  
  },  
  "entity2": {  
    "conceptIRI": "phone",  
    "primaryKey": "phoneNum",  
    "properties": {  
      "name": {  
        "index": 1  
      }  
    }  
  }  
}
```

If the start vertex and end vertex are of the same type (for example, the start vertex is a mobile number and the end vertex is a mobile number), entities in the mapper file are defined as follows:

```
"entities": {  
  "entity1": {  
    "conceptIRI": "phone",  
    "primaryKey": "phoneNum",  
    "properties": {  
      "name": {  
        "index": 0  
      }  
    }  
  },  
  "entity2": {  
    "conceptIRI": "phone",  
    "primaryKey": "phoneNum",  
    "properties": {  
      "name": {  
        "index": 1  
      }  
    }  
  }  
}
```

#### 2.5.3.4 Data Export

##### NOTE

When exporting data, check whether the specified HDFS path exists. If it does not, check whether the default HDFS path exists. If it does, delete the path. Otherwise, an error is reported and the task fails.

## Prerequisites

Install clients for all components in the cluster.

## Configuring Data Collection

The mapper file is used to collect the parameter information required during the export. The following figure shows the relationships between the vertex with label set to Person and Tag and the edge with label set to hasInterest:

The mapper file of the Person vertex is as follows:

```
{  
    "entities": {  
        "entity1": {  
            "conceptIRI": "Person",           ----- This item specifies label (type) of the vertex.  
            "primaryKey": "personId",       ----- This item specifies primaryKey of the vertex.  
            "properties": {  
                "personId": {  
                    "index": 0                  ----- This item specifies the attribute key of the vertex.  
                },  
                "firstName": {  
                    "index": 1                  ----- This item specifies the attribute key of the vertex.  
                },  
                "lastName": {  
                    "index": 2                  ----- This item specifies the attribute key of the vertex.  
                },  
                "gender": {  
                    "index": 3                  ----- This item specifies the attribute key of the vertex.  
                },  
                "birthDay": {  
                    "index": 4                  ----- This item specifies the attribute key of the vertex.  
                },  
                "creationDate": {  
                    "index": 5                  ----- This item specifies the attribute key of the vertex.  
                },  
                "locationIP": {  
                    "index": 6                  ----- This item specifies the attribute key of the vertex.  
                },  
                "browserUsed": {  
                    "index": 7                  ----- This item specifies the attribute key of the vertex.  
                }  
            }  
        }  
    }  
}
```

The mapper file of the Tag vertex is as follows:

```
{  
    "entities": {  
        "entity1": {  
            "conceptIRI": "Tag",           ----- This item specifies label (type) of the vertex.  
            "primaryKey": "tagId",         ----- This item specifies primaryKey of the vertex.  
            "properties": {  
                "tagId": {  
                    "index": 0                  ----- This item specifies the attribute key of the vertex.  
                },  
                "name": {  
                    "index": 1                  ----- This item specifies the attribute key of the vertex.  
                }  
            }  
        }  
    }  
}
```

```

        "url": {
          "index": 2
        }
      }
    }
  }
}
----- This item specifies the attribute key of the vertex.

```

The mapper file of the hasInterest edge is as follows:

```

{
  "entities": {
    "sourceEntity": {
      "conceptIRI": "Person",
      "primaryKey": "personId",
      "createIfAbsent": false,
      "properties": {
        "personId": {
          "index": 0
        }
      }
    },
    "targetEntity": {
      "conceptIRI": "Tag",
      "primaryKey": "tagId",
      "createIfAbsent": false,
      "properties": {
        "tagId": {
          "index": 1
        }
      }
    }
  },
  "relationships": [
    {
      "source": "sourceEntity",
      "target": "targetEntity",
      "labelType": "constant",
      "label": "hasInterest"
    }
  ]
}
----- This item specifies the attribute of the outvertex.
----- This item specifies the label (type) of the outvertex.
----- This item specifies the primaryKey of the outvertex.
----- This item specifies the attribute key of the outvertex.
----- This item specifies the attribute of the invertex.
----- This item specifies the label (type) of the invertex.
----- This item specifies the primaryKey of the invertex.
----- This item specifies the attribute key of the invertex.
----- This item specifies the entity of the outvertex.
----- This item specifies the entity of the invertex.
----- This item specifies the label (type) of the edge

```

## Modifying Configuration Files

The configuration file directory is **/opt/hadoopclient/GraphBase/graphreader/conf/**.

### 1. Modify the **vertex.properties** file.

The parameter configurations are listed in the following table.

| Parameter | Definition  | Example   |
|-----------|---|-----------|
| graphname | Name of the graph instance to be operated. This parameter is mandatory. | graphbase |
| label     | Type of the vertex to be exported. This parameter is mandatory.         | Forum     |

| Parameter         | Definition  | Example                    |
|-------------------|---|----------------------------|
| propertykeylist   | Property key list of the vertex to be exported. This parameter is mandatory. The primary key must be specified. If multiple properties need to be exported, separate the property keys by commas (,). The primary key must be placed in the first place.  | forumId,title,creationDate |
| dest.storage.path | HDFS path for storing the data to be exported. This parameter is optional and not recommended. Assume that the current domain name is HADOOP.COM, by default, the data is stored in <b>/user/graphtest@HADOOP.COM/graphbase/vertex/Person</b> . In the preceding directory, <b>graphtest</b> indicates the user name, <b>graphbase</b> indicates the graph name, and <b>Person</b> indicates the vertex type. | /user/vertex               |

| Parameter | Definition  | Example   |
|-----------|---|---|
| delimiter | Separator between properties of the data to be exported. The separator can be a common character, a special character, or a unicode. The separators specified for exporting the incoming and outgoing vertices must be the same. If you do not configure this parameter, commas (,) are used as the separators by default. This parameter is optional.    | \u002a  |
| filters   | Filtering conditions of properties in the data to be exported. The data format is JSONArray. For details, see the description for <i>PropertyFilter</i> in section "GraphBase" > "REST" > "Performing Full Graph Query on Vertices" in <i>MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)</i> . This parameter is optional | [<br>{"propertyName":"age","predicate":">>","values":[27]},<br>{"propertyName":"name","predicate":string_contains _prefix","values":["m"]}] |

2. Modify the **edge.properties** file.

The parameter configuration is listed in the following table.

| Parameter | Definition  | Example   |
|-----------|---|-----------|
| graphname | Name of the diagram instance to be operated. This parameter is mandatory. | graphbase |

| Parameter            | Definition  | Example   |
|----------------------|---|-----------|
| label                | Type of the edge to be exported. This parameter is mandatory.   | hasMember |
| outvertex.label      | Type of the outvertex at the two vertices corresponding to the edge to be exported. This parameter is mandatory.  | Forum     |
| invertex.label       | Type of the invertex at the two vertices corresponding to the edge to be exported. This parameter is mandatory.   | Person    |
| outvertex.primarykey | The primary key of the incoming vertex of the edge to be exported. This parameter is mandatory.   | forumId   |
| invertex.primarykey  | The primary key of the outgoing vertex of the edge to be exported. This parameter is mandatory.   | personId  |
| propertykeylist      | Attribute key list of the edge to be exported. This parameter is optional. If multiple attributes need to be exported, use commas (,) to separate all attribute keys. | joinDate  |

| Parameter         | Definition   | Example    |
|-------------------|--|------------|
| dest.storage.path | HDFS path for storing the data to be exported. This parameter is optional and not recommended. Assume that the current domain name is HADOOP.COM, by default, the data is stored in <b>/user/graphtest@HADOO P.COM/graphbase/edge/friend</b> . In the preceding path, <b>graphtest</b> is the created username, <b>graphbase</b> is the graph name, and <b>friend</b> is the type of the edge. | /user/edge |
| delimiter         | Separator between attributes of the data to be exported. The separator can be a common character, a special character, or a unicode. The separators specified for exporting the incoming and outgoing vertices must be the same. If you do not configure this parameter, commas (,) are used as the separators by default. This parameter is optional.   | \uu02a     |

| Parameter | Definition   | Example   |
|-----------|--|---|
| filters   | Filtering conditions of properties in the data to be exported. The data format is JSONArray. For details, see the description for <i>PropertyFilter</i> in section "GraphBase" > "REST" > "Performing Full Graph Query on Vertices" in <i>MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)</i> . This parameter is optional. | [<br>{"propertyName":"age","predicate":">>","values":[27]},<br>{"propertyName":"name","predicate":}"string_contains _prefix","values":["m"]}<br>] |

3. Modify the **resource.properties** file.

The parameter configurations are listed in the following table.

| Parameter             | Definition   | Example   |
|-----------------------|--|---|
| BINDING_SPARK_SERVICE | Bound Spark service, which is used to adapt to multiple instances. | Spark   |
| RESOURCE              | --executor-memory  | Memory size allocated to each executor in Spark |
|                       | --driver-memory  | Memory size allocated to driver in Spark        |
|                       | --num-executors  | Number of executors started by Spark            |
|                       | --executor-cores   | Number of cores started in each executor        |

| Parameter | Definition  | Example |
|-----------|---|---------|
|           | --conf spark.hbase.obtainToken.enabled<br>Whether to dynamically obtain the token information of the HBase. | true    |
|           | --conf spark.inputFormat.cache.enabled<br>Whether to enable the HBase cache                                 | false   |

### NOTE

The following special characters can be used as separators.

\u0020 Space  
\u0021 ! Exclamation mark  
\u0022 " Double quotation marks  
\u0023 # Pond key  
\u0024 \$ Currency symbol  
\u0025 % Percentage symbol  
\u0026 & And sign  
\u0027 ' Single quotation mark  
\u0028 ( Open parenthesis  
\u0029 ) Close parenthesis  
\u002a \* Asterisk  
\u002b + Plus sign  
\u002c , Comma  
\u002d - Hyphen

## Parameter Optimization

### 1. Parameter Description

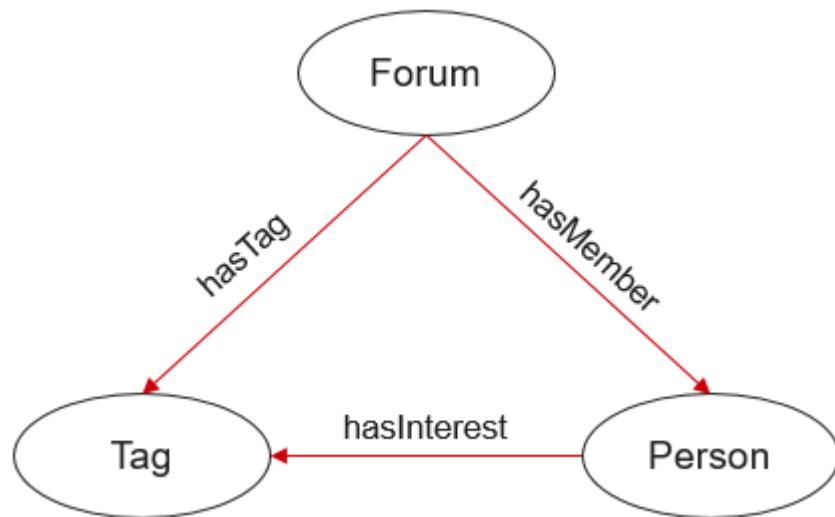

- In the **RESOURCE** configuration, the product of **num-executors** and **executor-cores** is the total number of **executor-core**, which determines the task concurrency capability.
- The product of the number of partitions and the number of nodes in the configuration item **graph.regions-per-server** in GraphBase is the total number of partitions, which determines the total number of started tasks.
- In the **RESOURCE** configuration, the product of **num-executors** and **executor-memory** is the total memory required by the task. The **yarn.nodemanager.resource.memory-mb** configuration item in Yarn determines the total memory that can be used.
- In the RESOURCE configuration, the value of **executor-memory** divided by **executor-cores** is the memory that can be used by each executor-core.

### 2. Parameter Optimization

- If the resources are sufficient, you can set the total number of executor-cores to be the same as the total number of partitions. In practice, you are advised to set **executor-cores** to a smaller value and increase the value of **num-executors**.
- The total memory configured for a task cannot exceed the total memory configured for Yarn, preventing memory overflow.
- If the memory is sufficient, you can increase the value of **executor-memory** to increase the memory size of each executor-core. You can also increase the value of **spark.yarn.executor.memoryOverhead** to dynamically increase executor memory to prevent performance deterioration caused by long GC time.

## Exporting Data

For example, the graph name is **graphbase** and the username is **graphtest**. The following figure shows the relationships between the vertex with label set to Forum, Person and Tag and the edge with label set to hasMember, hasInterest and hasTag.

1. Export the vertex.

Access the **graphreader** directory:

```
cd /opt/hadoopclient/GraphBase/graphreader
```

Run the following command to execute the environment variable:

```
source /opt/hadoopclient/bigdata_env
```

- Export a vertex whose type is Forum.

Copy the configuration file:

```
cp conf/vertex.properties conf/Forum.properties
```

Modify the **Forum.properties** configuration file.

```
vim conf/vertex.properties
```

For example:

```
propertykeylist = forumId,title,creationDate  
dest.storage.path =  
graphname = graphbase  
label = Forum
```

```
delimiter = \u002a  
filters =
```

Run the script to export data:

**./bin/graphReader.sh vertex Forum.properties**

If the command is executed successfully, the following information is displayed:

```
[root@8-5-199-1 graphreader]# ./bin/graphReader.sh vertex Forum.properties  
-----  
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2  
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false  
graphName=graphbase  
type=vertex  
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/Forum.properties  
  
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your  
platform... using builtin-java classes where applicable |  
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)

cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)  
[root@8-5-199-1 graphreader]#
```

- Export the vertex whose type is Person.

Copy the configuration file:

**cp conf/vertex.properties conf/Person.properties**

Modify the **Person.properties** configuration file:

**vim conf/Person.properties**

For example:

```
propertykeylist = personId,firstName,lastName,gender,birthDay  
dest.storage.path =  
graphname = graphbase  
label = Person  
delimiter = \u002a  
filters =
```

Run the script to export data:

**./bin/graphReader.sh vertex Person.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh vertex Person.properties  
-----  
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2  
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false  
graphName=graphbase  
type=vertex  
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/Person.properties  
  
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your  
platform... using builtin-java classes where applicable |  
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)

cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)  
[root@10-5-199-1 graphreader]#
```

- Export the vertex whose type is Tag.

Copy the configuration file:

**cp conf/vertex.properties conf/Tag.properties**

Modify the **Tag.properties** configuration file:

**vim conf/Tag.properties**

For example:

```
propertykeylist = tagId,name,url  
dest.storage.path =  
graphname = graphbase  
label = Tag  
delimiter = \u002a  
filters =
```

Run the script to export data:

**./bin/graphReader.sh vertex Tag.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh vertex Tag.properties  
-----  
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2  
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false  
graphName=graphbase  
type=vertex  
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/Tag.properties  
-----  
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your  
platform... using builtin-java classes where applicable |  
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)  
spark.yarn.am.memory is set but does not apply in cluster mode.  
spark.yarn.am.cores is set but does not apply in cluster mode.  
2019-03-07 10:26:49,315 | WARN | main | spark.yarn.am.extraJavaOptions will not take effect in  
cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)  
[root@10-5-199-1 graphreader]#
```

## 2. Export the edge.

Access **graphreader** directory:

**cd /opt/hadoopclient/GraphBase/graphreader**

Run the following command to execute the environment variable:

**source /opt/hadoopclient/bigdata\_env**

- Export the edge whose type is hasMember.

Copy the configuration file:

**cp conf/edge.properties conf/hasMember.properties**

Modify the **hasMember.properties** configuration file.

**vim conf/hasMember.properties**

For example:

```
invertex.primarykey = personId  
outvertex.primarykey = forumId  
propertykeylist =  
invertex.label = Person  
dest.storage.path =  
graphname = graphbase  
outvertex.label = Forum  
label = hasMember  
delimiter = \u002a  
filters =
```

Run the script to export data:

**./bin/graphReader.sh edge hasMember.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh edge hasMember.properties
-----
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false
graphName=graphbase
type=edge
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/hasMember.properties

2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your
platform... using builtin-java classes where applicable |
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)
spark.yarn.am.memory is set but does not apply in cluster mode.
spark.yarn.am.cores is set but does not apply in cluster mode.
2019-03-07 10:26:49,315 | WARN | main | spark.yarn.am.extraJavaOptions will not take effect in
cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)
[root@10-5-199-1 graphreader]#
```

- Export the edge whose type is hasInterest.

Copy the configuration file:

**cp conf/edge.properties conf/hasInterest.properties**

Modify the **hasInterest.properties** configuration file:

**vim conf/hasInterest.properties**

For example:

```
invertex.primarykey = tagId
outvertex.primarykey = personId
propertykeylist =
invertex.label = Tag
dest.storage.path =
graphname = graphbase
outvertex.label = Person
label = hasInterest
delimiter = \u002a
filters =
```

Run the script to export data:

**./bin/graphReader.sh edge hasInterest.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh edge hasInterest.properties
-----
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false
graphName=graphbase
type=edge
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/hasInterest.properties

2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your
platform... using builtin-java classes where applicable |
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)
spark.yarn.am.memory is set but does not apply in cluster mode.
spark.yarn.am.cores is set but does not apply in cluster mode.
2019-03-07 10:26:49,315 | WARN | main | spark.yarn.am.extraJavaOptions will not take effect in
cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)
[root@10-5-199-1 graphreader]#
```

- Export the edge whose type is hasTag.

Copy the configuration file:

**cp conf/edge.properties conf/hasTag.properties**

Modify the **hasTag.properties** configuration file:

**vim conf/hasTag.properties**

For example:

```
invertex.primarykey = tagId
outvertex.primarykey = forumId
propertykeylist =
invertex.label = Tag
dest.storage.path =
graphname = graphbase
outvertex.Label = Forum
label = hasTag
delimiter = \u002a
filters =
```

Run the script to export data:

**./bin/graphReader.sh edge hasTag.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh edge hasTag.properties
```

```
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false
graphName=graphbase
type=edge
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/hasTag.properties
```

```
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your
platform... using builtin-java classes where applicable |
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)
spark.yarn.am.memory is set but does not apply in cluster mode.
```

```
spark.yarn.am.cores is set but does not apply in cluster mode.
2019-03-07 10:26:49,315 | WARN | main | spark.yarn.am.extraJavaOptions will not take effect in
cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)
```

```
[root@10-5-199-1 graphreader]#
```

## Viewing Execution Results

- Check the execution process on Yarn.
  - Log in to FusionInsight Manager, choose **Cluster > Name of the desired cluster > Services > Yarn**, and select **ResourceManager (Active)** in **Basic Information** on the **Overview** page. The Yarn WebUI is displayed.

The screenshot shows the Yarn ResourceManager Overview page. It displays a table of applications, each with a task ID, user, queue, application name, state, and other metrics like memory used and progress. There are four visible tasks, all in the 'RUNNING' state.

| Task ID                        | User | Queue   | Application Name        | State   | Memory Used (MB) | Progress (%) |
|--------------------------------|------|---------|-------------------------|---------|------------------|--------------|
| application_1552331280773_0001 | root | default | graphbase_1552331280773 | RUNNING | 1024             | 100          |
| application_1552331280773_0002 | root | default | graphbase_1552331280773 | RUNNING | 1024             | 100          |
| application_1552331280773_0003 | root | default | graphbase_1552331280773 | RUNNING | 1024             | 100          |
| application_1552331280773_0004 | root | default | graphbase_1552331280773 | RUNNING | 1024             | 100          |

- Click the task ID to view the task overview.

The screenshot shows the Yarn Application Overview page for task application\_1552331280773\_0001. It provides detailed information about the application, including its configuration, logs, and resource usage.

**Application Configuration:**

- Queue: default
- Queue Root: /
- Application Type: MapReduce
- Application Name: graphbase\_1552331280773
- Application ID: application\_1552331280773\_0001
- Non-Application ID: 1552331280773
- Final Status: FINISHED
- Final Application State: FINISHED
- Final Application Type: MAPREDUCE
- Final Application Name: graphbase\_1552331280773
- Final Application ID: application\_1552331280773\_0001
- Final Non-Application ID: 1552331280773

**Application Metrics:**

- Total Resource Requested (memory): 4096 MB
- Total Number of AM Requests Preempted: 0
- Resource Requested from Current Attempt: 1024 MB
- Number of Non-AM Requests Preempted: 0
- Number of Non-AM Requests from Current Attempt: 0
- Aggregate Resource Allocation: 1024 MB via 100 seconds, 100 msec

- c. Click **ApplicationMaster** to view the task execution progress.

2. Check the exported data on HDFS.

Log in to FusionInsight Manager, choose **Cluster > Name of the desired cluster > Services > HDFS**, and select **NameNode (Active)** in **Basic Information** on the **Overview** page. On the HDFS WebUI that is displayed, choose **Utilities > Browse the file system** to go to the root directory.

- Go to the Person vertex export directory and check the Person data.

### NOTE

Data export formats of the Date and Geoshape are as follows:

- Date

During the import, the data may be the time of the long type:  
1552894952164 or time of the date type: Mon Mar 18 15:43:34 GMT+08:00  
2019.

During the export, the format is 2016-03-18 15:45:18.

- Geoshape

Data to be imported may be longitude and latitude: 23,52 (longitude,  
latitude) or a circle area: 23,52,18 (longitude,latitude,radius).

After the data export, if a comma (,) is used as the separator, the data format  
remains unchanged: 23,52 (longitude, longitude) or 23,52,18  
(longitude,longitude,radius).

## 2.5.3.5 REST API Development

REST APIs are provided by GraphBase 8.3.1 and used by developers for secondary  
development based on the GraphBase platform.

The GraphBase API provides unified access for upper-layer applications and  
encapsulates the unified operations performed on the GraphBase platform  
through highly flexible REST APIs.

When an HTTP requester sets up a connection to the server and sends an HTTP  
request, no other requests can be sent from the connection until responses to the  
sent request are received.

## 2.5.3.6 REST API Invocation Examples and Running Results

### 2.5.3.6.1 Example

This section describes an example of creating a PropertyKey API. For details about  
how to create other APIs, see **GraphBase in MapReduce Service (MRS) 3.3.1-LTS**  
**API Reference (for Huawei Cloud Stack 8.3.1)**. The code snippet is in the  
GraphBaseRestExample class in the **com.huawei.util** package of the sample  
project. After code is run, the result is returned on the console.

 NOTE

1. Ensure that the input parameters and the invoked URL are correct.
2. Ensure that the entered IP address, port number, username, and password are correct.

1. Initialize the configuration of **graphbase.properties**. For details, see [Preparing for Security Authentication](#).

2. Obtain the connection information and perform security authentication.

```
GraphHttpClient client = null;
InputStream inputStream = null;
inputStream = new FileInputStream(System.getProperty("user.dir") + File.separator +
DEFAULT_CONFIG_FILE);
Properties p = new Properties();
p.load(inputStream);
HttpAuthInfo httpAuthInfo = HttpAuthInfo.newBuilder()
    .setIp(p.getProperty("ip"))
    .setPort(Integer.valueOf(p.getProperty("port")))
    .setService(RestApi.SERVICE)
    .setUsername(p.getProperty("userName"))
/*.setPassword(p.getProperty("password"))*/
    .setKeytabFile(System.getProperty("user.dir") + File.separator + KEY_TAB)
    .build();
client = GraphHttpClient.newKeytabClient(httpAuthInfo);
RestApi api = new RestApi(client);
```

3. Prepare the metadata-related classes, including PropertyKey, EdgeLabel, and VertexLabel in **com.huawei.entity** of the sample code.

4. Create the related REST APIs, for example, a property key API. (For details, see the sample project **com.huawei.graphbase.RestApi**.)

```
//Create a propertyKey interface.
public boolean addPropertyKey(PropertyKey propertyKey, String graphName) {
    JSONObject rspJson = null;
    try {
//Invoke the REST API URL and transfer the request parameter propertyKey.
        rspJson = sendHttpPostReq("/graph/" + graphName + "/schema/property-key",
RestHelper.toJsonString(propertyKey));
    } catch (JsonProcessingException e) {
        LOG.info(ERROR_MSG);
    }
//Parse the returned rspJson parameter.
    final boolean isSuccessfully = (null == rspJson ? false : rspJson.getString("code").equals("0"));
//Print logs to the console.
    String log = String.format("[%-s]: create property key[%s] %s",
        (isSuccessfully ? "SUCCESS" : "FAIL"),
        propertyKey.getName(),
        (isSuccessfully ? "successfully." : "fail."));
    System.out.println(log);
    return isSuccessfully;
}
//Send a request containing CSRF_TOKEN.
private JSONObject sendHttpPostReq(String uri, JSONObject reqJson) {
    return sendHttpPostReq(uri, reqJson.toString());
}

private JSONObject sendHttpPostReq(String uri) {
    return sendHttpPostReq(uri, "");
}

private JSONObject sendHttpPostReq(String uri, String reqJsonStr) {
    String fullUrl = buildUrl(uri);
    HttpPut httpPut = new HttpPut(fullUrl);
    httpPut.addHeader(CSRF_TOKEN, this.client.csrfToken);

    CloseableHttpResponse response = null;
    JSONObject rspJson = null;
```

```
try {
    if (reqJsonStr != null && !reqJsonStr.isEmpty()) {
        httpPut.setEntity(new StringEntity(reqJsonStr, ContentType.create("text/plain",
Consts.UTF_8)));
    }
    printHttpReqHeader(httpPut);
    printHttpReqBody(reqJsonStr);

    response = client.httpClient.execute(httpPut);
    RestHelper.checkHttpRsp(response);

    rspJson = new JSONObject(EntityUtils.toString(response.getEntity(), Charset.forName("UTF-8")));
    printHttpRspBody(rspJson);
} catch (Exception e) {
    LOG.info(e.getMessage());
    return null;
} finally {
    if (null != response) {
        try {
            response.close();
        } catch (IOException e) {
            // nothing to do
        }
    }
}
return rspJson;
}
```

### 2.5.3.6.2 Creating or Deleting a Graph

To invoke Rest APIs to perform operations on graphs, refer to the following examples provided in com.huawei.graphbase.GraphBaseRestExample:

Create a graph.

```
String graphName = "graphbase";
api.createGraph(graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph HTTP/1.1
REQ BODY: {"graphName":"graphbase"}
RSP BODY: {
    "msg": "create graph success.",
    "code": "0"
}
[SUCCESS]: create graph[graphbase] successfully.
```

Delete a graph.

```
String graphName = "graphbase";
api.deleteGraph(graphName);
```

The command output is as follows:

```
REQ HEADER: DELETE https://10.7.66.150:22380/graphbase/graph?graphName=graphbase HTTP/1.1
REQ BODY: null
RSP BODY: {
    "msg": "delete graph success.",
    "code": "0"
}
[SUCCESS]: delete graph[graphbase] successfully.
```

### 2.5.3.6.3 Creating a Schema by Uploading an XML File

**graphName** specifies the name of a graph. This parameter is required when the specified REST API is invoked.

In the example, the com.huawei.graphbase.GraphBaseRestExample class has defined global variables. You can modify the configuration as required.

```
String graphName = "graphbase";
```

1. Save the XML file defined in [Compiling a Schema File \(XML\)](#) to a local directory.
2. Import the sample project. For details, see [Configuring and Importing Sample Projects](#).
3. Invoke the REST API of the addSchema class in **com.huawei.graphbase.GraphBaseRestExample**.

```
File file = new File(System.getProperty("user.dir") + File.separator + SCHEMA_FILE);
api.addSchema(file, graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema HTTP/1.1
RSP BODY: {
    "msg": "Make schema file successful",
    "code": "0"
}
[SUCCESS]: create schema successfully.
```

### 2.5.3.6.4 Creating a Schema

The following code snippets are used as an example. For complete codes, see **com.huawei.graphbase.GraphBaseRestExample**.

- Create a property key.

```
PropertyKey propertyKey = new PropertyKey();
propertyKey.setDataType(DataType.String);
propertyKey.setName("name");
api.addPropertyKey(propertyKey, graphName);
propertyKey = new PropertyKey();
propertyKey.setDataType(DataType.Integer);
propertyKey.setName("age");
api.addPropertyKey(propertyKey, graphName);
propertyKey = new PropertyKey();
propertyKey.setDataType(DataType.String);
propertyKey.setName("telephone");
api.addPropertyKey(propertyKey, graphName);
propertyKey = new PropertyKey();
propertyKey.setDataType(DataType.Float);
propertyKey.setName("weight");
api.addPropertyKey(propertyKey, graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/property-key
HTTP/1.1
REQ BODY: {"name":"name","dataType":"String"}
RSP BODY: {
    "msg": "success",
    "code": "0",
    "data": {
        "dataType": "String",
        "name": "name",
        "cardinality": "SINGLE"
    }
}
[SUCCESS]: create property key[name] successfully.
```

- Query a property key based on the name.

```
api.queryPropertyKey("name",graphName);
```

The command output is as follows:

```
REQ HEADER: GET https://10.7.66.150:22380/graphbase/graph/graphbase/schema/property-key/  
p_name HTTP/1.1  
RSP BODY: {  
  "msg": "success",  
  "code": "0",  
  "data": {  
    "dataType": "String",  
    "name": "name",  
    "cardinality": "SINGLE",  
    "ttl":0  
  }  
}  
[SUCCESS]: query property key[name] successfully.
```

- Query all property keys.

```
api.queryAllPropertyKey(graphName);
```

The command output is as follows:

```
REQ HEADER: GET https://10.7.66.150:22380/graphbase/graph/graphbase/schema/property-key  
HTTP/1.1  
RSP BODY: {  
  "msg": "success",  
  "code": "0",  
  "data": {"propertyKeyList": [  
    {  
      "dataType": "String",  
      "name": "name",  
      "cardinality": "SINGLE",  
      "ttl":0  
    },  
    {  
      "dataType": "Integer",  
      "name": "age",  
      "cardinality": "SINGLE",  
      "ttl":0  
    },  
    {  
      "dataType": "String",  
      "name": "telephone",  
      "cardinality": "SINGLE",  
      "ttl":0  
    },  
    {  
      "dataType": "Float",  
      "name": "weight",  
      "cardinality": "SINGLE",  
      "ttl":0  
    }  
  ]}  
}  
[SUCCESS]: query all property key successfully.
```

- Create a vertex label.

```
api.addVertexLabel("person",graphName);  
api.addVertexLabel("phone",graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/vertex-label  
HTTP/1.1  
REQ BODY: {"name":"person"}  
RSP BODY: {  
  "msg": "success",  
  "code": "0",  
  "data": {  
    "name": "person"  
  }  
}
```

```
}
```

[SUCCESS]: create vertex label[person] successfully.

REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/vertex-label  
HTTP/1.1

REQ BODY: {"name":"person"}

RSP BODY: {  
"msg": "success",  
"code": "0",  
"data": {  
"name": "phone"  
}  
}  
}

[SUCCESS]: create vertex label[phone] successfully.

- Query a vertex label based on the name.  
api.queryVertexLabel("person",graphName);

The command output is as follows:

```
REQ HEADER: GET https://10.7.66.150:22380/graphbase/graph/graphbase/schema/vertex-label/person  
HTTP/1.1
```

RSP BODY: {  
"msg": "success",  
"code": "0",  
"data": {  
"name": "person"  
}  
}  
}

[SUCCESS]: query vertex label[person] successfully.

- Query all vertex labels.  
api.queryAllVertexLabel(graphName);

The command output is as follows:

```
REQ HEADER: GET https://10.5.199.50:22380/graphbase/graph/graphbase/schema/vertex-label  
HTTP/1.1
```

RSP BODY: {  
"msg": "success",  
"code": "0",  
"data": {"vertexLabelList": [  
{  
"name": "person"  
},  
{  
"name": "phone"  
}  
]}  
}

[SUCCESS]: query all vertex label successfully.

- Create an edge label.

```
EdgeLabel edgeLabel = new EdgeLabel();  
edgeLabel.setName("friend");  
api.addEdgeLabel(edgeLabel,graphName);  
edgeLabel = new EdgeLabel();  
edgeLabel.setName("knows");  
api.addEdgeLabel(edgeLabel,graphName);  
edgeLabel = new EdgeLabel();  
edgeLabel.setName("call");  
api.addEdgeLabel(edgeLabel,graphName);  
edgeLabel = new EdgeLabel();  
edgeLabel.setName("has");  
api.addEdgeLabel(edgeLabel,graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/edge-label  
HTTP/1.1
```

REQ BODY: {"name":"friend"}

"msg": "success",  
"code": "0",  
"data": {

```
"multiplicity": "MULTI",
"name": "friend",
"ttl":0
}
}
[SUCCESS]: create edge label[friend] successfully.
```

- Query an edge label based on the name.

```
api.queryEdgeLabel("friend",graphName);
```

The command output is as follows:

```
REQ HEADER: GET https://10.7.66.150:22380/graphbase/graph/graphbase/schema/edge-label/
friendHTTP/1.1
RSP BODY: {
"msg": "success",
"code": "0",
"data": {
"multiplicity": "MULTI",
"name": "friend",
"ttl":0
}
}
[SUCCESS]: query edge label[friend] successfully.
```

## Periodic Data Deletion

GraphBase provides the following periodic data deletion functions:

- When creating a property key, you can set the **ttl** parameter for the property. The value must be an integer, in seconds. For example, if you set **ttl** for the **name** property to **120**, the **name** property of all vertices will be deleted 120s later after being created.

This parameter takes effect only for vertex properties, and does not take effect for edge properties.

**Note:** If a vertex has only one property and the **ttl** parameter is set for the property, the vertex cannot be queried using this property after the property is deleted. However, this vertex can be queried by performing full-graph traversal, and the vertex ID is also recorded on the corresponding edge of the vertex. You are not advised to configure **ttl** for the unique property of a vertex.

- When creating an edge label, you can set the **ttl** parameter for the edge label. The value must be an integer, in seconds. For example, if you set **ttl** for the **know** label to **120**, edges labeled by the **know** label will be deleted 120s later after being created.

**Note:** The **ttl** parameter is not allowed for data stored in Elasticsearch. For example, if a MIXED index is created for the property of an edge labeled by **know**, the index data of the edge cannot be deleted with the edge 120s later, and the deleted edge cannot be found using the index. To delete the index data, you are advised to create a MIXED index for the corresponding edge property and recreate the index. After the index is successfully recreated, delete the original MIXED index.

### NOTICE

If **ttl** is set to **0** or a negative number, the corresponding property or edges are not deleted. The default value is **0**.

### 2.5.3.6.5 Creating an Index

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

- Create an index.

#### NOTE

MIXED: specifies the mixed index that is a kind of external hybrid match index. This type of indexes searches vertices and edges using any combination of indexes created in the databases. The property key corresponding to such indexes is in the <key, value> format. The options of value are as follows: **TEXT**, **TEXTSTRING**, **PREFIX\_TREE**, and **DEFAULT** (these values are case insensitive.) External indexes are used for non-exact match queries.

COMPOSITE: specifies the composite index that is a kind of internal exact match index. This type of indexes retrieve vertices or edges using a fixed combination of one or more properties. Such indexes are accurate, simple, and efficient, and can greatly accelerate the retrieval speed, but have high requirements on the property sequence in the combination. The property key corresponding to such indexes is in the <key, ""> format. Built-in indexes are used for exact match queries.

You can create an index only after a schema is created and before a vertex or edge is created. Otherwise, data cannot be queried. You need to recreate indexes to query data.

```
//Create indexes for all vertices and edges.  
addIndex(api, graphName);  
private static void addIndex(RestApi api, String graphName) {  
    //Create a built-in index for the vertex property name.  
    GraphIndexReqObj graphIndexReqObj = new GraphIndexReqObj();  
    graphIndexReqObj.setElementCategory(ElementCategory.VERTEX);  
    graphIndexReqObj.setName("name_index");  
    graphIndexReqObj.setType(IndexType.COMPOSITE);  
    List<KeyTextType> keyTextTypeList1 = new ArrayList<>();  
    KeyTextType keyTextType = new KeyTextType();  
    keyTextType.setName("name");  
    KeyTextType.setTextType(""); //If IndexType is set to COMPOSITE, TextType is empty.  
    keyTextTypeList1.add(keyTextType);  
    graphIndexReqObj.setKeyTextTypeList(keyTextTypeList1);  
    api.addGraphIndex(graphIndexReqObj, graphName);  
    //Create a built-in index for the vertex property age.  
    graphIndexReqObj = new GraphIndexReqObj();  
    graphIndexReqObj.setElementCategory(ElementCategory.VERTEX);  
    graphIndexReqObj.setName("age_index");  
    graphIndexReqObj.setType(IndexType.COMPOSITE);  
    List<KeyTextType> keyTextTypeList2 = new ArrayList<>();  
    KeyTextType keyTextType = new KeyTextType();  
    keyTextType.setName("age");  
    KeyTextType.setTextType(""); //If IndexType is set to COMPOSITE, TextType is empty.  
    keyTextTypeList2.add(keyTextType);  
    graphIndexReqObj.setKeyTextTypeList(keyTextTypeList2);  
    api.addGraphIndex(graphIndexReqObj, graphName);  
    //Create a mixed index for the vertex property telephone.  
    graphIndexReqObj = new GraphIndexReqObj();  
    graphIndexReqObj.setElementCategory(ElementCategory.VERTEX);  
    graphIndexReqObj.setName("telephone_index");  
    graphIndexReqObj.setType(IndexType.COMPOSITE);  
    List<KeyTextType> keyTextTypeList3 = new ArrayList<>();  
    KeyTextType keyTextType = new KeyTextType();  
    keyTextType.setName("telephone");  
    KeyTextType.setTextType(""); //If IndexType is set to COMPOSITE, TextType is empty.  
    keyTextTypeList3.add(keyTextType);  
    graphIndexReqObj.setKeyTextTypeList(keyTextTypeList3);  
    api.addGraphIndex(graphIndexReqObj, graphName);  
    ...//Creates a mixed index for the edge property weight.  
    graphIndexReqObj = new GraphIndexReqObj();  
    graphIndexReqObj.setElementCategory(ElementCategory.EDGE);
```

```
graphIndexReqObj.setName("weight_index");
graphIndexReqObj.setType(IndexType.MIXED);
List<KeyTextType> keyTextTypeList4 = new ArrayList<>();
keyTextType = new KeyTextType();
keyTextType.setName("weight");
...KeyTextType.setTextType("DEFAULT");//If IndexType is set to MIXED, TextType is transferred based
on the information provided in the interface document.
keyTextTypeList4.add(keyTextType);
graphIndexReqObj.setKeyTextTypeList(keyTextTypeList4);
api.addGraphIndex(graphIndexReqObj, graphName);
}
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/index/graph
HTTP/1.1

[SUCCESS]: query all index successfully.
```

### 2.5.3.6.6 Creating and Querying a Vertex or an Edge

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

- Create a vertex.

```
//Create four nodes labeled as person 1, person 4, person 5, and person 8.
addVertexPerson(api, graphName);
private static void addVertexPerson(RestApi api, String graphName) {
...//Create the node person 1.
    AddVertexReqObj addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("person");
    List<PropertyReqObj> propertyReqObjList1 = new ArrayList<>();
    PropertyReqObj propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("name");
    propertyReqObj.setValue("marko");
    propertyReqObjList1.add(propertyReqObj);
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("age");
    propertyReqObj.setValue(29);
    propertyReqObjList1.add(propertyReqObj);
    addVertexReqObj.setPropertyList(propertyReqObjList1);
    api.addVertex(addVertexReqObj, graphName);
//Create the node person 4.
    addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("person");
    List<PropertyReqObj> propertyReqObjList2 = new ArrayList<>();
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("name");
    propertyReqObj.setValue("josh");
    propertyReqObjList2.add(propertyReqObj);
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("age");
    propertyReqObj.setValue(32);
    propertyReqObjList2.add(propertyReqObj);
    addVertexReqObj.setPropertyList(propertyReqObjList2);
    api.addVertex(addVertexReqObj, graphName);
...//Create the node person 5.
    addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("person");
    List<PropertyReqObj> propertyReqObjList3 = new ArrayList<>();
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("name");
    propertyReqObj.setValue("vadas");
    propertyReqObjList3.add(propertyReqObj);
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("age");
    propertyReqObj.setValue(27);
    propertyReqObjList3.add(propertyReqObj);
    addVertexReqObj.setPropertyList(propertyReqObjList3);
    api.addVertex(addVertexReqObj, graphName);
...//Create the node person 8.
    addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("person");
    List<PropertyReqObj> propertyReqObjList4 = new ArrayList<>();
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("name");
    propertyReqObj.setValue("blame");
    propertyReqObjList4.add(propertyReqObj);
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("age");
    propertyReqObj.setValue(30);
```

```
        propertyReqObjList4.add(propertyReqObj);
        addVertexReqObj.setPropertyList(propertyReqObjList4);
        api.addVertex(addVertexReqObj, graphName);
    }
    //Create four nodes labeled as phone 2, phone 3, phone 6, and phone 7, respectively.
    addVertexPhone(api, graphName);
    private static void addVertexPhone(RestApi api, String graphName) {
        //Create the node phone 2.
        AddVertexReqObj addVertexReqObj = new AddVertexReqObj();
        addVertexReqObj.setVertexLabel("phone");
        List<PropertyReqObj> propertyReqObjList1 = new ArrayList<>();
        PropertyReqObj propertyReqObj = new PropertyReqObj();
        propertyReqObj.setName("telephone");
        propertyReqObj.setValue("15000000000");
        propertyReqObjList1.add(propertyReqObj);
        addVertexReqObj.setPropertyList(propertyReqObjList1);
        api.addVertex(addVertexReqObj, graphName);
        //Create the node phone 3.
        addVertexReqObj = new AddVertexReqObj();
        addVertexReqObj.setVertexLabel("phone");
        List<PropertyReqObj> propertyReqObjList2 = new ArrayList<>();
        propertyReqObj = new PropertyReqObj();
        propertyReqObj.setName("telephone");
        propertyReqObj.setValue("15222222222");
        propertyReqObjList2.add(propertyReqObj);
        addVertexReqObj.setPropertyList(propertyReqObjList2);
        api.addVertex(addVertexReqObj, graphName);
        //Create the node phone 6.
        addVertexReqObj = new AddVertexReqObj();
        addVertexReqObj.setVertexLabel("phone");
        List<PropertyReqObj> propertyReqObjList3 = new ArrayList<>();
        propertyReqObj = new PropertyReqObj();
        propertyReqObj.setName("telephone");
        propertyReqObj.setValue("13777777777");
        propertyReqObjList3.add(propertyReqObj);
        addVertexReqObj.setPropertyList(propertyReqObjList3);
        api.addVertex(addVertexReqObj, graphName);
        //Create the node phone 7.
        addVertexReqObj = new AddVertexReqObj();
        addVertexReqObj.setVertexLabel("phone");
        List<PropertyReqObj> propertyReqObjList4 = new ArrayList<>();
        propertyReqObj = new PropertyReqObj();
        propertyReqObj.setName("telephone");
        propertyReqObj.setValue("13666666666");
        propertyReqObjList4.add(propertyReqObj);
        addVertexReqObj.setPropertyList(propertyReqObjList4);
        api.addVertex(addVertexReqObj, graphName);
    }
}
```

The command output is as follows:

```

### 2.5.3.6.7 Performing a Full Graph Query

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

- Perform full graph query for vertices.

```
//Perform full graph query for vertices in the following scenario: To query the users who are older than 29 years old and list the users by age in ascending order. The upper limit of the number of users is 3.
VertexSearchReqObj vertexSearchReqObj = new VertexSearchReqObj();
vertexSearchReqObj.setVertexLabel("person");
List<PropertyFilter> propertyFilterList = new ArrayList<>();
PropertyFilter propertyFilter = new PropertyFilter();
propertyFilter.setProperty("age");
propertyFilter.setPredicate(PropertyPredicate.GREATER_THAN);
List<Integer> values = new ArrayList();
values.add(29);
propertyFilter.setValues(values);
propertyFilterList.add(propertyFilter);
vertexSearchReqObj.setFilterList(propertyFilterList);
List<PropertyKeySort> sortList = new ArrayList<>();
PropertyKeySort propertyKeySort = new PropertyKeySort();
propertyKeySort.setPropertyKeyName("age");
propertyKeySort.setSortType("ASC");
sortList.add(propertyKeySort);
vertexSearchReqObj.setPropertyKeySortList(sortList);
vertexSearchReqObj.setLimit(3);
//Perform full graph query for vertices.
api.searchVertex(vertexSearchReqObj, graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/vertex/search HTTP/1.1
REQ BODY: {"filterList":[{"propertyName":"age","predicate":">>","values": [29]}],"vertexLabel":"person","propertyKeySortList": [{"propertyKeyName":"age","sortType":"ASC"}],"limit":3}
RSP BODY: {
  "msg": "success",
  "code": "0",
  "data": {
    "totalHits": 2,
    "vertexList": [
      {
        "propertyList": [
          {
            "name": "name",
            "id": "atc7-vozc-4if9",
            "value": "blame"
          },
          {
            "name": "age",
            "value": "29"
          }
        ]
      }
    ]
  }
}
```

```

        "id": "dmh3-vozc-5wzp",
        "value": "30"
    }
],
"id": "1478712",
"vertexLabel": "person"

### 2.5.3.6.8 Performing a Path Query

- Graph traversal: Access the vertices of the graph along the side from any vertex of the graph. Graph traversal is a basic operation in graph databases, and it is similar to tree traversal. In a narrow sense, a vertex can be accessed only once in a graph traversal. The graph traversal described in this document is that in a broad sense.
- Graph path: indicates the set of vertices and edges that passed by during graph traversal. The number of edges in a path is called the path depth.

Use marko in [Typical Application Scenario](#) as an example, the paths formed by the vertices and edges found based on the first layer expansion query are as follows:

- marko -[friend]-> josh
- marko -[has]-> 150000000000
- marko -[knows]-> vadas

In this example, the person name or mobile number indicates the entity object. `-[relationship]->` is used to indicate the edge, and the relationship in the square brackets([]) indicates the edge label. The depth of these paths is 1.

Continue traversing based on the preceding path result, and obtain a second layer edge and a vertex of marko to form a new path. The original path is named the parent path of the new path, and the new path is named the sub-path of the original path.

Example:

- Original path (path A): marko -[friend]-> josh
- New path (path B): marko -[friend]-> josh -[has]-> 1522222222
- Path A is the parent path of path B, and path B is the sub-path of path A.
- Full path: indicates all graph paths between two vertices that meet specified conditions.

Scenario 1: Query the full path between node 1 and node 8.

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

```
allPathSearch(api, graphName);
private static void allPathSearch(RestApi api, String graphName) {
    PathSearchReqObj pathSearchReqObj = new PathSearchReqObj();
    List<String> vertexIdList = new ArrayList<>();
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "marko"));
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "blame"));
    pathSearchReqObj.setVertexIdList(vertexIdList);
    pathSearchReqObj.setLayer(7);
    api.searchPath(pathSearchReqObj, graphName);
}
```

The command output is as follows:

REQ HEADER: POST https://10.7.66.150:22380/graphbase/default/paths HTTP/1.1

REQ BODY: {"vertexIdList":["1793880","2842456"],"layer":7}

[SUCCESS]: search path successfully.
=====
format=====
|---msg          message
|---code         code
|---data         Result data storage location
|---pathSet      All path data. Multiple vertex pairs correspond to multiple data structures.
|---start        Start node ID
|---end          End node ID
|---edgeList     Detailed data of all relationships in the data result
|---vertexList   Detailed data of all vertices included in the current data result
|---pathList     Path set. Each path stores only the relationship access sequence table. Only
relationship IDs are recorded.
=====
=====
```

Build a path based on the path result (applicable to all paths):

- Find a path from the path list. For example:

```
[  
    "cy23-12g60-2sb9-17808",  
    "6kdl-17808-46vp-1ox94"  
]
```

- Find an edge from the edge list based on the edge ID. For example:

Find the edge with the ID of cy23-12g60-2sb9-17808:

```
{  
    "propertyList": [{  
        "name": "weight",  
        "value": "1.0"  
    }],  
    "start": "1793880",  
    "end": "2016584",  
    "id": "cy23-12g60-2sb9-17808",  
    "label": "friend",  
    "type": "edge"  
}
```

- Identify the start vertex, obtain the end node ID based on the edge data in **b**, and obtain the vertex data from the vertex list. For example:

Start from the edge with the ID of cy23-12g60-2sb9-17808 to find the end node with the vertex ID of 2016584

```
{  
    "labelList": ["person"],  
    "propertyList": [  
        {  
            "name": "name",  
            "value": "josh"  
        },  
        {  
            "name": "age",  
            "value": "32"  
        }  
    ],  
    "id": "2016584",  
    "type": "vertex"  
}
```

- Repeat **b** and **c** until the data in **a** is exhausted.

The path in the preceding example is simplified as follows:

```
(1793880,marko) -[cy23-12g60-2sb9-17808:friend]-> (2016584,josh)  
-[6kdl-17808-46vp-1ox94:knows]-> (2842456:blame)
```

Vertices are marked in parentheses and in the format of (Vertex ID, Person name). Edges are marked in square brackets and in the format of -[Edge ID:Edge type]->

- Shortest path

It indicates the shortest path between two vertices, specifically the path with the smallest sum of relationship weights. This document considers that the path with the smallest sum of path relationship weights is not the shortest path. Instead, the shortest path must comply with the specified weight rule. If the weight calculation rule is not specified, the shortest path is the path with the minimum path depth by default. The shortest path complying with the relationship weighting rule is the weight-based shortest path.

Scenario 2: Query the shortest path from node 1 to node 8.

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

```
shortestPathSearch(api, graphName);
private static void shortestPathSearch(RestApi api, String graphName) {
    PathSearchReqObj pathSearchReqObj = new PathSearchReqObj();
    List<String> vertexIdList = new ArrayList<>();
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "marko"));
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "blame"));
    pathSearchReqObj.setVertexIdList(vertexIdList);
    pathSearchReqObj.setLayer(7);
    ...PathSearchReqObj.setOption("shortest");//If option is not transferred, the default value is all, that
    is, the full path.
    api.searchPath(pathSearchReqObj, graphName);
}
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/default/paths HTTP/1.1
```

```
REQ BODY: {"vertexIdList":["1793880","2842456"],"layer":7,"option":"shortest"}
```

```

=====
=====
```

- Scenario 3: Query the paths where the **age** values of all nodes are greater than or equal to 29 between node 1 and node 8.

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

```
vertexFilterPathSearch(api, graphName);
private static void vertexFilterPathSearch(RestApi api, String graphName) {
    PathSearchReqObj pathSearchReqObj = new PathSearchReqObj();
    List<String> vertexIdList = new ArrayList<>();
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "marko"));
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "blame"));
    pathSearchReqObj.setVertexIdList(vertexIdList);
    VertexFilter vertexFilter = new VertexFilter();
    List<PropertyFilter> propertyFilterList3 = new ArrayList<>();
    PropertyFilter propertyFilter = new PropertyFilter();
    propertyFilter.setProperty("age");
    propertyFilter.setPredicate(PropertyPredicate.GREATER_THAN_EQUAL);
    List<Integer> values2 = new ArrayList();
    values2.add(29);
    propertyFilter.setValues(values2);
    propertyFilterList3.add(propertyFilter);
    vertexFilter.setFilterList(propertyFilterList3);
    pathSearchReqObj.setVertexFilter(vertexFilter);
    pathSearchReqObj.setLayer(7);
    api.searchPath(pathSearchReqObj, graphName);
}
```

The command output is as follows:

### 2.5.3.6.9 Performing a Line Expansion Query

- Line Expansion Query
  - Similar to graph traversal, a line expansion query starts from a specified vertex and traverses the incident edges to find the target vertex. In a graph traversal, the process of finding the vertices that have direct connection with the specified vertex is the first layer expansion for the vertex.
  - The graph traversal proceeds with the query from these vertices directly connected with the start vertex to find the vertices that are indirectly connected with the start vertex. This process is called second layer

expansion. In this way the graph traversal will expand n layers to find all vertices that are directly and indirectly connected with the start vertex.

```
//Scenario: Start from node 1 and expand two layers.  
//Layer 1 query condition: To query the vertices whose age is equal to or less than 29.  
//Layer 2 query condition: To query the vertices whose vertexlabel is phone.  
lineSearch(api, graphName);  
private static void lineSearch(RestApi api, String graphName) {  
    LineSearchReqObj lineSearchReqObj = new LineSearchReqObj();  
    List<Integer> vertexIdList = new ArrayList<>();  
    String vertexId = getVertexIdByProperty(api, graphName, "person", "name", "marko");  
    vertexIdList.add(Integer.valueOf(vertexId));  
    lineSearchReqObj.setVertexIdList(vertexIdList);  
    List<VertexFilter> vertexFilterList = new ArrayList<>();  
    VertexFilter vertexFilter = new VertexFilter();  
    List<PropertyFilter> propertyFilterList1 = new ArrayList<>();  
    PropertyFilter propertyFilter = new PropertyFilter();  
    propertyFilter.setProperty("age");  
    propertyFilter.setPredicate(PropertyPredicate.LESS_THAN_EQUAL);  
    List<Integer> values2 = new ArrayList();  
    values2.add(29);  
    propertyFilter.setValues(values2);  
    propertyFilterList1.add(propertyFilter);  
    vertexFilter.setFilterList(propertyFilterList1);  
    vertexFilterList.add(vertexFilter);  
    vertexFilter = new VertexFilter();  
    List<String> vertexLabelList = new ArrayList<>();  
    vertexLabelList.add("phone");  
    vertexFilter.setVertexLabelList(vertexLabelList);  
    vertexFilterList.add(vertexFilter);  
    lineSearchReqObj.setVertexFilterList(vertexFilterList);  
    lineSearchReqObj.setLayer(2);  
    lineSearchReqObj.setLimit(5);  
    api.searchLines(lineSearchReqObj, graphName);  
}
```

The command output is as follows:

REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/lines HTTP/1.1

### 2.5.3.6.10 Analyzing the Typical Application Scenario

#### Direct Contact Search

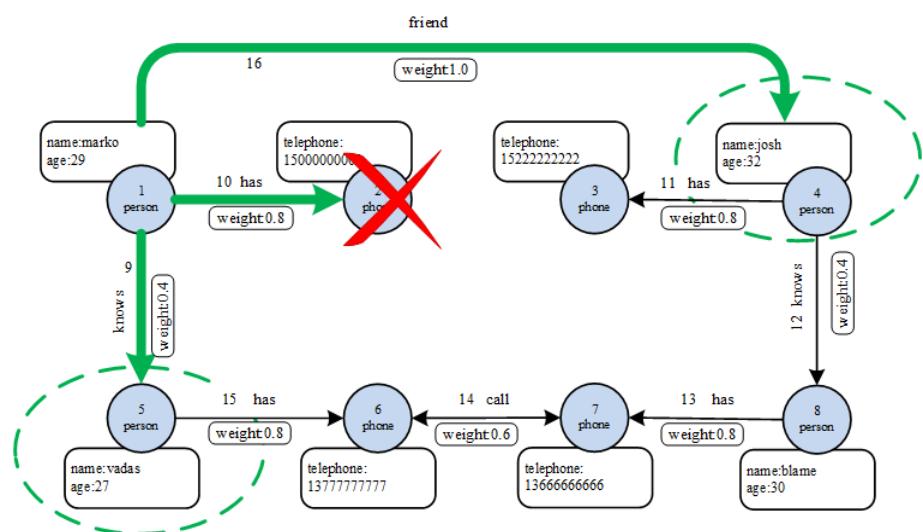

Direct contact: A person who has direct contact with a specified person.

The following graph shows the relationship between persons and their direct contacts in the typical scenario. (marko is used as an example. The direct contacts of marko are marked using the red dotted ovals.)

In GraphBase, the line expansion query function can be used to implement this scenario. **Figure 2-105** shows how to find the direct contacts for marko. (The green arrows indicate the expansion direction, the red cross mark indicates that the vertex does not meet the search condition, and the green dotted ovals indicate the search result.)

**Figure 2-105** Direct contact search in GraphBase

As shown in the preceding graph, josh and vadas are directly connected with marko. The related code is as follows:

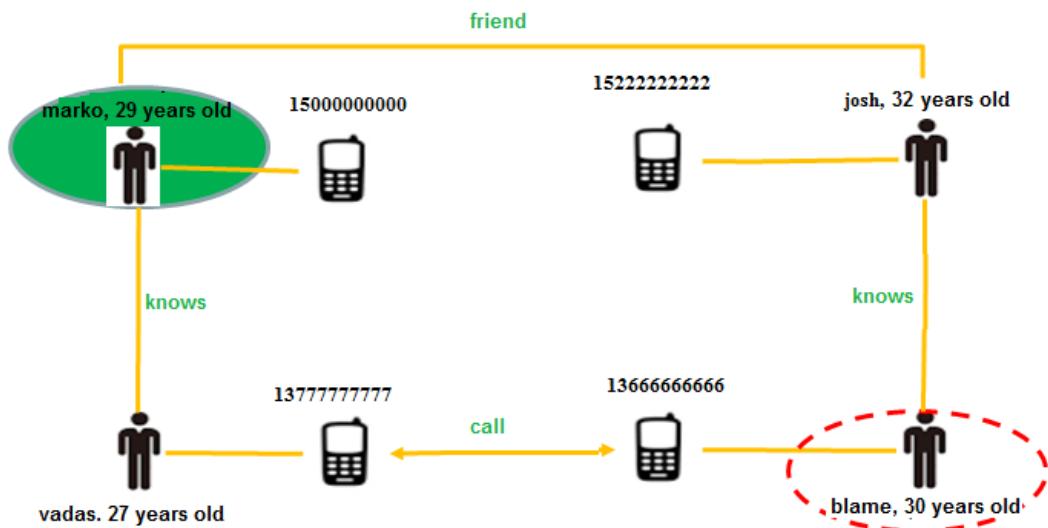

```
/*
 * <p> Search for the direct contact</p>
 * @param api REST API encapsulation
 * @param graphName Graph name
 * @param startNodeId Start node ID
 * NOTE: The search result is the response data of the end node.
 */
static String findDirectRelations(RestApi api, String graphName, String startNodeId)
{
    // Node preparation
    LineSearchReqObj lineSearchReqObj = new LineSearchReqObj();
    List<Integer> vertexIdList = new ArrayList<>();
    vertexIdList.add(Integer.valueOf(startNodeId));
    lineSearchReqObj.setVertexIdList(vertexIdList);
```

```
// Query depth
lineSearchReqObj.setLayer(1);
// End node condition (the label is person)
List<VertexFilter> vertexFilterList = new ArrayList<>();
VertexFilter vertexFilter = new VertexFilter();
List<String> vertexLabelList = new ArrayList<>();
vertexLabelList.add("person");
vertexFilter.setVertexLabelList(vertexLabelList);
vertexFilterList.add(vertexFilter);
lineSearchReqObj.setVertexFilterList(vertexFilterList);
// Perform line expansion query. (The query result is displayed as strings in JSON format.)
String result = api.searchLines(lineSearchReqObj, graphName);
return result;
}
```

## Indirect Contact Search

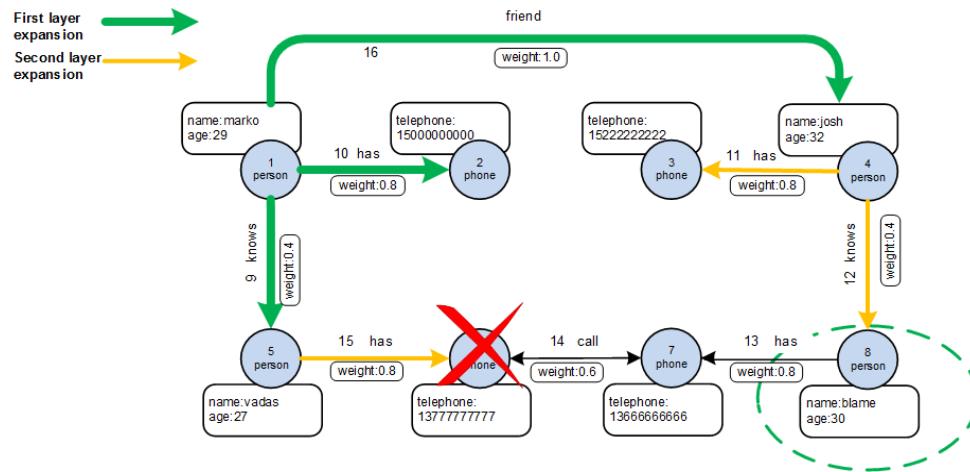

Indirect contact: A person who has indirect contact with a specified person.

The following graph shows the relationship between persons and their indirect contacts in the typical scenario. (marko is used as an example. The indirect contacts of marko are marked using the red dotted ovals.)

In GraphBase, the line expansion query can be used to find the indirect contact of marko in this scenario. [Figure 2-106](#) shows how the indirect contacts are searched in GraphBase. In the scenario, two layers are expanded: the green arrows indicate the query at the first layer, the yellow arrows indicate the query at the second layer. The red cross indicates that the vertex does not meet the search criteria, and the green dotted oval marks out the search result.

**Figure 2-106** Graph example of indirect contact search

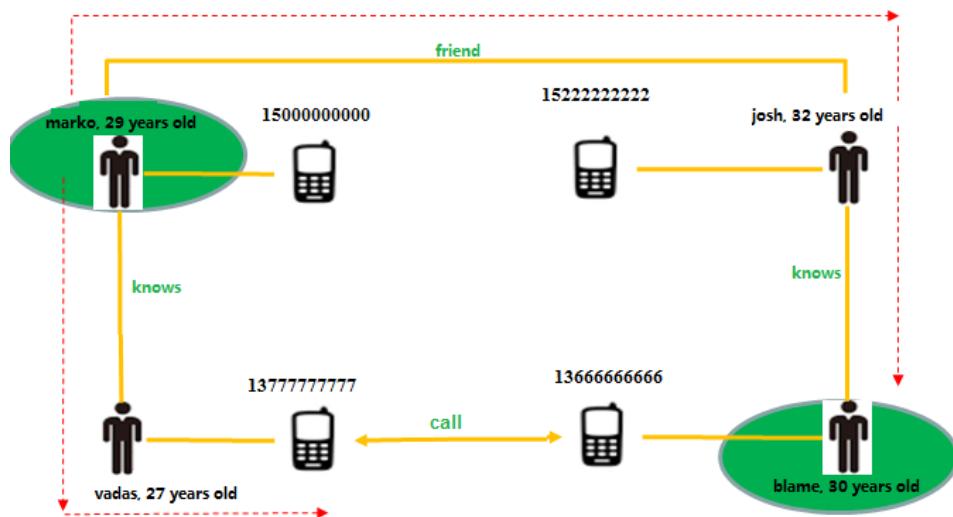

As shown in the preceding graph, only one link between marko and blame meets the search criteria. The related code is as follows:

```
/*
 * <p> Search for the indirect contact</p>
 * @param api REST API encapsulation
 * @param graphName Graph name
 * @param startNodeID Start node ID
 * NOTE: The search result is the response data of the end node.
 */
static String findIndirectRelations(RestApi api, String graphName, String startNodeID)
{
    // Node preparation
    LineSearchReqObj lineSearchReqObj = new LineSearchReqObj();
    List<Integer> vertexIdList = new ArrayList<>();
    vertexIdList.add(Integer.valueOf(startNodeID));
    lineSearchReqObj.setVertexIdList(vertexIdList);
    // Query depth
    lineSearchReqObj.setLayer(2);
    // End node condition (the vertex label is person)
    List<VertexFilter> vertexFilterList = new ArrayList<>();
    VertexFilter vertexFilter = new VertexFilter();
    List<String> vertexLabelList = new ArrayList<>();
    vertexLabelList.add("person");
    vertexFilter.setVertexLabelList(vertexLabelList);
    vertexFilterList.add(vertexFilter);
    lineSearchReqObj.setVertexFilterList(vertexFilterList);
    // Perform line expansion query. (The query result is displayed as strings in JSON format.)
    String result = api.searchLines(lineSearchReqObj, graphName);
    return result;
}
```

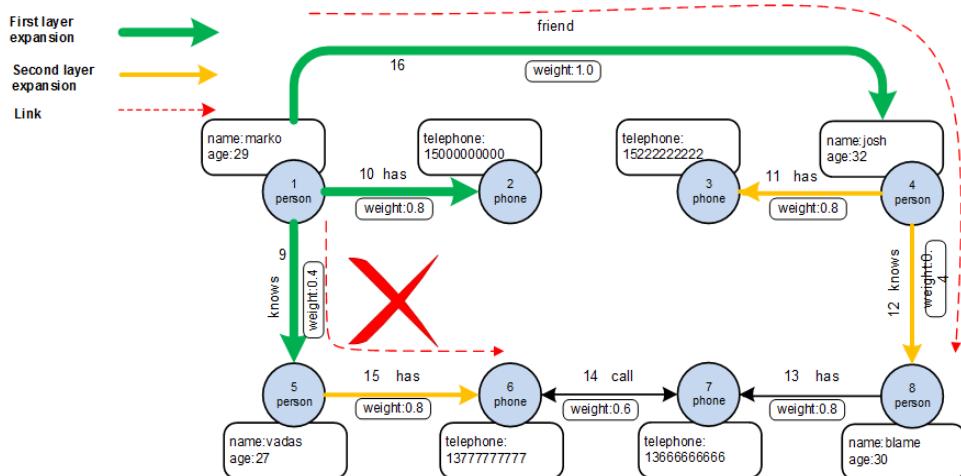

## Search for Link

Link refers to the link between two real world entities.

In the real world, the link between two persons is shown in the following graph. (The link between marko and blame is used as an example. The red dashed arrows indicate the link directions.)

In the link search scenario, the full path query function needs to be used. The following graph shows how to search for links in GraphBase. In this graph, the link between marko and blame is used as an example, and the path depth must be within two layers. The green arrows indicate the first layer expansion, the yellow arrow indicate the line expansion at the second layer, the red doted arrows indicate the link direction, and the red cross indicates that the link does not meet the requirements.

As shown in the preceding graph, only one link between marko and blame meets the search conditions. The related code is as follows:

```
/*
 * <p> Search for links </p>
 * @param api REST API encapsulation
 * @param graphName Graph name
 * @param startNodeId Start node ID
 * @param endNodeId End node ID
 * NOTE: The result data is the path set of the response data.
 */
static String findLinkedPaths(RestApi api, String graphName, String startNodeId, String endNodeId)
{
    // Node preparation
    PathSearchReqObj pathSearchReqObj = new PathSearchReqObj();
    List<String> vertexIdList = new ArrayList<>();
    vertexIdList.add(startNodeId);
    vertexIdList.add(endNodeId);
```

```
pathSearchReqObj.setVertexIdList(vertexIdList);
// Query depth.
pathSearchReqObj.setLayer(2);
// Perform full path query. (The query result is displayed as strings in JSON format).
String result = api.searchPath(pathSearchReqObj, graphName);
return result;
}
```

### 2.5.3.7 Gremlin Console

#### Prerequisites

You have installed all component clients required in the cluster.

#### Performing Query Using Gremlin Statements

1. Use PuTTY to log in to the node where the client is installed as user **root**.
2. Go to the **/GraphBase/gremlinserver/gremlin-console** directory where the GraphBase client is installed.

```
cd /opt/hadoopclient/GraphBase/gremlinserver/gremlin-console
```

In this example, the GraphBase client is installed in the /opt/hadoopclient directory.

3. Run the required environment variables as user **root**.  
**source /opt/hadoopclient/bigdata\_env**
4. Run the required environment variables as user **root**.  
**source /opt/hadoopclient/bigdata\_env**
5. Enter the Gremlin operation block.  
**sh bin/gremlin.sh**
6. Connect to the remote GraphBase.  
**:remote connect tinkerpop.server conf/remote-graphbase-gremlinserver.yaml**
7. Omit the remote command "**:**".  
**:remote console** (This operation is optional. If you perform this operation, you do not need to add "**:**" before the Gremlin language.)
8. Traverse a specified graph.  
**:remote config alias g Graph name**
9. Query a vertex, as shown in the following example. (For other application scenarios, see [Gremlin Application Scenarios](#).)  
gremlin> **:> g.V(13464736).valueMap()**  
==>[name:[zhangsan],age:[30]]  
gremlin> **:remote console**  
==>All scripts will now be sent to Gremlin Server - [szvphicprb00285/10.4.64.123:22375] - type  
'remote console' to return to local mode  
gremlin> **g.V(13464736).valueMap()**  
==>[name:[zhangsan],age:[30]]

```
[root@hd-123 gremlin-console]#source /opt/graphbaseClient/bigdata_env
[root@hd-123 gremlin-console]#kinit zky
Password for zky@HADOOP.COM:
[root@hd-123 gremlin-console]#sh bin/gremlin.sh

```

## 2.5.3.8 Gremlin Java

### 2.5.3.8.1 Connecting Gremlin Servers and Clients

- Modify the Gremlin client configuration file **remote-objects.yaml**.

Change the host name in hosts to the actual IP address.

```
hosts:[10.7.66.111,10.7.66.151,10.7.66.220]
port: 22381
connectionPool: {
  maxContentLength: 65536000,
  maxInProcessPerConnection: 60,
  maxSize: 16,
  resultIterationBatchSize: 960
}
protocol: gremlinserver
jaasEntry: GremlinConsole
serializer:
  { className: org.apache.tinkerpop.gremlin.driver.ser.GryoMessageSerializerV1d0, config:
    { ioRegistries: [org.janusgraph.graphdb.tinkerpop.JanusGraphIoRegistry] } }
  serializer:
    { className: org.apache.tinkerpop.gremlin.driver.ser.GryoMessageSerializerV1d0, config:
      { serializeResultToString: true } }
```

- Configure the mapping between the service IP Address of GraphServer and the host name in the local HOSTS file.

Directory of the HOSTS file on the Windows OS: **C:\Windows\System32\drivers\etc\hosts**

Directory of the HOSTS file on the Linux OS: **/etc/hosts**

```
#Mapping between the IP address and host name.
10.7.66.111 hd-111
10.7.66.151 hd-151
10.7.66.220 hd-220
```

- Connect the server and client.

Method 1:

```
//Connect the client and one or more Gremlin server instances.
Cluster cluster = GremlinClient.getInstance().getCluster();
//Create a client based on a cluster object.
Client client = cluster.connect().alias ("Graph name");
```

Method 2:

```
//Connect the client and one or more Gremlin server instances.
Cluster cluster = GremlinClient.getInstance().getCluster();
//Configure a remote graph traversal object on the client.
Graph graph = GremlinClient.getInstance().getGraph();
```

```
GraphTraversalSource g = graph.traversal().withRemote(DriverRemoteConnection.using (cluster,  
"Graph name"));
```

### 2.5.3.8.2 Running Gremlin Java API Example Code

- Submit Gremlin DSL statements as a client object.

```
//Submit Gremlin DSL statements synchronously.  
ResultSet resultSet = Client.submit("g.V().has('propertyKey', 'huawei').valueMap().limit(10)");  
//Submit Gremlin DSL statements asynchronously.  
Future<ResultSet> resultSet =  
Client.submitAsync("g.V().hasLabel('person').valueMap('name','age').limit(10)");  
//Generate the result.  
==>{name=[vadas], age=[27]}  
==>{name=[josh], age=[32]}  
==>{name=[blame], age=[30]}  
==>{name=[marko], age=[29]}
```

- Perform a graph traversal.

```
//Perform vertex traversal.  
Iterator<Map<String, Object>> iterator = g.V(ids).valueMap(properties).limit(10)  
//Perform edge traversal.  
Iterator<Map<String, Object>> iterator = g.E(ids).valueMap(properties).limit(10)  
//Generate the result.  
==>{name=[vadas], age=[27]}  
==>{name=[josh], age=[32]}  
==>{name=[blame], age=[30]}  
==>{name=[marko], age=[29]}
```

### 2.5.3.9 Gremlin Application Scenarios

#### 2.5.3.9.1 Querying a Specified Graph Object

- Query a specified vertex.

```
//Taverse all properties of the vertex based on the vertex ID.  
gremlin> g.V(1151560,1195696).valueMap()  
==>{name=[vadas], age=[27]}  
==>{name=[josh], age=[32]}
```

- Query a specified edge.

```
gremlin> g.E('fryh-oojs-93th-108hc', '102fq-pmls-6aol-vegw').valueMap()  
==>{weight=0.8}  
==>{weight=0.4}
```

#### 2.5.3.9.2 Queries One or More Properties

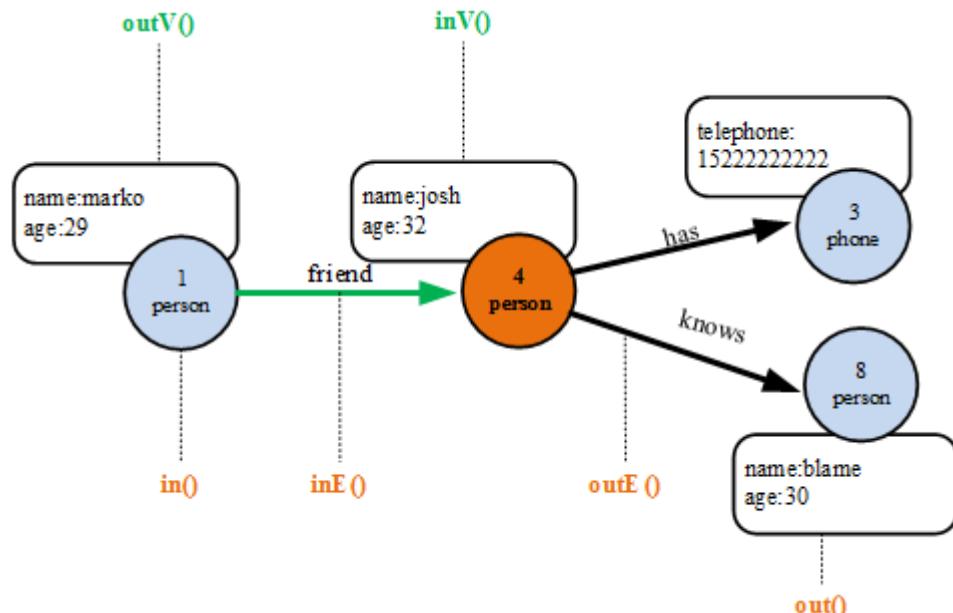

Querying one or more properties of a graph object.

```
gremlin> g.V().hasLabel('person').valueMap('name','age')  
==>{name=[vadas], age=[27]}  
==>{name=[josh], age=[32]}  
==>{name=[blame], age=[30]}  
==>{name=[marko], age=[29]}
```

#### 2.5.3.9.3 Traversing a Graph Object

| Graph Object<br>Traversal | Description   |
|---------------------------|---|
| Out(string )              | Move to the outgoing adjacent vertices given the edge labels. |

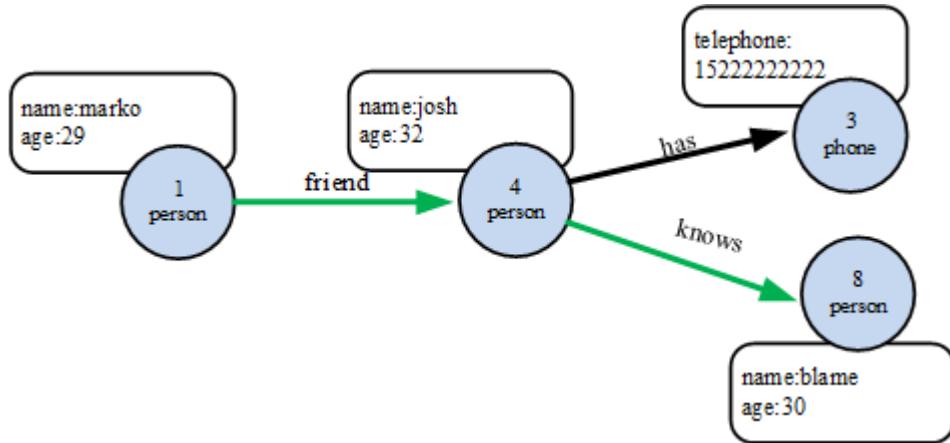

| Graph Object<br>Traversal | Description   |
|---------------------------|---|
| In(string )               | Move to the incoming adjacent vertices given the edge labels.                   |
| Both(string )             | Move to both the incoming and outgoing adjacent vertices given the edge labels. |
| OutE(string )             | Move to the outgoing incident edges given the edge labels.                      |
| InE(string )              | Move to the incoming incident edges given the edge labels.                      |
| BothE(string )            | Move to both the incoming and outgoing incident edges given the edge labels.    |
| outV()                    | Move to the outgoing vertex.  |
| inV()                     | Move to the incoming vertex.  |
| bothV()                   | Move to both vertices.  |

```
//Start from vertex 4 and traverse the edge to the out direction to obtain the incomming vertex of the edge.
gremlin> g.V(4).outE().inV()
==>v[3]
==>v[8]
//Move from vertex 4 to the out direction to obtain the peer vertex.
gremlin> g.V(4).out()
==>v[3]
==>v[8]
//Start from vertex 4 and traverse all edges to the out direction.
gremlin> g.V(4).outE()
==>e[10][4-has->3]
==>e[11][4-knows->8]
```

```
//Start from vertex 4 and traverse the edge to the out or in direction. The edge labels must be of a specified edge type, such as knows, has, or friend.
gremlin> g.V(4).bothE('knows','has','friend')
==>e[10][4-has->3]
==>e[11][4-knows->8]
==>e[8][1-friend->4]
```

#### 2.5.3.9.4 Traversing a Path

Function: path()

```
//Start from vertex 1 and traverse two layers to the out direction to obtain the peer vertex of the second layer.
gremlin> g.V(1).out().out().values('name')
==>blame
//Start from vertex 1 and traverse two layers to the out direction to return the track path of the traversal.
gremlin> g.V(1).out().out().values('name').path()
==>[v[1],v[4],v[8],blame]
```

#### 2.5.3.9.5 Filtering by Condition

- Filtering function: has()

| has                    | Description  |
|------------------------|--|
| has(key, value)        | Remove the traverser if its element does not have the provided key/value property.                     |
| has(label, key, value) | Remove the traverser if its element does not have the specified label and provided key/value property. |
| has(key, predicate)    | Remove the traverser if its element does not have a key value that satisfies the predicate.            |
| HasLabel(labels )      | Remove the traverser if its element does not have any of the labels.                                   |
| HasId(ids )            | Remove the traverser if its element does not have any of the IDs.                                      |
| HasKey(keys )          | Remove the traverser if the property does not have all of the provided keys.                           |

| has               | Description  |
|-------------------|--|
| HasValue(values ) | Remove the traverser if its property does not have all of the provided values. |
| has(key)          | Remove the traverser if its element does not have a value for the key.         |
| hasNot(key)       | Remove the traverser if its element has a value for the key.                   |

- Expression: predicate

| Predicate                | Description   |
|--------------------------|---|
| eq(object)               | Is the incoming object equal to the provided object?  |
| neq(object)              | Is the incoming object not equal to the provided object?  |
| lt(number)               | Is the incoming number less than the provided number?   |
| lte(number)              | Is the incoming number less than or equal to the provided number?                                   |
| gt(number)               | Is the incoming number greater than the provided number?  |
| gte(number)              | Is the incoming number less than or equal to the provided number?                                   |
| inside(number, number)   | Is the incoming number greater than the first provided number and less than the second?             |
| outside(number, number)  | Is the incoming number less than the first provided number or greater than the second?              |
| between(number, number)  | Is the incoming number greater than or equal to the first provided number and less than the second? |
| Within(objects )         | Is the incoming object in the array of provided objects?  |
| Without(objects )        | Is the incoming object not in the array of the provided objects?                                    |
| TextP.startsWith(string) | Does the incoming String start with the provided String?  |
| TextP.endsWith(string)   | Does the incoming String end with the provided String?  |
| TextP.contains(string)   | Does the incoming String contain the provided String?   |

| Predicate                     | Description  |
|-------------------------------|--|
| TextP.notStartingWith(string) | Does the incoming String not start with the provided String? |
| TextP.notEndingWith(string)   | Does the incoming String not end with the provided String?   |
| TextP.notContaining(string)   | Does the incoming String not contain the provided String?    |

```
//Traverse the vertices that are of the person type.
gremlin> g.V().hasLabel('person')
==>v[1151560]
==>v[1195696]
==>v[1465088]
==>v[1421128]
//Traverse the vertices with the age property.
gremlin> g.V().properties().hasKey('age').value()
==>27
==>32
==>30
==>29
//Traverse the vertices where the values of the age properties are within the range from 20 to 30.
gremlin> g.V().has('age',inside(20,30)).values('age')
==>29
==>27
//Traverse the veretxes where the value of the name property is josh or marko.
gremlin> g.V().has('name',within('josh','marko')).valueMap()
==>{name=[josh], age=[32]}
==>{name=[marko], age=[29]}
```

### 2.5.3.9.6 Sorting the Result

```
//Sort the result based on the value of the age property in ascending order.
gremlin> g.V().hasLabel('person').order().by('age', incr).valueMap('name','age')
==>{name=[vadas], age=[27]}
==>{name=[marko], age=[29]}
==>{name=[blame], age=[30]}
==>{name=[josh], age=[32]}
//Sort the result based on the value of the age property in descending order.
gremlin> g.V().hasLabel('person').order().by('age', decr).valueMap('name','age')
==>{name=[josh], age=[32]}
==>{name=[blame], age=[30]}
==>{name=[marko], age=[29]}
==>{name=[vadas], age=[27]}
```

### 2.5.3.9.7 Displaying the Result in Multiple Pages

```
//Sort the result based on the value of the age property in ascending order and only obtain the first two data records.
gremlin> g.V().hasLabel('person').order().by('age', incr).limit(2).valueMap('name','age')
==>{name=[vadas], age=[27]}
==>{name=[marko], age=[29]}
//Sort the result based on the value of the age property in ascending order and obtain data from the third to the fourth records.
gremlin> g.V().hasLabel('person').order().by('age', incr).range(2,4).valueMap('name','age')
==>{name=[blame], age=[30]}
==>{name=[josh], age=[32]}
```

### 2.5.3.9.8 Calculating the Intersection Between Two Data Sets

```
//During the traversal, the concept of the intersection between two data sets must be differentiated from the join operation in the SQL syntax.
```

```
gremlin> g.V().hasLabel('person').match(
    __.as('c').values('name').as('name'),//Data set 1. The column alias is name.
    __.as('c').out('friend','knows').values('name').as('friend_or_knows') //Data set 2. The column alias is friend_or_knows.
    ).select('name', 'friend_or_knows')//Calculate the intersection between the two data sets.
==>{name=josh, friend_or_knows=blame}
==>{name=marko, friend_or_knows=josh}
==>{name=marko, friend_or_knows=vadas}
```

### 2.5.3.9.9 Calculating the Union of Two Data Sets

```
//During the traversal, calculate the union of the following two data sets.
gremlin> g.V().has('name','josh').union(
    __.in('friend').values('name'),//Data set 1
    __.out('knows').values('name'))//Data set 2
==>marko
==>blame
```

### 2.5.3.9.10 Using Statistical Functions

| Function | Description                   |
|----------|-------------------------------|
| count()  | Collects data.                |
| max()    | Calculates the maximum value. |
| min()    | Calculates the minimum value. |
| mean()   | Calculates the average value. |
| sum()    | Sums up data.                 |

```
//Calculate the number of vertices whose type is person
gremlin> g.V().hasLabel('person').count()
==>4
//Traverse all vertices to obtain the maximum value of the age property.
gremlin> g.V().values('age').max()
==>32
```

## 2.5.4 Application Commissioning

### 2.5.4.1 Commissioning an Application in Windows

#### 2.5.4.1.1 Compiling and Running an Application

##### Scenario

After the code development is complete, you can run the application in the Windows development environment. If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

If IBM JDK is used in the Windows environment, the application cannot be run in the Windows environment.

## Procedure

In the development environment (for example, running the REST API on the IntelliJ IDEA environment), right-click **GraphBaseRestExample.java** and choose **Run > GraphBaseRestExample.main()**.

### 2.5.4.1.2 Viewing Windows Commissioning Results

#### Scenario

After the running of GraphBase application completes, you can view the running results in the IntelliJ IDEA running result.

#### Procedure

The following information is displayed in the running results:

```
REQ HEADER: POST https://10.4.64.110:22380/graphbase/graph HTTP/1.1
REQ BODY: {"graphName":"graphbase"}
RSP BODY: {
    "msg": "create graph success.",
    "code": "0"
}
[SUCCESS]: create graph[graphbase] successfully.
REQ HEADER: POST https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1
REQ BODY: {"name":"person"}
RSP BODY: {
    "msg": "Success.",
    "code": "0",
    "data": {
        "name": "person"
    }
}
[SUCCESS]: create vertex label[person] successfully.
REQ HEADER: POST https://10.154.4.90:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1
REQ BODY: {"name":"phone"}
RSP BODY: {
    "msg": "Success.",
    "code": "0",
    "data": {
        "name": "phone"
    }
}
[SUCCESS]: create vertex label[phone] successfully.
REQ HEADER: GET https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label/person
HTTP/1.1
RSP BODY: {
    "msg": "Success.",
    "code": "0",
    "data": {
        "name": "person"
    }
}
[SUCCESS]: query vertex label[person] successfully.
REQ HEADER: GET https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1
RSP BODY: {
    "msg": "Success.",
    "code": "0",
    "data": {"vertexLabelList": [
        {
            "name": "person"
        },
        {
            "name": "phone"
        }
    ]}
}
```

```
}
```

[SUCCESS]: query all vertex label successfully.

...

## 2.5.4.2 Commissioning an Application in Linux

### 2.5.4.2.1 Compiling and Running an Application

#### Scenario

GraphBase applications can run in a Linux OS. After application code development is complete, you can upload a JAR file to the Linux environment to run applications.

#### Prerequisites

- A JDK has been installed in the Linux environment. The version of the JDK must be consistent with that of the JDK used by the JAR package exported by IntelliJIDEA.
- If the Linux host is not a node in the cluster, set the mapping between the host name and the IP address in the **hosts** file on the node. The host name and IP address must be in one-to-one mapping.

#### Procedure

##### Step 1 Export a JAR package.

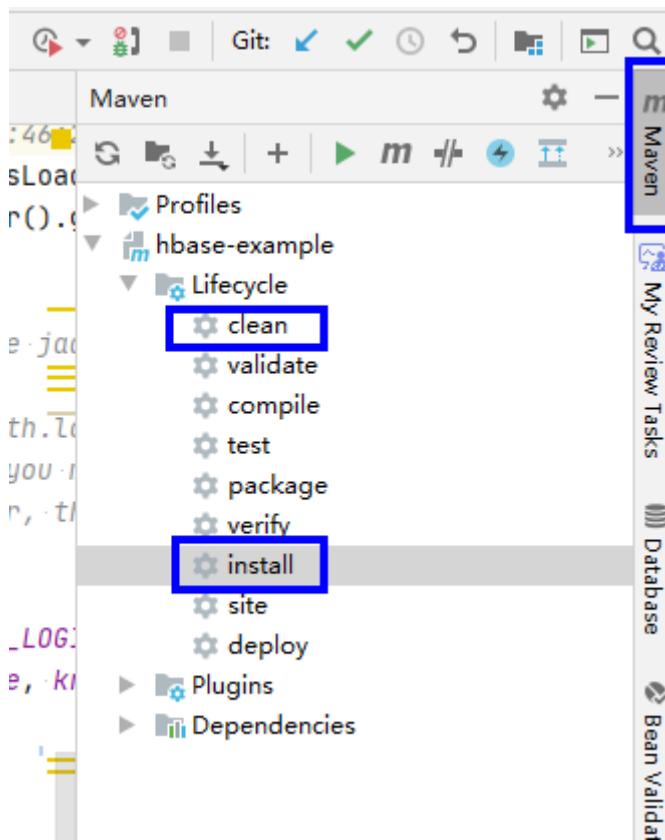

You can build a JAR package in either of the following ways:

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean**. Double-click **clean** to run the clean command of Maven.

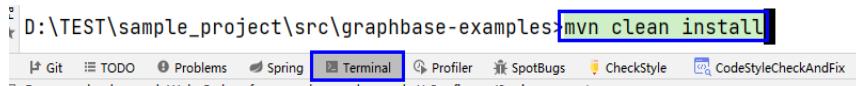

Choose **Maven** > *Sample project name* > **Lifecycle** > **install**. Double-click **install** to run the install command of Maven.

Figure 2-107 clean and install

- Method 2: Access the directory where the **pom.xml** file is located in the **Terminal** window at the bottom of the IDEA. Run the **mvn clean install** command to compile the file.

Figure 2-108 mvn clean install

After the compilation is complete, "Build Success" is printed, and the target directory is generated. The generated JAR package is stored in the target directory.

### Step 2 Export the JAR package on which the sample project depends.

Access the directory where the pom.xml file is located in the Terminal window or other command line tools at the bottom of the IDEA, and then run the following command:

```
mvn dependency:copy-dependencies -DoutputDirectory=lib
```

The lib folder is generated in the pom.xml directory, which contains the JAR package on which the sample project depends.

### Step 3 Prepare for the required JAR packages and configuration files.

- In the Linux environment, create a directory, for example, **/opt/test**, and create subdirectories**conf** and **lib**. Upload the JAR packages in **Step 1** and **Step 2**.

- 2 to the **lib** directory in Linux. Upload the conf configuration files in the sample project to the **conf** directory in Linux.
2. Import the user authentication credential files.  
Import the authentication credential files (**user.keytab** and **krb5.conf**) of the current user to the **conf** directory. On the FusionInsight Manager page, choose **System > Permission > User** to obtain the authentication credential files. Locate the row that contains the user whose authentication credentials need to be exported, and choose **More > Download Authentication Credential**.
3. In **/opt/test**, create the**GraphBase.sh** script, modify the following content, and save the file:

```
function Startup()
{
    SCRIPT_PATH=$(cd $(dirname $(readlink -f "${BASH_SOURCE[0]}")) && pwd )
    for f in ${SCRIPT_PATH}/lib/*.jar;
    do
        CLASSPATH=${CLASSPATH}:$f
    done
    JAVA_EXE=java
    JAVA_OPTS="$JAVA_OPTS -Xms2G -Xmx4G"
    ${JAVA_EXE} ${JAVA_OPTS} -classpath ${CLASSPATH}
    com.huawei.graphbase.example.GraphBaseRestExample
}
Startup
```

In the preceding content, "com.huawei.graphbase.example.GraphBaseRestExample" is used as an example.

**Step 4** Go to **/opt/test** and run the following commands to run the JAR packages:

**./graphbase.sh**

----End

### 2.5.4.2.2 Viewing Linux Commissioning Results

#### Scenario

After an GraphBase application is run, you can check the running result through one of the following methods:

- Viewing the command output.
- Viewing GraphBase logs.

#### Procedure

The following information is displayed in the running results:

```
REQ HEADER: POST https://10.4.64.110:22380/graphbase/graph HTTP/1.1
REQ BODY: {"graphName":"graphbase"}
RSP BODY: {
    "msg": "create graph success.",
    "code": "0"
}
[SUCCESS]: create graph[graphbase] successfully.
REQ HEADER: POST https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1
REQ BODY: {"name":"person"}
RSP BODY: {
    "msg": "Success.",
```

```
"code": "0",
"data": {
    "name": "person",
    "isPartitioned": "false"
}
}
[SUCCESS]: create vertex label[person] successfully.
REQ HEADER: POST https://10.154.4.90:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1
REQ BODY: {"name":"phone"}
RSP BODY: {
    "msg": "Success.",
    "code": "0",
    "data": {
        "name": "phone",
        "isPartitioned": "false"
    }
}
[SUCCESS]: create vertex label[phone] successfully.
REQ HEADER: GET https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label/person
HTTP/1.1
RSP BODY: {
    "msg": "Success.",
    "code": "0",
    "data": {
        "name": "person",
        "isPartitioned": false
    }
}
[SUCCESS]: query vertex label[person] successfully.
REQ HEADER: GET https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1
RSP BODY: {
    "msg": "Success.",
    "code": "0",
    "data": {"vertexLabelList": [
        {
            "name": "person",
            "isPartitioned": false
        },
        {
            "name": "phone",
            "isPartitioned": false
        }
    ]}
}
[SUCCESS]: query all vertex label successfully.
```

## 2.5.5 More Information

### 2.5.5.1 Common APIs

#### 2.5.5.1.1 REST API

For details about the complete and detailed description of GraphBase REST APIs, see *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

#### 2.5.5.1.2 Gremlin API

For details about the GraphBase Gremlin API, see [Gremlin Console](#), [Gremlin Java](#) and [Gremlin Application Scenarios](#).

## 2.6 HBase Development Guide

### 2.6.1 Overview

#### 2.6.1.1 Application Development Overview

##### HBase Introduction

HBase is a column-oriented scalable distributed storage system featuring high reliability and high performance. HBase is designed to break through the limitation when relational databases are used to process massive data.

HBase applies to the following application scenarios:

- Massive data processing (higher than the TB or PB level).
- Scenarios that require high throughput.
- Scenarios that require efficient random read of massive data.
- Scenarios that require good scalability.
- Structured and unstructured data is concurrently processed.
- The Atomicity, Consistency, Isolation, Durability (ACID) feature supported by traditional relational databases is not required.
- HBase tables provide the following features:
  - Large: One table contains a hundred million rows and one million columns.
  - Column-oriented: Storage and rights control is implemented based on columns (families), and columns (families) are independently retrieved.
  - Sparse: Null columns do not occupy storage space, so a table is sparse.

##### Interface Type Introduction

The Java language is recommended for HBase application development because HBase is developed based on Java and Java is a concise, universal, and easy-to-understand language.

HBase adopts the same interfaces as those of Apache HBase. For details, see *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

**Table 2-60** describes the functions that HBase can provide by invoking interfaces.

**Table 2-60** Functions provided by HBase interfaces

| Function           | Description                                       |
|--------------------|---|
| Data CRUD function | Data creating, retrieving, updating, and deleting |

| Function            | Description                              |
|---------------------|--|
| Advanced feature    | Filter, secondary index, and coprocessor |
| Management function | Table management and cluster management  |

### 2.6.1.2 Common Concepts

- **Filter**

Filters provide powerful features to help users improve the table data processing efficiency of HBase. Users can use the filters predefined in HBase and customized filters.

- **Coprocessor**

Coprocessors enable users to perform region-level operations and provide functions similar to those of triggers in relational database management systems (RDBMSs).

- **Client**

Users can access the server from the client through the Java API, HBase Shell or WebUI to read and write HBase tables. The HBase client in this document indicates the HBase client installation package, see [External Interfaces](#).

### 2.6.1.3 Development Process

This document describes HBase application development based on the Java API.

For information about each phase in the development process, see [Figure 2-109](#) and [Table 2-61](#).

Figure 2-109 HBase application development process

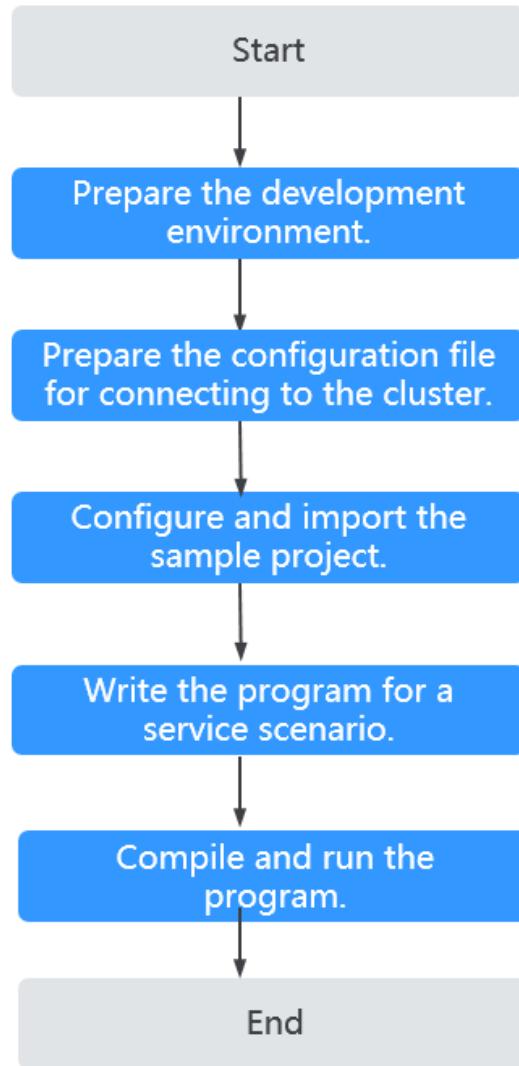

Table 2-61 HBase application development process description

| Phase                                | Description   | Reference Document  |
|--------------------------------------|---|---|
| Prepare the development environment. | Before developing an application, you need to prepare the development environment. You are advised to use the Java language and IntelliJ IDEA tool for development. In addition, you need to complete the initial configuration of the JDK and Maven. | <a href="#">Preparing for Development and Operating Environment</a> |

| Phase   | Description   | Reference Document  |
|---|---|---|
| Prepare the Configuration File for Connecting to the Cluster. | During application development or running, you need to connect to the MRS cluster through cluster configuration files. Configuration files include cluster component information files. You can obtain related content from the created MRS cluster.<br><br>Nodes used for program commissioning or running must be able to communicate with nodes in the MRS cluster and the hosts domain name must be configured. | <a href="#">Preparing the Connection Cluster Configuration File</a> |
| Configure and import the sample project.                      | HBase provides multiple sample programs in different scenarios. You can obtain sample projects and import them to the local development environment for program learning.   | <a href="#">Configuring and Importing Sample Projects</a>           |
| Develop programs based on business scenarios.                 | Develop programs based on actual service scenarios and invoke component interfaces to implement corresponding functions.  | <a href="#">Developing an Application</a>                           |
| Compile and run the application.                              | You can commission and run the program in the local Windows development environment, or compile the program into a JAR package and submit it to the Linux node for running.   | <a href="#">Application Commissioning</a>                           |

#### 2.6.1.4 HBase Sample Project Introduction

To obtain the MRS sample project, visit <https://github.com/huaweicloud/huaweicloud-mrs-example>. Switch to the version branch that matches the MRS

cluster, download the package to the local PC, and decompress the package to obtain the sample code project of each component.

Currently, MRS provides the following HBase-related sample projects. You can select an example based on the actual service scenario:

**Table 2-62** HBase-related sample projects

| Sample Project Location             | Function Description  |
|-------------------------------------|---|
| hbase-examples/hbase-example        | <p>Application development example of HBase data read/write operations and global secondary indexes. The following functions can be implemented by calling HBase APIs:</p> <ul style="list-style-type: none"><li>• You can call HBase APIs to create user tables, import user data, add user information, query user information, and create secondary indexes for user tables. For details, see <a href="#">Service Scenario Description</a>.</li><li>• Creates and deletes global secondary indexes, modifies the status of global secondary indexes, and queries data based on global secondary indexes. For details about related service scenarios, see <a href="#">Service Scenario Description</a>.</li><li>• When multiple threads concurrently read data from or write data into an HBase table, region information can be preloaded. For details about related service scenarios, see <a href="#">Sample Program for Preloading Meta Tables When Request Concurrency Is High</a>.</li></ul> |
| hbase-examples/hbase-rest-example   | <p>HBase REST API development sample. Using REST APIs to query clusters, obtain tables, operate Namespaces, and operate tables. For details, see <a href="#">HBase Rest API Invoking Sample Program</a>.</p>  |
| hbase-examples/hbase-thrift-example | <p>Access the HBase ThriftServer development sample. Accessing ThriftServer to operate tables, writing data to tables, and reading data from tables. For details, see <a href="#">Accessing the HBase ThriftServer Sample Program</a>.</p>  |

| Sample Project Location         | Function Description   |
|---------------------------------|--|
| hbase-examples/hbase-zk-example | Application development example for HBase to access ZooKeeper.<br>The same client process accesses both the FusionInsight ZooKeeper and third-party ZooKeeper. The HBase client accesses the FusionInsight ZooKeeper, and the customer application accesses the third-party ZooKeeper. For details, see <a href="#">Sample Program for HBase to Access Multiple ZooKeepers</a> . |
| springboot/hbase-examples       | Provide an example of connecting Phoenix to SpringBoot.<br>This example describes how to interconnect HBase with Phoenix with Spring Boot. For details, see <a href="#">Example Configuration for Interconnecting HBase/Phoenix with SpringBoot</a> .  |

## 2.6.2 Environment Preparation

### 2.6.2.1 Preparing for Development and Operating Environment

[Table 2-63](#) describes the environment required for secondary development.

**Table 2-63** Development environment

| Item | Description   |
|------|---|
| OS   | <ul style="list-style-type: none"><li>• Development environment: Windows OS. Windows 7 or later is supported.</li><li>• Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul> |

| Item   | Description   |
|--|---|
| Installing JDK                               | <p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul> |
| IntelliJ IDEA installation and configuration | <p>Tool used for developing HBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>  |
| JUnit plug-in installation                   | Basic configuration for the development environment   |

| Item                  | Description  |
|-----------------------|--|
| Installation of Maven | Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development.<br><br>Huawei provides an open-source mirror site, Huawei Mirrors. You can download the supportive JAR packages of the sample projects from this site. You can download the rest open-source JAR packages from the Maven central repository or other user-defined repositories. For details, see <a href="#">Configuring Huawei Open-Source Mirrors</a> . |
| 7-zip                 | Used to decompress .zip and .rar packages.<br>7-Zip 16.04 is supported.  |

## 2.6.2.2 Preparing the Connection Cluster Configuration File

### Preparing an Operating Environment

During application development or running, you need to connect to the MRS cluster through cluster configuration files. Configuration files include cluster component information files. You can obtain related content from the created MRS cluster.

Nodes used for program commissioning or running must be able to communicate with nodes in the MRS cluster and the hosts domain name must be configured.

- Scenario 1: Prepare the configuration files required by the commissioning program in the local Windows development environment.
  - a. Log in to the FusionInsight Manager, click **Download Client** in the upper right corner of the Homepage, set **Select Client Type** to **Configuration Files Only** and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client configuration file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles** directory on the local PC.
  - b. Go to the client configuration file decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles\HBase\config**, obtain related configuration files from the [Table 2-64](#).

**Table 2-64** Configuration files

| file           | Function                           |
|----------------|------------------------------------|
| core-site.xml  | Configures Hadoop Core parameters. |
| hbase-site.xml | Configures HBase parameters.       |
| hdfs-site.xml  | Configures HDFS parameters.        |

 NOTE

To obtain the configuration file required by the HBase ThriftServer sample project, see [Preparing the ThriftServer Instance Configuration File](#).

- c. Copy the content in the **hosts** file in the decompression directory to the local **hosts** file.

 NOTE

- During application development, if you need to commission applications in the local Windows system, ensure that the local node can communicate with the hosts listed in the hosts file.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.
- When configuring IPv6 hosts on the local PC running Windows, add % and InterfaceIndex of the network interface card (NIC) to the end of the IPv6 address. The InterfaceIndex can be obtained by running the **ipconfig** command.

Example:

fec1:0:0:e505:8:99:5:1%10

- Scenario 2: Prepare the configuration file required for running programs in the Linux environment.
  - a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.
  - b. To obtain the configuration file.
    - i. Log in to the FusionInsight Manager, click **Download Client** in the upper right corner of the Homepage, set **Select Client Type** to **Configuration Files Only** and click **OK**. Download the client configuration file to the active OMS node in the cluster.
    - ii. Log in to the active OMS node as user **root**, go to the directory where the client configuration file is stored (the default directory is **/tmp/FusionInsight-Client/**), and decompress the software package to obtain the configuration files in the **Table 2-64** in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/HBase/config** directory.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, the download path is **/tmp/FusionInsight-Client** on the active management node.

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar
```

```
tar -xvf  
FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles
```

 NOTE

HBase ThriftServer sample project, see [Preparing the ThriftServer Instance Configuration File](#).

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

## Preparing the ThriftServer Instance Configuration File

To access HBase ThriftServer and perform table-related operations, perform the following steps:

- Step 1** Log in to FusionInsight Manager, choose **Cluster > Service > HBase > Configuration** and click **All Configurations**, search for and modify the parameter **hbase.thrift.security.qop** of the ThriftServer instance. The value of this parameter must be the same as that of **hbase.rpc.protection**. Save the configuration and restart the node service for the configuration to take effect.

 NOTE

The mapping between **hbase.rpc.protection** and **hbase.thrift.security.qop** is as follows:

- "privacy" - "auth-conf"
- "authentication" - "auth"
- "integrity" - "auth-int"

- Step 2** Obtain the configuration file of the ThriftServer instance in the cluster.

- Method 1: Choose **Cluster > Service > HBase > Instance**, click the ThriftServer instance to go to the details page. In the **Configuration File** area of the **Dashboard** page, click the names of the configuration files **hdfs-site.xml**, **core-site.xml**, and **hbase-site.xml** to obtain the configuration files.
- Method 2: Obtain the configuration files by decompressing the client file in [Preparing an Operating Environment](#). Manually add the following configuration to **hbase-site.xml**. The value of **hbase.thrift.security.qop** must be the same as that in [Step 1](#).

```
<property>  
<name>hbase.thrift.security.qop</name>  
<value>auth</value>  
</property>  
<property>  
<name>hbase.thrift.kerberos.principal</name>  
<value>thrift/hadoop.hadoop.com@HADOOP.COM</value>  
</property>  
<property>  
<name>hbase.thrift.keytab.file</name><value>/opt/huawei/Bigdata/FusionInsight_HD_XXX/install/  
FusionInsight-HBase-2.4.14/keytabs/HBase/thrift.keytab</value>  
</property>
```

----End

### 2.6.2.3 Configuring and Importing Sample Projects

#### Background

Obtain the HBase development example project . Import the project to IntelliJ IDEA for learning.

#### Prerequisites

Ensure that the difference between the local PC time and the MRS cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the MRS cluster time in the bottom-right corner on FusionInsight Manager.

- Ensure that the difference between the local PC time and the MRS cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the MRS cluster time in the bottom-right corner on FusionInsight Manager.
- The development environment and MRS cluster configuration files have been prepared. For details, see [Preparing the Connection Cluster Configuration File](#).

#### Procedure

- Step 1** Obtain the sample project from the `src` directory in the directory where the sample code is decompressed by referring to [Obtaining Sample Projects from Huawei Mirrors](#). You can select an example based on the actual service scenario. For details about the example, see [HBase Sample Project Introduction](#).
- Step 2** If you need to debug the sample code on the local Windows PC, place the configuration files required by each sample project as required in [Table 2-65](#).

**Table 2-65** Configuration files required by each sample project

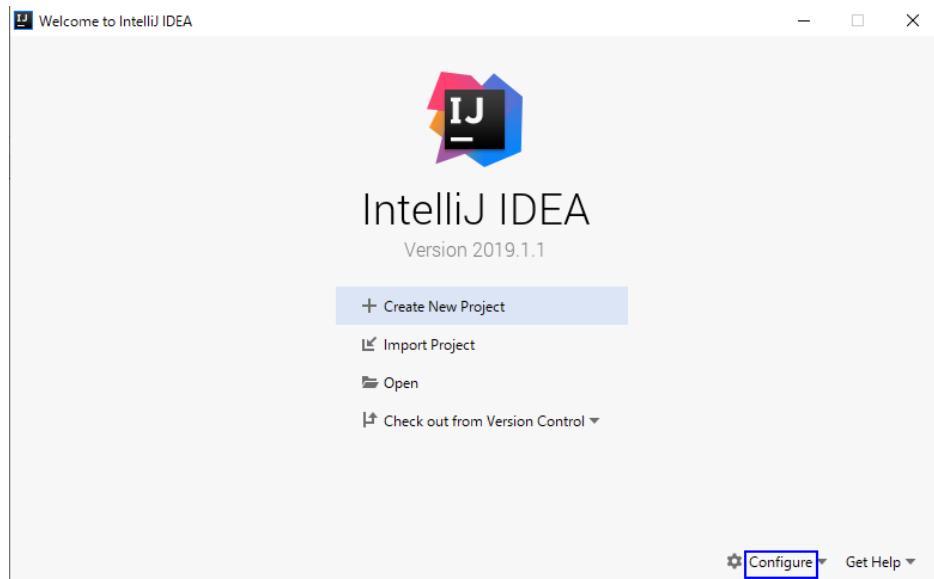

Sample Project Location	Configuration/authentication files to be placed
hbase-examples/hbase-example (single cluster)	Save the <code>core-site.xml</code> , <code>hbase-site.xml</code> , and <code>hdfs-site.xml</code> files obtained in the <a href="#">Preparing an Operating Environment</a> to the <code>../src/main/resources/conf</code> directory of the sample project.

Sample Project Location	Configuration/authentication files to be placed
hbase-examples/hbase-example (multi-cluster)	<p>Place the configuration file of a cluster with the same user name in the mutual trust scenario to the <code>..src/main/resources/hadoopDomain</code> directory, and place the configuration file of the other cluster to the <code>..src/main/resources/hadoop1Domain</code> directory.</p> <p>The configuration files are <code>core-site.xml</code>, <code>hbase-site.xml</code>, and <code>hdfs-site.xml</code> obtained in section <a href="#">Preparing an Operating Environment</a>.</p>
hbase-examples/hbase-rest-example	-
hbase-examples/hbase-thrift-example	<p>Save the <code>core-site.xml</code>, <code>hbase-site.xml</code>, and <code>hdfs-site.xml</code> files obtained in the <a href="#">Preparing the ThriftServer Instance Configuration File</a> to the <code>..src/main/resources/conf</code> directory of the sample project.</p>
hbase-examples/hbase-zk-example	<p>Place the following files in the <code>..src/main/resources/conf</code> directory of the sample project:</p> <ul style="list-style-type: none"> <li>The configuration files are <code>core-site.xml</code>, <code>hbase-site.xml</code>, and <code>hdfs-site.xml</code> obtained in <a href="#">Preparing an Operating Environment</a>.</li> <li>Ensure that the <code>zoo.cfg</code> and <code>jaas.conf</code> files required for authentication in the <a href="#">Accessing Multiple ZooKeepers</a> exist in the directory.</li> </ul>
springboot/hbase-examples	<p>Save the <code>core-site.xml</code>, <code>hbase-site.xml</code>, and <code>hdfs-site.xml</code> files obtained in <a href="#">Preparing an Operating Environment</a> to the local Windows operating system.</p>

**Step 3** After the IntelliJ IDEA and JDK are installed, configure the JDK in IntelliJ IDEA.

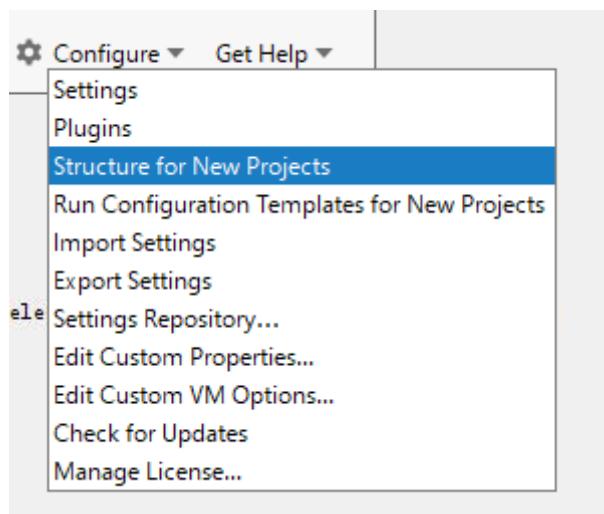

1. Start the IntelliJ IDEA and click **Configure**.

Figure 2-110 Quick Start

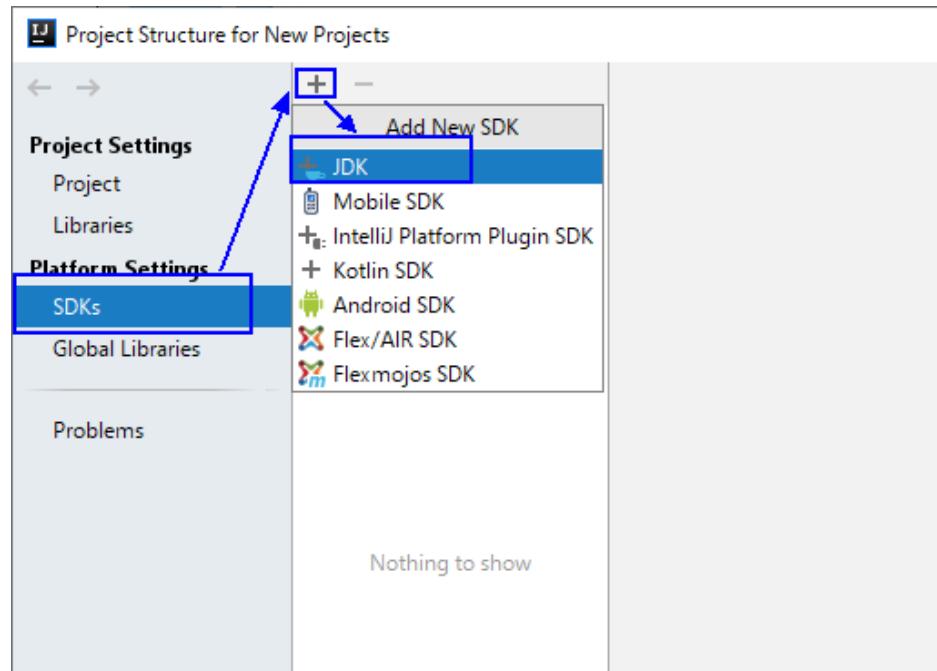

2. Click **Structure for New Projects** from the drop-down list.

Figure 2-111 Configure

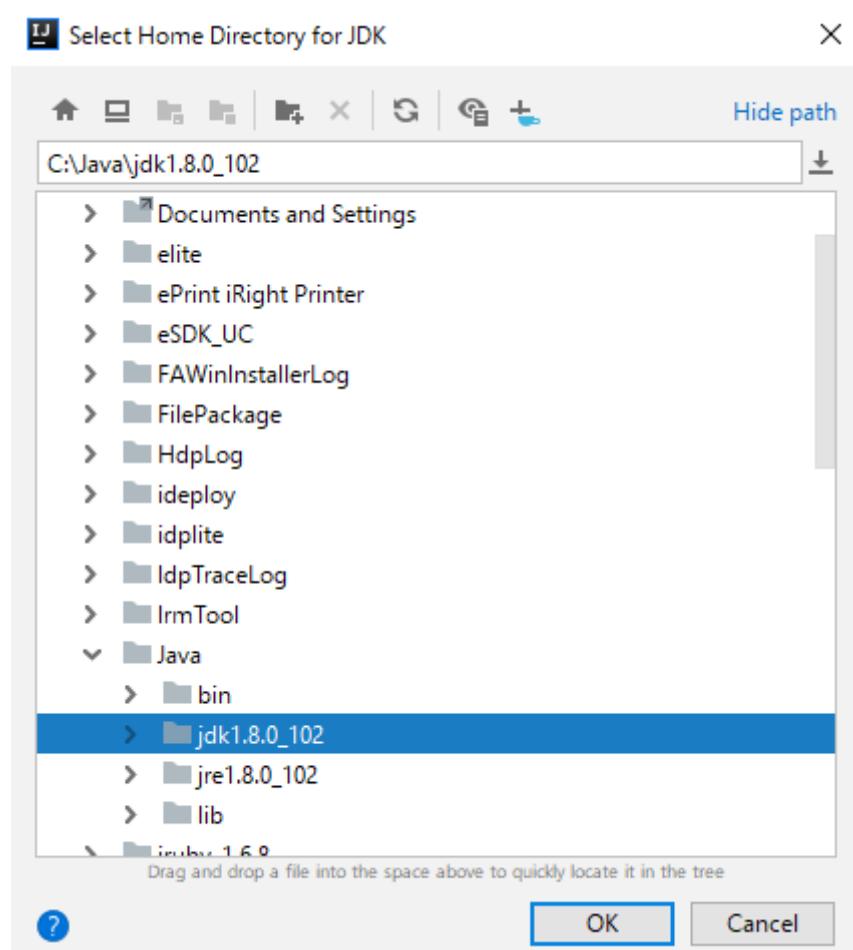

3. On the displayed **Project Structure for New Projects** page, select **SDKs** and click the plus sign (+) to add the **JDK**.

Figure 2-112 Project Structure for New Projects

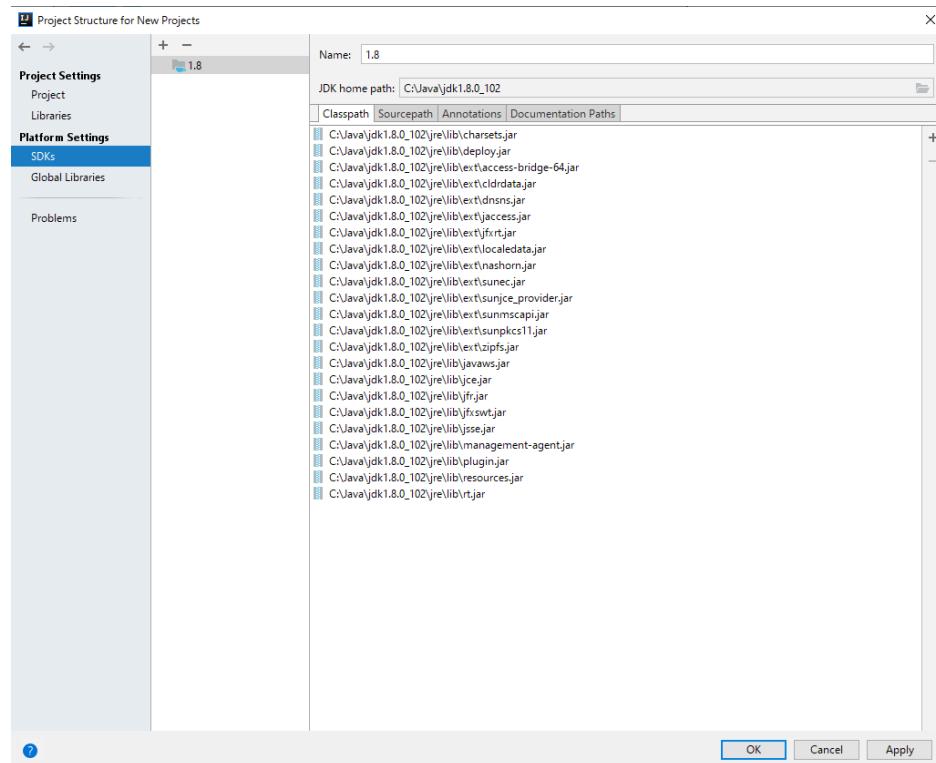

4. In the **Select Home Directory for JDK** window that is displayed, select the JDK directory, and click **OK**.

Figure 2-113 Select Home Directory for JDK

5. After selecting the JDK, click **OK** to complete the configuration.

Figure 2-114 Complete JDK configuration

**NOTE**

The operations vary by the IDEA version. The operation procedure varies according to the actual version.

**Step 4** Import the example project to the IntelliJ IDEA development environment.

1. Start the IntelliJ IDEA, and click **Import Project** on the Open or Import.

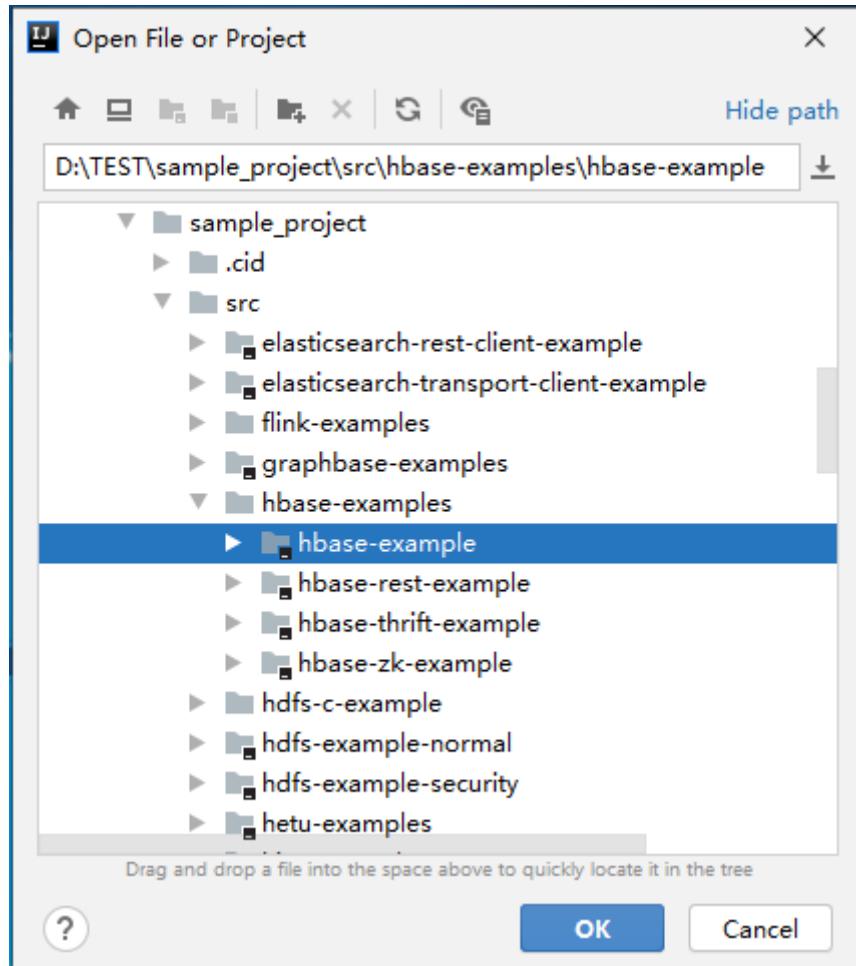

For the IDEA tool that has been used, you can choose **File > Import project...** on the main interface to import the sample project.

Figure 2-115 Open or Import (Quick Start page)

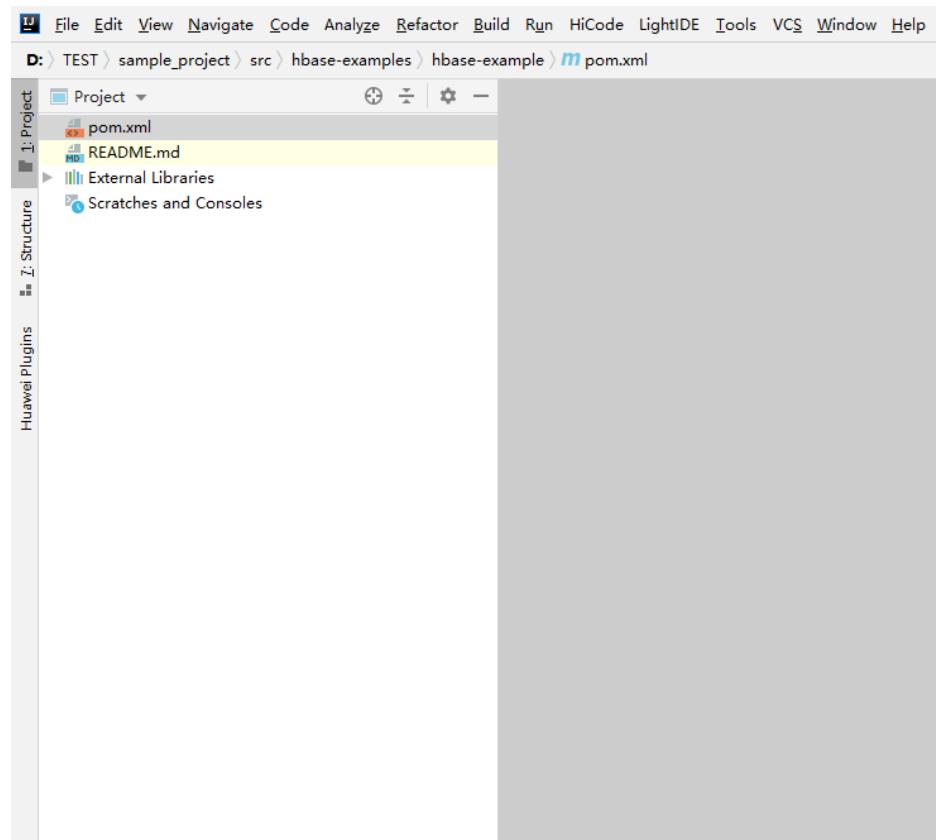

2. Select the example project folder **hbase-example**, and click **OK**.

**Figure 2-116** Select File or Directory to Import

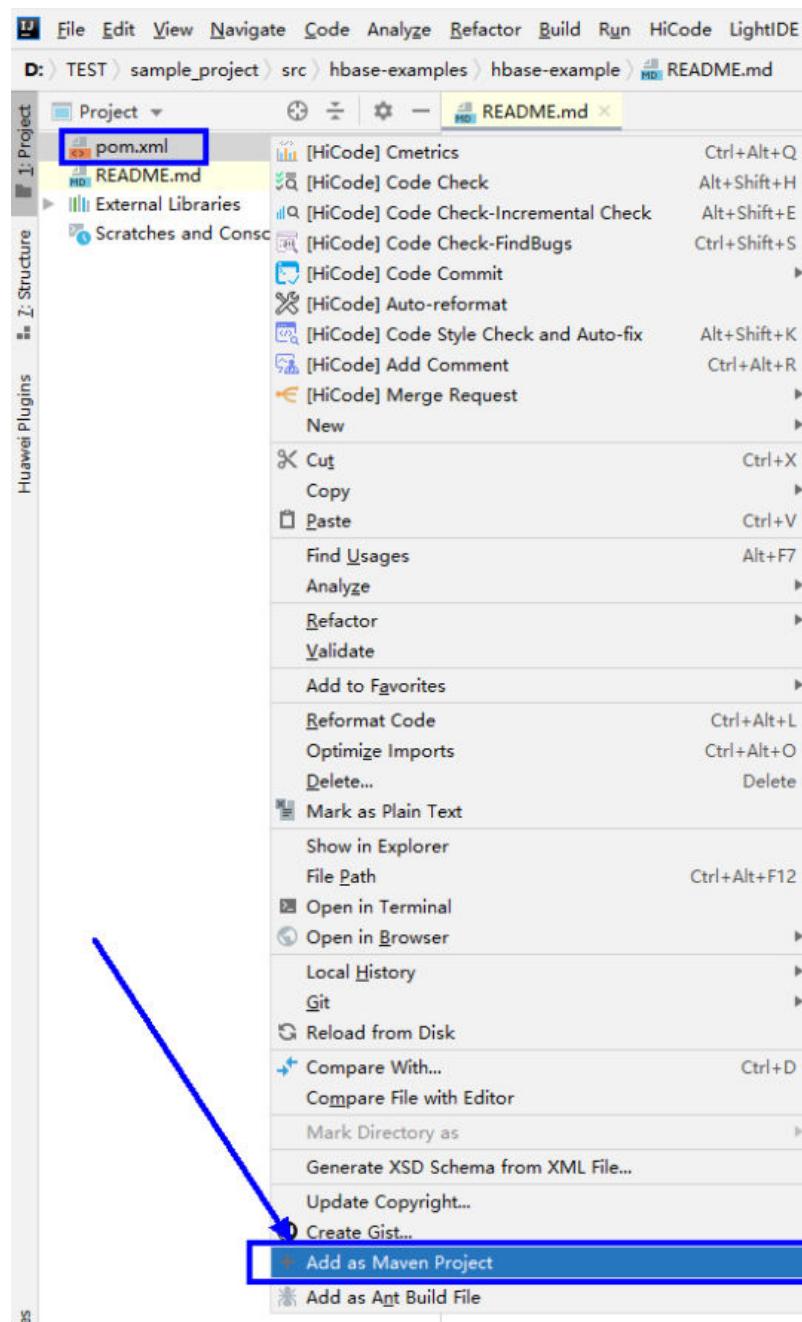

3. After the import, the imported sample project is displayed on the IDEA home page.

Figure 2-117 Successfully importing the sample project

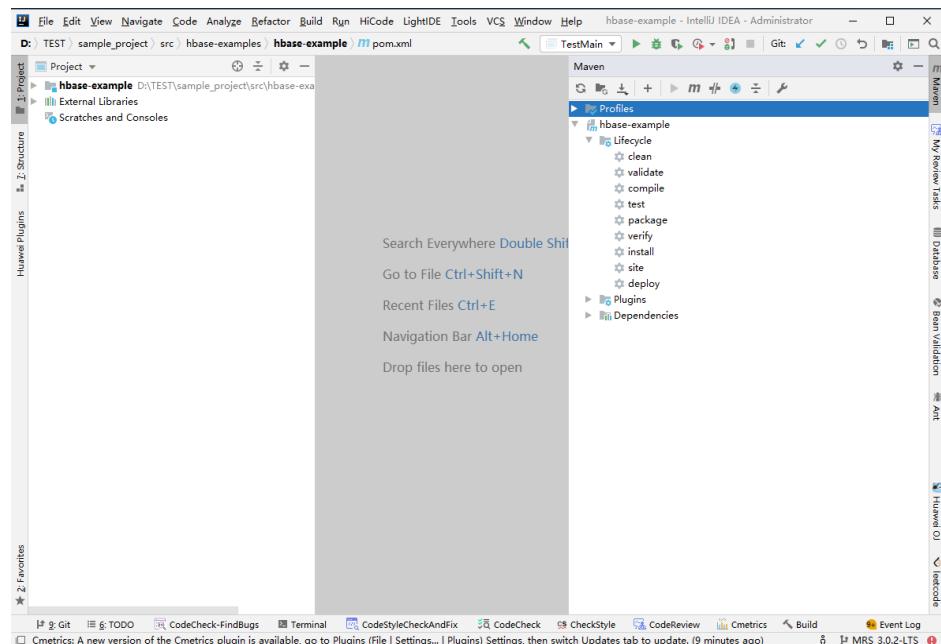

4. Right-click **pom.xml** and choose **Add as Maven Project** from the shortcut menu to add the project as a Maven Project. If the **pom.xml** icon is as shown in , go to the next step.

Figure 2-118 Add as Maven Project

In this case, the IDEA can identify the project as a Maven project.

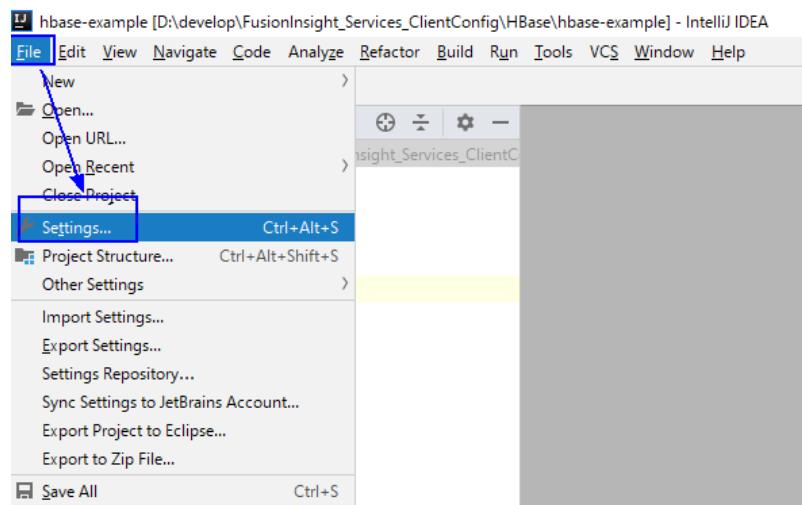

Figure 2-119 Sample project displayed in IDEA as a Maven project

### Step 5 Set the Maven version used by the project.

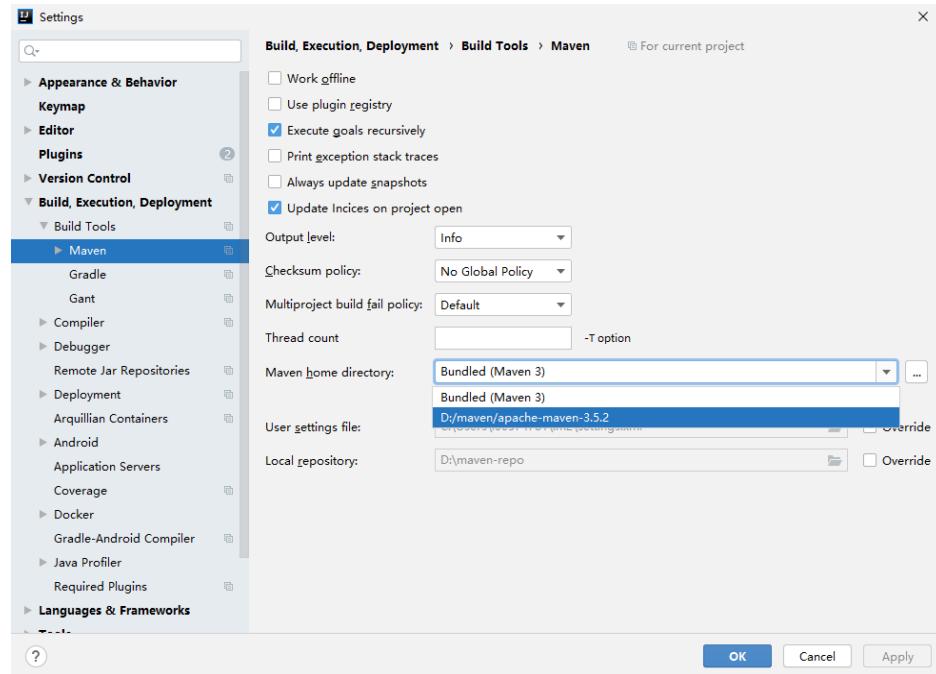

1. Choose **File > Settings...** from the main menu of IntelliJ IDEA.

Figure 2-120 Settings

2. Choose **Build,Execution,Deployment > Maven** and set **Maven home directory** to the Maven version installed on the local host.  
Set **User settings file** and **Local repository** parameters based on the site requirements, and choose **Apply > OK**.

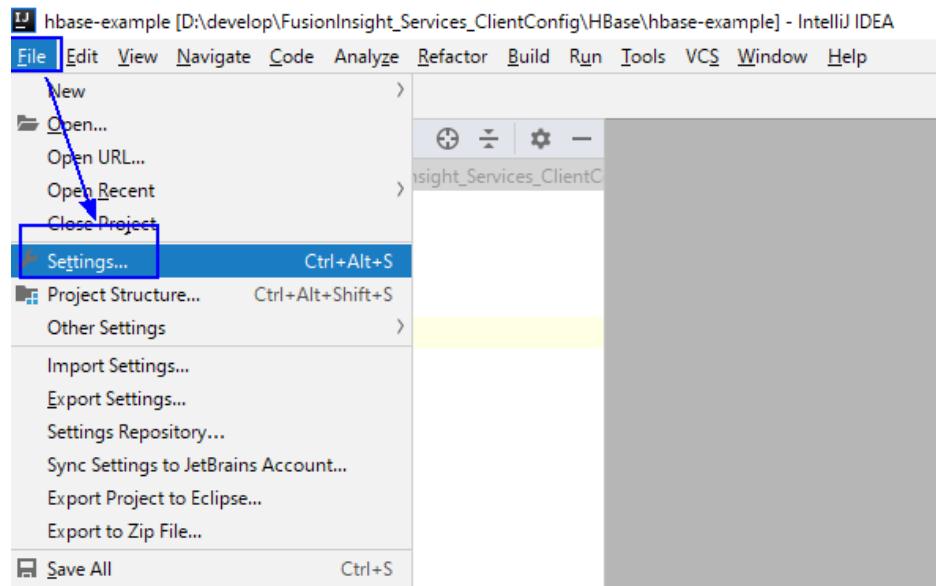

Figure 2-121 Selecting the local Maven installation directory

**Step 6** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

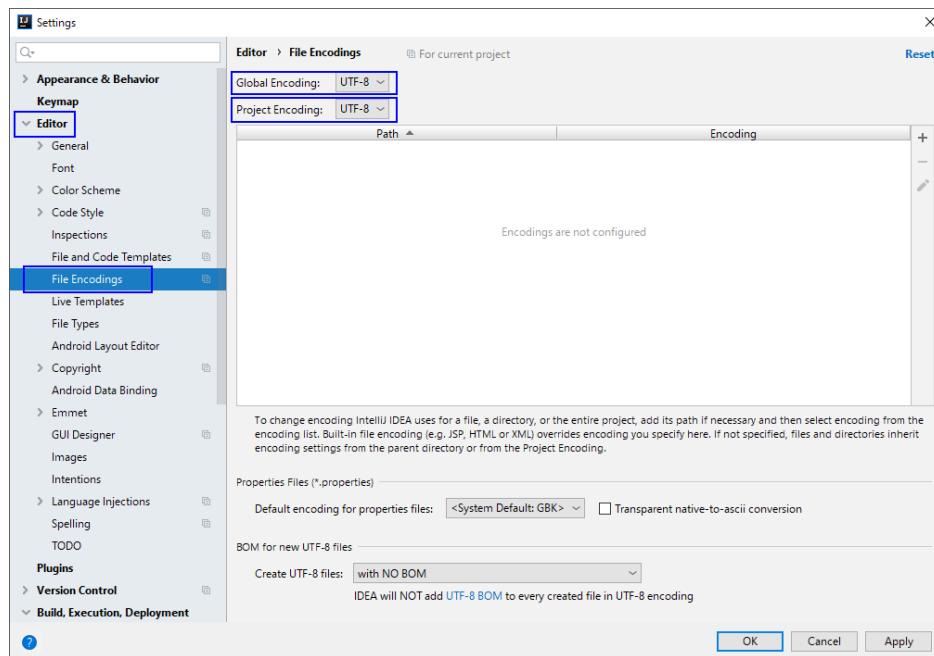

1. On the IntelliJ IDEA menu bar, choose **File > Settings....**

Figure 2-122 Settings

2. In the navigation tree of the **Settings** page, choose **Editor > File Encodings**, and select **UTF-8** for **Global Encoding** and **Project Encoding**.

Figure 2-123 File Encodings

- Click **Apply** and **OK** to complete the encoding configuration.

----End

## 2.6.3 Developing an Application

### 2.6.3.1 HBase Data Read/Write Sample Program

#### 2.6.3.1.1 Service Scenario Description

Based on typical scenarios, users can quickly learn and master the HBase development process and know important interface functions.

#### Scenario

Develop an application to manage information about users who use service A in an enterprise. **Table 2-66** provides the user information. The operation process of service A is described as follows:

- Create a user information table.
- Add diplomas and titles to the user information table.
- Query user names and addresses by user ID.
- Query information by user name.
- Query information about users whose ages range from 20 to 29.
- Collect statistics on the number and the maximum, minimum, and average ages of users.
- Deregister users, and delete user data.
- Delete the user information table after service A ends.

**Table 2-66** User information

ID	Name	Gender	Age	Address
12005000201	Zhang San	Male	19	Shenzhen, Guangdong
12005000202	Li Wanting	Female	23	Shijiazhuang, Hebei
12005000203	Wang Ming	Male	26	Ningbo, Zhejiang
12005000204	Li Gang	Male	18	Xiangyang, Hubei
12005000205	Zhao Enru	Female	21	Shangrao, Jiangxi
12005000206	Chen Long	Male	32	Zhuzhou, Hunan
12005000207	Zhou Wei	Female	29	Nanyang, Henan
12005000208	Yang Yiwen	Female	30	Kaixian, Chongqing
12005000209	Xu Bing	Male	26	Weinan, Shaanxi
12005000210	Xiao Kai	Male	25	Dalian, Liaoning

## Data Planning

Proper design of the table structure, RowKeys, and column names can give full play to the advantages of HBase. In this example, the unique ID is used as the RowKey, and columns are stored in the **info** column family.

---

**⚠ CAUTION**

HBase tables are stored in *Namespace:Table name* format. If no namespace is specified when a table is created, the table is stored in **default**. The **hbase** namespace is the system table namespace. Do not create service tables or read or write data in the system table namespace.

---

### 2.6.3.1.2 Application Development Approach

#### Function Decomposition

Functions are decomposed based on the preceding service scenario. **Table 2-67** provides the functions to be developed.

**Table 2-67** Functions to be developed in HBase

No.	Procedure	Code Implementation
1	Create a table based on <a href="#">Table 2-66</a> .	For details, see <a href="#">Creating a Table</a> .
2	Import user data.	For details, see <a href="#">Inserting Data</a> .
3	Add the <b>Education</b> column family, and add diplomas and titles to the user information table.	For details, see <a href="#">Modifying a Table</a> .
4	Query user names and addresses by user ID.	For details, see <a href="#">Reading Data Using Get</a> .
5	Query information by user name.	For details, see <a href="#">Filtering Data</a> .
6	To improve query performance, create or delete secondary indexes.	For details, see <a href="#">Creating a Secondary Index</a> and <a href="#">Secondary Index-based Query</a> .
7	Deregister users, and delete user data.	For details, see <a href="#">Deleting Data</a> .
8	Delete the user information table after service A ends.	For details, see <a href="#">Deleting a Table</a> .

## Key Design Principle

HBase is a distributed database system based on the lexicographic order of RowKeys. The RowKey design has great impact on performance, so the RowKeys must be designed based on specific services.

### 2.6.3.1.3 Configuring Log4j Log Output

#### Function Description

This section describes how to output HBase client logs to a specified log file separately from service logs to facilitate HBase problem analyzing and locating. If the **log4j** configuration exists in the process, copy the RFA and RFAS configurations in **hbase-example\src\main\resources\log4j.properties** to the existing **log4j** configuration.

#### Sample Code

```
hbase.root.logger=INFO,console,RFA      //HBase client log output configuration. console: outputs to  
the console; RFA: outputs to the log files.  
hbase.security.logger=DEBUG,console,RFAS    //HBase client security logs output configuration. console:  
outputs to the console; RFAS: outputs the log files.  
hbase.log.dir=/var/log/Bigdata/hbase/client/ //Log directory. Modify based on the actual directory. Ensure  
that the directory has the write permission.  
hbase.log.file=hbase-client.log          //Log file name
```

```
hbase.log.level=INFO          //Log level. If detailed logs are required for fault locating, change it  
to DEBUG. The modification takes effect after restart.  
hbase.log.maxbackupindex=20    //Maximum number of log files that can be saved.  
# Security audit appender  
hbase.security.log.file=hbase-client-audit.log //Command of the audit log file
```

### 2.6.3.1.4 Creating Configuration

#### Function

HBase obtain configuration items by using the login method. The configuration items include user login information and security authentication information.

#### Example Codes

The following code snippet belongs to the **createClientConf** method in the **createClientConf** class of the **com.huawei.bigdata.hadoop.security.examples** package.

```
public static Configuration createClientConf() {  
    // In Windows environment  
    String userDir = Utils.class.getClassLoader().getResource(CONF_DIRECTORY).getPath() + File.separator;  
    // In Linux environment  
    // String userDir = System.getProperty("user.dir") + File.separator + CONF_DIRECTORY + File.separator;  
    return createConfByUserDir(userDir);  
}  
public static Configuration createConfByUserDir(String userDir) {  
    // Default load from conf directory  
    Configuration conf = HBaseConfiguration.create();  
    if (userDir == null || userDir.isEmpty()) {  
        return conf;  
    }  
    conf.addResource(new Path(userDir + CLIENT_CORE_FILE), false);  
    conf.addResource(new Path(userDir + CLIENT_HDFS_FILE), false);  
    conf.addResource(new Path(userDir + CLIENT_HBASE_FILE), false);  
    return conf;  
}
```

### 2.6.3.1.5 Creating Connection

#### Function

HBase creates a Connection object using the **ConnectionFactory.createConnection(configuration)** method. The transferred parameter is the Configuration created in the last step.

Connection encapsulates the connections between underlying applications and servers and ZooKeeper. Connection is instantiated using the **ConnectionFactory** class. Creating Connection is a heavyweight operation. Connection is thread-safe. Therefore, multiple client threads can share one Connection.

In a typical scenario, a client program uses a Connection, and each thread obtains its own Admin or Table instance and invokes the operation interface provided by the Admin or Table object. You are not advised to cache or pool Table and Admin. The lifecycle of Connection is maintained by invokers that frees up resources by invoking **close()**.

## Example Code

The following code snippet exemplifies login, creating Connection, and creating a table. It belongs to the **HBaseSample** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
private TableName tableName = null;  
private Connection conn = null;  
  
public HBaseSample(Configuration conf) throws IOException {  
    this.tableName = TableName.valueOf("hbase_sample_table");  
    this.conn = ConnectionFactory.createConnection(conf);  
}
```

Avoid invoking login code repeatedly.

### 2.6.3.1.6 Creating a Table

## Function

Create a table using the **createTable** method of the **org.apache.hadoop.hbase.client.Admin** object and specify the table name and column family name. Tables can be created in two modes. (The mode of creating a table using preassigned regions is strongly recommended.)

- Quickly create a table. A newly created table contains only one region which will be split into multiple new regions as data increases.
- Create a table using preassigned regions. Preassign multiple regions before creating a table. This mode accelerates data write at the beginning of massive data write.

The column name and column family name of an HBase table consists of letters, digits, and underscores and cannot contain any special characters.

## Example Code

The following code snippet belongs to the **testCreateTable** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testCreateTable() {  
    LOG.info("Entering testCreateTable.");  
    // Specify the table descriptor.  
    TableDescriptorBuilder htd = TableDescriptorBuilder.newBuilder(tableName);(1)  
  
    // Set the column family name to info.  
    ColumnFamilyDescriptorBuilder hcd =  
    ColumnFamilyDescriptorBuilder.newBuilder(Bytes.toBytes("info"));(2)  
  
    // Set data encoding methods, HBase provides DIFF,FAST_DIFF,PREFIX  
  
    hcd.setDataBlockEncoding(DataBlockEncoding.FAST_DIFF);  
    // Set compression methods, HBase provides two default compression  
    // methods:GZ and SNAPPY  
    // GZ has the highest compression rate, but low compression and  
    // decompression efficiency, fit for cold data  
    // SNAPPY has low compression rate, but high compression and  
    // decompression efficiency, fit for hot data.
```

```
// it is advised to use SNAANPPY
hcd.setCompressionType(Compression.Algorithm.SNAPPY); //Note [1]
htd.setColumnFamily(hcd.build()); (3)
Admin admin = null;
try {
    // Instantiate an Admin object.
    admin = conn.getAdmin(); (4)
    if (!admin.tableExists(tableName)) {
        LOG.info("Creating table...");
        admin.createTable(htd.build()); //Note [2] (5)
        LOG.info(admin.getClusterMetrics().toString());
        LOG.info(admin.listNamespaceDescriptors().toString());
        LOG.info("Table created successfully.");
    } else {
        LOG.warn("table already exists");
    }
} catch (IOException e) {
    LOG.error("Create table failed ", e);
} finally {
    if (admin != null) {
        try {
            // Close the Admin object.
            admin.close();
        } catch (IOException e) {
            LOG.error("Failed to close admin ", e);
        }
    }
}
LOG.info("Exiting testCreateTable.");
}
```

## Explanation

1. Create a table descriptor.
2. Create a column family descriptor.
3. Add the column family descriptor to the table descriptor.
4. Obtain an Admin object. The Admin object provides functions for creating a table, creating a column family, checking whether a table exists, modifying the table structure, modifying the column family structure, and deleting a table.
5. Invoke the table creation method of Admin.

## Precautions

- 1. The compression mode of a column family can be set. The code snippets are as follows:

```
// Set the encoding algorithm. HBase supports the DIFF, FAST_DIFF, PREFIX encoding algorithms.
hcd.setDataBlockEncoding(DataBlockEncoding.FAST_DIFF);

// Set the file compression mode. HBase provides the GZ and SNAPPY compression algorithms by
default.
// GZ provides a high compression rate but low compression and decompression performance. GZ is
suitable for cold data.
// SNAPPY provides a low compression rate but high compression and decompression performance.
SNAPPY is suitable for hot data.
// It is recommended that SNAPPY be enabled by default.
hcd.setCompressionType(Compression.Algorithm.SNAPPY);
```

- 2. A table can be created by specifying the start and end RowKeys or preassigning regions using RowKey arrays. The code snippets are as follows:

```
// Create a table whose regions are preassigned.
byte[][] splits = new byte[4][];
splits[0] = Bytes.toBytes("A");
```

```
splits[1] = Bytes.toBytes("H");
splits[2] = Bytes.toBytes("O");
splits[3] = Bytes.toBytes("U");
admin.createTable(htd, splits);
```

### 2.6.3.1.7 Deleting a Table

#### Function

Delete a table using the **deleteTable** method of **org.apache.hadoop.hbase.client.Admin**.

#### Example Code

The following code snippet belongs to the **dropTable** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void dropTable() {
    LOG.info("Entering dropTable.");
    Admin admin = null;
    try {
        admin = conn.getAdmin();
        if (admin.tableExists(tableName)) {
            // Disable the table before deleting it.
            admin.disableTable(tableName);
            // Delete table.
            admin.deleteTable(tableName); // Note[1]
        }
        LOG.info("Drop table successfully.");
    } catch (IOException e) {
        LOG.error("Drop table failed ",e);
    } finally {
        if (admin != null) {
            try {
                // Close the Admin object.
                admin.close();
            } catch (IOException e) {
                LOG.error("Close admin failed ",e);
            }
        }
    }
    LOG.info("Exiting dropTable.");
}
```

#### Precautions

A table can be deleted only when the table is disabled. Therefore, **deleteTable** is used together with **disableTable**, **enableTable**, **tableExists**, **isTableEnabled**, and **isTableDisabled**.

### 2.6.3.1.8 Modifying a Table

#### Function

Modify table information using the **modifyTable** method of **org.apache.hadoop.hbase.client.Admin**.

#### Example Code

The following code snippet belongs to the **testModifyTable** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testModifyTable() {
    LOG.info("Entering testModifyTable.");

    // Specify the column family name.
    byte[] familyName = Bytes.toBytes("education");
    Admin admin = null;
    try {
        // Instantiate an Admin object.
        admin = conn.getAdmin();
        // Obtain the table descriptor.
        TableDescriptor htd = admin.getDescriptor(tableName);
        // Check whether the column family is specified before modification.
        if (!htd.hasFamily(familyName)) {
            // Create the column descriptor.

TableDescriptor tableBuilder = TableDescriptorBuilder.newBuilder(htd)
    .setColumnFamily(ColumnFamilyDescriptorBuilder.newBuilder(familyName).build()).build();

        // Disable the table to get the table offline before modifying
        // the table.
        admin.disableTable(tableName); // Note[1]
        // Submit a modifyTable request.
        admin.modifyTable(tableBuilder);
        // Enable the table to get the table online after modifying the
        // table.
        admin.enableTable(tableName);
    }
    LOG.info("Modify table successfully.");
} catch (IOException e) {
    LOG.error("Modify table failed " ,e);
} finally {
    if (admin != null) {
        try {
            // Close the Admin object.
            admin.close();
        } catch (IOException e) {
            LOG.error("Close admin failed " ,e);
        }
    }
}
LOG.info("Exiting testModifyTable.");
}
```

## Precautions

**modifyTable** takes effect only when a table is disabled.

### 2.6.3.1.9 Inserting Data

#### Function

HBase is a column-oriented database. A row of data may have multiple column families, and a column family may contain multiple columns. When writing data, you must specify the columns (including the column family names and column names) to which data is written. In HBase, data (a row of data or data sets) is inserted using the **put** method of HTable.

#### Example Code

The following code snippet belongs to the **testPut** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testPut() {
    LOG.info("Entering testPut.");
```

```
// Specify the column family name.  
byte[] familyName = Bytes.toBytes("info");  
// Specify the column name.  
byte[][] qualifiers = {  
    Bytes.toBytes("name"), Bytes.toBytes("gender"), Bytes.toBytes("age"), Bytes.toBytes("address")  
};  
  
Table table = null;  
try {  
    // Instantiate an HTable object.  
    table = conn.getTable(tableName);  
    List<Put> puts = new ArrayList<Put>();  
  
    // Instantiate a Put object.  
    Put put = putData(familyName, qualifiers,  
        Arrays.asList("012005000201", "Zhang San", "Male", "19", "Shenzhen, Guangdong"));  
    puts.add(put);  
  
    put = putData(familyName, qualifiers,  
        Arrays.asList("012005000202", "Li Wanting", "Female", "23", "Shijiazhuang, Hebei"));  
    puts.add(put);  
  
    put = putData(familyName, qualifiers,  
        Arrays.asList("012005000203", "Wang Ming", "Male", "26", "Ningbo, Zhejiang"));  
    puts.add(put);  
  
    put = putData(familyName, qualifiers,  
        Arrays.asList("012005000204", "Li Gang", "Male", "18", "Xiangyang, Hubei"));  
    puts.add(put);  
  
    put = putData(familyName, qualifiers,  
        Arrays.asList("012005000205", "Zhao Enru", "Female", "21", "Shangrao, Jiangxi"));  
    puts.add(put);  
  
    put = putData(familyName, qualifiers,  
        Arrays.asList("012005000206", "Chen Long", "Male", "32", "Zhuzhou, Hunan"));  
    puts.add(put);  
  
    put = putData(familyName, qualifiers,  
        Arrays.asList("012005000207", "Zhou Wei", "Female", "29", "Nanyang, Henan"));  
    puts.add(put);  
  
    put = putData(familyName, qualifiers,  
        Arrays.asList("012005000208", "Yang Yiwen", "Female", "30", "Kaixian, Chongqing"));  
    puts.add(put);  
  
    put = putData(familyName, qualifiers,  
        Arrays.asList("012005000209", "Xu Bing", "Male", "26", "Weinan, Shaanxi"));  
    puts.add(put);  
  
    put = putData(familyName, qualifiers,  
        Arrays.asList("012005000210", "Xiao Kai", "Male", "25", "Dalian, Liaoning"));  
    puts.add(put);  
  
    // Submit a put request.  
    table.put(puts);  
  
    LOG.info("Put successfully.");  
} catch (IOException e) {  
    LOG.error("Put failed ", e);  
} finally {  
    if (table != null) {  
        try {  
            // Close the HTable object.  
            table.close();  
        } catch (IOException e) {  
            LOG.error("Close table failed ", e);  
        }  
    }  
}
```

```
        }
    }
    LOG.info("Exiting testPut.");
}
```

## Precautions

Multiple threads are not allowed to use the same HTable instance at the same time. HTable is a non-thread safe class. If an HTable instance is used by multiple threads at the same time, concurrency problems will occur.

### 2.6.3.1.10 Deleting Data

#### Function

Delete data (a row of data or data sets) using the **delete** method of a Table instance.

#### Example Code

The following code snippet belongs to the **testDelete** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testDelete() {
    LOG.info("Entering testDelete.");
    byte[] rowKey = Bytes.toBytes("012005000201");

    Table table = null;
    try {
        // Instantiate an HTable object.
        table = conn.getTable(tableName);

        // Instantiate a Delete object.
        Delete delete = new Delete(rowKey);

        // Submit a delete request.
        table.delete(delete);

        LOG.info("Delete table successfully.");
    } catch (IOException e) {
        LOG.error("Delete table failed " ,e);
    } finally {
        if (table != null) {
            try {
                // Close the HTable object.
                table.close();
            } catch (IOException e) {
                LOG.error("Close table failed " ,e);
            }
        }
    }
    LOG.info("Exiting testDelete.");
}
```

#### NOTE

If secondary index is created in the family of the column where the deleted cell is, the index data is synchronously deleted.

### 2.6.3.1.11 Reading Data Using Get

#### Function

Before reading data from a table, instantiate the Table instance of the table, and then create a Get object. You can also set parameters for the Get object, such as the column family name and column name. Query results are stored in the Result object that stores multiple Cells.

#### Example Code

The following code snippet belongs to the **testGet** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testGet() {
    LOG.info("Entering testGet.");
    // Specify the column family name.
    byte[] familyName = Bytes.toBytes("info");
    // Specify the column name.
    byte[][] qualifier = { Bytes.toBytes("name"), Bytes.toBytes("address") };
    // Specify RowKey.
    byte[] rowKey = Bytes.toBytes("012005000201");
    Table table = null;
    try {
        // Create the Table instance.
        table = conn.getTable(tableName);
        // Instantiate a Get object.
        Get get = new Get(rowKey);
        // Set the column family name and column name.
        get.addColumn(familyName, qualifier[0]);
        get.addColumn(familyName, qualifier[1]);
        // Submit a get request.
        Result result = table.get(get);
        // Print query results.
        for (Cell cell : result.rawCells()) {
            LOG.info("{}:{}:{}",
                    Bytes.toString(CellUtil.cloneRow(cell)),
                    Bytes.toString(CellUtil.cloneFamily(cell)), Bytes.toString(CellUtil.cloneQualifier(cell)),
                    Bytes.toString(CellUtil.cloneValue(cell)));
        }
        LOG.info("Get data successfully.");
    } catch (IOException e) {
        LOG.error("Get data failed ",e);
    } finally {
        if (table != null) {
            try {
                // Close the HTable object.
                table.close();
            } catch (IOException e) {
                LOG.error("Close table failed ",e);
            }
        }
    }
    LOG.info("Exiting testGet.");
}
```

### 2.6.3.1.12 Reading Data Using Scan

#### Function

Before reading data from a table, instantiate the Table instance of the table, create a Scan object, and set parameters for the Scan object based on search criteria. To improve query efficiency, you are advised to specify **StartRow** and

**StopRow.** Query results are stored in the ResultScanner object where each row of data is stored as a Result object that stores multiple Cells.

## Example Code

The following code snippet belongs to the **testScanData** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testScanData() {
    LOG.info("Entering testScanData.");
    Table table = null;
    // Instantiate a ResultScanner object.
    ResultScanner rScanner = null;
    try {
        // Create the Configuration instance.
        table = conn.getTable(tableName);
        // Instantiate a Get object.
        Scan scan = new Scan();
        scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("name"));
        // Set the cache size.
        scan.setCaching(1000);

        // Submit a scan request.
        rScanner = table.getScanner(scan);
        // Print query results.
        for (Result r = rScanner.next(); r != null; r = rScanner.next()) {
            for (Cell cell : r.rawCells()) {
                LOG.info("{}:{}:{}",
                    Bytes.toString(CellUtil.cloneRow(cell)),
                    Bytes.toString(CellUtil.cloneFamily(cell)),
                    Bytes.toString(CellUtil.cloneQualifier(cell)),
                    Bytes.toString(CellUtil.cloneValue(cell)));
            }
        }
        LOG.info("Scan data successfully.");
    } catch (IOException e) {
        LOG.error("Scan data failed " ,e);
    } finally {
        if (rScanner != null) {
            // Close the scanner object.
            rScanner.close();
        }
        if (table != null) {
            try {
                // Close the HTable object.
                table.close();
            } catch (IOException e) {
                LOG.error("Close table failed " ,e);
            }
        }
    }
    LOG.info("Exiting testScanData.");
}
```

## Precautions

1. You are advised to specify **StartRow** and **StopRow** to ensure good performance with a specified Scan scope.
2. You can set **Batch** and **Caching**.
  - **Batch**  
Indicates the maximum number of records returned each time when the **next** interface is invoked using Scan. This parameter is related to the number of columns read each time.
  - **Caching**

Indicates the maximum number of **next** records returned for a remote procedure call (RPC) request. This parameter is related to the number of rows read by an RPC.

### 2.6.3.1.13 Filtering Data

#### Function

HBase Filter is used to filter data during Scan and Get. You can specify the filter criteria, such as filtering by RowKey, column name, or column value.

#### Example Code

The following code snippet belongs to the **testSingleColumnValueFilter** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testSingleColumnValueFilter() {
    LOG.info("Entering testSingleColumnValueFilter.");
    Table table = null;

    ResultScanner rScanner = null;

    try {
        table = conn.getTable(tableName);

        Scan scan = new Scan();
        scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("name"));
        // Set the filter criteria.
        SingleColumnValueFilter filter = new SingleColumnValueFilter(
            Bytes.toBytes("info"), Bytes.toBytes("name"), CompareOperator.EQUAL,
            Bytes.toBytes("Xu Bing"));
        scan.setFilter(filter);
        // Submit a scan request.
        rScanner = table.getScanner(scan);
        // Print query results.
        for (Result r = rScanner.next(); r != null; r = rScanner.next()) {
            for (Cell cell : r.rawCells()) {
                LOG.info("{}:{}:{},{}", Bytes.toString(CellUtil.cloneRow(cell)),
                    Bytes.toString(CellUtil.cloneFamily(cell)), Bytes.toString(CellUtil.cloneQualifier(cell)),
                    Bytes.toString(CellUtil.cloneValue(cell)));
            }
        }
        LOG.info("Single column value filter successfully.");
    } catch (IOException e) {
        LOG.error("Single column value filter failed ",e);
    } finally {
        if (rScanner != null) {
            // Close the scanner object.
            rScanner.close();
        }
        if (table != null) {
            try {
                // Close the HTable object.
                table.close();
            } catch (IOException e) {
                LOG.error("Close table failed ",e);
            }
        }
    }
    LOG.info("Exiting testSingleColumnValueFilter.");
}
```

## Precautions

Currently, secondary indexes do not support the comparators that use objects of the SubstringComparator class as filters.

For example, the following sample code is not supported:

```
Scan scan = new Scan();
filterList = new FilterList(FilterList.Operator.MUST_PASS_ALL);
filterList.addFilter(new SingleColumnValueFilter(Bytes
.toBytes(columnFamily), Bytes.toBytes(qualifier),
CompareOperator.EQUAL, new SubstringComparator(substring)));
scan.setFilter(filterList);
```

### 2.6.3.1.14 Creating a Secondary Index

#### Function

You can manage HBase secondary indexes using methods provided in **org.apache.hadoop.hbase.hindex.client.HIndexAdmin**. This class provides methods of creating an index.

#### NOTE

Secondary indexes cannot be modified. If you need to modify them, delete old indexes and create new ones.

#### Example Code

The following code snippet belongs to the **createIndex** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void createIndex() {
    LOG.info("Entering createIndex.");

    String indexName = "index_name";
    // Create hindex instance
    TableIndices tableIndices = new TableIndices();
    IndexSpecification iSpec = new IndexSpecification(indexName);
    iSpec.addIndexColumn(ColumnFamilyDescriptorBuilder.newBuilder(Bytes.toBytes("info")).build(),
        "name", ValueType.STRING);// Note[1]
    tableIndices.addIndex(iSpec);

    HIndexAdmin iAdmin = null;
    Admin admin = null;
    try {

        admin = conn.getAdmin();
        iAdmin = HIndexClient.newHIndexAdmin(admin);

        // add index to the table
        iAdmin.addIndices(tableName, tableIndices);

        LOG.info("Create index successfully.");
    } catch (IOException e) {
        LOG.error("Create index failed ",e);
    } finally {
        if (admin != null) {
            try {
                admin.close();
            } catch (IOException e) {
                LOG.error("Close admin failed ",e);
            }
        }
    }
}
```

```
if (iAdmin != null) {
    try {
        // Close IndexAdmin Object
        iAdmin.close();
    } catch (IOException e) {
        LOG.error("Close admin failed " ,e);
    }
}
LOG.info("Exiting createIndex.");
```

By default, newly created level-2 indexes are disabled. To enable a specified level-2 index, see the following code snippet. The following code snippet belongs to the `enableIndex` method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```
public void enableIndex() {
    LOG.info("Entering createIndex.");

    // Name of the index to be enabled
    String indexName = "index_name";

    List<String> indexNameList = new ArrayList<String>();
    indexNameList.add(indexName);

    HIndexAdmin iAdmin = null;
    Admin admin = null;
    try {
        admin = conn.getAdmin();
        iAdmin = HIndexClient.newHIndexAdmin(admin);

        // Alternately, enable the specified indices
        iAdmin.enableIndices(tableName, indexNameList);
        LOG.info("Successfully enable indices {} of the table {}", indexNameList, tableName);
    } catch (IOException e) {
        LOG.error("Failed to enable indices {} of the table {} . {}", indexNameList, tableName, e);
    } finally {
        if (admin != null) {
            try {
                admin.close();
            } catch (IOException e) {
                LOG.error("Close admin failed " , e);
            }
        }
        if (iAdmin != null) {
            try {
                iAdmin.close();
            } catch (IOException e) {
                LOG.error("Close admin failed " , e);
            }
        }
    }
}
```

## Precautions

Create a combination index.

HBase supports creation of secondary indexes on multiple fields, for example, the name and age columns.

```
HIndexSpecification iSpecUnite = new HIndexSpecification(indexName);
iSpecUnite.addIndexColumn(new HColumnDescriptor("info"), "name", ValueType.String, 10);
iSpecUnite.addIndexColumn(new HColumnDescriptor("info"), "age", ValueType.String, 3);
```

## Related Operations

Create an index table by running a command.

You can also use the TableIndexer tool to create an index in an existing user table.

The <table\_name> user table must exist.

```
hbase org.apache.hadoop.hbase.hindex.mapreduce.TableIndexer -Dtablename.to.index=<table_name> -  
Dindexspecs.to.add='IDX1=>cf1:[q1->datatype];cf2:[q2->datatype],[q3->datatype]#IDX2=>cf1:[q5->datatype]' -Dindexnames.to.build='IDX1'
```

"#" is used to separate indexes. ";" is used to separate column families. "," is used to separate columns.

**tablename.to.index**: indicates the name of the table where the index is created.

**indexspecs.to.add**: indicates the user table columns corresponding to the index.

The parameters in the command are described as follows:

- **IDX1**: indicates the index name.
- **cf1**: indicates the column family name.
- **q1**: indicates the column name.
- **datatype**: indicates the data type. Only the Integer, String, Double, Float, Long, Short, Byte and Char formats are supported.

### 2.6.3.1.15 Deleting an Index

## Function

You can manage HBase secondary indexes using methods provided in **org.apache.hadoop.hbase.hindex.client.HIndexAdmin**. This class provides methods of querying and deleting an index.

## Example Code

The following code snippet belongs to the **dropIndex** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void dropIndex() {  
    LOG.info("Entering dropIndex.");  
    String indexName = "index_name";  
    List<String> indexNameList = new ArrayList<String>();  
    indexNameList.add(indexName);  
  
    IndexAdmin iAdmin = null;  
    try {  
        // Instantiate HIndexAdmin Object  
        iAdmin = HIndexClient.newHIndexAdmin(conn.getAdmin());  
        // Delete Secondary Index  
        iAdmin.dropIndex(tableName, indexNameList);  
  
        LOG.info("Drop index successfully.");  
    } catch (IOException e) {  
        LOG.error("Drop index failed.");  
    } finally {  
        if (iAdmin != null) {
```

```
try {
    // Close Secondary Index
    iAdmin.close();
} catch (IOException e) {
    LOG.error("Close admin failed.");
}
}
LOG.info("Exiting dropIndex.");
}
```

## Precautions

- Use the dropIndex and dropIndexes interfaces to delete HBase level-2 indexes. Do not directly drop the index table, because it is an invalid operation and cannot update table information, leading to query failures at the time of index rebuilding.
- If a user table is deleted, the corresponding index table is also deleted.

### 2.6.3.1.16 Secondary Index-based Query

#### Function

In user tables with secondary indexes, you can use Filter to query data. The data query performance is higher than that in user tables without secondary indexes.

#### NOTE

- For details about the secondary index principles, see "HIndex" in the "Product Introduction > Components > HBase > HBase Enhanced Open Source Features".
- HIndex supports three Filter types: SingleColumnValueFilter, SingleColumnValueExcludeFilter, and SingleColumnValuePartitionFilter.
- HIndex supports the following Comparator types: BinaryComparator, BitComparator, LongComparator, DecimalComparator, DoubleComparator, FloatComparator, IntComparator, and NullComparator.

The secondary index usage rules are as follows:

- For scenarios in which a single index is created for one or multiple columns:
  - When you use this column for AND or OR query filtering, the index is used to improve the query performance.  
For example, Filter\_Condition(IndexCol1) AND/OR Filter\_Condition(IndexCol2).
  - When you use "Index Column AND Non-Index Column" for filtering in the query, this index is used to improve the query performance.  
For example, Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol2) AND Filter\_Condition(NonIndexCol1).
  - When you use "Index Column OR Non-Index Column" for filtering in the query, the index is not used and the query performance is not improved.  
For example, Filter\_Condition(IndexCol1) AND/OR Filter\_Condition(IndexCol2) OR Filter\_Condition(NonIndexCol1).
- For scenarios in which a combination index is created for multiple columns:
  - When the columns used for query are all or part of the columns of the combination index and are in the same sequence with the combination index, the index is used to improve the query performance.

For example, a combination index is created for C1, C2, and C3. The index takes effect in the following scenarios:

Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol2) AND  
Filter\_Condition(IndexCol3)

Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol2)

Filter\_Condition(IndexCol1)

The index does not take effect in the following scenarios:

Filter\_Condition(IndexCol2) AND Filter\_Condition(IndexCol3)

Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol3)

Filter\_Condition(IndexCol2)

Filter\_Condition(IndexCol3)

- When you use "Index Column AND Non-Index Column" for filtering in the query, this index is used to improve the query performance.

For example:

Filter\_Condition(IndexCol1) AND Filter\_Condition(NonIndexCol1)

Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol2) AND  
Filter\_Condition(NonIndexCol1)

- When you use "Index Column OR Non-Index Column" for filtering in the query, the index is not used and the query performance is not improved.

For example:

Filter\_Condition(IndexCol1) OR Filter\_Condition(NonIndexCol1)

(Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol2))OR  
( Filter\_Condition(NonIndexCol1))

- When multiple columns are used for query, a value range can be specified only for the last column in the combination index and the other columns can only be set to a specified value.

For example, a combination index is created for C1, C2, and C3. In range query, a value range can be set only for C3 and the filter criterion is "C1 = XXX, C2 = XXX, and C3 = value range".

- For scenarios in which secondary index is created in a user table, you can use Filter to query data. The query results of the single and combination index with filter are the same as those in the table without secondary index. The data query performance is higher than that in user tables without secondary indexes.

## Example Code

The following code snippet belongs to the **testScanDataByIndex** method in the **HBaseSample** class of the **com.huawei.hadoop.hbase.example** package.

### Example: Query data using secondary indexes.

```
public void testScanDataByIndex() {  
    LOG.info("Entering testScanDataByIndex.");  
    Table table = null;  
    ResultScanner scanner = null;  
    try {  
        table = conn.getTable(tableName);  
  
        // Create a filter for indexed column.  
    } catch (IOException e) {  
        LOG.error("Error occurred while creating filter for indexed column.", e);  
    } finally {  
        if (scanner != null) {  
            scanner.close();  
        }  
        if (table != null) {  
            try {  
                table.close();  
            } catch (IOException e) {  
                LOG.error("Error occurred while closing table.", e);  
            }  
        }  
    }  
}
```

```
Filter filter = new SingleColumnValueFilter(Bytes.toBytes("info"), Bytes.toBytes("name"),
    CompareOperator.EQUAL, "Li Gang".getBytes());
Scan scan = new Scan();
scan.setFilter(filter);
scanner = table.getScanner(scan);
LOG.info("Scan indexed data.");

for (Result result : scanner) {
    for (Cell cell : result.rawCells()) {
        LOG.info("{{:},{},{}]", Bytes.toString(CellUtil.cloneRow(cell)),
            Bytes.toString(CellUtil.cloneFamily(cell)), Bytes.toString(CellUtil.cloneQualifier(cell)),
            Bytes.toString(CellUtil.cloneValue(cell)));
    }
}
LOG.info("Scan data by index successfully.");
} catch (IOException e) {
    LOG.error("Scan data by index failed.");
} finally {
    if (scanner != null) {
        // Close the scanner object.
        scanner.close();
    }
    try {
        if (table != null) {
            table.close();
        }
    } catch (IOException e) {
        LOG.error("Close table failed.");
    }
}

LOG.info("Exiting testScanDataByIndex.");
}
```

## Precaution

Create secondary indexes for the **name** field first.

## Related Operations

Query a table using a secondary index.

The following provides an example:

Add an index to the **name** column of the **info** column family in **hbase\_sample\_table**. Run the following command on the client:

```
hbase org.apache.hadoop.hbase.hindex.mapreduce.TableIndexer -Dtablename.to.index=hbase_sample_table -
Dindexspecs.to.add='IDX1=>info:[name->String]' -Dindexnames.to.build='IDX1'
```

Query **info:name**. Run the following command on the HBase shell client:

```
>scan 'hbase_sample_table',
{FILTER=>"SingleColumnValueFilter(family,qualifier,compareOp,comparator,
!IterIfMissing,latestVersionOnly)"}
```

### NOTE

Use APIs to perform complex query on the HBase shell client.

The parameters are described as follows:

- **family**: indicates the column family where the column to be queried locates, such as **info**.
- **qualifier**: indicates the column to be queried, such as **name**.
- **compareOp**: indicates the comparison operator, such as = and >.
- **comparator**: indicates the target value to be queried, such as **binary:Zhang San**.
- **filterIfMissing**: indicates whether a row is filtered if the column does not exist in this row. The default value is **false**.
- **latestVersionOnly**: indicates whether only values of the latest version are to be queried. The default value is **false**.

For example:

```
>scan 'hbase_sample_table',{FILTER=>"SingleColumnValueFilter('info','name',=,'binary:Zhang San',true,true)"}
```

#### 2.6.3.1.17 Multi-Point Region Division

### Function

You can perform multi-point division by using **org.apache.hadoop.hbase.client.HBaseAdmin**. Note that the division operations take effect on empty regions only.

In this example, the multi-point division is performed on an HBase table by using **multiSplit**. The table will be split into 5 parts: "-∞~A", "A~D", "D~F", "F~H", and "H~+∞".

### Example Code

The following code snippet belongs to the **testMultiSplit** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testMultiSplit() {  
    LOG.info("Entering testMultiSplit.");  
  
    Table table = null;  
    Admin admin = null;  
    try {  
        admin = conn.getAdmin();  
  
        // initialize a HTable object  
        table = conn.getTable(tableName);  
        Set<HRegionInfo> regionSet = new HashSet<HRegionInfo>();  
        List<HRegionLocation> regionList = conn.getRegionLocator(tableName).getAllRegionLocations();  
        for(HRegionLocation hrl : regionList){  
            regionSet.add(hrl.getRegionInfo());  
        }  
        byte[][] sk = new byte[4][];  
        sk[0] = "A".getBytes();  
        sk[1] = "D".getBytes();  
        sk[2] = "F".getBytes();  
        sk[3] = "H".getBytes();  
        for (RegionInfo regionInfo : regionSet) {  
            admin.multiSplitSync(regionInfo.getRegionName(), sk);  
        }  
        LOG.info("MultiSplit successfully.");  
    } catch (Exception e) {
```

```
LOG.error("MultiSplit failed.");
} finally {
    if (table != null) {
        try {
            // Close table object
            table.close();
        } catch (IOException e) {
            LOG.error("Close table failed " ,e);
        }
    }
    if (admin != null) {
        try {
            // Close the Admin object.
            admin.close();
        } catch (IOException e) {
            LOG.error("Close admin failed " ,e);
        }
    }
}
LOG.info("Exiting testMultiSplit.");
```

Note that the division operations take effect on empty regions only.

### 2.6.3.1.18 Creating a Phoenix Table

#### Function

Phoenix can be installed on HBase to enable it to support SQL and JDBC APIs. This way, SQL users can access the HBase cluster.

#### Example Code

The following code snippet belongs to the **testCreateTable** method in the **PhoenixSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
/*
 * Create Table
 */
public void testCreateTable() {
    LOG.info("Entering testCreateTable.");
    String URL = "jdbc:phoenix:" + conf.get("hbase.zookeeper.quorum");
    // Create table
    String createTableSQL =
        "CREATE TABLE IF NOT EXISTS TEST (id integer not null primary key, name varchar, "
        + "account char(6), birth date)";
    try (Connection conn = DriverManager.getConnection(url, props)) {
        Statement stat = conn.createStatement();
        // Execute Create SQL
        stat.executeUpdate(createTableSQL);
        LOG.info("Create table successfully.");
    } catch (Exception e) {
        LOG.error("Create table failed.", e);
    }
    LOG.info("Exiting testCreateTable.");
}
/*
 * Drop Table
 */
public void testDrop() {
    LOG.info("Entering testDrop.");
    String URL = "jdbc:phoenix:" + conf.get("hbase.zookeeper.quorum");
    // Delete table
    String dropTableSQL = "DROP TABLE TEST";

    try (Connection conn = DriverManager.getConnection(url, props));
```

```
Statement stat = conn.createStatement();
stat.executeUpdate(dropTableSQL);
LOG.info("Drop successfully.");
} catch (Exception e) {
    LOG.error("Drop failed.", e);
}
LOG.info("Exiting testDrop.");
```

### 2.6.3.1.19 Writing Data to the PhoenixTable

#### Function

The Phoenix table enables data writing in HBase.

#### Example Code

The following code snippet belongs to the **testPut** method in the **PhoenixSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
/*
 * Put data
 */
public void testPut() {
    LOG.info("Entering testPut.");
    String URL = "jdbc:phoenix:" + conf.get("hbase.zookeeper.quorum");
    // Insert
    String upsertSQL =
        "UPSERT INTO TEST VALUES(1,'John','100000', TO_DATE('1980-01-01','yyyy-MM-dd'))";
    try (Connection conn = DriverManager.getConnection(url, props);
        Statement stat = conn.createStatement()){
        // Execute Update SQL
        stat.executeUpdate(upsertSQL);
        conn.commit();
        LOG.info("Put successfully.");
    } catch (Exception e) {
        LOG.error("Put failed.", e);
    }
    LOG.info("Exiting testPut.");
}
```

### 2.6.3.1.20 Reading the PhoenixTable

#### Function

The Phoenix table enables data reading.

#### Example Code

The following code snippet belongs to the **testSelect** method in the **PhoenixSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
/*
 * Select Data
 */
public void testSelect() {
    LOG.info("Entering testSelect.");
    String URL = "jdbc:phoenix:" + conf.get("hbase.zookeeper.quorum");
    // Query
    String querySQL = "SELECT * FROM TEST WHERE id = ?";
    Connection conn = null;
    PreparedStatement preStat = null;
    Statement stat = null;
```

```
ResultSet result = null;
try {
    // Create Connection
    conn = DriverManager.getConnection(url, props);
    // Create Statement
    stat = conn.createStatement();
    // Create PrepareStatement
    preStat = conn.prepareStatement(querySQL);
    // Execute query
    preStat.setInt(1, 1);
    result = preStat.executeQuery();
    // Get result
    while (result.next()) {
        int id = result.getInt("id");
        String name = result.getString(1);
        System.out.println("id: " + id);
        System.out.println("name: " + name);
    }
    LOG.info("Select successfully.");
} catch (Exception e) {
    LOG.error("Select failed.", e);
} finally {
    if (null != result) {
        try {
            result.close();
        } catch (Exception e2) {
            LOG.error("Result close failed.", e2);
        }
    }
    if (null != stat) {
        try {
            stat.close();
        } catch (Exception e2) {
            LOG.error("Stat close failed.", e2);
        }
    }
    if (null != conn) {
        try {
            conn.close();
        } catch (Exception e2) {
            LOG.error("Connection close failed.", e2);
        }
    }
}
LOG.info("Exiting testSelect.");
```

### 2.6.3.1.21 Using HBase Dual-Read Capacity

#### Scenario

The HBase client application loads the configuration items of the active and standby clusters by customization to implement the dual-read capability. HBase dual-read is a key feature that improves the high availability of the HBase cluster system. It applies to four query scenarios: reading data using **Get**, reading data in batches using **Get**, reading data using **Scan**, and querying data using a secondary index. HBase can read data from the active and standby clusters at the same time, reducing the query glitch time. The advantages are as follows:

- **High success rate:** The concurrent dual-read mechanism ensures a high success rate of read requests.
- **High availability:** When a single cluster is faulty, the query service is not interrupted. A short network jitter does not prolong the query time.

- High generality: The dual-read feature does not support dual-write, but does not affect the original real-time write scenario.
- Ease-of-use: Client encapsulation is performed, which is not sensed by services.

 NOTE

Restrictions on HBase dual-read:

- The HBase dual-read feature is implemented based on replication. Data read from the standby cluster may be different from that from the active cluster. Therefore, only eventual consistency can be achieved.
- Currently, the HBase dual-read feature is used only for query. When the active cluster breaks down, the latest data cannot be synchronized. As a result, the latest data cannot be queried in the standby cluster.
- A **Scan** operation of HBase may be split into multiple RPC operations. Data may not be completely the same because related session information is not synchronized between different clusters. Therefore, the dual-read feature takes effect only when an RPC operation is performed for the first time. Requests before ResultScanner close access the cluster used for the first RPC operation.
- The HBase Admin API and real-time write API access only the active cluster. Therefore, after the active cluster breaks down, the Admin API and real-time write API are unavailable, and only the **Get** and **Scan** query services are available.

HBase dual-read supports the following two methods to configure the active/standby cluster:

- Add active/standby cluster configurations to the **hbase-dual.xml** file.
- Add the active/standby cluster configuration to **HBaseMultiClusterConnection**.

## Add the Active/Standby Cluster Configuration to the **hbase-dual.xml** File

**Step 1** Obtain the client configuration files **core-site.xml**, **hbase-site.xml**, and **hdfs-site.xml** of the HBase active cluster and save them to the **src/main/resources/conf/active** directory. This directory needs to be created by yourself. For details, see [Preparing the Connection Cluster Configuration File](#).

**Step 2** Obtain the client configuration files **core-site.xml**, **hbase-site.xml**, and **hdfs-site.xml** of the standby cluster and save them to the **src/main/resources/conf/standby** directory. This directory needs to be created by yourself. For details, see [Preparing the Connection Cluster Configuration File](#).

**Step 3** Create the **hbase-dual.xml** configuration file and save it to the **src/main/resources/conf/** directory. For details about the configuration items in the configuration file, see [Table 2-70](#).

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration>
    <!--Configuration file directory of the active cluster-->
    <property>
        <name>hbase.dualclient.active.cluster.configuration.path</name>
        <value>{Sample code directory}\src\main\resources\conf\active</value>
    </property>
    <!--Configuration file directory of the standby cluster-->
    <property>
        <name>hbase.dualclient.standby.cluster.configuration.path</name>
        <value>{Sample code directory}\src\main\resources\conf\standby</value>
    </property>
    <!--Connection implementation of the dual-read mode-->
```

```
<property>
    <name>hbase.client.connection.impl</name>
    <value>org.apache.hadoop.hbase.client.HBaseMultiClusterConnectionImpl</value>
</property>
<!--Normal mode-->
<property>
    <name>hbase.security.authentication</name>
    <value>Simple</value>
</property>
<!--Normal mode-->
<property>
    <name>hadoop.security.authentication</name>
    <value>Simple</value>
</property>
</configuration>
```

**Step 4** Create a dual-read Configuration and delete the comment of **testHBaseDualReadSample** from the **main** method of the **TestMain** class in the **com.huawei.bigdata.hbase.examples** package. Ensure that the value of **IS\_CREATE\_CONNECTION\_BY\_XML** in the **HBaseDualReadSample** class in the **com.huawei.bigdata.hbase.examples** package is **true**.

**Step 5** Determining the data source cluster

- GET request. The following code snippet belongs to the **testGet** method in **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```
Result result = table.get(get);
if (result instanceof DualResult) {
    LOG.info(((DualResult)result).getClusterId());
}
```

- Scan request. The following code snippet belongs to the **testScanData** method in **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```
ResultScanner rScanner = table.getScanner(scan);
if (rScanner instanceof HBaseMultiScanner) {
    LOG.info(((HBaseMultiScanner)rScanner).getClusterId());
}
```

**Step 6** The client can print metric information.

Add the following content to the **log4j.properties** file so that the client can export metric information to the specified file: For details about the metrics, see [HBase Dual-Read Configuration Items](#).

```
log4j.logger.DUAL=debug,DUAL
log4j.appenders.DUAL=org.apache.log4j.RollingFileAppender
log4j.appenders.DUAL.File=/var/log/dual.log //Local dual-read log path on the client. Change the value to the actual directory, but ensure that the directory has the write permission.
log4j.additivity.DUAL=false
log4j.appenders.DUAL.MaxFileSize=${hbase.log.maxfilesize}
log4j.appenders.DUAL.MaxBackupIndex=${hbase.log.maxbackupindex}
log4j.appenders.DUAL.layout=org.apache.log4j.PatternLayout
log4j.appenders.DUAL.layout.ConversionPattern=%d{ISO8601} %-5p [%t] %c{2}: %m%n
```

----End

## Configure the Active/Standy Cluster Configuration in HBaseMultiClusterConnection

**Step 1** Create a dual-read Configuration and delete the comment of **testHBaseDualReadSample** from the **main** method of the **TestMain** class in the **com.huawei.bigdata.hbase.examples** package. Ensure that the value of

**IS\_CREATE\_CONNECTION\_BY\_XML** in the **HBaseDualReadSample** class in the **com.huawei.bigdata.hbase.examples** package is **false**.

- Step 2** Add related configurations to the **addHbaseDualXmlParam** method of the **HBaseDualReadSample** class. For details about related configuration items, see [HBase Dual-Read Configuration Items](#).

```
private void addHbaseDualXmlParam(Configuration conf) {  
    // We need to set the optional parameters contained in hbase-dual.xml to conf  
    // when we use configuration transfer solution  
    conf.set(CONNECTION_IMPL_KEY, DUAL_READ_CONNECTION);  
    // conf.set("", "");  
}
```

- Step 3** Add configurations related to the Active cluster client to the **initActiveConf** method of the **HBaseDualReadSample** class.

```
private void initActiveConf() {  
    // The hbase-dual.xml configuration scheme is used to generate the client configuration of the active  
    // cluster.  
    // In actual application development, you need to generate the client configuration of the active cluster.  
    String activeDir =  
        HBaseDualReadSample.class.getClassLoader().getResource(Utils.CONF_DIRECTORY).getPath()  
            + File.separator + ACTIVE_DIRECTORY + File.separator;  
    Configuration activeConf = Utils.createConfByUserDir(activeDir);  
    HBaseMultiClusterConnection.setActiveConf(activeConf);  
}
```

- Step 4** Add configurations related to the Standby cluster client to the **initStandbyConf** method of the **HBaseDualReadSample** class.

```
private void initStandbyConf() {  
    // The hbase-dual.xml configuration scheme is used to generate the client configuration of the standby  
    // cluster.  
    // In actual application development, you need to generate the client configuration of the standby cluster.  
    String standbyDir =  
        HBaseDualReadSample.class.getClassLoader().getResource(Utils.CONF_DIRECTORY).getPath()  
            + File.separator + STANDBY_DIRECTORY + File.separator;  
    Configuration standbyConf = Utils.createConfByUserDir(standbyDir);  
    HBaseMultiClusterConnection.setStandbyConf(standbyConf);  
}
```

- Step 5** Determining the data source cluster.

- GET request. The following code snippet belongs to the **testGet** method in **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```
Result result = table.get(get);  
if (result instanceof DualResult) {  
    LOG.info(((DualResult)result).getClusterId());  
}
```

- Scan request. The following code snippet belongs to the **testScanData** method in **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```
ResultScanner rScanner = table.getScanner(scan);  
if (rScanner instanceof HBaseMultiScanner) {  
    LOG.info(((HBaseMultiScanner)rScanner).getClusterId());  
}
```

- Step 6** The client can print metric information.

Add the following content to the **log4j.properties** file so that the client can export metric information to the specified file: For details about the metrics, see [HBase Dual-Read Configuration Items](#)

```
log4j.logger.DUAL=debug,DUAL  
log4j.appenders.DUAL=org.apache.log4j.RollingFileAppender  
log4j.appenders.DUAL.File=/var/log/dual.log //Local dual-read log path on the client. Change the value to
```

```
the actual directory, but ensure that the directory has the write permission.  
log4j.additivity.DUAL=false  
log4j.appendер.DUAL.MaxFileSize=${hbase.log.maxfilesize}  
log4j.appendер.DUAL.MaxBackupIndex=${hbase.log.maxbackupindex}  
log4j.appendер.DUAL.layout=org.apache.log4j.PatternLayout  
log4j.appendер.DUAL.layout.ConversionPattern=%d{ISO8601} %-5p [%t] %c{2}: %m%n
```

----End

## 2.6.3.2 HBase Global Secondary Index Sample Program

### 2.6.3.2.1 Service Scenario Description

HBase allows you to use global secondary indexes to accelerate conditional queries. This sample shows you how to manage and use global secondary indexes.

#### Scenario

Assume that you are developing an application that records user information and addresses. The following table lists the data to be recorded.

**Table 2-68** User information

<b>id</b>	<b>name</b>	<b>age</b>	<b>address</b>
1	Zhang	20	CityA
2	Li	30	CityB
3	Wang	35	CityC

#### Data Preparation

Proper design of a table structure, RowKeys, and column names enable you to make full use of HBase advantages. If you use a global secondary index in a scan condition query, the query is performed on an index table. You do not need to pay attention to the rowkeys of the user table. In this example, the rowkeys are in "r1", "r2", "r3"... format. All columns are stored in the **info** column family.

#### Sample Description

The examples in following content describe how to create and delete global secondary indexes, modify statuses, , and use them to accelerate queries.

### 2.6.3.2.2 Creating HBase Global Secondary Indexes

#### Function

Manage HBase global secondary indexes by calling the method in **org.apache.hadoop.hbase.hindex.global.GlobalIndexAdmin**. **addIndices** is used for creating global secondary indexes.

To create a global secondary index, you need to configure the index column, covering column (optional), and pre-created index table regions (recommended).

### NOTE

To create global secondary indexes on a table with existing data, you need to pre-create regions for the index table to prevent hot-spotting. The rowkeys of the index table data consists of index columns and separators. The format is `\x01/index value\x00`. Specify the format when you pre-create a region, for example, when the **id** and **age** columns are used as the index columns, both columns need to be integers. Use the **id** column to pre-create regions. You can specify the pre-created index table region as follows:

`\x010,\x011,\x012....`

## Code Sample

The following code snippets are in the **addIndices** method in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, an index named **index\_id\_age** is created for the **user\_table** data table. The **id** and **age** columns in the data are used as index columns and the **name** column is overwritten. (The query condition is not used, but the query result needs to return to this column).

```
/**  
 * createIndex  
 */  
public void testCreateIndex() {  
    LOG.info("Entering createIndex.");  
    // Create index instance  
    TableIndices tableIndices = new TableIndices();  
    // Create index spec  
    // idx_id_age covered info:name  
    HIndexSpecification indexSpec = new HIndexSpecification("idx_id_age");  
  
    // Set index column  
    indexSpec.addIndexColumn(Bytes.toBytes("info"), Bytes.toBytes("id"), ValueType.STRING);  
    indexSpec.addIndexColumn(Bytes.toBytes("info"), Bytes.toBytes("age"), ValueType.STRING);  
  
    // Set covered column  
    // If you want cover one column, use addCoveredColumn  
    // If you want cover all column in one column family, use addCoveredFamilies  
    // If you want cover all column of all column family, use setCoveredAllColumns  
    indexSpec.addCoveredColumn(Bytes.toBytes("info"), Bytes.toBytes("name"));  
  
    // Need specify index table split keys, it should specify by index column.  
    // Note: index data's row key has a same prefix "\x01"  
    // For example:  
    // Our index column include "id" and "age", "id" is a number, we  
    // could specify split key like \x010 \x011 \x012...  
    byte[][] splitKeys = new byte[10][];  
    for (int i = 0; i < 10; i++) {  
        splitKeys[i] = Bytes.toBytesBinary("\x01" + i);  
    }  
    indexSpec.setSplitKeys(splitKeys);  
    tableIndices.addIndex(indexSpec);  
  
    // iAdmin will close the inner admin instance  
    try (GlobalIndexAdmin iAdmin = GlobalIndexClient newIndexAdmin(conn.getAdmin())) {  
        // add index to the table  
        iAdmin.addIndices(tableName, tableIndices);  
        LOG.info("Create index successfully.");  
    } catch (IOException e) {  
        LOG.error("Create index failed.", e);  
    }  
    LOG.info("Exiting createIndex.");  
}
```

### 2.6.3.2.3 Querying Global Secondary Indexes

#### Function

Manage HBase global secondary index by calling the method in **org.apache.hadoop.hbase.hindex.global.GlobalIndexAdmin.listIndices** is used for querying indexes, including the definitions and status of all indexes related to the current user table.

#### Code Sample

The following code snippets are in the **listIndices** method in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, all indexes corresponding to the user table **user\_table** are queried.

```
/*
 * List indexes
 */
public void testListIndexes() {
    LOG.info("Entering testListIndexes.");
    try (GlobalIndexAdmin iAdmin = GlobalIndexClient.newIndexAdmin(conn.getAdmin())) {
        for (Pair<HIndexSpecification, IndexState> indexPair : iAdmin.listIndices(tableName)) {
            LOG.info("index spec:{} , index state:{}" , indexPair.getFirst(), indexPair.getSecond());
        }
        LOG.info("List indexes successfully.");
    } catch (IOException e) {
        LOG.error("List indexes failed." , e);
    }
    LOG.info("Exiting testListIndexes.");
}
```

### 2.6.3.2.4 Querying Based on Global Secondary Indexes

#### Function

When a user table with a global secondary index is used for query, the query can be converted to a range query of the index table. The query performance is higher than that of a user table without a secondary index. For details about global secondary indexes, see

"Introduction to Global Secondary Indexes" in MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1) in the MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1).

#### Code Sample

The following code snippets are in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, the values of **id**, **age**, and **name** of the specified **id** are queried, and the **idx\_id\_age** index is selected. The query results are completely overwritten. As a result, you do not need to query in the original table to achieve optimal query performance.

```
/*
 * Scan data by secondary index.
```

```

/*
public void testScanDataByIndex() {
    LOG.info("Entering testScanDataByIndex.");

    Scan scan = new Scan();
    // Create a filter for indexed column.
    SingleColumnValueFilter filter = new SingleColumnValueFilter(Bytes.toBytes("info"), Bytes.toBytes("id"),
        CompareOperator.EQUAL, Bytes.toBytes("3"));
    filter.setFilterIfMissing(true);
    scan.setFilter(filter);

    // Specify returned columns
    // If returned columns not included in index table, will query back user table,
    // it's not the fast way to get data, suggest to cover all needed columns.
    // If you want to confirm whether using index for scanning, please set hbase client log level to DEBUG.
    scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("id"));
    scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("age"));
    scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("name"));

    LOG.info("Scan indexed data.");
    try (Table table = conn.getTable(tableName); ResultScanner scanner = table.getScanner(scan)) {
        for (Result result : scanner) {
            for (Cell cell : result.rawCells()) {
                LOG.info("{}:{}:{},{}:{}:{}",
                    Bytes.toString(CellUtil.cloneRow(cell)),
                    Bytes.toString(CellUtil.cloneFamily(cell)), Bytes.toString(CellUtil.cloneQualifier(cell)),
                    Bytes.toString(CellUtil.cloneValue(cell)));
            }
        }
        LOG.info("Scan data by index successfully.");
    } catch (IOException e) {
        LOG.error("Scan data by index failed ", e);
    }
    LOG.info("Exiting testScanDataByIndex.");
}

```

### 2.6.3.2.5 Disabling Global Secondary Indexes

#### Function

The status of a global secondary index determines whether the index is valid. By modifying the index status, you can disable, enable, or discard an index (no index data will be generated). You can modify the index status by calling the method in **org.apache.hadoop.hbase.hindex.global.GlobalIndexAdmin**. For details, see "Introduction to Global Secondary Index APIs" in MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1) in the MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1).

#### Code Sample

The following code snippets are in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, the **idx\_id\_age** index is disabled. That is, the index is not used during query, but index data is generated.

```

/**
 * alter index to UNUSABLE state.
 */
public void testAlterIndex() {
    LOG.info("Entering testAlterIndex.");
    List<String> indexNameList = Lists.newArrayList("idx_id_age");
    // Instantiate HIndexAdmin Object
    try (GlobalIndexAdmin iAdmin = GlobalIndexClient newIndexAdmin(conn.getAdmin())) {
        iAdmin.alterGlobalIndicesUnusable(tableName, indexNameList);
    }
}

```

```
        LOG.info("Alter indices to UNUSABLE successfully.");
    } catch (IOException e) {
        LOG.error("Alter indices to UNUSABLE failed.", e);
    }
    LOG.info("Exiting testAlterIndex.");
}
```

### 2.6.3.2.6 Deleting Global Secondary Indexes

#### Function

Manage HBase global secondary indexes by calling the method in **org.apache.hadoop.hbase.hindex.global.GlobalIndexAdmin**.

**dropIndices** is used to delete indexes.

#### Code Sample

The following code snippets are in the **dropIndices** method in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, the **idx\_id\_age** index is deleted from the **user\_table** table.

```
/*
 * dropIndex
 */
public void testDropIndex() {
    LOG.info("Entering testDropIndex.");
    List<String> indexNameList = Lists.newArrayList("idx_id_age");
    // Instantiate HIndexAdmin Object
    try (GlobalIndexAdmin iAdmin = GlobalIndexClient newIndexAdmin(conn.getAdmin())) {
        // Delete Secondary Index
        iAdmin.dropIndices(tableName, indexNameList);
        LOG.info("Drop index successfully.");
    } catch (IOException e) {
        LOG.error("Drop index failed ", e);
    }
    LOG.info("Exiting testDropIndex.");
}
```

### 2.6.3.3 Sample Program for Preloading Meta Tables When Request Concurrency Is High

#### 2.6.3.3.1 Service Scenario Description

When there is a large number of concurrent access requests to a data table, the client caches the required region location information again after an application is restarted. Each thread waits until the cache is complete before executing the requests. If the client timeout is too short and the target table contains a large number of regions, a large number of requests will be retried due to timeout. To prevent this issue, you need to cache the region information in the table before the application threads run so that subsequent requests will not time out.

This sample contains HBase multi-thread read/write tasks. The meta table will be preloaded before the thread tasks are started.

#### NOTE

In this sample, multiple threads concurrently access HBase, where:

- The number of regions of the HBase table is greater than or equal to 100.
- The data table is concurrently accessed by a single application.
- The HBase request timeout on the application side is less than 2s.

### 2.6.3.3.2 Preloading Meta Tables When Request Concurrency Is High

#### Function

Preload region location information in the scenario where multiple threads concurrently read and write HBase tables.

#### Code Sample

The following code snippets are in the **MultiThreadSample** class of the **com.huawei.bigdata.hbase.examples** package.

- Create a user table, pre-split 300 regions, and compress the table using SNAPPY.

```
private void createUserTable() {
    // Use number id as the first part of rowKey and pre-split 300 regions by the decimal string split
    // algorithm.
    ColumnFamilyDescriptor cf = ColumnFamilyDescriptorBuilder
        .newBuilder(Bytes.toBytes("f"))
        .setCompressionType(Compression.Algorithm.SNAPPY)
        .build();
    TableDescriptor td = TableDescriptorBuilder
        .newBuilder(tableName)
        .setColumnFamily(cf)
        .build();
    try (Admin admin = conn.getAdmin()) {
        if (!admin.tableExists(tableName)) {
            RegionSplitter.SplitAlgorithm splitAlgo = RegionSplitter
                .newSplitAlgoInstance(this.conn.getConfiguration(),
                    RegionSplitter.DecimalStringSplit.class.getName());
            admin.createTable(td, splitAlgo.split(REGION_NUMS));
            LOG.info("Create table success.");
        } else {
            LOG.warn("Table already exists.");
        }
    } catch (IOException e) {
        LOG.error("Create table failed!", e);
    }
}
```

- Preload the meta table and obtain the location information of all regions in the user table.

```
private void preLoadTableRegionLocations() {
    try (RegionLocator rl = conn.getRegionLocator(tableName)) {
        long startTime = System.currentTimeMillis();
        rl.getAllRegionLocations();
        LOG.info("Cache table region location success, cost {} ms.", System.currentTimeMillis() -
            startTime);
    } catch (IOException e) {
        LOG.error("Cache table region location failed!", e);
    }
}
```

- Perform multi-thread read and write operations.

```
private void doOperations() {
    int cores = Math.max(32, Runtime.getRuntime().availableProcessors());
```

```
// Pool for user service including HBase data read/write.
ThreadPoolExecutor pool = new ThreadPoolExecutor(cores, cores,
    60,
    TimeUnit.SECONDS,
    new LinkedBlockingQueue<>(cores * 100),
    new ThreadFactoryBuilder()
        .setDaemon(true)
        .setUncaughtExceptionHandler((t, e) ->
            LOG.warn("Thread:{} exited with Exception:{}", t, StringUtils.stringifyException(e)))
        .setNameFormat("Application-Pool-%d").build());

for (int i = 0; i < OPERATIONS_COUNT; i++) {
    pool.execute(() -> {
        try (Table table = conn.getTable(tableName)) {
            Put put = new Put(Bytes.toBytes(
                ThreadLocalRandom.current().nextLong(0, 100000L) + "#"
                    + RandomStringUtils.randomAlphabetic(5)));
            put.addColumn(Bytes.toBytes("f"), Bytes.toBytes("name"),
                Bytes.toBytes(RandomStringUtils.randomAlphabetic(10)));
            put.addColumn(Bytes.toBytes("f"), Bytes.toBytes("ts"),
                Bytes.toBytes(Long.toString(System.currentTimeMillis())));
            table.put(put);
        } catch (IOException e) {
            LOG.error("Put data failed ", e);
        }
    });
    pool.execute(() -> {
        Scan scan = new Scan()
            .withStartRow(Bytes.toBytes(
                ThreadLocalRandom.current().nextLong(0, 100000L) + "#"))
            .setLimit(1);
        try (Table table = conn.getTable(tableName);
            ResultScanner scanner = table.getScanner(scan)) {
            Result result;
            while ((result = scanner.next()) != null) {
                for (Cell cell : result.rawCells()) {
                    LOG.info("ROW:{};CF:{};CQ:{};VALUE:{}",
                        Bytes.toString(CellUtil.cloneRow(cell)),
                        Bytes.toString(CellUtil.cloneFamily(cell)),
                        Bytes.toString(CellUtil.cloneQualifier(cell)),
                        Bytes.toString(CellUtil.cloneValue(cell)));
                }
            }
        } catch (IOException e) {
            LOG.error("Scan data failed ", e);
        }
    });
}
shutDownPool(pool);
LOG.info("Finish do operations.");
}

private void shutDownPool(ThreadPoolExecutor pool) {
    pool.shutdown();
    try {
        if (!pool.awaitTermination(SHUT_DOWN_POOL_WAIT_TIMEOUT_SEC, TimeUnit.SECONDS)) {
            pool.shutdownNow();
        }
    } catch (InterruptedException e) {
        pool.shutdownNow();
    }
}
```

- Clear the user table.

```
private void dropUserTable() {
    try (Admin admin = conn.getAdmin()) {
        admin.disableTable(tableName);
        admin.deleteTable(tableName);
        LOG.info("Drop table success.");
    } catch (IOException e) {
        LOG.error("Drop table failed ", e);
    }
}
```

```
}
```

## 2.6.3.4 HBase Rest API Invoking Sample Program

### 2.6.3.4.1 Querying Cluster Information Using REST

#### Function

Use the REST service to transfer the URL consisting of the host and port to obtain the cluster version and status information through HTTP.

#### Example Code

- Connecting to the RestServer Service

In normal mode, users can connect to the RestServer service without logging in. Therefore, comment out the following code statements related to login in the **main** method of the **HBaseRestTest** class in the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** package:

```
//In Windows environment
//String userdir = HBaseRestTest.class.getClassLoader().getResource("conf").getPath() +
File.separator;
//In Linux environment
//String userdir = System.getProperty("user.dir") + File.separator + "conf" + File.separator;
//userKeytabFile = userdir + "user.keytab";
//krb5File = userdir + "krb5.conf";
//String principal = "hbaseuser1";
//login(principal, userKeytabFile, krb5File);
```

The following code snippets are in the **main** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
// RESTServer's hostname.
String restHostName = "xxx.xxx.xxx.xxx";[1]
String securityModeUrl = new
StringBuilder("https://").append(restHostName).append(":21309").toString();
String nonSecurityModeUrl = new
StringBuilder("http://").append(restHostName).append(":21309").toString();
HBaseRestTest test = new HBaseRestTest();

//If cluster is non-security mode,use nonSecurityModeUrl as parameter.
test.test(nonSecurityModeUrl);[2]
```

[1] Change the value of **restHostName** to the IP address of the node where the RestServer instance to be accessed is located, and configure the node IP address in the hosts file on the local host where the sample code is run.

[2] In non-security mode, access the HBase REST service in HTTP mode and use **nonSecurityModeUrl** as the **test.test()** parameter.

- Obtaining the cluster version information

The following code snippets are in the **getClusterVersion** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getClusterVersion(String url) {
    String endpoint = "/version/cluster";
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);
    handleNormalResult((Optional<ResultModel>) result);
}
```

- Obtaining the cluster status information

The following code snippets are in the **getClusterStatus** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getClusterStatus(String url) {  
    String endpoint = "/status/cluster";  
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);  
    handleNormalResult(result);  
}
```

#### 2.6.3.4.2 Obtaining All Tables Using REST

### Function

Use the REST service and transfer the URL consisting of the host and port to obtain all tables using HTTP.

### Example Code

The following code snippets are in the **getAllUserTables** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getAllUserTables(String url) {  
    String endpoint = "/";  
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);  
    handleNormalResult(result);  
}
```

#### 2.6.3.4.3 Operate Namespaces Using REST

### Function

Use the REST service to import the URL consisting of the host and port and the specified namespace, Use HTTP to create, query, and delete namespaces, and obtain tables in the specified namespace.

#### ⚠ CAUTION

HBase tables are stored in *Namespace*.*Table name* format. If no namespace is specified when a table is created, the table is stored in **default**. The **hbase** namespace is the system table namespace. Do not create service tables or read or write data in the system table namespace.

### Example Code

- Invoking methods

```
// Namespace operations.  
createNamespace(url, "testNs");  
getAllNamespace(url);  
deleteNamespace(url, "testNs");  
getAllNamespaceTables(url, "default");
```

- Creating a namespace

The following code snippets are in the **createNamespace** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void createNamespace(String url, String namespace) {  
    String endpoint = "/namespaces/" + namespace;  
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.POST, null);  
    if (result.orElse(new ResultModel()).getStatusCode() == HttpStatus.SC_CREATED) {  
        LOG.info("Create namespace '{}' success.", namespace);  
    } else {  
        LOG.error("Create namespace '{}' failed.", namespace);  
    }  
}
```

- Querying all namespaces

The following code snippets are in the **getAllNamespace** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getAllNamespace(String url) {  
    String endpoint = "/namespaces";  
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);  
    handleNormalResult(result);  
}
```

- Deleting a specified namespace

The following code snippets are in the **deleteNamespace** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void deleteNamespace(String url, String namespace) {  
    String endpoint = "/namespaces/" + namespace;  
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.DELETE, null);  
    if (result.orElse(new ResultModel()).getStatusCode() == HttpStatus.SC_OK) {  
        LOG.info("Delete namespace '{}' success.", namespace);  
    } else {  
        LOG.error("Delete namespace '{}' failed.", namespace);  
    }  
}
```

- Obtain tables in a specified namespace.

The following code snippets are in the **getAllNamespaceTables** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getAllNamespaceTables(String url, String namespace) {  
    String endpoint = "/namespaces/" + namespace + "/tables";  
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);  
    handleNormalResult(result);  
}
```

## 2.6.3.4.4 Operate Tables Using REST

### Function

Use the REST service to transfer the URL consisting of the host and port as well as the specified **tableName** and **jsonHTD** to query, modify, create, and delete table information through HTTP.

### Example Code

- Invoking methods

```
// Add a table with specified info.  
createTable(url, "testRest",  
    "{\"name\":\"\\\"default:testRest\\\", \"ColumnSchema\":{\"name\":\"cf1\"}, \"name\":\"cf2\"}}");
```

```
// Add column family 'testCF1' if not exist, else update the 'VERSIONS' to 3.
// Notes: The unspecified property of this column family will be updated to default value.
modifyTable(url, "testRest",
    "{\"name\":\"testRest\",\"ColumnSchema\":[{\"name\":\"testCF1\",\"VERSIONS\":\"3\"}]}");

// Describe specific Table.
descTable(url, "default:testRest");

// delete a table with specified info.
deleteTable(url, "default:testRest",
    "{\"name\":\"default:testRest\",\"ColumnSchema\":[{\"name\":\"testCF\",\"VERSIONS\":\"3\"}]}");

```

- **Querying table information**

The following code snippets are in the **descTable** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void descTable(String url, String tableName) {
    String endpoint = "/" + tableName + "/schema";
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);
    handleNormalResult((Optional<ResultModel>) result);
}
```

- **Modifying table information**

The following code snippets are in the **modifyTable** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void modifyTable(String url, String tableName, String jsonHTD) {
    LOG.info("Start modify table.");
    String endpoint = "/" + tableName + "/schema";
    JsonElement tableDesc = new JsonParser().parse(jsonHTD);

    // Add a new column family or modify it.
    handleNormalResult(sendAction(url + endpoint, MethodType.POST, tableDesc));
}
```

- **Creating a table**

The following code snippets are in the **createTable** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void createTable(String url, String tableName, String jsonHTD) {
    LOG.info("Start create table.");
    String endpoint = "/" + tableName + "/schema";
    JsonElement tableDesc = new JsonParser().parse(jsonHTD);

    // Add a table.
    handleCreateTableResult(sendAction(url + endpoint, MethodType.PUT, tableDesc));
}
```

- **Deleting a table**

The following code snippets are in the **deleteTable** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void deleteTable(String url, String tableName, String jsonHTD) {
    LOG.info("Start delete table.");
    String endpoint = "/" + tableName + "/schema";
    JsonElement tableDesc = new JsonParser().parse(jsonHTD);

    // delete a table.
    handleNormalResult(sendAction(url + endpoint, MethodType.DELETE, tableDesc));
}
```

## 2.6.3.5 Accessing the HBase ThriftServer Sample Program

### 2.6.3.5.1 Accessing the ThriftServer Operation Table

#### Scenario

After importing the host where the ThriftServer instances are located and the port that provides services, you can create a Thrift client using the authentication credential and configuration file, access ThriftServer, and obtain table names, create a table, and delete a table based on the specified namespace.

#### Procedure

- Step 1** Log in to FusionInsight Manager, choose **Cluster > Service > HBase > Configuration** and click **All Configurations**, search for and modify the parameter **hbase.thrift.security.qop** of the ThriftServer instance. The value of this parameter must be the same as that of **hbase.rpc.protection**. Save the configuration and restart the node service for the configuration to take effect.

##### NOTE

The mapping between **hbase.rpc.protection** and **hbase.thrift.security.qop** is as follows:

- "privacy" - "auth-conf"
- "authentication" - "auth"
- "integrity" - "auth-int"

- Step 2** Obtain the configuration file of the ThriftServer instance in the cluster.

- Method 1: Choose **Cluster > Service > HBase > Instance**, click the ThriftServer instance to go to the details page, and obtain the configuration files **hdfs-site.xml**, **core-site.xml**, and **hbase-site.xml**.
- Method 2: Obtain the configuration files by decompressing the client file in [Preparing for Development and Operating Environment](#). Manually add the following configuration to **hbase-site.xml**. The value of **hbase.thrift.security.qop** must be the same as that in [Step 1](#).

```
<property>
<name>hbase.thrift.security.qop</name>
<value>auth</value>
</property>
<property>
<name>hbase.thrift.kerberos.principal</name>
<value>thrift/hadoop.hadoop.com@HADOOP.COM</value>
</property>
<property>
<name>hbase.thrift.keytab.file</name>
<value>/opt/huawei/Bigdata/FusionInsight_HD_XXX/install/FusionInsight-HBase-2.4.14/keytabs/HBase/
thrift.keytab</value>
</property>
```

----End

#### Example Code

- Initializing configuration

The following code snippets belong to the **TestMain** class in the **com.huawei.bigdata.hbase.examples** package of the **hbase-thrift-example** sample project.

```
private static void init() throws IOException {
    // Default load from conf directory
    conf = HBaseConfiguration.create();

    String userdir = TestMain.class.getClassLoader().getResource("conf").getPath() + File.separator;
[1]    //In Linux environment
    //String userdir = System.getProperty("user.dir") + File.separator + "conf" + File.separator;
    conf.addResource(new Path(userdir + "core-site.xml"), false);
    conf.addResource(new Path(userdir + "hdfs-site.xml"), false);
    conf.addResource(new Path(userdir + "hbase-site.xml"), false);
}
```

[1] **userdir** obtains the **conf** directory in the resource path after compilation. The **core-site.xml**, **hdfs-site.xml**, and **hbase-site.xml** files used for initial configuration must be stored in the **src/main/resources/conf** directory.

- Connecting to a ThriftServer instance

The following code snippets belong to the **TestMain** class in the **com.huawei.bigdata.hbase.examples** package of the **hbase-thrift-example** sample project.

```
try {
    test = new ThriftSample();
    test.test("xxx.xxx.xxx.xxx", THRIFT_PORT, conf);[2]
} catch (TException | IOException e) {
    LOG.error("Test thrift error", e);
}
```

[2] The value of the input parameter **test.test()** is the IP address of the node where the ThriftServer instance to be accessed is located. Change the IP address to the actual one. The IP address of the node must be configured in the hosts file of the local host where the sample code is run.

**THRIFT\_PORT** is the value of **hbase.regionserver.thrift.port** configured for the ThriftServer instance.

- Invoking methods

```
// Get table of specified namespace.
getTableNamesByNamespace(client, "default");
// Create table.
createTable(client, TABLE_NAME);
// Delete specified table.
deleteTable(client, TABLE_NAME);
```

- Obtaining table names based on the specified namespace

The following code snippets are in the **getTableNamesByNamespace** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getTableNamesByNamespace(THBaseService.Iface client, String namespace) throws
TException {
    client.getTableNamesByNamespace(namespace)
        .forEach(
            tTableName -> LOGGER.info("{}: {}, TableName.valueOf(tTableName.getNs(),",
            tTableName.getQualifier())));
}
```

- Creating a table

The following code snippets are in the **createTable** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void createTable(THBaseService.Iface client, String tableName) throws TException,
IOException {
    TTableName table = getTableName(tableName);
    TTableDescriptor descriptor = new TTableDescriptor(table);
    descriptor.setColumns(
```

```

        Collections.singletonList(new
TColumnFamilyDescriptor(). setName(COLUMN_FAMILY.getBytes())));
if (client.tableExists(table)) {
    LOGGER.warn("Table {} is exists, delete it.", tableName);
    client.disableTable(table);
    client.deleteTable(table);
}
client.createTable(descriptor, null);
if (client.tableExists(table)) {
    LOGGER.info("Created {}.", tableName);
} else {
    LOGGER.error("Create {} failed.", tableName);
}
}

```

- Deleting a table

The following code snippets are in the **deleteTable** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```

private void deleteTable(THBaseService.Iface client, String tableName) throws TException,
IOException {
    TTableName table = getTableName(tableName);
    if (client.tableExists(table)) {
        client.disableTable(table);
        client.deleteTable(table);
        LOGGER.info("Deleted {}.", tableName);
    } else {
        LOGGER.warn("{} not exist.", tableName);
    }
}

```

### 2.6.3.5.2 Accessing ThriftServer to Write Data

#### Function

After importing the host where the ThriftServer instances are located and the port that provides services, you can create a Thrift client using the authentication credential and configuration file, access the ThriftServer, and use Put and putMultiple to write data.

#### Example Code

- Invoking methods

```

// Write data with put.
putData(client, TABLE_NAME);

// Write data with putlist.
putDataList(client, TABLE_NAME);

```

- Using Put to write data.

The following code snippets are in the **putData** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```

private void putData(THBaseService.Iface client, String tableName) throws TException {
    LOGGER.info("Test putData.");
    TPut put = new TPut();
    put.setRow("row1".getBytes());

    TColumnValue columnValue = new TColumnValue();
    columnValue.setFamily(COLUMN_FAMILY.getBytes());
    columnValue.setQualifier("q1".getBytes());
    columnValue.setValue("test value".getBytes());
    List<TColumnValue> columnValues = new ArrayList<>(1);
}

```

```
columnValues.add(columnValue);
put.setColumnValues(columnValues);

ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());
client.put(table, put);
LOGGER.info("Test putData done.");
}
```

- Using `putMultiple` to write data.

The following code snippets are in the `putDataList` method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void putDataList(THBaseService.Iface client, String tableName) throws TException {
    LOGGER.info("Test putDataList.");
    TPut put1 = new TPut();
    put1.setRow("row2".getBytes());
    List<TPut> putList = new ArrayList<>();

    TColumnValue q1Value = new TColumnValue(ByteBuffer.wrap(COLUMN_FAMILY.getBytes()),
        ByteBuffer.wrap("q1".getBytes()), ByteBuffer.wrap("test value".getBytes()));
    TColumnValue q2Value = new TColumnValue(ByteBuffer.wrap(COLUMN_FAMILY.getBytes()),
        ByteBuffer.wrap("q2".getBytes()), ByteBuffer.wrap("test q2 value".getBytes()));
    List<TColumnValue> columnValues = new ArrayList<>(2);
    columnValues.add(q1Value);
    columnValues.add(q2Value);
    put1.setColumnValues(columnValues);
    putList.add(put1);

    TPut put2 = new TPut();
    put2.setRow("row3".getBytes());

    TColumnValue columnValue = new TColumnValue();
    columnValue.setFamily(COLUMN_FAMILY.getBytes());
    columnValue.setQualifier("q1".getBytes());
    columnValue.setValue("test q1 value".getBytes());
    put2.setColumnValues(Collections.singletonList(columnValue));
    putList.add(put2);

    ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());
    client.putMultiple(table, putList);
    LOGGER.info("Test putDataList done.");
}
```

### 2.6.3.5.3 Accessing ThriftServer to Read Data

#### Function

After importing the host where the ThriftServer instances are located and the port that provides services, you can create a Thrift client using the authentication credential and configuration file, access the ThriftServer, and use **get** and **scan** methods to read data.

#### Example Code

- Invoking methods

```
// Get data with single get.
getData(client, TABLE_NAME);

// Get data with getlist.
getDataList(client, TABLE_NAME);

// Scan data.
scanData(client, TABLE_NAME);
```

- Using the **get** method to write data.

The following code snippets are in the **getData** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getData(THBaseService.Iface client, String tableName) throws TException {
    LOGGER.info("Test getData.");
    TGet get = new TGet();
    get.setRow("row1".getBytes());

    ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());
    TResult result = client.get(table, get);
    printResult(result);
    LOGGER.info("Test getData done.");
}
```

- Using the **getlist** method to write data.

The following code snippets are in the **getDataList** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getDataList(THBaseService.Iface client, String tableName) throws TException {
    LOGGER.info("Test getDataList.");
    List<TGet> getList = new ArrayList<>();
    TGet get1 = new TGet();
    get1.setRow("row1".getBytes());
    getList.add(get1);

    TGet get2 = new TGet();
    get2.setRow("row2".getBytes());
    getList.add(get2);

    ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());
    List<TResult> resultList = client.getMultiple(table, getList);
    for (TResult tResult : resultList) {
        printResult(tResult);
    }
    LOGGER.info("Test getDataList done.");
}
```

- Using the **scan** method to write data.

The following code snippets are in the **scanData** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void scanData(THBaseService.Iface client, String tableName) throws TException {
    LOGGER.info("Test scanData.");
    int scannerId = -1;
    try {
        ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());
        TScan scan = new TScan();
        scan.setLimit(500);
        scannerId = client.openScanner(table, scan);
        List<TResult> resultList = client.getScannerRows(scannerId, 100);
        while (resultList != null && !resultList.isEmpty()) {
            for (TResult tResult : resultList) {
                printResult(tResult);
            }
            resultList = client.getScannerRows(scannerId, 100);
        }
    } finally {
        if (scannerId != -1) {
            client.closeScanner(scannerId);
            LOGGER.info("Closed scanner {}.", scannerId);
        }
    }
    LOGGER.info("Test scanData done.");
}
```

## 2.6.3.6 Sample Program for HBase to Access Multiple ZooKeepers

### 2.6.3.6.1 Accessing Multiple ZooKeepers

#### Function

This function allows simultaneous access to FusionInsight ZooKeeper from the HBase client and third-party ZooKeeper from the customer application in the same client process.

#### Example code

The following code snippet is in the **TestZKSample** class of the **hbase-zk-example** **\src\main\java\com\huawei\hadoop\hbase\example**. You need to pay attention to the **login** and **connectApacheZK** methods.

```
private static void login(String keytabFile, String principal) throws IOException {
    conf = HBaseConfiguration.create();
    //In Windows environment
    String confDirPath = TestZKSample.class.getClassLoader().getResource("").getPath() + File.separator;
[1]    //In Linux environment
    //String confDirPath = System.getProperty("user.dir") + File.separator + "conf" + File.separator;

    // Set zoo.cfg for hbase to connect to fi zookeeper.
    conf.set("hbase.client.zookeeper.config.path", confDirPath + "zoo.cfg");
    if (User.isHBaseSecurityEnabled(conf)) {
        // jaas.conf file, it is included in the client package file
        System.setProperty("java.security.auth.login.config", confDirPath + "jaas.conf");
        // set the kerberos server info, point to the kerberosclient
        System.setProperty("java.security.krb5.conf", confDirPath + "krb5.conf");
        // set the keytab file name
        conf.set("username.client.keytab.file", confDirPath + keytabFile);
        // set the user's principal
        try {
            conf.set("username.client.kerberos.principal", principal);
            User.login(conf, "username.client.keytab.file", "username.client.kerberos.principal",
                      InetAddress.getLocalHost().getCanonicalHostName());
        } catch (IOException e) {
            throw new IOException("Login failed.", e);
        }
    }
}
private void connectApacheZK() throws IOException, org.apache.zookeeper.KeeperException {
    try {
        // Create apache zookeeper connection.
        ZooKeeper digestZk = new ZooKeeper("127.0.0.1:24002", 60000, null);
        LOG.info("digest directory: {}", digestZk.getChildren("/", null));
        LOG.info("Successfully connect to apache zookeeper.");
    } catch (InterruptedException e) {
        LOG.error("Found error when connect apache zookeeper ", e);
    }
}
```

- [1]The value of **userdir** is the path of the **conf** directory in the resource path after compilation. Place the **core-site.xml**, **hdfs-site.xml**, and **hbase-site.xml** configuration files to the **src/main/resources/conf** directory.
- The **jaas.conf** file specified by the **java.security.auth.login.config** parameter in the **login** method is used to set the authentication information for accessing ZooKeeper. The example code contains the Client\_new and Client configurations. The Client\_new configuration is used to access FusionInsight ZooKeeper and the Client configuration is used to access Apache ZooKeeper.

- The **hbase.client.zookeeper.config.path** parameter in the **login** method controls the access to the FusionInsight ZooKeeper client. The following parameters are involved:
  - **zookeeper.sasl.clientconfig**: Specifies the configuration in the **jaas.conf** file used for accessing FusionInsight ZooKeeper.
  - **zookeeper.server.principal**: Specifies the principle of the ZooKeeper server. The format is **zookeeper/hadoop.System domain name**, for example, **zookeeper/hadoop.HADOOP.COM**. To obtain the system domain name, log in to FusionInsight Manager, choose **System > Permission > Domain and Mutual Trust**, and view the value of Local Domain.
  - **zookeeper.sasl.client**: If the cluster works in the security mode, set this parameter to **true**. Otherwise, set this parameter to **false**. If this parameter is set to **false**, the **zookeeper.sasl.clientconfig** and **zookeeper.server.principal** parameters do not take effect.

### 2.6.3.7 Example Configuration for Interconnecting HBase/Phoenix with SpringBoot

#### Scenario

Run Spring Boot interface sample code of MRS HBase/Phoenix.

#### Prerequisites

You have obtained the configuration file required for running the sample project. For details, see [Preparing the Connection Cluster Configuration File](#).

#### Procedure

**Step 1** In the IntelliJ IDEA development environment, click the **springclient.properties** file in the **src/springboot/hbase-examples/src/main/resources** directory and modify the parameters listed in [Table 2-69](#) as needed:

**Table 2-69** Configuration parameters

Parameter	Definition
conf.path	Directory where the HBase configuration file is stored, that is, <b>hbase-example\src\main\resources\conf</b>

----End

### 2.6.4 Application Commissioning

#### 2.6.4.1 Commissioning an Application in Windows

### 2.6.4.1.1 Compiling and Running an Application

#### Scenario

After the code development is complete, you can run the application in the Windows development environment.

If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

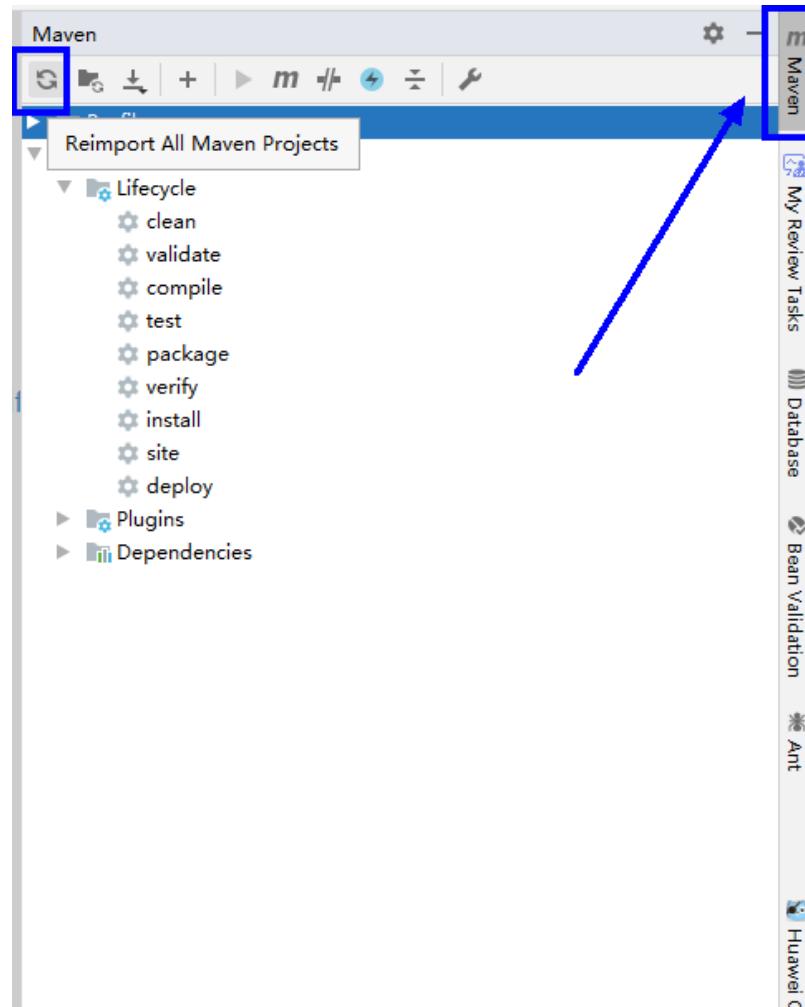

#### NOTE

- If IBM JDK is used in the Windows development environment, the application cannot be run in the Windows environment.
- You need to set the mapping between the host names and IP addresses of the access nodes in the hosts file on the local host where the sample code is run. The host names and IP addresses must be mapped one by one.

#### Procedure

**Step 1** Click **Reimport All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

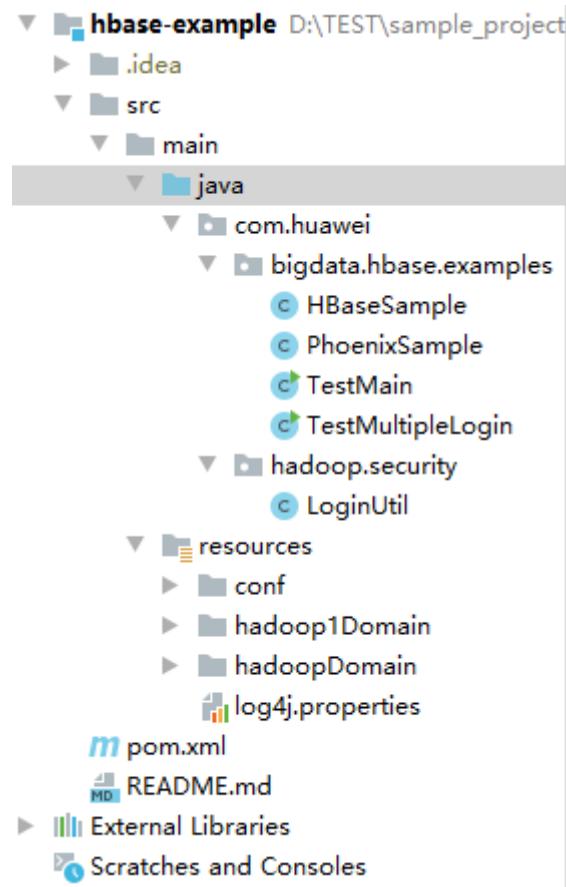

**Figure 2-124** reimport projects

**Step 2** Compile and run an application.

Place the configuration file directory and modify the code to match the login user. See [Figure 2-125](#).

**Figure 2-125** Directory list of **hbase-example** to be compiled

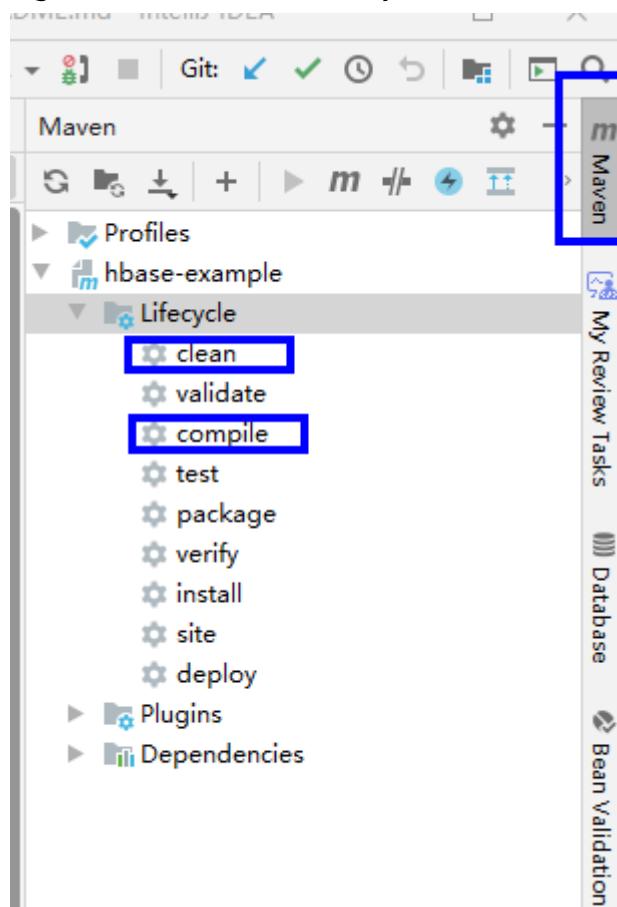

1. Compile an application.

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean** and double-click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **compile**, double click **compile** to run the **compile** command of Maven.

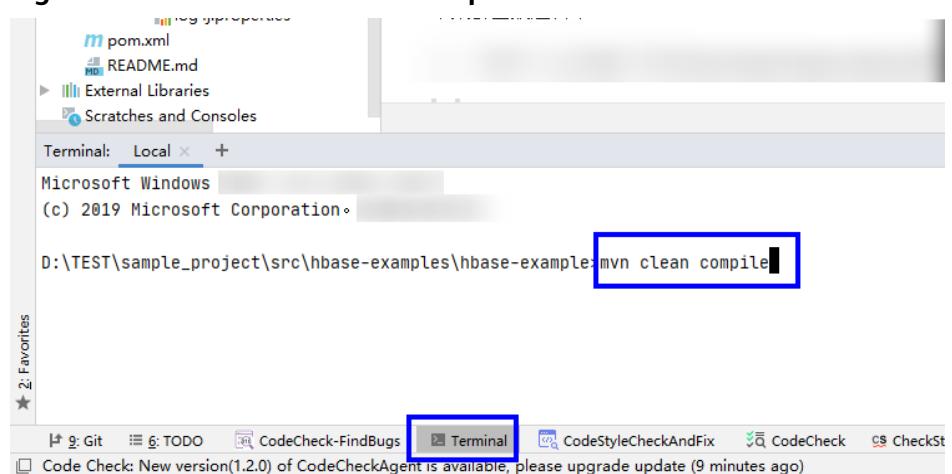

Figure 2-126 clean and compile tools of Maven

- Method 2:

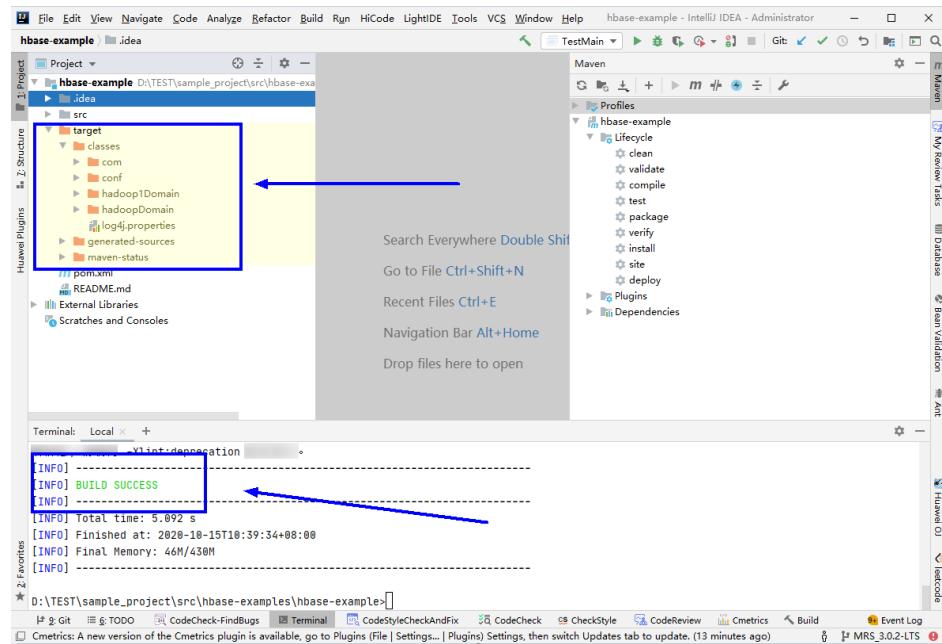

Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean compile** command to compile the **pom.xml** file.

Figure 2-127 Enter **mvn clean compile** in the IDEA Terminal text box.

2. After the compilation is complete, the message "Build Success" is displayed and the **target** directory is generated.

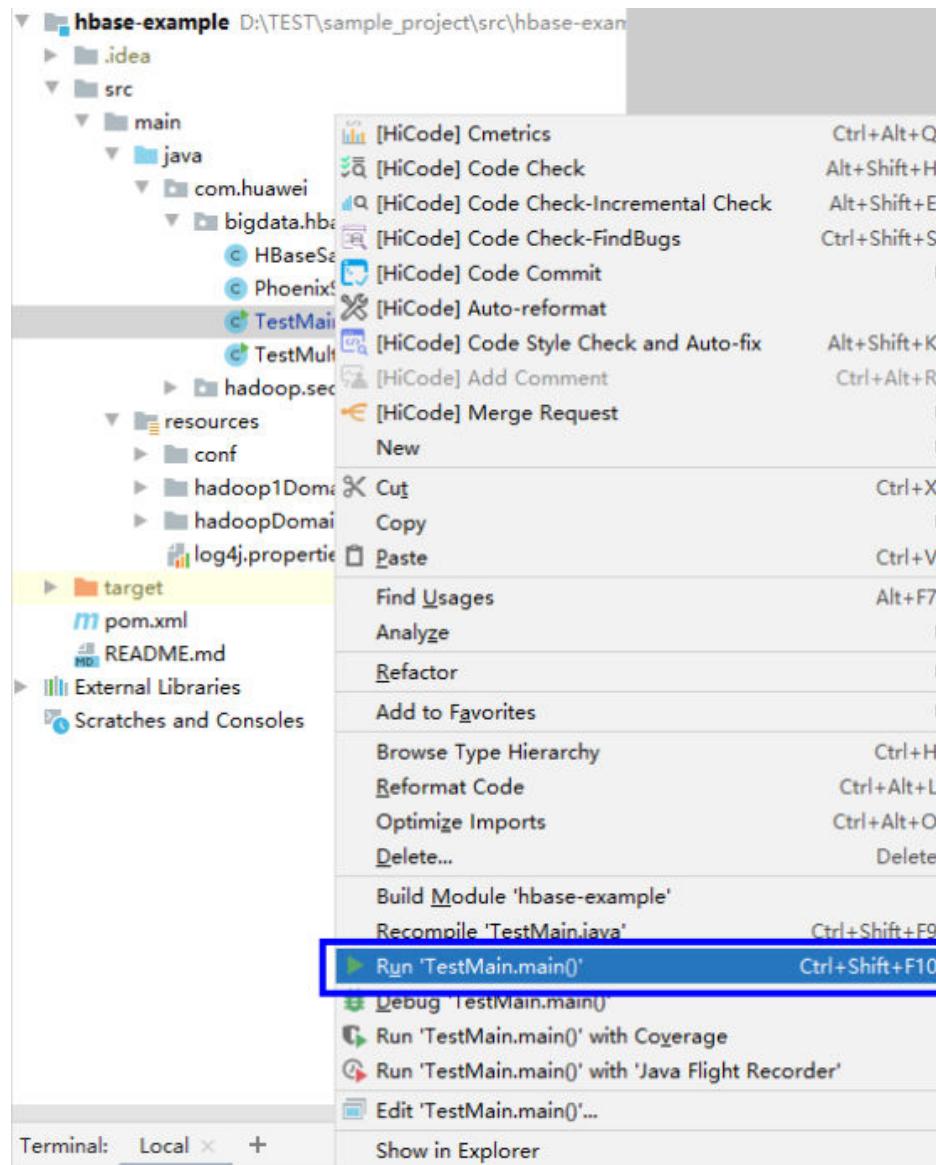

Figure 2-128 Compilation completed

3. Run the program.

Right-click the **TestMain.java** file and choose **Run'TestMain.main()** from the shortcut menu.

Figure 2-129 Run the application.

----End

#### 2.6.4.1.2 Viewing Windows Commissioning Results

##### Scenario

After an HBase application is run, you can check the running result through one of the following methods:

- Viewing the IntelliJ IDEA running result.
- Viewing HBase logs.
- Logging in to the HBase WebUI, see **More Information > External Interfaces > WebUI**.
- Using HBase Shell command, see **More Information > External Interfaces > Shell**.

## Procedure

- After the **hbase-sample** is successfully executed, the following information is displayed:

```
2016-07-13 14:36:12,736 INFO [main] basic.CreateTableSample: Create table sampleNameSpace:sampleTable successful!
2016-07-13 14:36:15,426 INFO [main] basic.ModifyTableSample: Modify table sampleNameSpace:sampleTable successfully.
2016-07-13 14:36:16,708 INFO [main] basic.MultiSplitSample: Mmulti split table sampleNameSpace:sampleTable successfully.
2016-07-13 14:36:17,299 INFO [main] basic.PutDataSample: Successfully put 9 items data into sampleNameSpace:sampleTable.
2016-07-13 14:36:18,992 INFO [main] basic.ScanSample: Scan data successfully.
2016-07-13 14:36:20,532 INFO [main] basic.DeleteDataSample: Successfully delete data from table sampleNameSpace:sampleTable.
2016-07-13 14:36:21,006 INFO [main] acl.AclSample: Grant ACL for table sampleNameSpace:sampleTable successfully.
2016-07-13 14:36:27,836 INFO [main] index.CreateIndexSample: Successfully add index for table sampleNameSpace:sampleTable.
```

### NOTE

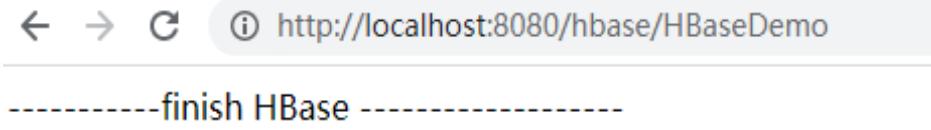

In the Windows environment, the following exception occurs but does not affect services.

`java.io.IOException: Could not locate executable null\bin\winutils.exe in the Hadoop binaries.`

- Result of interconnecting HBase/Phoenix with SpringBoot:

Open a browser and access **http://IP address of the sample running node:8080/hbase/HBaseDemo** and **http://IP address of the sample running node:8080/hbase/PhoenixDemo**. IDEA prints logs normally, and "finish HBase" and "finish Phoenix" are returned.

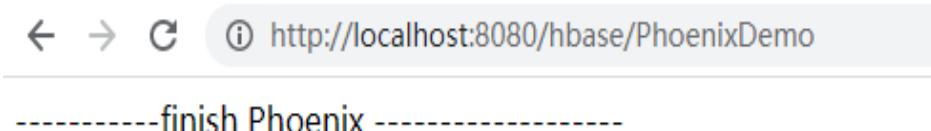

**Figure 2-130** "finish HBase" displayed

← → ⌂ ⓘ <http://localhost:8080/hbase/HBaseDemo>

-----finish HBase-----

**Figure 2-131** "finish Phoenix" returned

← → ⌂ ⓘ <http://localhost:8080/hbase/PhoenixDemo>

-----finish Phoenix-----

- Log description

The log level is **INFO** by default and more detailed information can be viewed by changing the log level (**DEBUG**, **INFO**, **WARN**, **ERROR**, and **FATL**). You can modify the **log4j.properties** file to change log levels, for example:

```
hbase.root.logger=INFO,console
...
log4j.logger.org.apache.zookeeper=INFO
#log4j.logger.org.apache.hadoop.fs.FSNamesystem=DEBUG
log4j.logger.org.apache.hadoop.hbase=INFO
# Make these two classes DEBUG-level. Make them DEBUG to see more zk debug.
log4j.logger.org.apache.hadoop.hbase.zookeeper.ZKUtil=INFO
```

```
log4j.logger.org.apache.hadoop.hbase.zookeeper.ZooKeeperWatcher=INFO  
...
```

## 2.6.4.2 Commissioning an Application in Linux

### 2.6.4.2.1 Compiling and Running an Application When a Client Is Installed

#### Scenario

In a Linux environment where an HBase client is installed, you can upload the JAR package to the Linux and then run an application after the code development is complete.

#### Prerequisites

- You have installed the HBase client.
- If the host where the client is installed is not a node in the cluster, set the mapping between the host name and the IP address in the **hosts** file on the node where the client locates. The host name and IP address must be in one-to-one mapping.
- The JDK has been installed and Java environment variables have been correctly configured before Windows commissioning and compilation.

#### Procedure

##### Step 1 Export a JAR package.

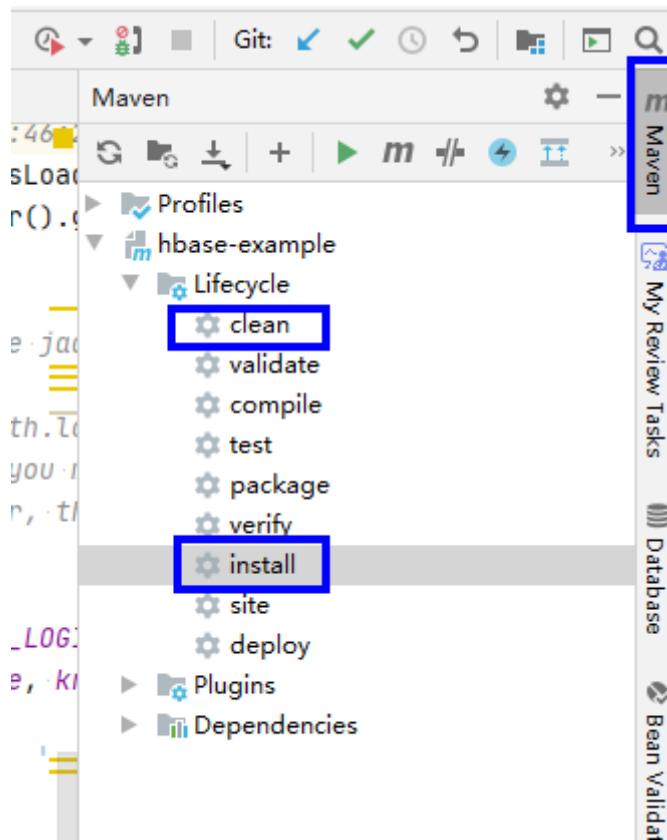

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven** > *Sample projectname* > **Lifecycle** > **clean**, double click **clean** to run the **clean** command of Maven.

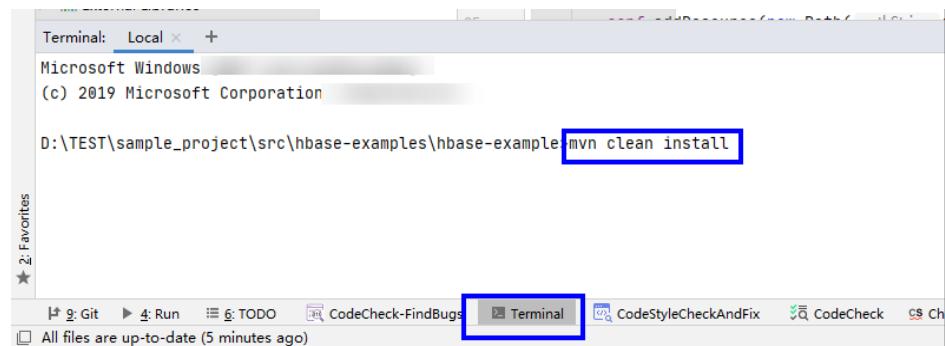

Choose **Maven** > *Sample project name* > **Lifecycle** > **install**, double click **install** to run the **install** command of Maven.

Figure 2-132 Maven tools: clean and install

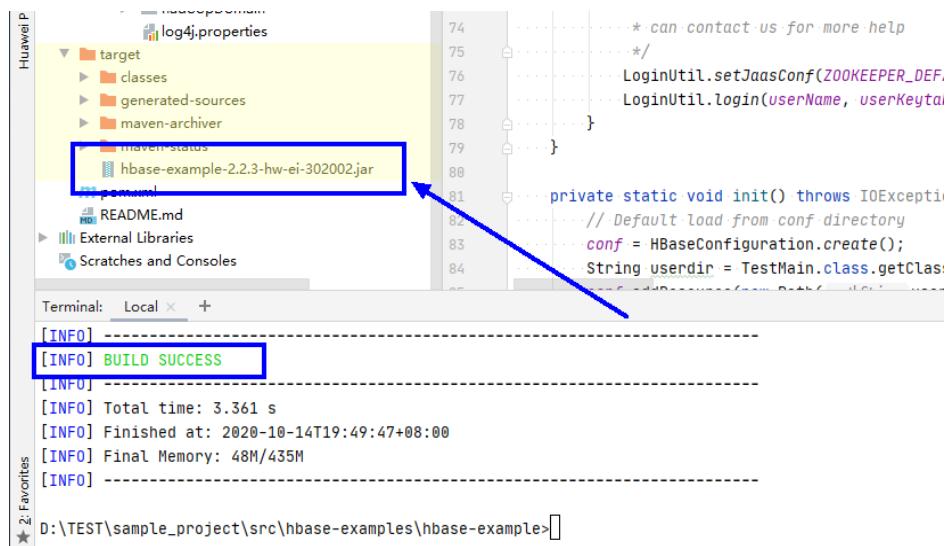

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean install** command to compile the **pom.xml** file.

Figure 2-133 Enter mvn clean compile in the IDEA Terminal text box.

After the compilation is completed, the message "Build Success" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

Figure 2-134 When the compilation is completed, the JAR file is generated.

**Step 2** Example of whether to run HBase/Phoenix to interconnect with SpringBoot:

- If yes, perform the following steps to run the sample:
  - a. Create a running directory in the Linux environment and place **hbase-springboot-\*.jar** in the target directory to the directory. Upload the configuration file to the corresponding path specified in [Step 1](#).
  - b. Switch to the running directory and run the following command to run the JAR package:  
**java -jar hbase-springboot-\*.jar**
- If no, go to [Step 3](#).

**Step 3** Export the JAR file on which the sample project depends.

Access the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of IDEA or by using other command line tools.

Run the command **mvn dependency:copy-dependencies -DoutputDirectory=lib**.

The **lib** folder is generated in the directory where the **pom.xml** file is located. The **lib** folder contains the JAR files on which the sample project depends.

**Step 4** Run the JAR package.

1. Before running the JAR package on the Linux client, run the following command to go to the client directory:

**cd \$BIGDATA\_CLIENT\_HOME**

**NOTE**

**\$BIGDATA\_CLIENT\_HOME** is the installation directory of the HBase client.

2. Then run the following command:

**source bigdata\_env**

 NOTE

After the multi-instance function is enabled, run the following command to switch to the client of the specified service instance before performing application development for the HBase service instance.

For example, for HBase2, run the `source /opt/hadoopclient/HBase2/component_env` command.

3. Upload the JAR file (non-dependent JAR file) of the sample project generated in the application development environment to the *Client installation directory/HBase/hbase/lib* directory in the client running environment. If the HBase dual-read sample needs to be executed, Upload the hbase-dualclient JAR package exported in [Step 3](#) to the directory. In addition, you need to copy the configuration file required by the example project obtained from [Preparing the Connection Cluster Configuration File](#) to the *client installation directory/HBase/hbase/conf* directory.
4. Go to the `$BIGDATA_CLIENT_HOME/HBase/hbase` directory and run the following command to run the JAR package. The task is complete.  
`hbase com.huawei.bigdata.hbase.examples.TestMain`  
In the preceding command, `hbase com.huawei.bigdata.hbase.examples.TestMain` is used as an example.

----End

#### 2.6.4.2.2 Compiling and Running an Application When No Client Is Installed

##### Scenario

In a Linux environment where no HBase client is installed, you can upload the JAR package to the Linux and then run an application after the code development is complete.

##### Prerequisites

- A JDK has been installed in the Linux environment. The version of the JDK must be consistent with that of the JDK used by the JAR package exported by IntelliJ IDEA.
- If the Linux host is not a node in the cluster, set the mapping between the host name and the IP address in the `hosts` file on the node. The host name and IP address must be in one-to-one mapping.

##### Procedure

**Step 1** Export a JAR package. For details, see [Step 1](#) in section [Compiling and Running an Application When a Client Is Installed](#).

**Step 2** Example of whether to run HBase/Phoenix to interconnect with SpringBoot:

- If yes, perform the following steps to run the sample:
  - a. Create a running directory in the Linux environment and place `hbase-springboot-*jar` in the target directory to the directory. Upload the configuration file to the corresponding path specified in [Step 1](#).
  - b. Switch to the running directory and run the following command to run the JAR package:

**java -jar hbase-springboot-\*jar**

- If no, go to [Step 3](#).

**Step 3** Prepare for the required JAR packages and configuration files.

1. In the Linux environment, create a directory, for example, **/opt/test**, and create subdirectories **lib** and **conf**. Export the JAR package that the sample project depends on. For details about how to export the JAR package, see [Step 3 in 1.4.2.1 Compiling and Running an Application When a Client Is Installed](#). Upload this JAR file and that exported in [Step 1](#) to the **lib** directory on the Linux server. Upload the configuration file obtained in section [Preparing the Connection Cluster Configuration File](#) to the **conf** directory on Linux.
2. In **/opt/test**, create the **run.sh** script, modify the following content, and save the file:

```
#!/bin/sh  
BASEDIR=`cd $(dirname $0);pwd`  
cd ${BASEDIR}  
for file in ${BASEDIR}/lib/*.jar  
do  
i_cp=$i_cp:$file  
echo "$file"  
done  
for file in ${BASEDIR}/conf/*  
do  
i_cp=$i_cp:$file  
done  
  
java -cp .${i_cp} com.huawei.bigdata.hbase.examples.TestMain
```

**Step 4** Go to **/opt/test** and run the following commands to run the JAR packages:

**sh run.sh**

----End

### 2.6.4.2.3 Viewing Linux Commissioning Results

#### Scenario

After an HBase application is run, you can check the running result through one of the following methods:

- Viewing the command output.
- Viewing HBase logs.
- Logging in to the HBase WebUI, see [More Information > External Interfaces > WebUI](#).
- Using HBase Shell command, see [More Information > External Interfaces > Shell](#).

#### Procedure

- You can view the execution details of the submitted application in the run logs. For example, after the **hbase-sample** is successfully executed, the following information is displayed:

```
2020-07-13 14:36:12,736 INFO [main] basic.CreateTableSample: Create table
```

```
sampleNameSpace:sampleTable successful!
```

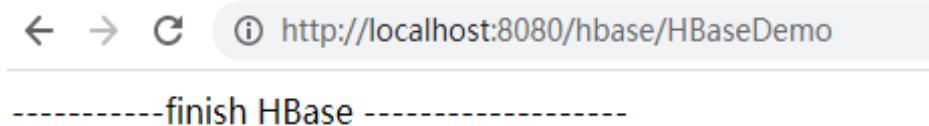

```
2020-07-13 14:36:15,426 INFO [main] basic.ModifyTableSample: Modify table
```

```
sampleNameSpace:sampleTable successfully.  
2020-07-13 14:36:16,708 INFO [main] basic.MultiSplitSample: Mmulti split table  
sampleNameSpace:sampleTable successfully.  
2020-07-13 14:36:17,299 INFO [main] basic.PutDataSample: Successfully put 9 items data into  
sampleNameSpace:sampleTable.  
2020-07-13 14:36:18,992 INFO [main] basic.ScanSample: Scan data successfully.  
2020-07-13 14:36:20,532 INFO [main] basic.DeleteDataSample: Successfully delete data from table  
sampleNameSpace:sampleTable.  
2020-07-13 14:36:21,006 INFO [main] acl.AclSample: Grant ACL for table  
sampleNameSpace:sampleTable successfully.  
2020-07-13 14:36:27,836 INFO [main] index.CreateIndexSample: Successfully add index for table  
sampleNameSpace:sampleTable.
```

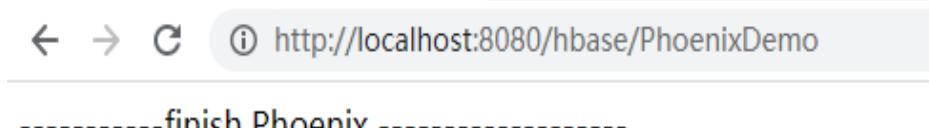

- Result of interconnecting HBase/Phoenix with SpringBoot:

Open a browser and access **http://IP address of the sample running node:8080/hbase/HBaseDemo** and **http://IP address of the sample running node:8080/hbase/PhoenixDemo**. IDEA prints logs normally, and "finish HBase" and "finish Phoenix" are returned.

**Figure 2-135 "finish HBase" displayed**

**Figure 2-136 "finish Phoenix" returned**

## 2.6.5 More Information

### 2.6.5.1 SQL Query

#### Function

Phoenix is an intermediate structured query language (SQL) layer built on HBase. Phoenix provides a JDBC driver that can be embedded in a client. The Phoenix query engine converts input SQL statements to one or multiple HBase scans, and compiles and executes the scan tasks to generate a standard JDBC result set.

#### Example Code

- The **hbase-example/conf/hbase-site.xml** file on the client is used to configure the temporary directory for storing query results. If the client program configures the temporary directory in a Linux environment, configure a Linux path. If the client program configures the temporary directory in a Windows environment, configure a Windows path.

```
<property>  
  <name>phoenix.spool.directory</name>
```

```
<value>[1] Temporary directory for storing intermediate query results</value>
</property>
```

- JAVA Example: Use the JDBC interface to access HBase.

```
public String getURL(Configuration conf)
{
    String phoenix_jdbc = "jdbc:phoenix";
    String zkQuorum = conf.get("hbase.zookeeper.quorum");
    return phoenix_jdbc + ":" + zkQuorum;
}

public void testSQL()
{
    String tableName = "TEST";
    // Create table
    String createTableSQL = "CREATE TABLE IF NOT EXISTS TEST(id integer not null primary key,
name varchar, account char(6), birth date)";

    // Delete table
    String dropTableSQL = "DROP TABLE TEST";

    // Insert
    String upsertSQL = "UPSERT INTO TEST VALUES(1,'John','100000',
TO_DATE('1980-01-01','yyyy-MM-dd'))";

    // Query
    String querySQL = "SELECT * FROM TEST WHERE id = ?";

    // Create the Configuration instance
    Configuration conf = getConfiguration();

    // Get URL
    String URL = getURL(conf);

    Connection conn = null;
    PreparedStatement preStat = null;
    Statement stat = null;
    ResultSet result = null;

    try
    {
        // Create Connection
        conn = DriverManager.getConnection(URL);
        // Create Statement
        stat = conn.createStatement();
        // Execute Create SQL
        stat.executeUpdate(createTableSQL);
        // Execute Update SQL
        stat.executeUpdate(upsertSQL);
        // Create PrepareStatement
        preStat = conn.prepareStatement(querySQL);
        conn.commit();
        // Execute query
        preStat.setInt(1,1);
        result = preStat.executeQuery();
        // Get result
        while (result.next())
        {
            int id = result.getInt("id");
            String name = result.getString(1);
        }
    }
    catch (Exception e)
    {
        // handler exception
    }
    finally
    {
        if(null != result){
            try {
```

```
        result.close();
    } catch (Exception e2) {
        // handler exception
    }
}
if(null != stat){
    try {
        stat.close();
    } catch (Exception e2) {
        // handler exception
    }
}
if(null != conn){
    try {
        conn.close();
    } catch (Exception e2) {
        // handler exception
    }
}
}
```

## Precaution

- You need to configure a temporary directory for storing intermediate query results in **hbase-site.xml**. The size of the query result set is restricted by the directory size.
- Phoenix provides most **java.sql** interfaces and follows the ANSI SQL standard.

### 2.6.5.2 HBase Dual-Read Configuration Items

This section provides the details of all the configurations required for the HBase dual-read feature.

## HBase Dual-Read Operations

**Table 2-70** Configuration items in hbase-dual.xml

Configuration Item	Description	Default Value	Level
hbase.dualclient.active.cluster.configuration.path	HBase client configuration directory of the active cluster	None	Mandatory
hbase.dualclient.standby.cluster.configuration.path	HBase client configuration directory of the standby cluster	None	Mandatory
dual.client.schedule.update.table.delay.second	DR table update interval	5	Optional

Configuration Item	Description	Default Value	Level
hbase.dualclient.gitchtimeout.ms	Maximum glitch time can be tolerated in the active cluster	50	Optional
hbase.dualclient.slow.query.timeout.ms	Slow query alarm log	180000	Optional
hbase.dualclient.active.cluster.id	Active cluster ID	ACTIVE	Optional
hbase.dualclient.standby.cluster.id	Standby cluster ID	STANDBY	Optional
hbase.dualclient.active.executor.threads.max	Maximum size of the thread pool for processing requests to the active cluster	100	Optional
hbase.dualclient.active.executor.threads.core	Core size of the thread pool for processing requests to the active cluster	100	Optional
hbase.dualclient.active.executor.queue	Queue size of the thread pool for processing requests to the active cluster	256	Optional
hbase.dualclient.standby.executor.threads.max	Maximum size of the thread pool for processing requests to the standby cluster	100	Optional
hbase.dualclient.standby.executor.threads.core	Core size of the thread pool for processing requests to the standby cluster	100	Optional
hbase.dualclient.standby.executor.queue	Queue size of the thread pool for processing requests to the standby cluster	256	Optional

Configuration Item	Description	Default Value	Level
hbase.dualclient.clear.executor.threads.max	Maximum size of the thread pool for clearing resources	30	Optional
hbase.dualclient.clear.executor.threads.core	Core size of the thread pool for clearing resources	30	Optional
hbase.dualclient.clear.executor.queue	Queue size of the thread pool for clearing resources	Integer.MAX_VALUE	Optional
dual.client.metrics.enable	Whether to print client metric information	true	Optional
dual.client.schedule.metrics.second	Interval for printing client metric information	300	Optional
dual.client.asynchronous.enable	Whether to asynchronously request the active and standby clusters	false	Optional

## Printing Metric Information

**Table 2-71** Basic specifications

Metric Name	Description	Log level
total_request_count	Total number of queries in a period	INFO
active_success_count	Number of successful queries in the active cluster in a period	INFO
active_error_count	Number of failed queries in the active cluster in a period	INFO
active_timeout_count	Number of query timeouts in the active cluster in a period	INFO

Metric Name	Description	Log level
standby_success_count	Number of successful queries in the standby cluster in a period	INFO
standby_error_count	Number of failed queries in the standby cluster in a period	INFO
Active Thread pool	Periodically printed information about the thread pool for processing requests to the active cluster	DEBUG
Standby Thread pool	Periodically printed information about the thread pool for processing requests to the standby cluster	DEBUG
Clear Thread pool	Periodically printed information about the thread pool for releasing resources	DEBUG

**Table 2-72 Histogram indicators for GET, BatchGET, and SCAN requests**

Metric Name	Description	Log level
averageLatency(ms)	Average latency	INFO
minLatency(ms)	Minimum latency	INFO
maxLatency(ms)	Maximum latency	INFO
95thPercentileLatency(ms)	Maximum latency of 95% requests	INFO
99thPercentileLatency(ms)	Maximum latency of 99% requests	INFO
99.9PercentileLatency(ms)	Maximum latency of 99.9% requests	INFO
99.99PercentileLatency(ms)	Maximum latency of 99.99% requests	INFO

### 2.6.5.3 External Interfaces

### 2.6.5.3.1 Shell

You can directly perform operations on HBase using Shell on the server. Versions of Shell interfaces of HBase need to be consistent with those in the open-source community. For details, see <http://learnhbase.wordpress.com/2013/03/02/hbase-shell-commands/>.

Methods of running the Shell command:

Go to any directory on the HBase client and run the following command:

**hbase shell**

Go to the running mode of the HBase command (also called CLI client connection).

```
hbase(main):001:0>
```

Run the **help** command to obtain the help information of the HBase command parameters.

## Precautions

The **count** command does not support conditional statistics. It supports only full table statistics.

## Command to retrieve HBase replication metrics

All the required metrics will be added for the shell command "status".

- Command to view replication source metrics.

```
hbase(main):019:0> status 'replication', 'source'
```

The output is as follows:

```
version 2.4.14
1 live servers
BLR1000006595:
SOURCE: PeerID=1, SizeOfLogQueue=0, ShippedBatches=0, ShippedOps=0, ShippedBytes=0,
LogReadInBytes=1389, LogEditsRead=4, LogEditsFiltered=4, SizeOfLogToReplicate=0,
TimeForLogToReplicate=0, ShippedHFiles=0, SizeOfHFileRefsQueue=0, AgeOfLastShippedOp=0,
TimeStampsOfLastShippedOp=Wed May 25 20:44:42 CST 2016, Replication Lag=0 PeerID=3,
SizeOfLogQueue=0, ShippedBatches=0, ShippedOps=0, ShippedBytes=0, LogReadInBytes=1389,
LogEditsRead=4, LogEditsFiltered=4, SizeOfLogToReplicate=0,
TimeForLogToReplicate=0, ShippedHFiles=0, SizeOfHFileRefsQueue=0, AgeOfLastShippedOp=0,
TimeStampsOfLastShippedOp=Wed May 25 20:44:42 CST 2016, Replication Lag=0,
FailedReplicationAttempts=0
```

- Command to view replication sink metrics.

```
hbase(main):020:0> status 'replication', 'sink'
```

The output is as follows:

```
version 2.4.14
1 live servers
BLR1000006595:
SINK : AppliedBatches=0, AppliedOps=0, AppliedHFiles=0, AgeOfLastAppliedOp=0,
TimeStampsOfLastAppliedOp=Wed May 25 17:55:21 CST 2016
```

- Command to view both replication source and replication sink metrics.

```
hbase(main):018:0> status 'replication'
```

The output is as follows:

```
version 2.4.14
1 live servers
```

```
BLR1000006595:  
SOURCE: PeerID=1, SizeOfLogQueue=0, ShippedBatches=0, ShippedOps=0, ShippedBytes=0,  
LogReadInBytes=1389, LogEditsRead=4, LogEditsFiltered=4, SizeOfLogToReplicate=0,  
TimeForLogToReplicate=0, ShippedHFiles=0, SizeOfHFileRefsQueue=0, AgeOfLastShippedOp=0,  
TimeStampsOfLastShippedOp=Wed May 25 20:43:24 CST 2016, Replication Lag=0 PeerID=3,  
SizeOfLogQueue=0, ShippedBatches=0, ShippedOps=0, ShippedBytes=0, LogReadInBytes=1389,  
LogEditsRead=4, LogEditsFiltered=4, SizeOfLogToReplicate=0,  
TimeForLogToReplicate=0, ShippedHFiles=0, SizeOfHFileRefsQueue=0, AgeOfLastShippedOp=0,  
TimeStampsOfLastShippedOp=Wed May 25 20:43:24 CST 2016, Replication Lag=0,  
FailedReplicationAttempts=0  
SINK : AppliedBatches=0, AppliedOps=0, AppliedHFiles=0, AgeOfLastAppliedOp=0,  
TimeStampsOfLastAppliedOp=Wed May 25 17:55:21 CST 2016
```

### 2.6.5.3.2 Java APIs

For details about HBase APIs, see *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

### API Usage Suggestions

- org.apache.hadoop.hbase.Cell rather than org.apache.hadoop.hbase.KeyValue is recommended as the KV data object.
- It is recommended that Connection connection = ConnectionFactory.createConnection(conf) be used to create a connection. The HTablePool is abandoned.
- org.apache.hadoop.hbase.mapreduce rather than org.apache.hadoop.hbase.mapred is recommended.
- You are advised to obtain the HBase client operation object using the getAdmin() method of the constructed Connection object.

### Common HBase APIs

Common HBase Java classes are as follows:

- Interface class Admin: It is the core class of HBase client applications, which encapsulates APIs for HBase management, such as table creation and table deletion. For details, see [Table 2-73](#).
- Interface class Table: It is a class for HBase read/write, which encapsulates APIs for reading and writing HBase tables. For details, see [Table 2-74](#).

**Table 2-73** org.apache.hadoop.hbase.client.Admin

Method	Description
boolean tableExists(final TableName tableName)	This method is used to check whether a specified table exists. If the table exists in the <b>hbase:meta</b> table, <b>true</b> is returned. Otherwise, <b>false</b> is returned.

Method	Description
HTableDescriptor[] listTables(String regex)	This method is used to view the user table that complies with the specified regular expression format. There are two other overload methods, one with the input parameter type of Pattern, and the other with the empty input parameter. When the input parameter is empty, all user tables are queried by default.
HTableDescriptor[] listTables(final Pattern pattern, final boolean includeSysTables)	The function of this method is similar to that of the previous method. Users can use this method to specify whether the returned result contains the system table. The previous method returns only the user table.
TableName[] listTableNames(String regex)	This method is used to view the user table that complies with the specified regular expression format. There are two other overload methods, one with the input parameter type of Pattern, and the other with the empty input parameter. When the input parameter is empty, all user tables are queried by default. The function of this method is similar to that of listTables. The only difference is that this method returns TableName[].
TableName[] listTableNames(final Pattern pattern, final boolean includeSysTables)	The function of this method is similar to that of the previous method. Users can use this method to specify whether the returned result contains the system table. The previous method returns only the user table.
void createTable(HTableDescriptor desc)	This method is used to create a table with only one region.
void createTable(HTableDescriptor desc, byte[] startKey, byte[] endKey, int numRegions)	This method is used to create a table with a specified number of regions. The endKey of the first region is the StartKey, and the StartKey of the last region is the endKey. If there are a large number of regions, the invoking of this method may time out.

Method	Description
void createTable(final HTableDescriptor desc, byte[][] splitKeys)	This method is used to create a table. The number of regions in the table and the StartKey of each region are determined by splitKeys. If there are a large number of regions, the invoking of this method may time out.
void createTable(final HTableDescriptor desc, final byte[][] splitKeys)	This method is used to create a table. The number of regions in the table and the StartKey of each region are determined by splitKeys. This method uses asynchronous invoking, and does not wait for the created table to be online.
void deleteTable(final TableName tableName)	This method is used to delete a specified table.
public void truncateTable(final TableName tableName, final boolean preserveSplits)	This method is used to re-create a specified table. If the second parameter is set to <b>true</b> , the region of the reconstructed table is the same as that of the previous table. Otherwise, there is only one region.
void enableTable(final TableName tableName)	This method is used to enable a specified table. If there are a large number of regions in a table, the invoking of this method may time out.
void enableTableAsync(final TableName tableName)	This method is used to enable a specified table. This method uses asynchronous invoking, and does not wait for all regions to be online.
void disableTable(final TableName tableName)	This method is used to disable a specified table. If there are a large number of regions in a table, the invoking of this method may time out.
void disableTableAsync(final TableName tableName)	This method is used to disable a specified table. This method uses asynchronous invoking, and does not wait for all regions to be offline.
boolean isTableEnabled(TableName tableName)	This method is used to check whether a table is enabled. This method can be used with the enableTableAsync method to check whether the operation of enabling a table is complete.

Method	Description
boolean isTableDisabled(TableName tableName)	This method is used to check whether a table is disabled. This method can be used with the disableTableAsync method to check whether the operation of disabling a table is complete.
void addColumn(final TableName tableName, final HColumnDescriptor column)	This method is used to add a column family to a specified table.
void deleteColumn(final TableName tableName, final HColumnDescriptor column)	This method is used to delete a specified column family from a specified table.
void modifyColumn(final TableName tableName, final HColumnDescriptor column)	This method is used to modify a specified column family.

**Table 2-74** org.apache.hadoop.hbase.client.Table

Method	Description
boolean exists(Get get)	This method is used to check whether the specified rowkey exists in the table.
boolean[] existsAll(List<Get> gets)	This method is used to check whether the specified rowkey exists in the table. The returned Boolean array result corresponds to the input parameter position.
Result get(Get get)	This method is used to read data based on the specified RowKey.
Result[] get(List<Get> gets)	This method is used to read data in batches by specifying a batch of RowKeys.
ResultScanner getScanner(Scan scan)	This method is used to obtain a scanner object in the table. The query parameters can be specified by the input parameter scan, including <b>StartRow</b> , <b>StopRow</b> , and <b>caching</b> .
void put(Put put)	This method is used to write a data record to the table.
void put(List<Put> puts)	This method is used to write a batch of data records to the table.

Method	Description
void close()	This method is used to release the resources held by the table object.

 NOTE

[Table 2-73](#) and [Table 2-74](#) list only some common methods. For more methods, see *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

### 2.6.5.3.3 SQLLine

You can run `sqlline.py` on the client to perform SQL operations on HBase. The SQLLine APIs of Phoenix are the same as those of the open-source community. For details, see <http://phoenix.apache.org/>.

[Table 2-75](#) lists common SQLline syntax, [Table 2-76](#) lists common functions, and [Phoenix Command Line](#) describes how to use commands.

**Table 2-75** Common syntax

Command	Description	Example
<b>CREATE TABLE</b>	Creates a table.	CREATE TABLE MY_TABLE(id BIGINT not null primary key, name VARCHAR);
<b>ALTER</b>	Alters a table or a view.	ALTER TABLE MY_TABLE DROP COLUMN name;
<b>DROP TABLE</b>	Deletes a table.	DROP TABLE MY_TABLE;
<b>UPSERT VALUES</b>	Inserts or changes data.	UPSERT INTO MY_TABLE VALUES(1,'abc');
<b>SELECT</b>	Queries data.	SELECT * FROM MY_TABLE;
<b>CREATE INDEX</b>	Creates a global index.	CREATE INDEX MY_IDX ON MY_TABLE(name);
<b>CREATE LOCAL INDEX</b>	Creates a local index.	CREATE LOCAL INDEX MY_LOCAL_IDX ON MY_TABLE(id,name);
<b>ALTER INDEX</b>	Changes the index status.	ALTER INDEX MY_IDX ON MY_TABLE DISABLE;
<b>DROP INDEX</b>	Deletes an index.	DROP INDEX MY_IDX ON MY_TABLE;
<b>EXPLAIN</b>	Displays an execution plan.	EXPLAIN SELECT name FROM MY_TABLE;
<b>CREATE SEQUENCE</b>	Creates a sequence.	CREATE SEQUENCE MY_SEQUENCE;

Command	Description	Example
<b>DROP SEQUENCE</b>	Deletes a sequence.	DROP SEQUENCE MY_SEQUENCE;
<b>CREATE VIEW</b>	Creates a view.	CREATE VIEW MY_VIEW AS SELECT * FROM MY_TABLE;
<b>DROP VIEW</b>	Deletes a view.	DROP VIEW MY_VIEW;
<b>CREATE SCHEMA</b>	Creates a schema.	CREATE SCHEMA MY_SCHEMA;
<b>USE</b>	Modifies the default schema.	USE MY_SCHEMA;
<b>DROP SCHEMA</b>	Deletes a schema.	DROP SCHEMA MY_SCHEMA;

**Table 2-76** Common functions

Function Type	Function	Description	Example
String functions	<b>SUBSTR</b>	Extracts a part of a string.	SUBSTR('[Hello]', 2, 5)
	<b>INSTR</b>	Queries the position of the first occurrence of a string in another string.	INSTR('Hello World', 'World')
	<b>TRIM</b>	Removes whitespaces from both ends of a string.	TRIM(' Hello ')
	<b>LTRIM</b>	Removes whitespaces found on the left-hand side of the string.	LTRIM(' Hello')
	<b>RTRIM</b>	Removes whitespaces found on the right-hand side of the string.	RTRIM('Hello ')
	<b>LPAD</b>	Left-pads a string with another string.	LPAD('John',30,'*')

Function Type	Function	Description	Example
	<b>LENGTH</b>	Gets the length of a given string.	LENGTH('Hello')
	<b>UPPER</b>	Converts all the characters in a string to uppercase characters.	UPPER('Hello')
	<b>LOWER</b>	Converts all the characters in a string to lowercase characters.	LOWER('HELLO')
	<b>REVERSE</b>	Reverses a string.	REVERSE('Hello')
	<b>REGEXP_SPLIT</b>	Splits a string using a regular expression.	REGEXP_SPLIT('ONE,TWO,THREE', ',')
	<b>REGEXP_REPLACE</b>	Returns a string by applying a regular expression and replacing the matches with the replacement string.	REGEXP_REPLACE('abc123ABC', '[0-9]+', '#')
	<b>REGEXP_SUBSTR</b>	Returns a substring from a string based on a regular expression pattern.	REGEXP_SUBSTR('na1-appsrv35-sj35', '[-]+')
Aggregate functions	<b>AVG</b>	Gets the average value.	AVG(X)
	<b>COUNT</b>	Gets the number of data records.	COUNT(*)
	<b>MAX</b>	Gets the maximum value.	MAX(NAME)
	<b>MIN</b>	Gets the minimum value.	MIN(NAME)
	<b>SUM</b>	Gets the sum of all values.	SUM(X)

Function Type	Function	Description	Example
	<b>STDDEV_POP</b>	Gets the population standard deviation of all values.	STDDEV_POP( X )
	<b>STDDEV_SAMP</b>	Gets the sample standard deviation of all values.	STDDEV_SAMP( X )
	<b>NTH_VALUE</b>	Gets the Nth value in each distinct group ordered according to the <b>ORDER BY</b> specification.	NTH_VALUE( name, 2 ) WITHIN GROUP ( ORDER BY salary DESC )
Time and date functions	<b>NOW</b>	Returns the current date.	NOW()
	<b>CURRENT_TIME</b>	Returns the current time.	CURRENT_TIME()
	<b>CURRENT_DATE</b>	Returns the current date.	CURRENT_DATE()
	<b>TO_DATE</b>	Parses a string and returns a date.	TO_DATE('1970-01-01', 'yyyy-MM-dd', 'GMT+1')
	<b>TO_TIME</b>	Converts the given string into a <b>TIME</b> instance.	TO_TIME('1970-01-01', 'yyyy-MM-dd', 'GMT+1')
	<b>TO_TIMESTAMP</b>	Converts the given string into a <b>TIMESTAMP</b> instance.	TO_TIMESTAMP('1970-01-01', 'yyyy-MM-dd', 'GMT+1')
	<b>YEAR</b>	Returns the year of the specified date.	YEAR(TO_DATE('2015-6-05'))
	<b>MONTH</b>	Returns the month of the specified date.	MONTH(TO_TIMESTAMP('2015-6-05'))
	<b>WEEK</b>	Returns the week of the specified date.	WEEK(TO_TIME('2010-6-15'))

Function Type	Function	Description	Example
	<b>HOUR</b>	Returns the hour of the specified date.	HOUR(TO_TIMESTAMP('2015-6-05'))
	<b>MINUTE</b>	Returns the minute of the specified date.	MINUTE(TO_TIME('2015-6-05'))
	<b>SECOND</b>	Returns the second of the specified date.	SECOND(TO_DATE('2015-6-05'))
Numeric functions	<b>ROUND</b>	Rounds the numeric or timestamp expression to the nearest scale or time unit specified.	ROUND(2.56)
	<b>CEIL</b>	Rounds any fractional value up to the next even multiple.	CEIL(2.34)
	<b>FLOOR</b>	Rounds any fractional value down to the previous even multiple.	FLOOR(2.34)
	<b>TRUNC</b>	Rounds any fractional value down to the previous even multiple (same as <b>FLOOR</b> ).	TRUNC(2.34)
	<b>TO_NUMBER</b>	Formats a string as a number.	TO_NUMBER('-123.33')
	<b>RAND</b>	Returns a random number.	RAND()
	<b>ABS</b>	Returns the absolute value of the given numeric expression.	ABS(-1)

Function Type	Function	Description	Example
	<b>SQRT</b>	$\sqrt{x}$	SQRT(1.1)
	<b>EXP</b>	$e^x$	EXP(-1)
	<b>POWER</b>	$x^y$	POWER(2, 3)
	<b>LN</b>	$\ln(x)$	LN(3)
	<b>LOG</b>	$\log_x(y)$	LOG(2, 3)
Array functions	<b>ARRAY_ELEM</b>	Uses the array subscript notation to access an array element.	ARRAY_ELEM(ARRAY[1,2,3], 1)
	<b>ARRAY_APPEND</b>	Appends the given element to the beginning of the array.	ARRAY_APPEND(ARRAY[1,2,3], 4)
	<b>ARRAY_CAT</b>	Concatenates the input arrays and returns the result.	ARRAY_CAT(ARRAY[1,2], ARRAY[3,4])
	<b>ARRAY_FILL</b>	Fills an array with values.	ARRAY_FILL(1, 3)
	<b>ARRAY_TO_STRING</b>	Converts the elements of an array to a string and joins them using the specified delimiter.	ARRAY_TO_STRING(ARRAY['a','b','c'], ',')

Function Type	Function	Description	Example
	<b>ANY</b>	Used on the right-hand side of a comparison expression to test that any array element satisfies the comparison expression against the left-hand side.	10 > ANY(my_array)
	<b>ALL</b>	Used on the right-hand side of a comparison expression to test that all array elements satisfy the comparison expression against the left-hand side.	10 > ALL(my_array)
Other functions	<b>MD5</b>	Computes the MD5 hash of the argument.	MD5(my_column)
	<b>ENCODE</b>	Encodes the expression according to the encoding format provided.	ENCODE(myNumber, 'BASE62')
	<b>DECODE</b>	Decodes the expression according to the encoding format provided.	DECODE('000000008512af277fff fff8', 'HEX')

#### 2.6.5.3.4 JDBC APIs

Phoenix implements most **java.sql** interfaces. The SQL syntax follows the ANSI SQL standard.

For details about the functions that are supported, visit:

<http://phoenix.apache.org/language/functions.html>

For details about the syntax that is supported, visit:

<http://phoenix.apache.org/language/index.html>

### 2.6.5.3.5 WebUI

#### Scenario

The web user interface (WebUI) displays the HBase cluster status, including summary of a cluster and information about RegionServer, Master, snapshots, and running processes. You can determine the HBase cluster status based on the information displayed on the WebUI.

##### NOTE

Contact the administrator to obtain a service account that has the permission to access the WebUI and obtain its password.

#### Procedure

1. **Accessing FusionInsight Manager of an MRS Cluster.** Choose **Cluster > Name of the desired cluster > Services > HBase > HMaster(Active)** to open the HBase WebUI.
2. On the home page of the HBase WebUI, view the HBase summary. The following information is included.
  - a. On the **Region Servers** page, view basic information about the RegionServer, as shown in [Figure 2-137](#).

**Figure 2-137** Region Servers

Region Servers			
Base Stats	Memory	Requests	Storefiles
ServerName	Start time	Requests Per Second	Num. Regions
VM-3,21302,1415117599935	Wed Nov 05 00:13:19 CST 2014	0	1
VM-4,21302,1415117602775	Wed Nov 05 00:13:22 CST 2014	0	3
VM-5,21302,1415117607877	Wed Nov 05 00:13:27 CST 2014	0	0
Total:3		0	4

- b. On the **Backup Masters** page, view information about the Backup Master, as shown in [Figure 2-138](#).

**Figure 2-138** Backup Masters

Backup Masters		
ServerName	Port	Start Time
VM-4	21300	Wed Nov 05 00:13:08 CST 2014
Total:1		

- c. On the **Tables** page, view HBase table information, including **User Tables**, **Catalog Tables**, and **Snapshots**, as shown in [Figure 2-139](#).

**Figure 2-139 Tables**

Tables		
User Tables	Catalog Tables	Snapshots
1 table(s) in set. [Details]		
Table Name	Online Regions	Description
t	1	't', {NAME => 'd'}

- d. On the **Tasks** page, view information about tasks running on HBase, including the start time and status, as shown in [Figure 2-140](#).

**Figure 2-140 Tasks**

Tasks				
Show All Monitored Tasks	Show non-RPC Tasks	Show All RPC Handler Tasks	Show Active RPC Calls	Show Client Operations
<a href="#">View as JSON</a>				
Start Time	Description	State	Status	
Wed Nov 05 03:06:35 CST 2014	Closing region availabilityCheck_VM-5_1415127994683.1d82d088fbf4ba672ee2235fd98ae695.	COMPLETE (since 44sec ago)	Closed (since 44sec ago)	
Wed Nov 05 00:20:13 CST 2014	RpcServer.reader=0,port=21300	WAITING (since 2mins, 36sec ago)	Waiting for a call (since 2mins, 36sec ago)	
Wed Nov 05 00:19:49 CST 2014	RpcServer.reader=9,port=21300	WAITING (since 2mins, 53sec ago)	Waiting for a call (since 2mins, 53sec ago)	
Wed Nov 05 00:19:17 CST 2014	RpcServer.reader=8,port=21300	WAITING (since 3mins, 8sec ago)	Waiting for a call (since 3mins, 8sec ago)	
Wed Nov 05 00:15:10 CST 2014	RpcServer.reader=7,port=21300	WAITING (since 3mins, 46sec ago)	Waiting for a call (since 3mins, 46sec ago)	
Wed Nov 05 00:14:52 CST 2014	RpcServer.reader=6,port=21300	WAITING (since 5mins, 2sec ago)	Waiting for a call (since 5mins, 2sec ago)	
Wed Nov 05 00:14:36 CST 2014	RpcServer.reader=5,port=21300	WAITING (since 10sec ago)	Waiting for a call (since 10sec ago)	
Wed Nov 05 00:14:01 CST 2014	RpcServer.reader=4,port=21300	WAITING (since 0sec ago)	Waiting for a call (since 0sec ago)	

3. On the **Table Details** page of the HBase WebUI, view the summary of HBase storage tables, as shown in [Figure 2-141](#).

**Figure 2-141 Table Details**

User Tables	
1 table(s) in set.	
Table	Description

#### 2.6.5.4 Phoenix Command Line

Phoenix supports SQL statements to operate HBase. The following describes how to use SQL statements to create tables, insert data, query data, and delete tables.

#### Prerequisites

The HBase client has been installed. For details, see [Installing a Client](#). For example, the client has been installed in the `/opt/hadoopclient` directory. The client directory in the following operations is only an example. Change it based on the actual installation directory onsite. Before using the client, download and update the client configuration file, and ensure that the active management node of Manager is available.

## Procedure

**Step 1 Optional:** Log in to the node where the client is installed as the client installation user.

Access the HBase client installation directory:

```
cd /opt/hadoopclient
```

**Step 2** Run the following command to configure environment variables:

```
source bigdata_env
```

**Step 3** If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The current user must have the permission to create HBase tables. If Kerberos authentication is disabled for the current cluster, skip this step:

```
kinit MRS cluster user
```

For example, **kinit hbaseuser**.

**Step 4** Running Commands on the Phoenix Client.

```
sqlline.py
```

**Step 5** Create a table:

```
CREATE TABLE TEST (id VARCHAR PRIMARY KEY, name VARCHAR);
```

**Step 6** Insert data:

```
UPSERT INTO TEST(id,name) VALUES ('1','jamee');
```

**Step 7** Query data:

```
SELECT * FROM TEST;
```

**Step 8** Deleting a table:

```
DROP TABLE TEST;
```

**Step 9** Exit the Phoenix CLI:

```
!quit
```

```
----End
```

### 2.6.5.5 FAQs

#### 2.6.5.5.1 How to Rectify the Fault When an Exception Occurs During the Running of an HBase-developed Application and "org.apache.hadoop.hbase.ipc.controller.ServerRpcControllerFactory" Is Displayed in the Error Information?

**Step 1** Check whether the **hbase.rpc.controllerfactory.class** configuration item is included in the **hbase-site.xml** configuration file.

```
<name>hbase.rpc.controllerfactory.class</name>
<value>org.apache.hadoop.hbase.ipc.controller.ServerRpcControllerFactory</value>
```

**Step 2** If this configuration item is included in the current application development project, you need to import the **phoenix-core-\*jar** package. You can obtain this package from **HBase/hbase/lib** in the HBase client installation directory.

**Step 3** If you do not import this JAR package, you need to delete **hbase.rpc.controllerfactory.class** from the **hbase-site.xml** configuration file.

----End

### 2.6.5.5.2 What Are the Application Scenarios of the bulkload and put Data-loading Modes?

#### Question

Both the bulkload and put data-loading modes can be used to load data to HBase. Though the bulkload mode loads data faster than the put mode, the bulkload mode has its own disadvantages. The following describes the application scenarios of these two data-loading modes.

#### Answer

The bulkload starts MapReduce tasks to generate HFile files, and then registers HFile files with HBase. Incorrect use of the bulkload mode will consume more cluster memory and CPU resources due to started MapReduce tasks. The large number of HFile files may frequently trigger Compaction, decreasing the query speed drastically.

Incorrect use of the put mode may cause a slow data loading rate. If the memory allocated to RegionServer is not sufficient, the process may exit.

The application scenarios of the bulkload and put modes are as follows:

- bulkload:
  - Load a large amount of data to HBase in the one-off manner.
  - Load data to HBase with low reliability requirements and without generating WAL files.
  - Low loading and query speed if the put mode is used.
  - The size of the HFile generated after data loading is similar to the size of HDFS block.
- put:
  - The size of the data loaded to one Region at a time is smaller than half the size of an HDFS block.
  - Load data to HBase in real time.
  - The query speed does not decrease wildly during data loading.

### 2.6.5.5.3 An Error Occurred When Building a JAR Package

#### Question

When the sample code is compiled using Maven to build a JAR package, the error message "Could not transfer artifact org.apache.commons:commons-crypto:pom:\${commons-crypto.version}" is displayed and the package building fails.

#### Answer

The hbase-common module depends on commons-crypto. In the **pom.xml** file of hbase-common, the **\${commons-crypto.version}** variable is used to introduce

commons-crypto. The parsing logic of this variable is as follows: If the OS is AArch64, the value is **1.0.0-hw-aarch64**. If the OS is x86\_64, the value is **1.0.0**. If Maven fails to parse the variable using the OS due to incorrect configuration in the compilation environment, you can manually modify the **pom.xml** file to prevent correct compilation.

In the **pom.xml** file, manually change the dependency of the hbase-common module to the following to exclude the commons-crypto dependency:

```
<dependency>
    <groupId>org.apache.hbase</groupId>
    <artifactId>hbase-common</artifactId>
    <version>${hbase.version}</version>
    <exclusions>
        <exclusion>
            <groupId>org.apache.commons</groupId>
            <artifactId>commons-crypto</artifactId>
        </exclusion>
    </exclusions>
</dependency>
```

Manually add the commons-crypto dependency of the specified version. Enter a correct version based on the OS architecture (x86\_64 or AArch64).

```
<dependency>
    <groupId>org.apache.commons</groupId>
    <artifactId>commons-crypto</artifactId>
    <version>1.0.0</version>
</dependency>
```

#### 2.6.5.5.4 How to Rectify the Fault When an Exception Occurs During the Running of an HBase-developed Application and "java.lang.OutOfMemoryError: Direct buffer memory" Is Displayed in the Error Information?

**Step 1** Run the **java -version** command to check whether the JDK version is JDK1.8u102 or later.

- If yes, go to [Step 2](#).
- If no, the client for secondary development supports only the built-in OpenJDK 1.8 (jdk-8u181-linux-x64). If the JDK version is not JDK1.8u102 or later, upgrade it to JDK1.8u102 or later, and then go to [Step 2](#).

**Step 2** When running the program, set the JVM parameter - **Djdk.nio.maxCachedBufferSize=262144** to limit the size of the direct memory used by each thread.

----End

## 2.7 HDFS Development Guide

### 2.7.1 Overview

### 2.7.1.1 Introduction to HDFS

#### Introduction to HDFS

Hadoop distribute file system (HDFS) is a distributed file system with high fault tolerance. HDFS supports data access with high throughput and applies to processing of large data sets.

HDFS applies to the following application scenarios:

- Massive data processing (higher than the TB or PB level).
- Scenarios that require high throughput.
- Scenarios that require high reliability.
- Scenarios that require good scalability.

#### Introduction to HDFS Interface

HDFS can be developed by using Java language. For details of API reference, see [Java API](#).

### 2.7.1.2 Basic Concepts

#### DataNode

A DataNode is used to store data blocks of each file and periodically report the storage status to the NameNode.

#### NameNode

A NameNode is used to manage the namespace, directory structure, and metadata information of a file system and provide the backup mechanism. NameNodes are classified into the following two types:

- Active NameNode: manages the file system namespace, maintains the directory structure tree and metadata information of a file system, and records the relationship between each data block and the file to which the data block belongs.
- Standby NameNode: Data in a standby NameNode is synchronous with those in an active NameNode. A standby NameNode takes over services from the active NameNode if the active NameNode is exception.

#### JournalNode

A JournalNode synchronizes metadata between the active and standby NameNodes in the High Availability (HA) cluster.

#### ZKFC

ZKFC must be deployed for each NameNode. It is responsible for monitoring NameNode status and writing status information to the ZooKeeper. ZKFC also has permission to select the active NameNode.

## Colocation

Colocation is used to store associated data or the data to be associated on the same storage node. The HDFS Colocation stores files to be associated on a same data node so that data can be obtained from the same data node during associated operations. This greatly reduces network bandwidth consumption.

## Federation

Federation is adopted to solve most problems in the HDFS architecture that allows only a single NameNode.

Federation allows multiple NameServices. The NameServices can be configured in the HA mode. In HA mode, a hot standby NameNode is provided for the active NameNode to address the single node failure. The standby NameNode is able to quickly take over services from the active NameNode when the active NameNode breaks down. The administrator can start the failover during maintenance.

This function applies only to MRS physical machine clusters.

## Client

The HDFS can be accessed from the Java application programming interface (API), C API, Shell, HTTP REST API and web user interface (WebUI).

For details, see [Common API Introduction](#) and [Shell Command Introduce](#).

- JAVA API  
Provides an application interface for the HDFS. This guide describes how to use the Java API to develop HDFS applications.
- C API  
Provides an application interface for the HDFS. This guide describes how to use the C API to develop HDFS applications.
- Shell  
Provides shell commands to perform operations on the HDFS.
- HTTP REST API  
Additional interfaces except Shell, Java API and C API. You can use the interfaces to monitor HDFS status.
- WEB UI  
Provides a visualized management web page.

### 2.7.1.3 Development Process

All stages of the development process are shown and described in [Figure 2-144](#) and [Table 2-77](#).

Figure 2-144 HDFS development process

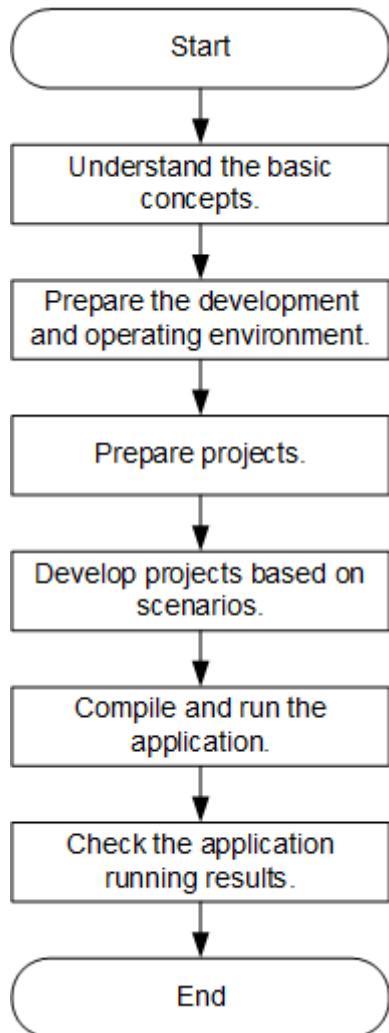

Table 2-77 Description of HDFS development process

Stage	Description	Reference
Understand the basic concepts.	Before the application development, the basic concepts of HDFS are required to be understood.	<a href="#">Basic Concepts</a>
Prepare the development and operating environment.	Use IntelliJ IDEA and configure the development environment based on the reference. The running environment of HDFS is the HDFS client. Install and configure the client based on the reference.	<a href="#">Development and Operating Environment</a>
Prepare projects.	HDFS provides sample projects in various scenarios. Sample projects can be imported for studying.	<a href="#">Configuring and Importing Sample Projects</a>

Stage	Description	Reference
Develop projects based on scenarios.	Provide the sample project. This helps users to learn about the programming interfaces of all HDFS components quickly.	<a href="#">Developing the Project</a>
Compile and run the application.	Users compile the developed application and deliver it for running based on the reference.	<a href="#">Commissioning the Application</a>
Check the application running results.	Application running results are stored in the directory specified by users. Users can also check the running results through the UI.	<a href="#">Commissioning the Application</a>

## 2.7.2 Environment Preparation

### 2.7.2.1 Development and Operating Environment

#### Preparing Development Environment

[Table 2-78](#) describes the environment required for application development.

**Table 2-78** Development Environment

Preparation	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows OS. Windows 7 or later is supported.</li><li>• Operating environment: Windows OS or Linux OS.</li></ul> <p>If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</p>

Preparation	Description
Installing JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>Oracle JDK 1.8</li><li>IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>For security purposes, the server supports only TLS V1.2 or later.</li><li>By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <code>com.ibm.jsse2.overrideDefaultTLS</code> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls</a>.</li><li>For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>It is the basic configuration for the development environment. IntelliJ IDEA 2019.1 or other compatible versions are used.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>
Maven installation	Basic configuration of the development environment for project management throughout the lifecycle of software development.
7-zip	Used to decompress <b>.zip</b> and <b>.rar</b> packages. 7-Zip 16.04 is supported.

## Preparing an Operating Environment

During application development, you need to prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. **Accessing FusionInsight Manager of an MRS Cluster.** In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.
  - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\HDFS\config** and manually import the configuration file to the configuration file directory (usually the **conf** folder) of the HDFS sample project.
  - c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 **NOTE**

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.  
Ensure that the difference between the client time and the cluster time is less than 5 minutes.  
For details about how to install a cluster client, see [Installing a Client](#).
  - b. **Accessing FusionInsight Manager of an MRS Cluster.** Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/HDFS/config** directory and save them to the **conf** folder of the project code.  
For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path

is **/tmp/FusionInsight-Client** on the active management node, run the following command:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp HDFS/config/* root@IP address of the client node:/opt/  
hadoopclient/conf
```

**Table 2-79** Configuration files

File	Function
core-site.xml	Configures HDFS parameters.
hdfs-site.xml	Configures HDFS parameters.

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

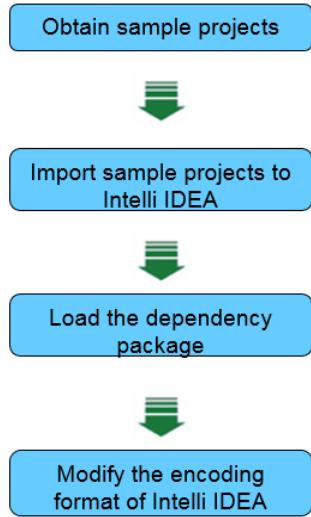

### 2.7.2.2 Configuring and Importing Sample Projects

#### Scenario

HDFS provides sample projects for multiple scenarios to help you quickly learn HDFS projects.

The procedure for importing HDFS example codes is described as follows: [Figure 2-145](#) shows the procedure.

Figure 2-145 Sample project importing procedure

## Procedure

**Step 1** Obtain the sample project folder **hdfs-example-normal** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

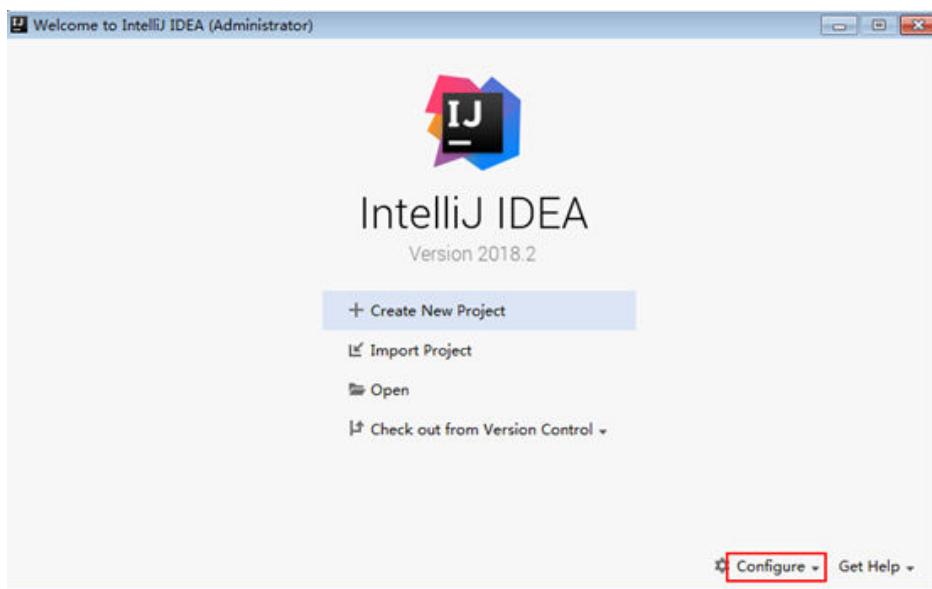

**Step 2** Import the example project to the IntelliJ IDEA development environment.

1. Open IntelliJ IDEA and choose **File > Open**.
2. Choose the directory of the example project **hdfs-example-normal**. Click **OK**.

**Step 3** After installing the IntelliJ IDEA and JDK tools, configure JDK in IntelliJ IDEA.

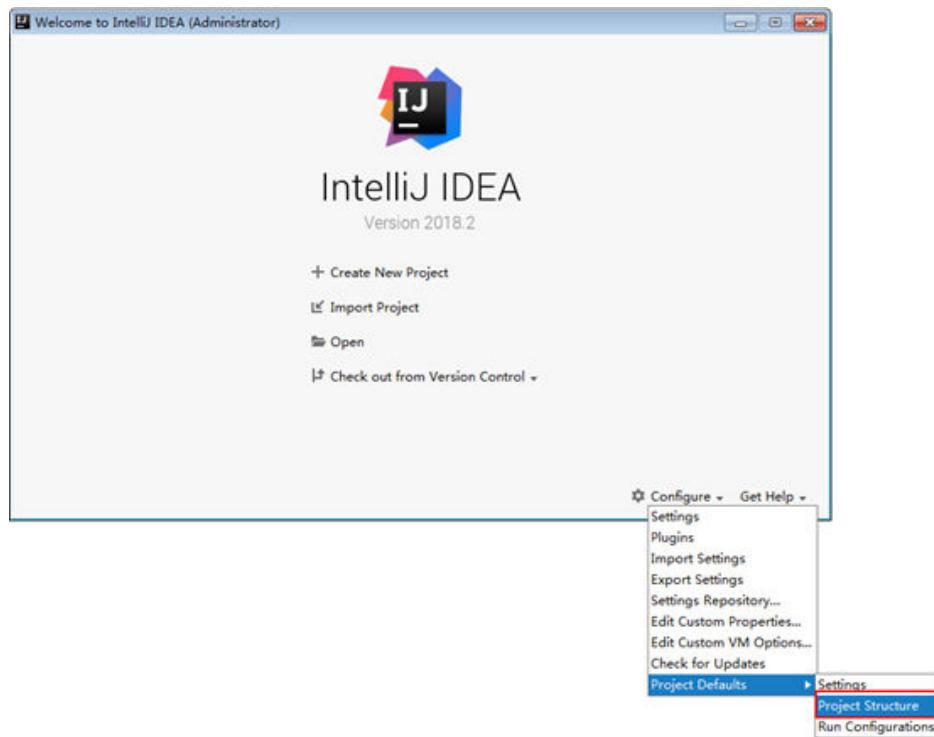

1. Open IntelliJ IDEA and click **Configure**.

Figure 2-146 Quick Start

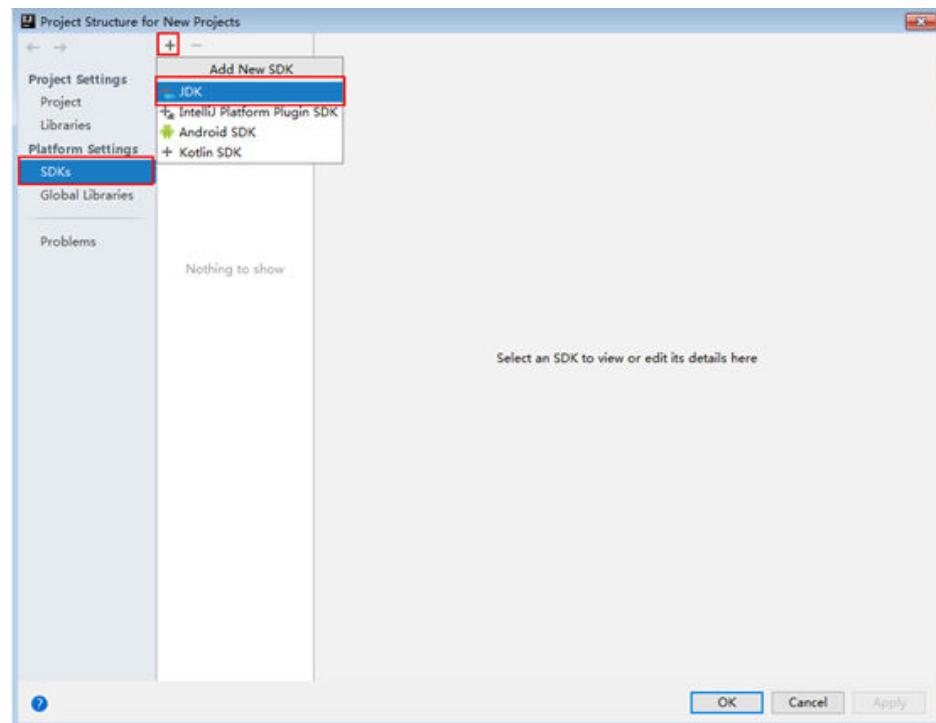

2. Choose **Project Defaults > Project Structure**.

**Figure 2-147** Configure

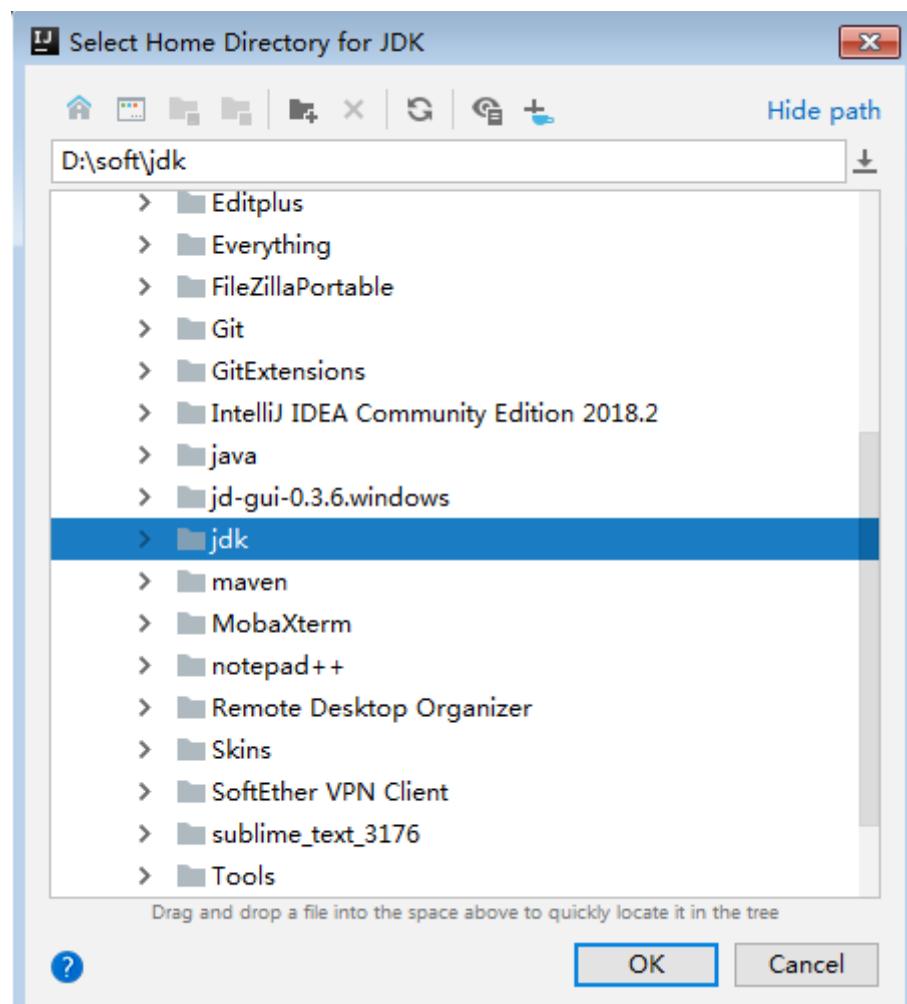

3. In the displayed **Project Structure for New Projects** interface, click **SDKs**. Then click the plus sign (+) and choose **JDK**.

Figure 2-148 Project Structure for New Projects

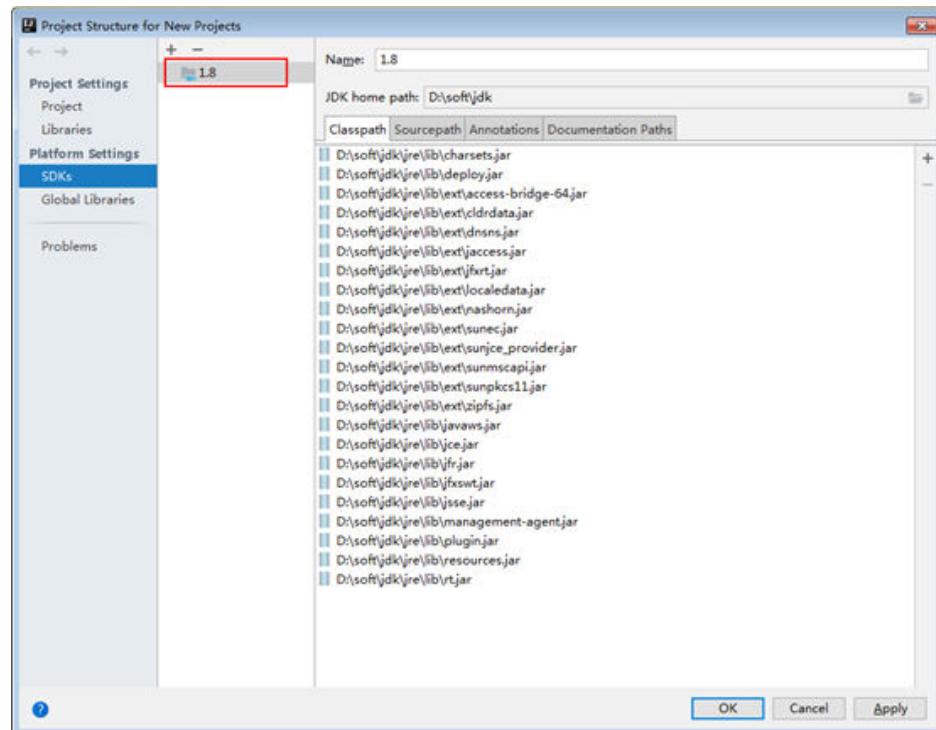

4. In the displayed **Select Home Directory for JDK** interface, select the JDK directory, and click **OK**.

Figure 2-149 Select Home Directory for JDK

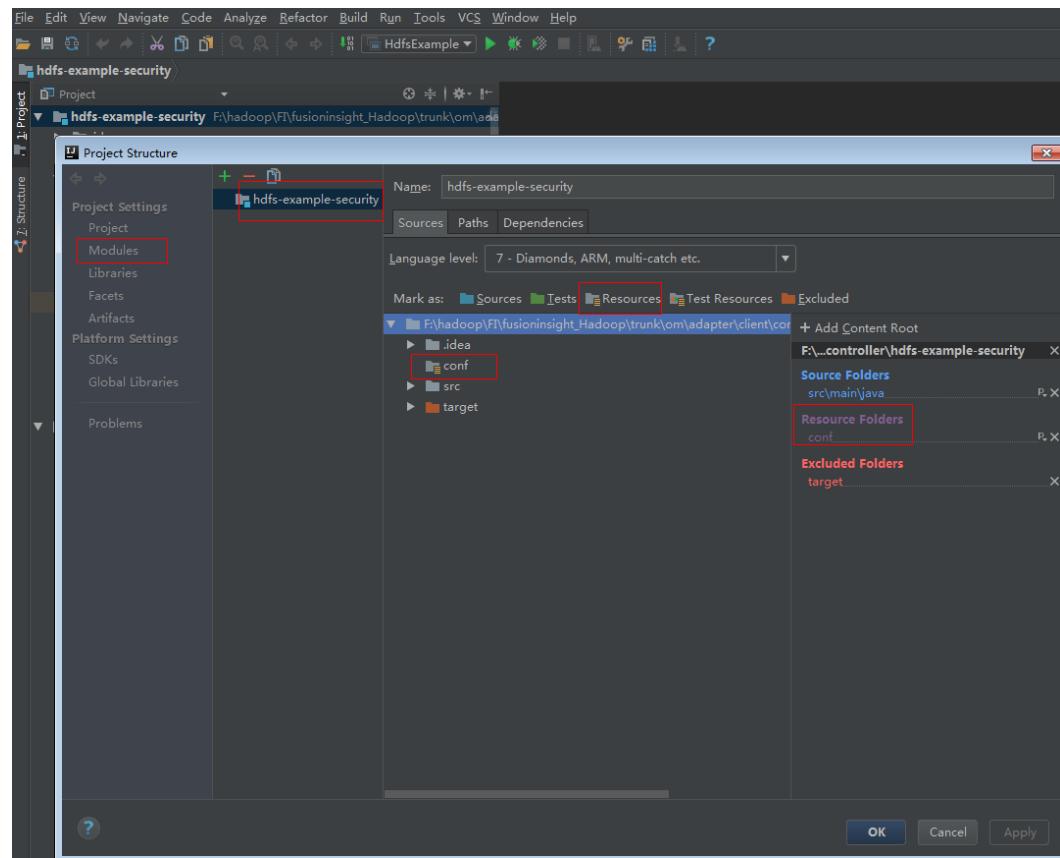

5. Click **OK**.

Figure 2-150 Completing the JDK configuration

**Step 4** Add the conf directory in the project to the resource path. On the menu bar of the IntelliJ IDEA, choose **File > Project Structure**. In the dialog box that is displayed, select the current project and click **Resources > conf > OK** to set the resource directory. The figure shows the directory for setting the project resource.

Figure 2-151 Setting the Project Resource Directory

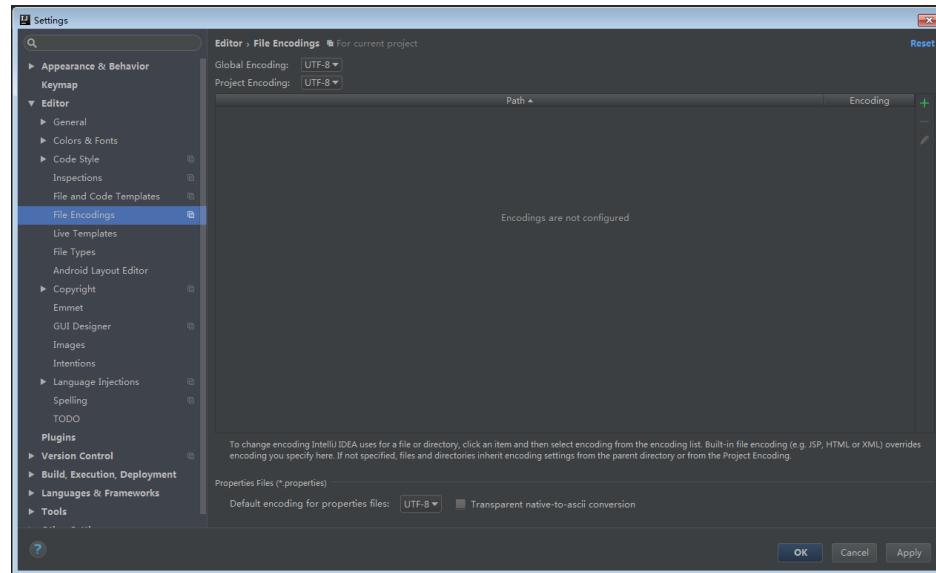

**Step 5** Add the related jar files the example project depending on into classpath.

If the sample project code is obtained from an open-source image site, dependency JAR files are automatically downloaded after Maven is configured (for details, see [Configuring Huawei Open-Source Mirrors](#)).

**Step 6** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

1. On the IntelliJ IDEA menu bar, choose **File > Settings**.
2. Choose **Editor > File Encodings** from the navigation tree of the **Settings** window. In the "Global Encoding" and "Project Encodings" area, set the value to **UTF-8**, click **Apply**, and click **OK**, as shown in [Figure 2-152](#)

Figure 2-152 Setting the IntelliJ IDEA coding format

----End

## 2.7.3 Developing the Project

### 2.7.3.1 Scenario

#### Typical Scenario Description

Based on typical scenarios, users can quickly learn and master the HDFS development process and know important interface functions.

#### Scenario

Service operation objects of HDFS are files. File operations in example codes include creating a folder, writing data into a file, appending data to a file, reading data from a file, and deleting a file or folder. HDFS also supports other services including setting file permission. You can learn how to perform other operations on HDFS after learning the example codes in this chapter.

The example codes are described in the following order:

1. Initializing the HDFS.
2. Creating directories.
3. Writing data into a file.
4. Appending data to a file.
5. Reading data from a file.
6. Deleting a file.
7. Deleting directories.
8. Multi-thread tasks
9. Setting storage policies.

10. Colocation.

### 2.7.3.2 Development Idea

#### Development Idea

According to the previous scenario description, the following provides the basic operations for HDFS files with read, write, and delete operations on the **/user/hdfs-examples/test.txt** file as an example:

1. Create a FileSystem object: fSystem.
2. Call the mkdir interface in fSystem to create a directory.
3. Call the create interface in fSystem to create an FSDataOutputStream object: out. Use the write method to write data into the object out.
4. Call the append interface in fSystem to create an FSDataOutputStream object: out. Use the write method to append data into the object out.
5. Call the open interface in fSystem to create an FSDataInputStream object: in. Use the read method to read files of the object in.
6. Call the delete interface in fSystem to delete the file.
7. Call the delete interface in fSystem to delete the folder.

### 2.7.3.3 Declare the Example Codes

#### 2.7.3.3.1 Initializing the HDFS

##### Function

Hadoop distributed file system (HDFS) initialization is a prerequisite for using application programming interfaces (APIs) provided by the HDFS. The process of initializing the HDFS is

1. Load the HDFS service configuration file.
2. Instantiate a FileSystem.

#### Configuration File Description

**Table 2-80** lists the configuration files to be used during the login to the HDFS. These files already imported to the **conf** directory of the **hadoop-examples** project.

**Table 2-80** Configuration files

File	Function
core-site.xml	Configures HDFS parameters.
hdfs-site.xml	Configures HDFS parameters.

#### NOTE

The **log4j.properties** file under the **conf** directory can be configured based on your needs.

### Example Codes

The following is code snippets. For complete codes, see the HdfsExample class in com.huawei.bigdata.hdfs.examples.

The initialization codes used when applications are run in Linux and the codes used when applications are run in Windows are the same. The example codes are as follows:

```
//initialization
/**confLoad();

// Creating a sample project
HdfsExample hdfs_examples = new HdfsExample("/user/hdfs-examples", "test.txt");
/**
*
* If the application is running in the Linux OS, the path of core-site.xml, hdfs-site.xml must be modified to
the absolute path of the client file in the Linux OS.
*
*/
private static void confLoad() throws IOException {
    conf = new Configuration();
    // conf file
    conf.addResource(new Path(PATH_TO_HDFS_SITE_XML));
    conf.addResource(new Path(PATH_TO_CORE_SITE_XML));
}

/**
*Create a sample project.
*/
public HdfsExample(String path, String fileName) throws IOException {
    this.DEST_PATH = path;
    this.FILE_NAME = fileName;
    instanceBuild();
}
private void instanceBuild() throws IOException {
    fSystem = FileSystem.get(conf);
}
```

#### NOTE

- (Optional) Specify a user to run the example code. To run the example code related to the Colocation operation, the user must be a member of the supergroup group. The following describes two ways to specify the user who runs the example code:

Add the environment variable **HADOOP\_USER\_NAME**: For operation details in a Windows-based environment, see [Step 1](#) in section **Compiling and Running an Application** For operation details in a Linux-based environment, see [Step 4](#) in section **Compiling and Running an Application with the Client Installed** or [Step 4](#).in section **Compiling and Running an Application with the Client Not Installed**.

Modify the code: If **HADOOP\_USER\_NAME** is not specified, modify "USER" in the code to the actual user name:

```
System.setProperty("HADOOP_USER_NAME", USER);
```

### 2.7.3.3.2 Creating Directories

#### Function

Process of creating a directory:

1. Call the exists method of the FileSystem instance to check whether the directory exists.
2. If yes, the method stops.
3. If no, call the mkdirs method in the FileSystem instance to create a directory.

## Example Codes

The following is a code snippet. For complete codes, see the **HdfsExample** class in **com.huawei.bigdata.hdfs.examples**.

```
/**  
 * Create a directory.  
 *  
 * @throws java.io.IOException  
 */  
private void mkdir() throws IOException {  
    Path destPath = new Path(DEST_PATH);  
    if (!createPath(destPath)) {  
        LOG.error("failed to create destPath " + DEST_PATH);  
        return;  
    }  
  
    LOG.info("success to create path " + DEST_PATH);  
}  
  
/**  
 * create file path  
 *  
 * @param filePath  
 * @return  
 * @throws java.io.IOException  
 */  
private boolean createPath(final Path filePath) throws IOException {  
    if (!fSystem.exists(filePath)) {  
        fSystem.mkdirs(filePath);  
    }  
    return true;  
}
```

### 2.7.3.3.3 Writing Data into a File

## Function

The process of writing data into a file is

1. Use the create method in the FileSystem instance to obtain the output stream of writing files.
2. Uses this data stream to write content into a specified file in the HDFS.

Close all requested resources after writing files.

## Example Codes

The following is code snippets. For complete codes, see HdfsMain and HdfsWriter classes in **com.huawei.bigdata.hdfs.examples**.

```
/**  
 * Write a file, write the data  
 *
```

```
* @throws IOException
* @throws ParameterException
*/
private void write() throws IOException {
    final String content = "hi, I am bigdata. It is successful if you can see me.";
    FSDatOutputStream out = null;
    try {
        out = fSystem.create(new Path(DEST_PATH + File.separator + FILE_NAME));
        out.write(content.getBytes());
        out.hsync();
        LOG.info("success to write.");
    } finally {
        // make sure the stream is closed finally.
        IOUtils.closeStream(out);
    }
}
```

### 2.7.3.3.4 Appending Data to a File

## Function

Append data to a specified file in the Hadoop distributed file system (HDFS). The process of appending data to a file is

1. Use the append method in the FileSystem instance to obtain the output stream of the appended data.
2. Use the output stream to add the content to be appended behind the specified file in the HDFS.

Close all requested resources after appending data.

## Example Codes

The following is code snippets. For complete codes, see HdfsMain and HdfsWriter classes in **com.huawei.bigdata.hdfs.examples**.

```
 /**
 * Append data to a file.
 *
 * @throws IOException
 */
private void append() throws IOException {
    final String content = "I append this content.";
    FSDatOutputStream out = null;
    try {
        out = fSystem.append(new Path(DEST_PATH + File.separator + FILE_NAME));
        out.write(content.getBytes());
        out.hsync();
        LOG.info("success to append.");
    } finally {
        // make sure the stream is closed finally.
        IOUtils.closeStream(out);
    }
}
```

### 2.7.3.3.5 Reading Data from a File

## Function

Read data from a specified file in the Hadoop distributed file system (HDFS). The process is:

1. Use the open method in the FileSystem instance to obtain the input stream of writing files.
2. Use the input stream to read the content of the specified file in the HDFS.

 NOTE

Close all requested resources after reading files.

## Example Codes

The following is code snippets. For complete codes, see the `HdfsMain` class in `com.huawei.bigdata.hdfs.examples`.

```
/*
 * Read a file.
 *
 * @throws IOException
 */
private void read() throws IOException {
    String strPath = DEST_PATH + File.separator + FILE_NAME;
    Path path = new Path(strPath);
    FSDataInputStream in = null;
    BufferedReader reader = null;
    StringBuffer strBuffer = new StringBuffer();
    try {
        in = fSystem.open(path);
        reader = new BufferedReader(new InputStreamReader(in));
        String sTempOneLine;
        // write file
        while ((sTempOneLine = reader.readLine()) != null) {
            strBuffer.append(sTempOneLine);
        }
        LOG.info("result is : " + strBuffer.toString());
        LOG.info("success to read.");
    } finally {
        // make sure the streams are closed finally.
        IOUtils.closeStream(reader);
        IOUtils.closeStream(in);
    }
}
```

### 2.7.3.3.6 Deleting a File

## Function

Delete a file from the Hadoop distributed file system (HDFS).

 NOTE

Exercise caution when you delete files because the deletion is irreversible.

## Example Codes

The following is code snippets. For complete codes, see the `HdfsMain` class in `com.huawei.bigdata.hdfs.examples`.

```
/*
 * Delete a file.
 *
 * @throws IOException
 */
private void delete() throws IOException {
    Path beDeletedPath = new Path(DEST_PATH + File.separator + FILE_NAME);
```

```
if (fSystem.delete(beDeletedPath, true)) {
    LOG.info("success to delete the file " + DEST_PATH + File.separator + FILE_NAME);
} else {
    LOG.warn("failed to delete the file " + DEST_PATH + File.separator + FILE_NAME);
}
```

### 2.7.3.3.7 Deleting Directories

## Function

Delete a specified directory from the HDFS.

Files in the deleted directory will be stored in the **Trash/Current** folder of the directory of the current user. In the event of mis-deletion, you can restore the folder from the directory.

## Example Codes

The following is a code snippet of file deletion. For complete codes, see the **HdfsExample** class in **com.huawei.bigdata.hdfs.examples**.

```
/*
 * delete the directory
 *
 * @throws java.io.IOException
 */
private void rmdir() throws IOException {
    Path destPath = new Path(DEST_PATH);
    if (!deletePath(destPath)) {
        LOG.error("failed to delete destPath " + DEST_PATH);
        return;
    }
    LOG.info("success to delete path " + DEST_PATH);
}

/*
 * delete file path
 *
 * @param filePath
 * @return
 * @throws java.io.IOException
 */
private boolean deletePath(final Path filePath) throws IOException {
    if (!fSystem.exists(filePath)) {
        return false;
    }
    // fSystem.delete(filePath, true);
    return fSystem.delete(filePath, true);
}
```

### 2.7.3.3.8 Multi-Thread Tasks

## Function

Create multi-threaded tasks and initiate multiple instances to perform file operations.

## Example Codes

The following is a code snippet of file deletion. For complete codes, see the **HdfsExample** class in **com.huawei.bigdata.hdfs.examples**.

```
// Service example 2: multi-thread tasks
final int THREAD_COUNT = 2;
for (int threadNum = 0; threadNum < THREAD_COUNT; threadNum++) {
    HdfsExampleThread example_thread = new HdfsExampleThread("hdfs_example_" + threadNum);
    example_thread.start();
}

class HdfsExampleThread extends Thread {
    private final static Log LOG = LogFactory.getLog(HdfsExampleThread.class.getName());
    /**
     *
     * @param threadName
     */
    public HdfsExampleThread(String threadName) {
        super(threadName);
    }
    public void run() {
        HdfsExample example;
        try {
            example = new HdfsExample("/user/hdfs-examples/" + getName(), "test.txt");
            example.test();
        } catch (IOException e) {
            LOG.error(e);
        }
    }
}
```

The **example.test()** method is the operation on files. The code is as follows:

```
/*
 * HDFS operation instance
 *
 * @throws IOException
 * @throws ParameterException
 *
 * @throws Exception
 */
public void test() throws IOException {
    // Create a directory.
    mkdir();

    // Write data into a file.
    write();

    // Append data to a file.
    append();

    // Read a file.
    read();

    // Delete a file.
    delete();

    // Delete a directory.
    rmdir();
}
```

### 2.7.3.3.9 Setting Storage Policies

#### Function

Specify storage policies for a file or folder in the HDFS.

## Example Code

1. **Accessing FusionInsight Manager of an MRS Cluster**, choose **Cluster > Name of the desired cluster > Services > HDFS > Configurations > All Configurations**.
2. Check whether the value of **dfs.storage.policy.enabled** is the default value **true**. If not, modify the value to **true**, click **Save**, and restart HDFS.
3. Check the code.

The following code segment is only an example. For details, see the **HdfsMain** class in **com.huawei.bigdata.hdfs.examples**.

```
/*
 * set storage policy to path
 * @param policyName
 * Policy Name can be accepted:
 * <li>HOT
 * <li>WARM
 * <li>COLD
 * <li>LAZY_PERSIST
 * <li>ALL_SSD
 * <li>ONE_SSD
 * @throws IOException
 */

private void setStoragePolicy(String policyName) throws IOException {
    if (fSystem instanceof DistributedFileSystem) {
        DistributedFileSystem dfs = (DistributedFileSystem) fSystem;
        Path destPath = new Path(DEST_PATH);
        Boolean flag = false;
        mkdir();
        BlockStoragePolicySpi[] storage = dfs.getStoragePolicies();
        for (BlockStoragePolicySpi bs : storage) {
            if (bs.getName().equals(policyName)) {
                flag = true;
            }
            LOG.info("StoragePolicy:" + bs.getName());
        }
        if (!flag) {
            policyName = storage[0].getName();
        }
        dfs.setStoragePolicy(destPath, policyName);
        LOG.info("success to set Storage Policy path " + DEST_PATH);
        rmdir();
    } else {
        LOG.info("SmallFile not support to set Storage Policy !!!");
    }
}
```

### 2.7.3.3.10 Colocation

#### Function Description

Colocation is to store associated data or data on which associated operations are performed on the same storage node. The HDFS Colocation feature stores files on which associated operations are performed on the same data node so that data can be obtained from the same data node during associated operations. This greatly reduces network bandwidth consumption.

Before using the Colocation function, you are advised to be familiar with the internal mechanisms of Colocation, including:

#### Colocation node allocation principle

## Capacity expansion and Colocation allocation

### Colocation and data node capacity

- **Colocation node allocation principle**

Colocation allocates data nodes to locators evenly according to the allocation node quantity.

 NOTE

The allocation algorithm principle is as follows: Colocation queries all locators, reads the data nodes allocated to the locators, and records the number of times. Based on the number of times, Colocation sorts the data nodes. The data nodes that are rarely used are placed at the beginning and selected first. The count increase by 1 each time after a node is selected. The nodes are shorted again, and the subsequent node will be selected.

- **Capacity expansion and Colocation allocation**

After cluster capacity expansion, you can select one of the following two policies shown in [Table 2-81](#) to balance the usage of data nodes and ensure that the allocation frequency of the newly added nodes is consistent with that of the old data nodes.

**Table 2-81** Allocation policies

No.	Policy	Description
1	Delete the original locators and create new locators for all data nodes in the cluster.	<ol style="list-style-type: none"><li>1. The original locator before the capacity expansion evenly uses all data nodes. After the capacity expansion, the newly added nodes are not allocated to existing locators, so Colocation stores data only to the old data nodes.</li><li>2. Data nodes are allocated to specific locators. Therefore, after capacity expansion, Colocation needs to reallocated data nodes to locators.</li></ol>
2	Create new locators and plan the data storage mode again.	The old locators use the old data nodes, while the newly created locators mainly use the new data nodes. Therefore, locators need to be planned again based on the actual service requirements on data.

 NOTE

Generally, you are advised to use the policy to reallocate data nodes to locators after capacity expansion to prevent data from being stored only to the new data nodes.

- **Colocation and data node capacity**

When Colocation is used to store data, the data is stored to the data node of a specified locator. If no locator planning is performed, the data node capacity will be uneven. [Table 2-82](#) summarizes the two usage principles to ensure even data node capacity.

**Table 2-82 Usage Principle**

No.	Usage Principle	Description
1	All the data nodes are used in the same frequency in locators.	Assume that there are N data nodes, the number of locators must be an integral multiple of N (N, 2 N, ...).
2	A proper data storage plan must be made for all locators to ensure that data is evenly stored in the locators.	None

During HDFS secondary development, you can obtain the DFSColocatinAdmin and DFSColocatinClient instances to create groups, delete groups, write files, and delete files in or from the location.

**BOOK NOTE**

- When the Colocation function is enabled and users specify DataNodes, the data volume will be large on some nodes. Serious data skew will result in HDFS data write failures.
- Because of data skew, MapReduce accesses only several nodes. In this case, the load is heavy on these nodes, while other nodes are idle.
- For a single application task, the DFSColocatinAdmin and DFSColocatinClient instances can be used only once. If the instances are used for many times, excessive HDFS links will be created and use up HDFS resources.
- If you need to perform the balance operation for a file uploaded by colocation, you can set the `oi.dfs.colocation.file.pattern` parameter on FusionInsight Manager to the file path to avoid invalid colocation. If there are multiple files, use commas (,) to separate the file paths, for example, `/test1,/test2`.
- Colocation stores associated data or data on which associated operations are performed on the same storage. When Balancer- or Mover-related operations are performed, data blocks will be moved. As a result, the Colocation function becomes unavailable. Therefore, when using the Colocation function, you are advised to set the HDFS configuration item `dfs.datanode.block-pinning.enabled` to `true`. In this case, files written by Colocation will not be moved when Balancer- or Mover-related operations are performed in the cluster, ensuring file colocation.

## Example Codes

For complete example codes, see  
`com.huawei.bigdata.hdfs.examples.ColocationExample`.

**BOOK NOTE**

- Specify a user to run a Colocation project. This user must be a member of the supergroup group.
- When the Colocation project is run, the HDFS parameter `fs.defaultFS` cannot be set to `viewfs://ClusterX`.

### 1. Initialization

The user to run the Colocation project must be specified before the running.

```
private static void init() throws IOException {
    // Set the user. If HADOOP_USER_NAME is not set for the use, use USER.
    if (System.getenv("HADOOP_USER_NAME") == null &&
```

```
System.getProperty("HADOOP_USER_NAME") == null) {  
    System.setProperty("HADOOP_USER_NAME", USER);  
}  
}
```

2. Obtain instances.

Example: Colocation operations require the DFSColocatinAdmin and DFSColocatinClient instances. Therefore, the instances must be obtained before operations, such as creating a group.

```
dfsAdmin = new DFSColocatinAdmin(conf);  
dfs = new DFSColocatinClient();  
dfs.initialize(URI.create(conf.get("fs.defaultFS")), conf);
```

3. Create a group.

Example: Create a gid01 group, which contains three locators.

```
/**  
 * create group  
 *  
 * @throws java.io.IOException  
 */  
private static void createGroup() throws IOException {  
    dfsAdmin.createColocationGroup(COLOCATION_GROUP_GROUP01,  
        Arrays.asList(new String[] { "lid01", "lid02", "lid03" }));  
}
```

4. Write data into a file. The related group must be created before writing data into the file.

Example: Write data into the testfile.txt file.

```
/**  
 * create and write file  
 *  
 * @throws java.io.IOException  
 */  
private static void put() throws IOException {  
    FSDatOutputStream out = dfs.create(new Path(TESTFILE_TXT), true,  
    COLOCATION_GROUP_GROUP01, "lid01");  
    // the data to be written to the hdfs.  
    byte[] readBuf = "Hello World".getBytes("UTF-8");  
    out.write(readBuf, 0, readBuf.length);  
    out.close();  
}
```

5. Delete a file.

Example: Delete the testfile.txt file.

```
/**  
 * delete file  
 *  
 * @throws java.io.IOException  
 */  
@SuppressWarnings("deprecation")  
private static void delete() throws IOException {  
    dfs.delete(new Path(TESTFILE_TXT));  
}
```

6. Delete a group.

Example: Delete gid01.

```
/**  
 * delete group  
 *  
 * @throws java.io.IOException  
 */  
private static void deleteGroup() throws IOException {  
    dfsAdmin.deleteColocationGroup(COLOCATION_GROUP_GROUP01);  
}
```

## 2.7.4 Commissioning the Application

### 2.7.4.1 Commissioning an Application in the Windows Environment

#### 2.7.4.1.1 Compiling and Running an Application

##### Scenario

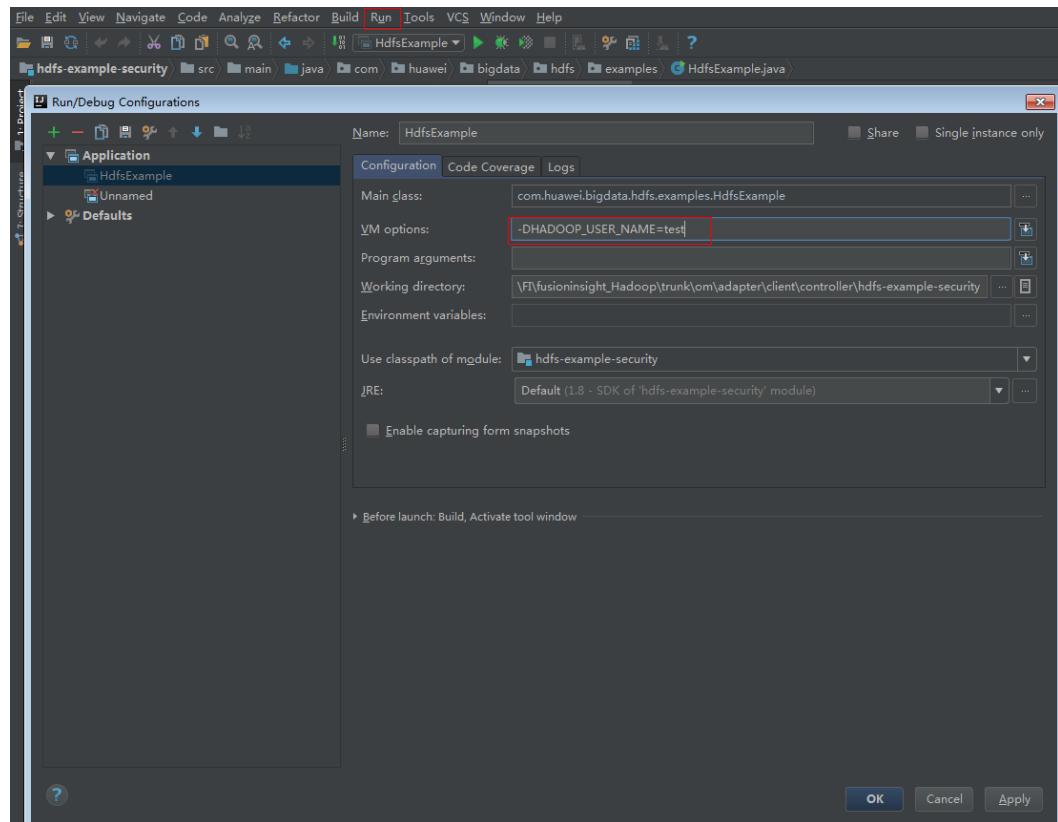

After the code development is complete, you can run an application in the Windows development environment. If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

##### Procedure

**Step 1** (Optional) In a development environment (for example, IntelliJ IDEA), a user must be specified to run the example code. There are two ways to specify the user:

Select the sample program HdfsExample.java or ColocationExample.java to be run, right-click the project, and choose Run Configurations from the shortcut menu. In the dialog box that is displayed, select JavaApplication > HdfsExample to set the running parameters. On the menu bar of the IntelliJ IDEA, choose Run > Edit Configurations. In the dialog box that is displayed, set the running user.

-DHADOOP\_USER\_NAME=test

 NOTE

The **test** user here is an example. To run the example code related to the Colocation operation, the user must be a member of the supergroup group.

**Step 2** If the environment variable is configured according to [Step 1](#) click **Run** to run the application. If not, choose the following two projects separately and run the projects:

- Choose HdfsExample.java, right-click the project and choose **Run 'HdfsExample.main()'** from the shortcut menu to run the project.
- Choose ColocationExample.java, right-click the project and choose **Run 'ColocationExample.main()'** from the shortcut menu to run the project.

 NOTE

- It is forbidden to restart HDFS service while HDFS application is in running status, otherwise the application will fail.
- When the Colocation project is run, the HDFS parameter **fs.defaultFS** cannot be set to **viewfs://ClusterX**.

----End

#### 2.7.4.1.2 Checking the Commissioning Result

##### Scenario

After an HDFS application is run, you can learn the application running conditions by viewing the running result or HDFS logs.

##### Procedure

- **Learn the application running conditions by viewing the running result.**
  - The running result of the HDFS windows example application is shown as follows:

```
1654 [main] WARN org.apache.hadoop.hdfs.shortcircuit.DomainSocketFactory - The short-circuit local reads feature cannot be used because UNIX Domain sockets are not available on Windows.
2013 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to create path /user/hdfs-examples
2137 [main] WARN org.apache.hadoop.util.NativeCodeLoader - Unable to load native-hadoop library for your platform... using builtin-java classes where applicable
2590 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to write.
3245 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to append.
4447 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - result is : hi, I am bigdata. It is successful if you can see me.I append this content.
4447 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to read.
4509 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete the file /user/hdfs-examples\test.txt
4618 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete path /user/hdfs-examples
4743 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to create path /user/hdfs-examples/hdfs_example_1
4743 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to create path /user/hdfs-examples/hdfs_example_0
5087 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to write.
5087 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to write.
6507 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to append.
6553 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to
```

```
append.  
7505 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - result is : hi, I  
am bigdata. It is successful if you can see me.I append this content.  
7505 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
read.  
7568 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
delete the file /user/hdfs-examples/hdfs_example_1\test.txt  
7583 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - result is : hi, I  
am bigdata. It is successful if you can see me.I append this content.  
7583 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
read.  
7630 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
delete the file /user/hdfs-examples/hdfs_example_0\test.txt  
7677 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
delete path /user/hdfs-examples/hdfs_example_1  
7739 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
delete path /user/hdfs-examples/hdfs_example_0
```

#### NOTE

In the Windows environment, the following exception occurs but does not affect services.

```
java.io.IOException: Could not locate executable null\bin\winutils.exe in the  
Hadoop binaries.
```

- The running result of the Colocation windows example application is shown as follows:

```
1623 [main] WARN org.apache.hadoop.hdfs.shortcircuit.DomainSocketFactory - The short-  
circuit local reads feature cannot be used because UNIX Domain sockets are not available on  
Windows.

```

- **Learn the application running conditions by viewing HDFS logs.**

The NameNode logs of HDFS offer immediate visibility into application running conditions. You can adjust application programs based on the logs.

### 2.7.4.2 Commissioning an Application in the Linux Environment

### 2.7.4.2.1 Compiling and Running an Application with the Client Installed

#### Scenario

The Hadoop distributed file system (HDFS) application can run in the Linux operating system (OS) with the HDFS client installed. After the application code has been developed, you can upload the jar packages to the prepared Linux client operating environment and run the application.

#### Prerequisite

- The HDFS client has been installed.
- When the host where the Linux OS runs is not a node of the cluster, you are required to set the mapping between the host name and IP address in the **hosts** file of the node where the client is installed. The host name must be correctly mapped to the IP address.

#### Procedure

**Step 1** Go to the local root directory of the sample project, copy the required configuration file to the conf folder of the local project, and run the following command in Windows CLI to compress the package:

```
mvn -s "{maven_setting_path}" clean package
```

##### NOTE

- In the preceding command, {maven\_setting\_path} is the path of the **settings.xml** file of the local Maven.
- After the package is successfully packed, obtain the JAR package, for example, *HDFSTest-XXX.jar*, from the **target** subdirectory in the root directory of the project. The name of the JAR package varies according to the actual package.

**Step 2** Upload the exported jar packages to any directory in the running environment of the client, for example, **/opt/hadoopclient**.

**Step 3** Configure the environment variables:

```
cd /opt/hadoopclient  
source bigdata_env
```

**Step 4** Specify a user to run the example. There are two ways to specify the user: add the environment variable **HADOOP\_USER\_NAME** and modify the code. If the code cannot be modified, run the following statement to add the environment variable:  
`export HADOOP_USER_NAME=test`

The **test** user here is an example. To run the example code related to the Colocation operation, the user must be a member of the supergroup group.

**Step 5** Run the following commands to execute the jar packages.

```
hadoop jar HDFSTest-XXX.jar com.huawei.bigdata.hdfs.examples.HdfsExample
```

```
hadoop jar HDFSTest-XXX.jar  
com.huawei.bigdata.hdfs.examples.ColocationExample
```

 NOTE

When `com.huawei.bigdata.hdfs.examples.ColocationExample` is run, the HDFS parameter `fs.defaultFS` cannot be set to `viewfs://ClusterX`.

----End

### 2.7.4.2.2 Compiling and Running an Application with the Client Not Installed

#### Scenario

The Hadoop distributed file system (HDFS) application can run in the Linux operating system (OS) with the HDFS client not installed. After the application code has been developed, you can upload the jar packages to the Linux OS and run the application.

#### Prerequisite

- A JDK has been installed in the Linux environment. The version of the JDK must be consistent with that of the JDK used by IDEA to export the JAR package.
- When the host where the Linux OS runs is not a node of the cluster, you are required to set the mapping between the host name and IP address in the **hosts** file of the node where the Linux OS runs. The host name must be correctly mapped to the IP address.

#### Procedure

**Step 1** Go to the local root directory of the project, copy the required configuration file to the conf folder of the local project and run the following command in Windows CLI to compress the package:

```
mvn -s "{maven_setting_path}" clean package
```

 NOTE

- In the preceding command, {maven\_setting\_path} is the path of the **settings.xml** file of the local Maven.
- After the package is successfully packed, obtain the JAR package from the target subdirectory in the root directory of the project.

**Step 2** Upload the exported jar packages to any directory in the running environment of the Linux OS, for example, **/opt/hadoopclient**.

**Step 3** Create a **lib** folder in the Linux operating environment directory (for example, **/opt/hadoopclient**) and upload the required **JAR** packages. The **lib** folder contains all the **JAR** packages that the project depends on. For details, see section [Preparing an Operating Environment](#).

**Step 4** Specify a user to run the example. There are two ways to specify the user: add the environment variable **HADOOP\_USER\_NAME** and modify the code. If the code cannot be modified, run the following statement to add the environment variable:

```
export HADOOP_USER_NAME=test
```

 NOTE

The **test** user here is an example. To run the example code related to the Colocation operation, the user must be a member of the supergroup group.

**Step 5** Run the following commands to execute the jar packages.

```
java -cp HDFSTest-XXX.jar.lib/* com.huawei.bigdata.hdfs.examples.HdfsExample
```

```
java -cp HDFSTest-XXX.jar.lib/*  
com.huawei.bigdata.hdfs.examples.ColocationExample
```

 NOTE

When **com.huawei.bigdata.hdfs.examples.ColocationExample** is run, the HDFS parameter **fs.defaultFS** cannot be set to **viewfs://ClusterX**.

----End

### 2.7.4.2.3 Checking the Commissioning Result

#### Scenario

After an HDFS application is run, you can learn the application running conditions by viewing the running result or HDFS logs.

#### Procedure

- **Learn the application running conditions by viewing the running result.**

- The running result of the HDFS example application is shown as follows:

```
[root@192-168-32-144 client]#hadoop jar HDFSTest-XXX.jar  
com.huawei.bigdata.hdfs.examples.HdfsExample  
WARNING: Use "yarn jar" to launch YARN applications.  
17/10/26 19:11:44 INFO examples.HdfsExample: success to create path /user/hdfs-examples  
17/10/26 19:11:44 INFO examples.HdfsExample: success to write.  
17/10/26 19:11:45 INFO examples.HdfsExample: success to append.  
17/10/26 19:11:45 INFO examples.HdfsExample: result is : hi, I am bigdata. It is successful if you  
can see me.l append this content.  
17/10/26 19:11:45 INFO examples.HdfsExample: success to read.  
17/10/26 19:11:45 INFO examples.HdfsExample: success to delete the file /user/hdfs-examples/  
test.txt  
17/10/26 19:11:45 INFO examples.HdfsExample: success to delete path /user/hdfs-examples/  
17/10/26 19:11:45 INFO examples.HdfsExample: success to create path /user/hdfs-examples/  
hdfs_example_1  
17/10/26 19:11:45 INFO examples.HdfsExample: success to create path /user/hdfs-examples/  
hdfs_example_0  
17/10/26 19:11:45 INFO examples.HdfsExample: success to write.  
17/10/26 19:11:45 INFO examples.HdfsExample: success to write.  
17/10/26 19:11:46 INFO examples.HdfsExample: success to append.  
17/10/26 19:11:46 INFO examples.HdfsExample: result is : hi, I am bigdata. It is successful if you  
can see me.l append this content.  
17/10/26 19:11:46 INFO examples.HdfsExample: success to read.  
17/10/26 19:11:46 INFO examples.HdfsExample: success to delete the file /user/hdfs-examples/  
hdfs_example_1/test.txt  
17/10/26 19:11:46 INFO examples.HdfsExample: success to delete path /user/hdfs-examples/  
hdfs_example_1  
17/10/26 19:11:46 INFO examples.HdfsExample: success to append.  
17/10/26 19:11:46 INFO examples.HdfsExample: result is : hi, I am bigdata. It is successful if you  
can see me.l append this content.  
17/10/26 19:11:46 INFO examples.HdfsExample: success to read.  
17/10/26 19:11:46 INFO examples.HdfsExample: success to delete the file /user/hdfs-examples/  
hdfs_example_0/test.txt  
17/10/26 19:11:46 INFO examples.HdfsExample: success to delete path /user/hdfs-examples/  
hdfs_example_0
```

- The running result of the Colocation example application is shown as follows:

```
[root@192-168-32-144 client]#hadoop jar HDFSTest-XXX.jar  
com.huawei.bigdata.hdfs.examples.ColocationExample

```

- **Learn the application running conditions by viewing HDFS logs.**

The NameNode logs of HDFS offer immediate visibility into application running conditions. You can adjust application programs based on the logs.

## 2.7.5 More Information

### 2.7.5.1 Common API Introduction

#### 2.7.5.1.1 Java API

For details about Hadoop distributed file system (HDFS) APIs, see:

<http://hadoop.apache.org/docs/r3.3.1/api/index.html>

#### HDFS Common API

Common HDFS Java classes are as follows:

- FileSystem: the core class of client applications. For details about common APIs, see [Table 2-83](#).
- FileStatus: record the status of files and directories. For details about common APIs, see [Table 2-84](#).
- DFSColocatinAdmin: API used to manage colocatiion group information. For details about common APIs, see [Table 2-85](#).
- DFSColocatinClient: API used to manage colocatiion files. For details about common APIs, see [Table 2-86](#).

 NOTE

- The system reserves only the mapping between nodes and locator IDs, but does not reserve the mapping between files and locator IDs. When a file is created using a Colocation interface, the file is created on the node that corresponds to a locator ID. File creation and writing must be performed using Colocation interfaces.
- After the file is written, subsequent operations on the file can use other open-source interfaces in addition to Colocation interfaces.
- The DFSColocatiionClient class inherits from the open-source DistributedFileSystem class and contains common file operation functions. If a user uses the DFSColocatiionClient class to create a Colocation file, the user is advanced to use the functions of this class in file operations.

**Table 2-83** Common FileSystem APIs

API	Description
public static FileSystem get(Configuration conf)	FileSystem is the API class provided for users in the Hadoop class library. FileSystem is an abstract class. Concrete classes can be obtained only using the get method. The get method has multiple overload versions and is commonly used.
public FSDataOutputStream create(Path f)	This API is used to create files in the HDFS. <i>f</i> indicates a complete file path.
public void copyFromLocalFile(Pat h src, Path dst)	This API is used to upload local files to a specified directory in the HDFS. <i>src</i> and <i>dst</i> indicate complete file paths.
public boolean mkdirs(Path f)	This API is used to create folders in the HDFS. <i>f</i> indicates a complete folder path.
public abstract boolean rename(Path src, Path dst)	This API is used to rename a specified HDFS file. <i>src</i> and <i>dst</i> indicate complete file paths.
public abstract boolean delete(Path f, boolean recursive)	This API is used to delete a specified HDFS file. <i>f</i> indicates the complete path of the file to be deleted, and <b>recursive</b> specifies recursive deletion.
public boolean exists(Path f)	This API is used to query a specified HDFS file. <i>f</i> indicates a complete file path.
public FileStatus getFileStatus(Path f)	This API is used to obtain the FileStatus object of a file or folder. The FsStatus object records status information of the file or folder, including the modification time and file directory.
public BlockLocation[] getFileBlockLoca tions(FileStatus file, long start, long len)	This API is used to query the block location of a specified file in an HDFS cluster. <i>file</i> indicates a complete file path, and <i>start</i> and <i>len</i> specify the block scope.

API	Description
public FSDataInputStream open(Path f)	This API is used to open the output stream of a specified file in the HDFS and read the file using the API provided by the FSDataInputStream class. <i>f</i> indicates a complete file path.
public FSDataOutputStream create(Path f, boolean overwrite)	This API is used to create the input stream of a specified file in the HDFS and write the file using the API provided by the FSDataOutputStream class. <i>f</i> indicates a complete file path. If <b>overwrite</b> is <b>true</b> , the file is rewritten if it exists; if <b>overwrite</b> is <b>false</b> , an error is reported if the file exists.
public FSDataOutputStream append(Path f)	This API is used to open the input stream of a specified file in the HDFS and write the file using the API provided by the FSDataOutputStream class. <i>f</i> indicates a complete file path.

**Table 2-84** Common FileStatus APIs

API	Description
public long getModificationTime()	This API is used to query the modification time of a specified HDFS file.
public Path getPath()	This API is used to query all files in an HDFS directory.

**Table 2-85** Common DFSColocationAdmin APIs

API	Description
public Map<String, List<DatanodeInfo>> createColocationGroup(String groupId,String file)	This API is used to create a group based on the locatorIds information in the file. <i>file</i> indicates the file path.
public Map<String, List<DatanodeInfo>> createColocationGroup(String groupId,List<String> locators)	This API is used to create a group based on the locatorIds information in the list in the memory.
public void deleteColocationGroup(String groupId)	This API is used to delete a group.
public List<String> listColocationGroups()	This API is used to return all group information of Colocation. The returned group ID arrays are sorted by the creation time.

API	Description
public List<DatanodeInfo> getNodesForLocator(String groupId, String locatorId)	This API is used to obtain the list of all nodes in the locator.

**Table 2-86** Common DFSColocationAdmin APIs

API	Description
public FSDataOutputStream create(Path f, boolean overwrite, String groupId, String locatorId)	This API is used to create a FSDataOutputStream in colocation mode to allow users to write files in f. f is the HDFS path. overwrite indicates whether an existing file can be overwritten. groupId and locatorId of the file specified by a user must exist.
public FSDataOutputStream create(final Path f, final FsPermission permission, final EnumSet<CreateFlag> cflags, final int bufferSize, final short replication, final long blockSize, final Progressable progress, final ChecksumOpt checksumOpt, final String groupId, final String locatorId)	The function of this API is the same as that of FSDataOutputStream create(Path f, boolean overwrite, String groupId, String locatorId), except that users are allowed to customize checksum.
public void close()	This API is used to close the connection.

**Table 2-87** HDFS client WebHdfsFileSystem API

API	Description
public RemoteIterator<FileStatus> listStatusIterator(final Path)	This API will help in fetching the child files and folders information through multiple request using remote iterator, thus avoiding the user interface from becoming slow when there are millions of child information to be fetched.

## Glob path pattern based API to get LocatedFileStatus and Open file from FileStatus

Following APIs are added in DistributedFileSystem to get the FileStatus with block location and open file from FileStatus object. These APIs will reduce the number of RPC calls from client to Namenodes.

**Table 2-88** FileSystem APIs

Interface	Description
public LocatedFileStatus[] globLocatedStatus(Path, PathFilter, boolean) throws IOException	Return an array of LocatedFileStatus objects whose path names match pathPattern and pass the in path filter.
public FSDataInputStream open(FileStatus stat) throws IOException	If the stat is an instance of LocatedFileStatusHdfs that already have the location information, the InputStream is created without contacting NameNode.

### 2.7.5.1.2 C API

#### Function Description

Users can use the C application programming interface (API) to create, read and write, append, and delete files. For details of the C API, see the following official guidelines:

<https://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-hdfs/LibHdfs.html>

#### Code Sample

The following code snippets are used as an example. For complete code, see the HDFS C sample code **HDFS/hdfs-c-example/hdfs\_test.c** in the HDFS sample code decompression directory.

1. Configure the HDFS NameNode parameter and create the link connecting to the HDFS files.

```
hdfsFS fs = hdfsConnect("default", 0);
fprintf(stderr, "hdfsConnect- SUCCESS!\n");
```

2. Create the HDFS directory.

```
const char* dir = "/tmp/nativeTest";
int exitCode = hdfsCreateDirectory(fs, dir);
if( exitCode == -1 ){
    fprintf(stderr, "Failed to create directory %s \n", dir );
    exit(-1);
}
fprintf(stderr, "hdfsCreateDirectory- SUCCESS! : %s\n", dir);
```

3. Write files.

```
const char* file = "/tmp/nativeTest/testfile.txt";
hdfsFile writeFile = openFile(fs, (char*)file, O_WRONLY |O_CREAT, 0, 0, 0);
fprintf(stderr, "hdfsOpenFile- SUCCESS! for write : %s\n", file);

if(!hdfsFileIsOpenForWrite(writeFile)){
    fprintf(stderr, "Failed to open %s for writing.\n", file);
    exit(-1);
}

char* buffer = "Hadoop HDFS Native file write!";

hdfsWrite(fs, writeFile, (void*)buffer, strlen(buffer)+1);
fprintf(stderr, "hdfsWrite- SUCCESS! : %s\n", file);
```

```
printf("Flushing file data ....\n");
if (hdfsFlush(fs, writeFile)) {
    fprintf(stderr, "Failed to 'flush' %s\n", file);
    exit(-1);
}
hdfsCloseFile(fs, writeFile);
fprintf(stderr, "hdfsCloseFile- SUCCESS! : %s\n", file);
```

4. Read files.

```
hdfsFile readFile = openFile(fs, (char*)file, O_RDONLY, 100, 0, 0);
fprintf(stderr, "hdfsOpenFile- SUCCESS! for read : %s\n", file);

if(!hdfsFileisOpenForRead(readFile)){
    fprintf(stderr, "Failed to open %s for reading.\n", file);
    exit(-1);
}

buffer = (char *) malloc(100);
tSize num_read = hdfsRead(fs, readFile, (void*)buffer, 100);
fprintf(stderr, "hdfsRead- SUCCESS!, Byte read : %d, File content : %s \n", num_read ,buffer);
hdfsCloseFile(fs, readFile);
```

5. From the specified location to read the file.

```
buffer = (char *) malloc(100);
readFile = openFile(fs, file, O_RDONLY, 100, 0, 0);
if (hdfsSeek(fs, readFile, 10)) {
    fprintf(stderr, "Failed to 'seek' %s\n", file);
    exit(-1);
}
num_read = hdfsRead(fs, readFile, (void*)buffer, 100);
fprintf(stderr, "hdfsSeek- SUCCESS!, Byte read : %d, File seek content : %s \n", num_read ,buffer);
hdfsCloseFile(fs, readFile);
```

6. Copy the file.

```
const char* destfile = "/tmp/nativeTest/testfile1.txt";
if (hdfsCopy(fs, file, fs, destfile)) {
    fprintf(stderr, "File copy failed, src : %s, des : %s \n", file, destfile);
    exit(-1);
}
fprintf(stderr, "hdfsCopy- SUCCESS!, File copied, src : %s, des : %s \n", file, destfile);
```

7. Move the file.

```
const char* mvfile = "/tmp/nativeTest/testfile2.txt";
if (hdfsMove(fs, destfile, fs, mvfile )) {
    fprintf(stderr, "File move failed, src : %s, des : %s \n", destfile , mvfile);
    exit(-1);
}
fprintf(stderr, "hdfsMove- SUCCESS!, File moved, src : %s, des : %s \n", destfile , mvfile);
```

8. Rename the file.

```
const char* renamefile = "/tmp/nativeTest/testfile3.txt";
if (hdfsRename(fs, mvfile, renamefile)) {
    fprintf(stderr, "File rename failed, Old name : %s, New name : %s \n", mvfile, renamefile);
    exit(-1);
}
fprintf(stderr, "hdfsRename- SUCCESS!, File renamed, Old name : %s, New name : %s \n", mvfile, renamefile);
```

9. Delete Files.

```
if (hdfsDelete(fs, renamefile, 0)) {
    fprintf(stderr, "File delete failed : %s \n", renamefile);
    exit(-1);
}
fprintf(stderr, "hdfsDelete- SUCCESS!, File deleted : %s\n",renamefile);
```

10. Set the number of replications.

```
if (hdfsSetReplication(fs, file, 10)) {
    fprintf(stderr, "Failed to set replication : %s \n", file );
    exit(-1);
}
fprintf(stderr, "hdfsSetReplication- SUCCESS!, Set replication 10 for %s\n",file);
```

11. Set users, user groups.

```
if (hdfsChown(fs, file, "root", "root")) {
    fprintf(stderr, "Failed to set chown : %s \n", file );
    exit(-1);
}
fprintf(stderr, "hdfsChown- SUCCESS!, Chown success for %s\n",file);
```

12. Set permissions.

```
if (hdfsChmod(fs, file, S_IRWXU | S_IRWXG | S_IROTH)) {
    fprintf(stderr, "Failed to set chmod: %s \n", file );
    exit(-1);
}
fprintf(stderr, "hdfsChmod- SUCCESS!, Chmod success for %s\n",file);
```

13. Set the file time.

```
struct timeval now;
gettimeofday(&now, NULL);
if (hdfsUtime(fs, file, now.tv_sec, now.tv_sec)) {
    fprintf(stderr, "Failed to set time: %s \n", file );
    exit(-1);
}
fprintf(stderr, "hdfsUtime- SUCCESS!, Set time success for %s\n",file);
```

14. Get file information.

```
hdfsFileInfo * fileInfo = NULL;
if((fileInfo = hdfsGetPathInfo(fs, file)) != NULL) {
    printFileInfo(fileInfo);
    hdfsFreeFileInfo(fileInfo, 1);
    fprintf(stderr, "hdfsGetPathInfo - SUCCESS!\n");
}
```

15. Variable directory.

```
hdfsFileInfo * fileList = 0;
int numEntries = 0;
if((fileList = hdfsListDirectory(fs, dir, &numEntries)) != NULL) {
    int i = 0;
    for(i=0; i < numEntries; ++i) {
        printFileInfo(fileList+i);
    }
    hdfsFreeFileInfo(fileList, numEntries);
}
fprintf(stderr, "hdfsListDirectory- SUCCESS!, %s\n", dir);
```

16. Stream builder interfaces.

```
buffer = (char *) malloc(100);
struct hdfsStreamBuilder *builder= hdfsStreamBuilderAlloc(fs, (char*)file, O_RDONLY);
hdfsStreamBuilderSetBufferSize(builder,100);
hdfsStreamBuilderSetReplication(builder,20);
hdfsStreamBuilderSetDefaultBlockSize(builder,10485760);
readFile = hdfsStreamBuilderBuild(builder);
num_read = hdfsRead(fs, readFile, (void*)buffer, 100);
fprintf(stderr, "hdfsStreamBuilderBuild- SUCCESS! File read success. Byte read : %d, File content : %s
\n", num_read ,buffer);
free(buffer);

struct hdfsReadStatistics *stats = NULL;
hdfsFileGetReadStatistics(readFile, &stats);
fprintf(stderr, "hdfsFileGetReadStatistics- SUCCESS! totalBytesRead : %" PRId64 " ,
totalLocalBytesRead : %" PRId64 " , totalShortCircuitBytesRead : %" PRId64 " ,
totalZeroCopyBytesRead : %" PRId64 "\n", stats->totalBytesRead , stats->totalLocalBytesRead, stats-
>totalShortCircuitBytesRead, stats->totalZeroCopyBytesRead);
hdfsFileFreeReadStatistics(stats);
```

17. Disconnect the HDFS links.

```
hdfsDisconnect(fs);
```

## Preparing Running Environment

Install a client on the node. For example, install a client in the **/opt/hadoopclient** directory.

## Compiling and Running Applications in Linux

1. Go to the **/opt/hadoopclient** directory and run the following command to import the environment variables of the C client:

```
cd /opt/hadoopclient  
source bigdata_env
```

2. Go to the **/opt/hadoopclient/HDFS/hadoop/hdfs-c-example** directory and run the following command to import the environment variables of the C client:

```
cd /opt/hadoopclient/HDFS/hadoop/hdfs-c-example  
source component_env_C_example
```

3. Run the following command to clean the object files and executable files that are generated before:

```
make clean
```

The running result is displayed as follows:

```
[root@10-120-85-2 hdfs-c-example]# make clean  
rm -f hdfs_test.o  
rm -f hdfs_test
```

4. Run the following command to compile the new object files and executable files:

```
make ( or make all )
```

The running result is displayed as follows:

```
[root@10-120-85-2 hdfs-c-example]# make  
cc -c -I/opt/hadoopclient/HDFS/hadoop/include -Wall -o hdfs_test.o hdfs_test.c  
cc -o hdfs_test hdfs_test.o -lhdfs
```

5. Run the following command to create, write and read, append, and delete files:

```
make run
```

The running result is displayed as follows:

```
[root@10-120-85-2 hdfs-c-example]# make run  
.hdfs_test  
hdfsConnect- SUCCESS!  
hdfsCreateDirectory- SUCCESS! : /tmp/nativeTest  
hdfsOpenFile- SUCCESS! for write : /tmp/nativeTest/testfile.txt  
hdfsWrite- SUCCESS! : /tmp/nativeTest/testfile.txt  
Flushing file data ....  
hdfsCloseFile- SUCCESS! : /tmp/nativeTest/testfile.txt  
hdfsOpenFile- SUCCESS! for read : /tmp/nativeTest/testfile.txt  
hdfsRead- SUCCESS!, Byte read : 31, File content : Hadoop HDFS Native file write!  
hdfsSeek- SUCCESS!, Byte read : 21, File seek content : S Native file write!  
hdfsPread- SUCCESS!, Byte read : 10, File phead content : S Native f  
hdfsCopy- SUCCESS!, File copied, src : /tmp/nativeTest/testfile.txt, des : /tmp/nativeTest/testfile1.txt  
hdfsMove- SUCCESS!, File moved, src : /tmp/nativeTest/testfile1.txt, des : /tmp/nativeTest/testfile2.txt  
hdfsRename- SUCCESS!, File renamed, Old name : /tmp/nativeTest/testfile2.txt, New name : /tmp/  
nativeTest/testfile3.txt  
hdfsDelete- SUCCESS!, File deleted : /tmp/nativeTest/testfile3.txt

hdfsExists- SUCCESS! /tmp/nativeTest/testfile.txt
hdfsConfGetStr- SUCCESS : hdfs://hacluster
hdfsStreamBuilderBuild- SUCCESS! File read success. Byte read : 31, File content : Hadoop HDFS
Native file write!
hdfsFileGetReadStatistics- SUCCESS! totalBytesRead : 31, totalLocalBytesRead : 0,
totalShortCircuitBytesRead : 0, totalZeroCopyBytesRead : 0
```

6. Enter the debug mode. (Optional)

**make gdb**

The running result is displayed as follows:

```
[root@10-120-85-2 hdfs-c-example]# make gdb
gdb hdfs_test

### 2.7.5.1.3 HTTP REST API

#### Function Description

Users can use the application programming interface (API) of Representational State Transfer (REST) to create, read and write, append, and delete files. For details of the REST API, see the following official guidelines:

<http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-hdfs/WebHDFS.html>.

#### Preparing Running Environment

**Step 1** Install the client. Install the client on the node. For example, install the client in the **/opt/hadoopclient** directory. See details in "Installing the Client."

1. Prepare files **testFile** and **testFileAppend** and write content 'Hello, webhdfs user!' and 'Welcome back to webhdfs!'. Run the following command to prepare **testFile** and **testFileAppend** files:

**touch testFile**

**vi testFile**

Write 'Hello, webhdfs user!', save the files, and exit.

**touch testFileAppend**

**vi testFileAppend**

Write 'Welcome back to webhdfs!', save the files, and exit.

- Step 2** In normal mode, only the HTTP service is supported. [Accessing FusionInsight Manager of an MRS Cluster](#), choose **Cluster > Name of the desired cluster > Services > HDFS > Configurations > All Configurations**. Type **dfs.http.policy** in the research box, select **HTTP\_ONLY**, click **Save Configuration**, and select **Restart the affected services or instances**. Click **OK** to restart the HDFS service.

**HTTP\_ONLY** is selected by default.

----End

## Procedure

- Step 1** [Accessing FusionInsight Manager of an MRS Cluster](#), click **Cluster > Name of the desired cluster > Services**, and then select **HDFS**. The HDFS page is displayed.

Because webhdfs is accessed through HTTP, you need to obtain the IP address of the active NameNode and the HTTP port.

1. Click **Instances**, view the host name and IP address of the active NameNode.
2. Click **Configurations**, search **namenode.http.port** in the search box (25002).

- Step 2** Create a directory by referring to the following link:

[http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-hdfs/WebHDFS.html#Make\\_a\\_Directory](http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-hdfs/WebHDFS.html#Make_a_Directory).

Click the link, **Figure 2-153** is displayed:

**Figure 2-153** Example code of creating a directory

The screenshot shows a browser interface for creating a directory. It includes a URL input field with the value "curl -i -X PUT \"http://:8033/webhdfs/v1/25002/tmp/testdir?op=MKDIRS&permissions=0777\"". Below it, a text area displays the response: "HTTP/1.1 200 OK Content-Type: application/json Transfer-Encoding: chunked {"boolean": true}".

Go to the **/opt/hadoopclient** directory, the installation directory of the client, and create the **huawei** directory.

1. Run the following command to check whether the **huawei** directory exists in the current path.

**hdfs dfs -ls /**

The running results are as follows:

```
linux1:/opt/hadoopclient # hdfs dfs -ls /
16/04/22 16:10:02 INFO hdfs.PeerCache: SocketCache disabled.
Found 7 items
-rw-r--r-- 3 hdfs supergroup          0 2016-04-20 18:03 /PRE_CREATE_DIR.SUCCESS
drwxr-x---  - flume hadoop          0 2016-04-20 18:02 /flume
drwx-----  - hbase hadoop          0 2016-04-22 15:19 /hbase
drwxrwxrwx  - mapred hadoop         0 2016-04-20 18:02 /mr-history
```

```
drwxrwxrwx - spark supergroup 0 2016-04-22 15:19 /sparkJobHistory  
drwxrwxrwx - hdfs hadoop 0 2016-04-22 14:51 /tmp  
drwxrwxrwx - hdfs hadoop 0 2016-04-22 14:50 /user
```

The **huawei** directory does not exist in the current path.

2. Run the command in [Figure 2-153](#) that is named with **huawei**. Replace the <HOST> and <PORT>in the command with the host name or IP address and port number that are obtained in [Step 1](#). Type the **huawei** as the directory in the <PATH>.

 NOTE

<HOST> can be replaced by the host name or IP address. It is noted that the port of HTTP is different from the port of HTTPS.

- Run the following command to access HTTP:  
`curl -i -X PUT --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei?  
user.name=test&op=MKDIRS"`

In the command, <HOST> is replaced by **linux1** and <PORT> is replaced by **25002**.

The test in the preceding command is the user who performs the operation. The user must confirm with the administrator for the permission.

- The running result is displayed as follows:

```
HTTP/1.1 200 OK  
Cache-Control: no-cache  
Expires: Thu, 14 Jul 2016 08:04:39 GMT  
Date: Thu, 14 Jul 2016 08:04:39 GMT  
Pragma: no-cache  
Expires: Thu, 14 Jul 2016 08:04:39 GMT  
Date: Thu, 14 Jul 2016 08:04:39 GMT  
Pragma: no-cache  
Content-Type: application/json  
X-FRAME-OPTIONS: SAMEORIGIN  
Set-Cookie: hadoop.auth="u=hdfs&p=hdfs&t=simple&e=1468519479514&s=/j/J  
+ZnVrN7NSz1yKnB2JViwkj0="; Path=/; Expires=Thu, 14-Jul-2016 18:04:39 GMT; HttpOnly  
Transfer-Encoding: chunked  
{"boolean":true}
```

If {"boolean":true} returns, the **huawei** directory is successfully created.

3. Run the following command to check the **huawei** directory in the path.

```
linux1:/opt/hadoopclient # hdfs dfs -ls /  
16/04/22 16:14:25 INFO hdfs.PeerCache: SocketCache disabled.  
Found 8 items  
-rw-r--r-- 3 hdfs supergroup 0 2016-04-20 18:03 /PRE_CREATE_DIR.SUCCESS  
drwxr-x--- - flume hadoop 0 2016-04-20 18:02 /flume  
drwx----- - hbase hadoop 0 2016-04-22 15:19 /hbase  
drwxr-xr-x - hdfs supergroup 0 2016-04-22 16:13 /huawei  
drwxrwxrwx - mapred hadoop 0 2016-04-20 18:02 /mr-history  
drwxrwxrwx - spark supergroup 0 2016-04-22 16:12 /sparkJobHistory  
drwxrwxrwx - hdfs hadoop 0 2016-04-22 14:51 /tmp  
drwxrwxrwx - hdfs hadoop 0 2016-04-22 16:10 /user
```

**Step 3** Create a command of the upload request to obtain the information about Location where the DataNode IP address is written in.

- Run the following command to access HTTP:  
`linux1:/opt/hadoopclient # curl -i -X PUT --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/  
testHdfs?user.name=test&op=CREATE"`

- The running result is displayed as follows:

```
HTTP/1.1 307 TEMPORARY_REDIRECT  
Cache-Control: no-cache  
Expires: Thu, 14 Jul 2016 08:53:07 GMT  
Date: Thu, 14 Jul 2016 08:53:07 GMT
```

```
Pragma: no-cache
Expires: Thu, 14 Jul 2016 08:53:07 GMT
Date: Thu, 14 Jul 2016 08:53:07 GMT
Pragma: no-cache
Content-Type: application/octet-stream
X-FRAME-OPTIONS: SAMEORIGIN
Set-Cookie: hadoop.auth="u=hdfs&p=hdfs&t=simple&e=1468522387880&s=OlksfRJvEkh/
Out9y2Ot2FvrxWk="; Path=/; Expires=Thu, 14-Jul-2016 18:53:07 GMT; HttpOnly
Location:
http://10-120-180-170:25010/webhdfs/v1/testHdfs?
op=CREATE&user.name=hdfs&namenoderpcaddress=hacluster&createflag=&createparent=true&overwr
ite=false
Content-Length: 0
```

**Step 4** According to the Location information, create the **testHdfs** file in the **/huawei/testHdfs** file on the HDFS and upload the content in the local **testFile** file into the **testHdfs** file.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -i -X PUT -T testFile --negotiate -u: "http://10-120-180-170:25010/
webhdfs/v1/testHdfs?
op=CREATE&user.name=test&namenoderpcaddress=hacluster&createflag=&createparent=true&overwr
ite=false"
```

- The running result is displayed as follows:

```
HTTP/1.1 100 Continue
HTTP/1.1 201 Created
Location: hdfs://hacluster/testHdfs
Content-Length: 0
Connection: close
```

**Step 5** Go to the **/huawei/testHdfs** directory and read the content of **testHdfs** file.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -L --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/testHdfs??
user.name=test&op=OPEN"
```

- The running result is displayed as follows:

```
Hello, webhdfs user!
```

**Step 6** Create a command of the upload request to obtain the information about Location where the DataNode IP address of **testHdfs** file is written in.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -i -X POST --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/
testHdfs??user.name=test&op=APPEND"
```

- The running result is displayed as follows:

```
HTTP/1.1 307 TEMPORARY_REDIRECT
Cache-Control: no-cache
Expires: Thu, 14 Jul 2016 09:18:30 GMT
Date: Thu, 14 Jul 2016 09:18:30 GMT
Pragma: no-cache
Expires: Thu, 14 Jul 2016 09:18:30 GMT
Date: Thu, 14 Jul 2016 09:18:30 GMT
Pragma: no-cache
Content-Type: application/octet-stream
X-FRAME-OPTIONS: SAMEORIGIN
Set-Cookie: hadoop.auth="u=hdfs&p=hdfs&t=simple&e=1468523910234&s=JGK
+6M6PsVMFdAw2cg!HaKU1kBm="; Path=/; Expires=Thu, 14-Jul-2016 19:18:30 GMT; HttpOnly
Location:
http://10-120-180-170:25010/webhdfs/v1/testHdfs?
op=APPEND&user.name=hdfs&namenoderpcaddress=hacluster
Content-Length: 0
```

**Step 7** According to the Location information, add the content in the local **testFileAppend** file to the **testHdfs** file that is in the **/huawei/testHdfs** directory of HDFS.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -i -X POST -T testFileAppend --negotiate -u: "http://linux1:25010/webhdfs/v1/huawei/testHdfs?user.name=test&op=APPEND&namenoderpcaddress=hacluster"
```

- The running result is displayed as follows:

```
HTTP/1.1 100 Continue  
HTTP/1.1 200 OK  
Content-Length: 0  
Connection: close
```

**Step 8** Go to the **/huawei/testHdfs** directory and read all content in the **testHdfs** file.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -L --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/testHdfs?user.name=test&op=OPEN"
```

- The running result is displayed as follows:

```
Hello, webhdfs user!  
Welcome back to webhdfs!
```

**Step 9** List details of all directory and file information in the **huawei** directory of the HDFS.

LISTSTATUS will return all child files and folders information in a single request.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/testHdfs?user.name=test&op=LISTSTATUS"
```

- The result is displayed as follows:

```
{"FileStatuses":[{"FileStatus":{  
"accessTime":1462425245595,"blockSize":134217728,"childrenNum":0,"fileId":17680,"group":"supergr  
oup","length":70,"modificationTime":1462426678379,"owner":"test","pathSuffix":"","permission":"755",  
"replication":3,"storagePolicy":0,"type":"FILE"}  
}]}
```

LISTSTATUS along with size and startafter param will help in fetching the child files and folders information through multiple request, thus avoiding the user interface from becoming slow when there are millions of child information to be fetched.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/?user.name=test&op=LISTSTATUS&startafter=sparkJobHistory&size=1"
```

- The result is displayed as follows:

```
{"FileStatuses":[{"FileStatus":{  
"accessTime":1462425245595,"blockSize":134217728,"childrenNum":0,"fileId":17680,"group":"supergr  
oup","length":70,"modificationTime":1462426678379,"owner":"test","pathSuffix":"testHdfs","permmissio  
n":"755","replication":3,"storagePolicy":0,"type":"FILE"}  
}]}
```

**Step 10** Delete the **testHdfs** file that is in the **/huawei/testHdfs** directory of HDFS.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -i -X DELETE --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/testHdfs?user.name=test&op=DELETE"
```

- The running result is displayed as follows:

```
HTTP/1.1 200 OK  
Cache-Control: no-cache  
Expires: Thu, 14 Jul 2016 10:27:44 GMT  
Date: Thu, 14 Jul 2016 10:27:44 GMT  
Pragma: no-cache  
Expires: Thu, 14 Jul 2016 10:27:44 GMT  
Date: Thu, 14 Jul 2016 10:27:44 GMT  
Pragma: no-cache  
Content-Type: application/json  
X-FRAME-OPTIONS: SAMEORIGIN  
Set-Cookie: hadoop.auth="u=hdfs&p=hdfs&t=simple&e=1468528064220&s=HrvUEd72+V5L4GwCLC/
```

```
SG3xTl0o="; Path=/; Expires=Thu, 14-Jul-2016 20:27:44 GMT; HttpOnly  
Transfer-Encoding: chunked  
{\"boolean\":true}
```

----End

The Key Management Server (KMS) uses the HTTP REST API to provide key management services for external systems. For details about the API, see <https://hadoop.apache.org/docs/r3.3.1/hadoop-kms/index.html>.

#### NOTE

As REST API reference has done security hardening to prevent script injection attack. Through REST API reference, it cannot create directory and file name which contain those key words "<script ", "<iframe", "<frame", "javascript:".

### 2.7.5.2 Shell Command Introduce

#### HDFS Shell

You can use the Hadoop Distributed File System (HDFS) Shell command to perform operations on the HDFS, such as reading and writing files.

To run the HDFS Shell:

Go to the directory of HDFS client and enter the command. An example is shown as follows:

```
cd /opt/hadoopclient/HDFS/hadoop/bin
```

```
hdfs dfs -mkdir /tmp/input
```

You can run the following command to seek help about HDFS commands:

```
hdfs --help
```

For details about the shell, see

<http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-common/FileSystemShell.html>

**Table 2-89** Transparent encryption-related commands

Scenario	Operation	Command	Description
hadoop shell command management key	Create keys.	<b><i>hadoop key create &lt;keyname&gt; [-cipher &lt;cipher&gt;] [-size &lt;size&gt;] [-description &lt;description&gt;] [-attr &lt;attribute=value&gt;] [-provider &lt;provider&gt;] [-help]</i></b>	The create subcommand creates a key for the name specified by the <keyname> argument within the provider specified by the -provider argument. You may specify a cipher with the -cipher argument. The default keysize is 128. You may specify the requested key length using the -size argument. Arbitrary attribute=value style attributes may be specified using the -attr argument. The -attr may be specified for multiple times, once per attribute.
	Rollback	<b><i>hadoop key roll &lt;keyname&gt; [-provider &lt;provider&gt;] [-help]</i></b>	The roll subcommand creates a new version for the specified key within the provider indicated using the -provider argument.
	Delete keys	<b><i>hadoop key delete &lt;keyname&gt; [-provider &lt;provider&gt;] [-f] [-help]</i></b>	The delete subcommand deletes all versions of the key specified by the <keyname> argument within the provider specified by the -provider argument. The command asks for user confirmation unless -f is specified.
	View keys	<b><i>hadoop key list [-provider &lt;provider&gt;] [-metadata] [-help]</i></b>	The list subcommand displays the keynames contained in a particular provider as configured in core-site.xml or specified with the -provider argument. The -metadata argument displays the metadata.

**Table 2-90** Shell commands of Colocation client

Operation	Command	Description
Group creation	hdfs colocationadmin -createGroup -groupId <groupId> -locatorIDs <comma separated locatorIDs> or -file <path of the file contains all of locatorIDs>	Used to create a group. In the command, groupId is the group name and locatorID is the locator name. You can enter comma-separated locator IDs using command lines. You can also write locator IDs into a file so that the system can obtain the locator IDs by reading the file.
Group deletion	hdfs colocationadmin -deleteGroup <groupId>	Used to delete the specified group.
Group query	hdfs colocationadmin -queryGroup <groupId>	Used to query details about a specified group, including locators in the group and information about each locator and its corresponding DataNode.
Viewing all groups	hdfs colocationadmin -listGroups	Used to list all groups and their creation time.
Setting ACL permissions on Colocation directories	hdfs colocationadmin -setAcl	Used to set ACL permissions on Colocation directories in ZooKeeper. The default root directory of Colocation in ZooKeeper is <b>/hadoop/colocationDetails</b> .

## 2.8 HetuEngine Development Guide

### 2.8.1 Overview

#### 2.8.1.1 Introduction to HetuEngine

##### Introduction to HetuEngine

HetuEngine is a high-performance interactive SQL analysis and data virtualization engine developed by Huawei. It seamlessly integrates with the big data ecosystem

to implement interactive query of massive amounts of data within seconds, and supports cross-source and cross-domain unified data access to enable one-stop SQL convergence analysis in the data lake, between lakes, and between lakehouses.

### 2.8.1.2 Concepts

#### Basic Concepts

- HSFabric: unified entry for the HetuEngine services. It receives external requests and supports cross-network access to the HetuEngine services.
- HSBroker: service management of the HetuEngine services. It is used for resource management verification, health monitoring, and automatic maintenance of compute instances.
- Coordinator: coordinator of the HetuEngine services. It is responsible for SQL parsing and optimization.
- Worker: compute node of the HetuEngine compute instances. It executes tasks and processes data.
- Connector: an API for HetuEngine to access the database. Through the connector driver, HetuEngine connects to the data sources, reads data source metadata, and operates data (adding, deleting, modification, and query).
- Catalog: the catalog configuration file corresponds to a data source in HetuEngine. A data source can have multiple catalog configurations, which can be configured in the **properties** file of a data source.
- Schema: schema name of the database.
- Table: table name of the database.

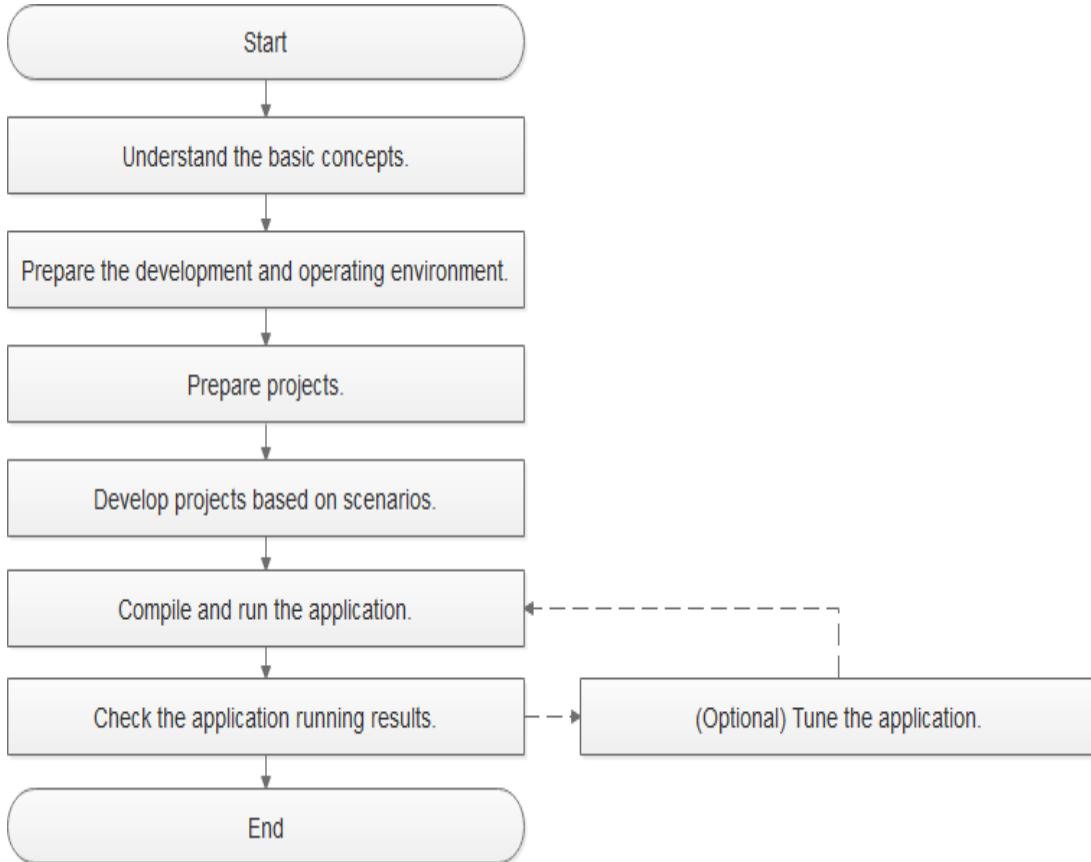

### 2.8.1.3 Connection Modes

Connection Mode	Support for Cross - Network-Segment Client Access	Prerequisite
HSFabric	Yes	<ul style="list-style-type: none"><li>The node running user services can communicate with the service nodes where HSFabric resides on the HetuEngine server side.</li><li>Dual-plane network scenarios are supported.</li><li>Only fixed IP addresses and ports need to be opened for HSFabric.</li><li>Supported version: MRS 3.1.3 or later.</li></ul>
HSBroker	No	<ul style="list-style-type: none"><li>The node running user services can communicate with the service nodes where HSBroker and Coordinator (randomly distributed in Yarn NodeManager) reside on the HetuEngine server side.</li><li>A large number of IP addresses and ports need to be opened for coordinators.</li><li>Supported version: MRS 3.1.0 or later</li></ul>

### 2.8.1.4 Development Process

This section describes the development process, as shown in [Figure 2-154](#).

**Figure 2-154 HetuEngine application development process**

**Table 2-91 Description of the HetuEngine application development process**

Phase	Description	Reference Documents
Understand basic concepts.	Before application development, learn basic concepts of HetuEngine, and understand the scenario requirements.	<a href="#">Concepts</a>
Prepare the development and running environment.	The HetuEngine application can invoke the JDBC interface in any language for development. The current example uses the Java language. You are advised to use the IDEA tool to configure development environments in different languages according to the guide. The HetuEngine running environment is a client. Install and configure the client according to the guide.	<a href="#">Preparing Development and Operating Environment</a>
Prepare a project.	HetuEngine provides sample projects for different scenarios. You can import a sample project to learn the application. You can also create a HetuEngine project according to the guide.	<a href="#">Configuring and Importing Sample Projects</a>

Phase	Description	Reference Documents
Develop a project based on the scenario.	A sample project in the Java language is provided, including an example project that connects the HetuEngine, SQL statement execution, result parsing, and disconnection.	<a href="#">Application Development</a>
Compile and run applications .	You can compile the developed application and submit it for running.	<a href="#">Application Commissioning</a>
Check the application running results.	The program running result is displayed in the expected display according to the implementation of the result parsing part.	<a href="#">Application Commissioning</a>

## 2.8.2 Preparing Environment

### 2.8.2.1 Preparing Development and Operating Environment

#### Preparing the Development Environment

This section describes the development and running environment to be prepared for application development, as listed in [Table 2-92](#).

**Table 2-92** Development environment

Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows 7 or later</li><li>• Running environment: Windows or Linux If the program needs to be commissioned locally, the operating environment must be able to communicate with the cluster service plane.</li></ul>

Item	Description
JDK installation	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>Basic configuration of the development environment. The version must be 2019.1 or other compatible versions.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you use the IBM JDK, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If you are using an Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If you are using an OpenJDK, ensure that the JDK configured in IntelliJ IDEA is the OpenJDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA projects.</li></ul>
Maven installation	Basic configuration of the development environment. It can be used for project management throughout the lifecycle of software development.

Item	Description
7-zip	Tool used to decompress *.zip and *.rar files. <b>7-Zip 16.04</b> is supported.

**Table 2-93** Python3 environment (required when the Python sample project is used)

Item	Description
Python3	Tool used to develop HetuEngine Python applications. The version must range from 3.6 to 3.9.
Setuptools	Basic configuration of the Python3 development environment. Version: 47.3.1
jaydebeapi	Basic configuration of the Python3 development environment. You can use this module to connect to the database using Java JDBC.

## Preparing the Operating Environment

During application development, prepare the environment for running and commissioning code to verify that the application can run properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required for commissioning; configure the network connection, and commission the application in Windows.
  - a. Log in to FusionInsight Manager. In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Complete Client**, select the correct platform type (**x86\_64** for x86 and **aarch64** for ARM) based on the platform type of the node where the client is to be installed, and click **OK**. After the client file package is generated, download it to the local PC as prompted and decompress it.  
For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.
  - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\HetuEngine\config** and manually import the configuration file to the configuration file directory (for example, **D:\hetuclient\conf**) of the HetuEngine sample project.  
**Table 2-94** describes the main configuration files. (Obtain the required files you need.)

**Table 2-94** Configuration files

File	Description
hdfs-site.xml	HDFS parameters
hetuserver-client.properties	HetuEngine client connection parameters
hetuserver-client-logging.properties	HetuEngine client log parameters

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 **NOTE**

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored, for example, in **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, install the client in the **/opt/hadoopclient** directory.  
The difference between the client time and the cluster time must be less than 5 minutes.  
For details about how to install a cluster client, see [Installing a Client](#).
  - b. **Accessing FusionInsight Manager of an MRS Cluster**. Download the cluster client software package to the active management node and decompress it. Then log in to the active management node as user **root**. Go to the decompression directory of the cluster client, and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/HetuEngine/config** directory to the client node to the **conf** directory where the compiled JAR package is stored, for example, **/opt/hadoopclient/conf**, for subsequent commissioning.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active OMS node, run the following commands:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig
```

```
scp HetuEngine/config/* root@IP address of the client node:/opt/
hadoopclient/conf
```

**Table 2-95** describes the main configuration files. (Obtain the required files you need.)

**Table 2-95** Configuration files

File	Description
hdfs-site.xml	HDFS parameters
hetuserver-client.properties	HetuEngine client connection parameters
hetuserver-client-logging.properties	HetuEngine client log parameters

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If there is no required information, copy the content of the **hosts** file in the decompression directory to the **hosts** file on the node where the client is deployed, to ensure that the local host can communicate with each host in the cluster.

### 2.8.2.2 Configuring and Importing Sample Projects

#### Scenario

The HetuEngine client installation program directory contains a HetuEngine development sample project. You can start the sample project learning by importing the project. This document uses IntelliJ IDEA 2020.1.3 (Community Edition) as an example.

#### Prerequisites

Ensure that the difference between the local PC time and the MRS cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the time of the MRS cluster in the upper-right corner on the FusionInsight Manager page.

#### Procedure

- Step 1** Obtain the sample project folder **hetu-examples** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.

1. Open IntelliJ IDEA and choose **File > New > General > Project from Existing Sources > Select File or Directory to Import** to go to the **Browse Folder** dialog box is displayed.
2. Select the sample project folder, choose **Import project from external model > Maven** during import, and click **Next** and then **Finish**.

 **NOTE**

The sample code is a Maven project. You can adjust the project configuration based on the site requirements.

----End

### 2.8.2.3 Setting Up a Python3 Project

#### Scenario

The following content describes the operations you need to do to run the python3 sample code of HetuEngine on FusionInsight MRS.

#### Procedure

- Step 1** Install Python 3.6 or a later version (before 3.9) on the client node.

The Python version can be viewed by running the **python3** command on the CLI of the client. The following information indicates that the Python version is 3.8.2.

```
Python 3.8.2 (default, Jun 23 2020, 10:26:03)
[GCC 4.8.5 20150623 (Red Hat 4.8.5-36)] on linux
Type "help", "copyright", "credits" or "license" for more information.
```

- Step 2** Setuptools 47.3.1 must be installed on the client.

Download the software from the official website <https://pypi.org/project/setuptools/#files>.

Copy the downloaded setuptools package to the client, decompress the package, go to the setuptools project directory, and run the **python3 setup.py install** command in the CLI of the client.

The following information indicates that setuptools 47.3.1 is installed successfully.

```
Finished processing dependencies for setuptools==47.3.1
```

 **NOTE**

If the system displays a message indicating that setuptools 47.3.1 fails to be installed, check whether the environment is faulty or Python is faulty.

- Step 3** The JayDeBeApi module must be installed on the client. You can use the Java JDBC to connect to the database through this module.

You can install it either of the following ways:

- pip:  
Run the **pip install JayDeBeApi** command on the client node.
- Script:
  - a. Download the **JayDeBeApi project** file from the official website at <https://pypi.org/project/JayDeBeApi/>

- b. Go to the **JayDeBeApi** project directory and run the **python3 setup.py install** command. During the installation, if the system displays a message indicating that the python3 module or package is missing, you need to add the module or package.

Take JayDeBeApi-1.2.3 as an example. If **Successfully installed JayDeBeApi-1.2.3** is displayed, the installation is successful.

**Step 4** Install Java on the client. For details about the supported Java versions, see "JDK Installation" in the [Table 1-105](#).

**Step 5** Obtain the Python3 sample code.

1. Obtain the sample project folder **python3-examples** in the **src\hetu-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
2. Go to the **python3-examples** folder.
  - **normal** folder: Python3 sample code for interconnecting with HetuEngine in common mode
  - **security** folder: Python3 sample code for interconnecting with HetuEngine in security mode

**Step 6** Obtain the **hetu-jdbc** JAR package.

- Download the client file to the local PC through Manager.
  - a. Log in to FusionInsight Manager and choose **Cluster > Services > HetuEngine > More > Download Client**.
  - b. Select **Complete Client**, select the correct platform type (**x86\_64** for x86 and **aarch64** for ARM) for the node where the client is to be installed, deselect **Save to Path**, and click **OK**. Wait until the client file package is generated and download it.
  - c. Decompress the downloaded software package to obtain the **hetu-jdbc** package and decompress it to obtain the JDBC package.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress the package to obtain the **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then decompress the package to obtain the **FusionInsight\_Cluster\_1\_Services\_ClientConfig** file. (The path cannot contain spaces.) Decompress **\FusionInsight\_Cluster\_1\_Services\_ClientConfig\HetuEngine\x86\hetu-jdbc.tar.gz** to obtain **hetu-jdbc-XXX.jar** and copy it to the user-defined path on the host where the sample code will run.

- Obtain the cluster client node.  
Log in to the node where the HetuEngine client has been installed. For example, if the client installation path is **/opt/hadoopclient**, obtain **hetu-jdbc-XXX.jar** from **/opt/hadoopclient/HetuEngine/hetuserver/jars/**, and copy the file to the user-defined path on the node where the sample code will run.

----End

## 2.8.2.4 Setting Up a Spring Boot Sample Project

### Scenario

This topic describes how to run the Spring Boot sample code of the HetuEngine component in MRS.

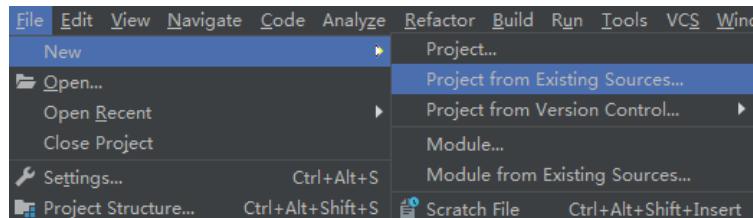

This example develops an application for connecting to the HetuEngine service using Spring Boot in a Windows environment.

### Procedure

**Step 1** Obtain the **src/springboot/hetu-examples** directory in the directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** In the application development environment, import the sample project to IntelliJ IDEA.

1. Choose **File > New > Project from Existing Sources....**

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **hetu-examples** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.

Select the recommended JDK version and click **Finish**.

----End

## 2.8.3 Application Development

### 2.8.3.1 Typical Application Scenario

You can quickly learn and master the HetuEngine development process and know key interface functions in a typical application scenario.

### Scenario

Assume that a user develops an application and needs to perform the join operation on table A of the Hive data source and table B of the MPPDB data source. In this case, HetuEngine can be used to implement data query of the Hive data source, the process is as follows:

1. Connect to a HetuEngine JDBC server.
2. Assemble SQL statements.
3. Execute SQL statements.

4. Parse the returned result.
5. Disconnect HetuEngine JDBC server.

### 2.8.3.2 Java Sample Code

#### 2.8.3.2.1 Accessing Hive Data Sources Using HSFabric

##### Description

This section describes how to use HSFabric to connect to HetuEngine, assemble SQL statements, and send the SQL statements to HetuEngine for execution to add, delete, modify, and query Hive data sources.

```
public class JDBCExampleFabric {  
    private static Properties properties = new Properties();  
    private static void init() throws ClassNotFoundException {  
        properties.setProperty("User", "YourUserName");  
        properties.setProperty("SSL", "false");  
        Class.forName("io.trino.jdbc.TrinoDriver");  
    }  
    /**  
     * Program entry  
     *  
     * @param args no need program parameter  
     */  
    public static void main(String[] args) {  
        Connection connection = null;  
        ResultSet result = null;  
        PreparedStatement statement = null;  
        String url = "jdbc:trino://192.168.1.130:29903,192.168.1.131:29903/hive/default?  
serviceDiscoveryMode=hsfabric";  
        try {  
            init();  
            String sql = "show tables";  
            connection = DriverManager.getConnection(url, properties);  
            statement = connection.prepareStatement(sql.trim());  
            result = statement.executeQuery();  
            ResultSetMetaData resultMetaData = result.getMetaData();  
            Integer colNum = resultMetaData.getColumnCount();  
            for (int j = 1; j <= colNum; j++) {  
                System.out.print(resultMetaData.getColumnLabel(j) + "\t");  
            }  
            System.out.println();  
            while (result.next()) {  
                for (int j = 1; j <= colNum; j++) {  
                    System.out.print(result.getString(j) + "\t");  
                }  
                System.out.println();  
            }  
        } catch (SQLException | ClassNotFoundException e) {  
            e.printStackTrace();  
        } finally {  
            if (result != null) {  
                try {  
                    result.close();  
                } catch (SQLException e) {  
                    e.printStackTrace();  
                }  
            }  
            if (statement != null) {  
                try {  
                    statement.close();  
                } catch (SQLException e) {  
                    e.printStackTrace();  
                }  
            }  
        }  
    }  
}
```

```
        if (connection != null) {
            try {
                connection.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
    }
}
```

**Table 2-96** describes the parameters in the preceding code.

**Table 2-96** Parameter description

Parameter	Description
url	<p>jdbc:trino:// <i>HSFabric1_IP.HSFabric1_Port,HSFabric2_IP.HSFabric2_Port,</i> <i>HSFabric3_IP.HSFabric3_Port/catalog/schema?</i> serviceDiscoveryMode=hsfabric</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• <i>catalog</i> and <i>schema</i> indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>• <i>HSFabric_IP:HSFabric_Port</i>: indicates the HSFabric URL. Use commas (,) to separate multiple URLs, for example, 192.168.81.37:29903,192.168.195.232:29903,192.168.169.84:29903. On FusionInsight Manager, choose <b>Cluster &gt; Services &gt; HetuEngine</b> and click <b>Instance</b> to obtain the service IP addresses of all HSFabric instances. On the <b>Configurations</b> page, search for <b>gateway.port</b> to obtain the port number of HSFabric.</li><li>• (Optional) <b>auditAddition</b>: custom information about the audit log. This field is recorded in the audit log. This parameter is used to supplement information for user audit.<ul style="list-style-type: none"><li>• Name of the image. The name can contain 1 to 255 characters.</li><li>• Only letters, digits, underscores (_), commas (,), and colons (:) are allowed.</li></ul></li></ul>
user	Username for accessing HetuEngine, that is, the username of the machine-machine user created in the cluster.
SSL	Indicates whether to use the HTTPS connection. The default value is <b>false</b> .

### 2.8.3.2.2 Accessing Hive Data Sources Using HSBroker

#### Description

This section describes how to use HSBroker to connect to HetuEngine, assemble SQL statements, and send the SQL statements to HetuEngine for execution to add, delete, modify, and query Hive data sources.

```
public class JDBCExampleBroker {
    private static Properties properties = new Properties();
```

```
private static void init() throws ClassNotFoundException {
    properties.setProperty("user", "YourUserName");
    properties.setProperty("SSL", "false");
    Class.forName("io.trino.jdbc.TrinoDriver");
}
/**
 * Program entry
 *
 * @param args no need program parameter
 */
public static void main(String[] args) {
    Connection connection = null;
    ResultSet result = null;
    PreparedStatement statement = null;
    String url = "jdbc:trino://192.168.1.130:29861,192.168.1.131:29861/hive/default?
serviceDiscoveryMode=hsbroker";
    try {
        init();
        String sql = "show tables";
        connection = DriverManager.getConnection(url, properties);
        statement = connection.prepareStatement(sql.trim());
        result = statement.executeQuery();
        ResultSetMetaData metaData = result.getMetaData();
        Integer colNum = metaData.getColumnCount();
        for (int j = 1; j <= colNum; j++) {
            System.out.print(resultMetaData.getColumnLabel(j) + "\t");
        }
        System.out.println();
        while (result.next()) {
            for (int j = 1; j <= colNum; j++) {
                System.out.print(result.getString(j) + "\t");
            }
            System.out.println();
        }
    } catch (SQLException | ClassNotFoundException e) {
        e.printStackTrace();
    } finally {
        if (result != null) {
            try {
                result.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
        if (statement != null) {
            try {
                statement.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
        if (connection != null) {
            try {
                connection.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
    }
}
```

**Table 2-97** describes the parameters in the preceding code.

**Table 2-97** Parameter description

Parameter	Description
url	<p>jdbc:trino:// <i>HSBroker1_IP.HSBroker1_Port,HSBroker2_IP.HSBroker2_Port,HSBroker3_IP.HSBroker3_Port/catalog/schema?</i> serviceDiscoveryMode=hsbroker</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• <i>catalog</i> and <i>schema</i> indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>• <i>HSBroker_IP:HSBroker_Port</i>: indicates the HSBroker URL. user	Username for accessing HetuEngine, that is, the username of the machine-machine user created in the cluster.
SSL	Indicates whether to use the HTTPS connection. The default value is <b>false</b> .

### 2.8.3.2.3 Querying the Execution Progress and Status of an SQL Statement Using JDBC

#### Description

This section describes how to use JDBC to connect to HetuEngine, and assemble and send the SQL statements to HetuEngine for execution.

```
import io.trino.jdbc.TrinoResultSet;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.ResultSetMetaData;
import java.sql.SQLException;
import java.util.Properties;
import java.util.Timer;
import java.util.TimerTask;

public class JDBCExampleStatementProgressPercentage{

    private static Properties properties = new Properties();
    public static Connection connection = null;
    public static ResultSet result = null;
    public static PreparedStatement statement = null;
    private static void init() throws ClassNotFoundException {
        properties.setProperty("user", "YourUserName");
        properties.setProperty("SSL", "false");
        Class.forName("io.trino.jdbc.TrinoDriver");
```

```
}

/**
 * Program entry
 *
 * @param args no need program parameter
 */
public static void main(String[] args) {
    String url = "jdbc:trino://192.168.1.130:29861,192.168.1.131:29861/hive/default?
serviceDiscoveryMode=hsbroker";
    try {
        init();
        String sql = "show tables";
        connection = DriverManager.getConnection(url, properties);
        statement = connection.prepareStatement(sql.trim());
        result = statement.executeQuery();

        TrinoResultSet rs = (TrinoResultSet) result;
        new Thread() {
            public void run() {
                Timer timer = new Timer();
                //The SQL statement is executed after 3 seconds and is executed every 2 seconds
                timer.schedule(new TimerTask() {
                    @Override
                    public void run() {
                        double statementProgressPercentage = rs.getProgressPercentage().orElse(0.0);
                        System.out.println("The Current Query Progress Percentage is " +
statementProgressPercentage*100 + "%");
                        if("FINISHED".equals(rs.getStatementStatus().orElse("")))) {
                            System.out.println("The Current Query Progress Percentage is 100%");
                            timer.cancel();
                            Thread.currentThread().interrupt();
                        }
                    }
                }, 3000, 2000);
            }
        }.start();

        ResultSetMetaData resultMetaData = result.getMetaData();
        int colNum = resultMetaData.getColumnCount();
        for (int j = 1; j <= colNum; j++) {
            try {
                System.out.print(resultMetaData.getColumnLabel(j) + "\t");
            } catch (SQLException throwables) {
                throwables.printStackTrace();
            }
        }

        while (result.next()) {
            for (int j = 1; j <= colNum; j++) {
                System.out.print(result.getString(j) + "\t");
            }
            System.out.println();
        }
    } catch (SQLException | ClassNotFoundException e) {
        e.printStackTrace();
    } finally {
        if (result != null) {
            try {
                result.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
        if (statement != null) {
            try {
                statement.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
    }
}
```

```
        }
    }
    if (connection != null) {
        try {
            connection.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

**Table 2-98** describes the parameters in the preceding code.

**Table 2-98** Parameter description

Parameter	Description
url	<code>jdbc:trino:// HSBroker1_IP.HSBroker1_Port,HSBroker2_IP.HSBroker2_Port,HSBroker3_IP.HSBroker3_Port/catalog/schema? serviceDiscoveryMode=hsbroker</code> <b>NOTE</b> <ul style="list-style-type: none"><li>• <i>catalog</i> and <i>schema</i> indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>• <i>HSBroker_IP:HSBroker_Port</i>: indicates the HSBroker URL. Use commas (,) to separate multiple URLs, for example, 192.168.81.37:29861,192.168.195.232:29861,192.168.169.84:29861.</li><li>• (Optional) <b>auditAddition</b>: custom information about the audit log. This field is recorded in the audit log. This parameter is used to supplement information for user audit.<ul style="list-style-type: none"><li>• Name of the image. The name can contain 1 to 255 characters.</li><li>• Only letters, digits, underscores (_), commas (,), and colons (:) are allowed.</li></ul></li></ul>
user	Username for accessing HetuEngine, that is, the username of the machine-machine user created in the cluster.
SSL	Indicates whether to use the HTTPS connection. The default value is <b>false</b> .
getStatementStatus()	Execution status of an SQL statement, which can be <b>RUNNING</b> , <b>FAILED</b> , <b>FINISHED</b> , <b>QUEUEED</b> , <b>WAITING_FOR_RESOURCES</b> , <b>DISPATCHING</b> , <b>PLANNING</b> , <b>STARTING</b> , <b>RESCHEDULING</b> , <b>RESUMING</b> , or <b>FINISHING</b> .
getProgressPercentage()	Execution progress of an SQL statement. The value range is 0 to 1.

### 2.8.3.3 Python3 Sample Code

### 2.8.3.3.1 Accessing Hive Data Sources Using HSBroker

This section describes how to use HSBroker to connect to HetuEngine, assemble SQL statements, and send them to HetuEngine for execution to add, delete, modify, and query Hive data sources.

```
import jaydebeapi  
  
driver = "io.trino.jdbc.TrinoDriver"  
  
# need to change the value based on the cluster information  
url = "jdbc:trino://192.168.37.61:29861,192.168.37.62:29861/hive/default?serviceDiscoveryMode=hsbroker"  
user = "YourUserName"  
tenant = "YourTenant"  
jdbc_location = "Your file path of the jdbc jar"  
  
sql = "show catalogs"  
  
if __name__ == '__main__':  
    conn = jaydebeapi.connect(driver, url, {"user": user,  
                                         "SSL": "false",  
                                         "tenant": tenant},  
                           [jdbc_location])  
    curs = conn.cursor()  
    curs.execute(sql)  
    result = curs.fetchall()  
    print(result)  
    curs.close()  
    conn.close()
```

The following table describes the parameters in the preceding code.

**Table 2-99** Parameter description

Parameter	Description
url	<p><code>jdbc:trino:// HSBroker1_IP.HSBroker1_Port,HSBroker2_IP.HSBroker2_Port,HSB roker3_IP.HSBroker3_Port/catalog/schema?serviceDiscovery- Mode=hsbroker</code></p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• <i>catalog</i> and <i>schema</i> indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>• <i>HSBroker_IP:HSBroker_Port</i> indicates the HSBroker URL. Use commas (,) to separate multiple URLs, for example, 192.168.81.37:29860,192.168.195.232:29860,192.168.169.84:29860.</li><li>• (Optional) <b>auditAddition</b>: custom information about the audit log. This field is recorded in the audit log. This parameter is used to supplement information for user audit.<ul style="list-style-type: none"><li>• Name of the image. The name can contain 1 to 255 characters.</li><li>• Only letters, digits, underscores (_), commas (,), and colons (:) are allowed.</li></ul></li></ul>
user	Username for accessing HetuEngine, that is, the username of the human-machine user created in the cluster.
tenant	Tenant resource queue for accessing HetuEngine compute instances

Parameter	Description
jdbc_location	Full path of the <b>hetu-jdbc-XXX.jar</b> package obtained in <a href="#">Setting Up a Python3 Project</a> . <ul style="list-style-type: none"><li>• Example path in Windows: <b>D:\\hetu-examples-python3\\hetu-jdbc-XXX.jar</b></li><li>• Example path in Linux: <b>/opt/hetu-examples-python3/hetu-jdbc-XXX.jar</b></li></ul>

### 2.8.3.3.2 Accessing Hive Data Sources Using HSFabric

This section describes how to use HSFabric to connect to HetuEngine, assemble SQL statements, and send them to HetuEngine for execution to add, delete, modify, and query Hive data sources.

```
import jaydebeapi
driver = "io.trino.jdbc.TrinoDriver"

# need to change the value based on the cluster information
url = "jdbc:trino://192.168.37.61:29903,192.168.37.61:29903/hive/default?serviceDiscoveryMode=hsfabric"
user = "YourUserName"
tenant = "YourTenant"
jdbc_location = "Your file path of the jdbc jar"

sql = "show catalogs"

if __name__ == '__main__':
    conn = jaydebeapi.connect(driver, url, {"user": user,
                                             "SSL": "false",
                                             "tenant": tenant},
                             [jdbc_location])
    curs = conn.cursor()
    curs.execute(sql)
    result = curs.fetchall()
    print(result)
    curs.close()
    conn.close()
```

The following table describes the parameters in the preceding code.

**Table 2-100** Parameter description

Parameter	Description
url	<p>jdbc:trino:// <i>HSFabric1_IP.HSFabric1_Port,HSFabric2_IP.HSFabric2_Port,HSFabric3_IP.HSFabric3_Port/catalog/schema?serviceDiscovery-Mode=hsfabric</i></p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• <b>catalog</b> and <b>schema</b> indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>• <b>HSFabric_IP:HSFabric_Port</b> indicates the HSFabric URL. Use commas (,) to separate multiple URLs, for example, 192.168.81.37:29902,192.168.195.232:29902,192.168.169.84:29902. On FusionInsight Manager, choose <b>Cluster &gt; Services &gt; HetuEngine</b> and click <b>Instance</b> to obtain the service IP addresses of all HSFabric instances. On the <b>Configurations</b> page, search for <b>gateway.port</b> to obtain the port number of HSFabric.</li><li>• (Optional) <b>auditAddition</b>: custom information about the audit log. This field is recorded in the audit log. This parameter is used to supplement information for user audit.<ul style="list-style-type: none"><li>• Name of the image. The name can contain 1 to 255 characters.</li><li>• Only letters, digits, underscores (_), commas (,), and colons (:) are allowed.</li></ul></li></ul>
user	Username for accessing HetuEngine, that is, the username of the human-machine user created in the cluster.
tenant	Tenant resource queue for accessing HetuEngine compute instances
jdbc_location	<p>Full path of the <b>hetu-jdbc-XXX.jar</b> package obtained in <a href="#">Setting Up a Python3 Project</a>.</p> <ul style="list-style-type: none"><li>• Example path in Windows: <b>D:\\hetu-examples-python3\\hetu-jdbc-XXX.jar</b></li><li>• Example path in Linux: <b>/opt/hetu-examples-python3/hetu-jdbc-XXX.jar</b></li></ul>

## 2.8.4 Application Commissioning

### 2.8.4.1 Commissioning Applications on Windows

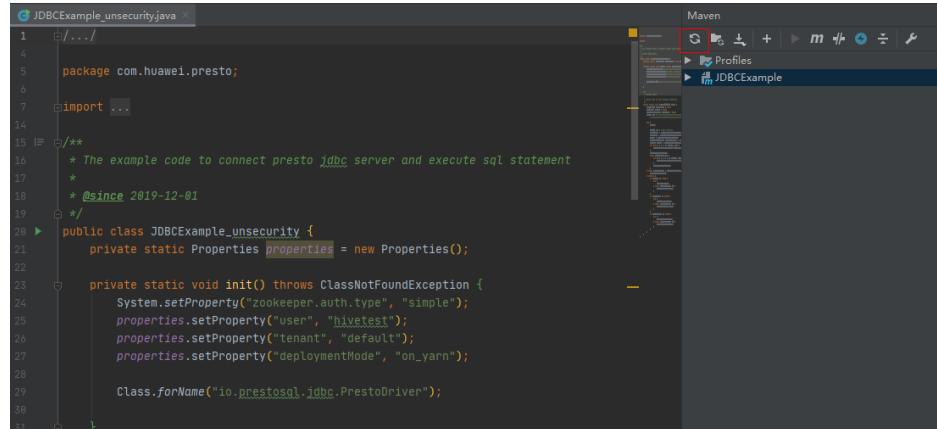

#### Scenario

After the program code is developed, you can compile the program in the Windows environment. If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

## Procedure

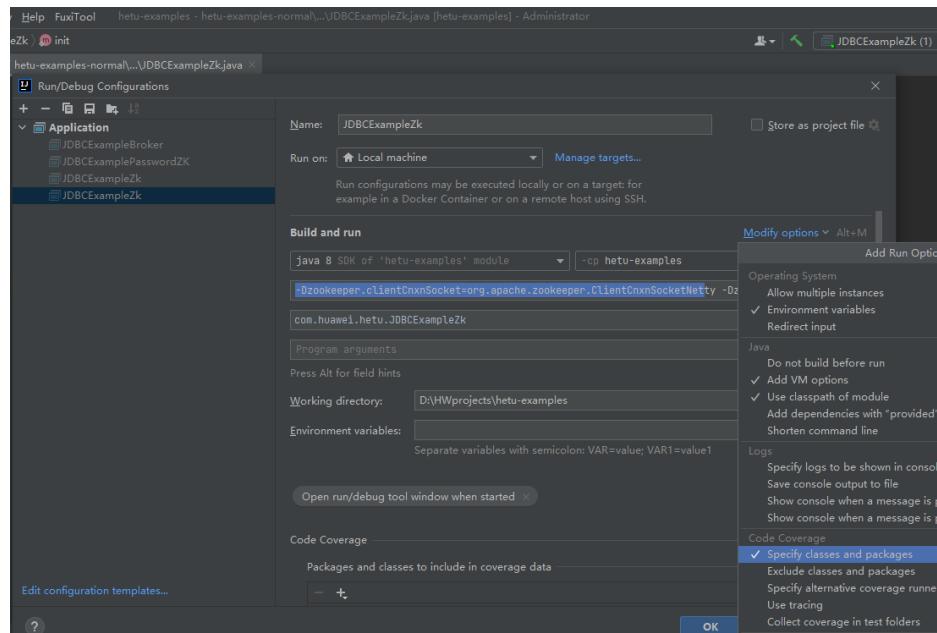

**Step 1** In the IntelliJ IDEA development environment on Windows, click **Maven** on the right of IDEA to import the dependency.

**Figure 2-155** Importing the dependency

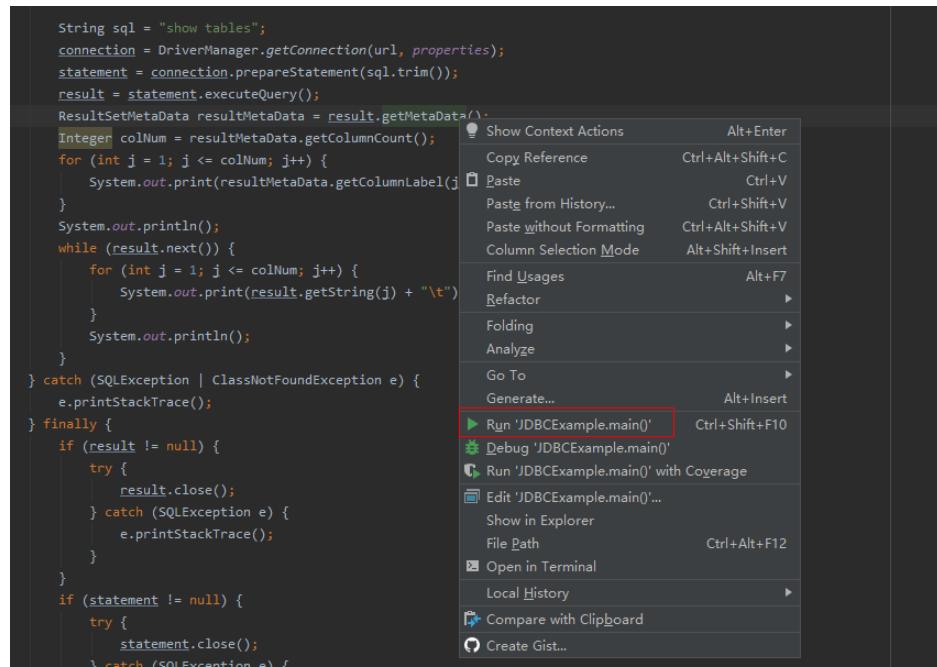

**Step 2** (Optional) If the SSL authentication communication function of ZooKeeper is enabled for the interconnected cluster, add the JVM configuration

**-Dzookeeper.clientCnxnSocket=org.apache.zookeeper.ClientCnxnSocketNetty -Dzookeeper.client.secure=true.**

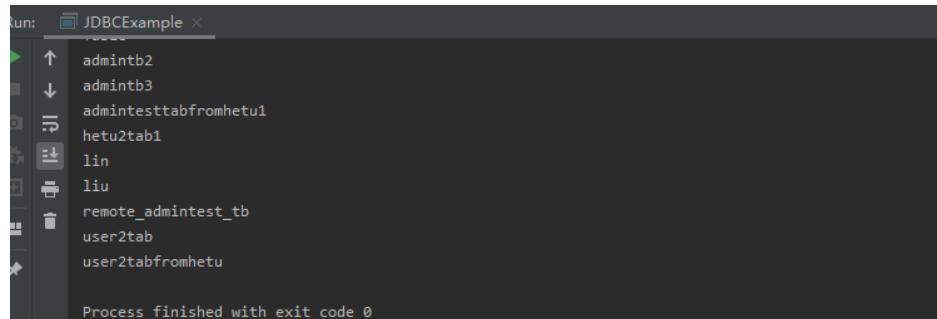

**Step 3** Right-click the **JDBCExampleZK.java** file and choose **Run'JDBCExampleZK.main()'** from the shortcut menu.

Figure 2-156 Running the program

You can view the output result on the console of the IDEA.

Figure 2-157 Outputs

----End

## 2.8.4.2 Commissioning Applications on Linux

### Scenario

After the code is developed, you can compile the code into a JAR file and upload it to a Linux environment for application function commissioning.

#### NOTE

Before commissioning applications on Linux, you need to pre-install a client on the Linux node.

## Procedure

- Step 1** In the Windows development environment IntelliJ IDEA, choose **Maven Projects > JDBCExample > Lifecycle** and perform the **clean** and **package** operations. After the compilation is complete, the **JDBCExample-1.0-SNAPSHOT.jar** file is generated in the target directory.
- Step 2** Upload the **JDBCExample-1.0-SNAPSHOT.jar** package to the Linux client installation directory, for example, **/opt/hadoopclient**.
- Step 3** Download and decompress the client file **FusionInsight\_Cluster\_Cluster ID\_HetuEngine\_Client.tar** by referring to [Preparing the Operating Environment](#), obtain the JDBC driver package, and upload it to the **/opt/hadoopclient** directory in the Linux environment.

### NOTE

To obtain the JDBC driver package:

Obtain the **hetu-jdbc-\*.jar** file from the **FusionInsight\_Cluster\_Cluster ID\_HetuEngine\_ClientConfig\HetuEngine\xxx\** directory.

Note: **xxx** can be **arm** or **x86**.

- Step 4** Run the following command to go to the client installation directory:

```
cd /opt/hadoopclient;
```

- Step 5** Run the following command to configure environment variables:

```
source bigdata_env;
```

- Step 6** Run the following command to debug the development program:

```
java -classpath JDBCExample-*.jar:hetu-jdbc-*.jar com.huawei.hetu.className
```

### NOTE

Replace the JDBC driver package name and class name with the actual ones, for example,  
**java -classpath JDBCExample-\*.jar:hetu-jdbc-\*.jar com.huawei.hetu.JDBCExampleZk**.

- Step 7** Check whether the command output is normal.

.....

Table  
testtable

----End

## 2.8.4.3 Commissioning the Python3 Sample Project

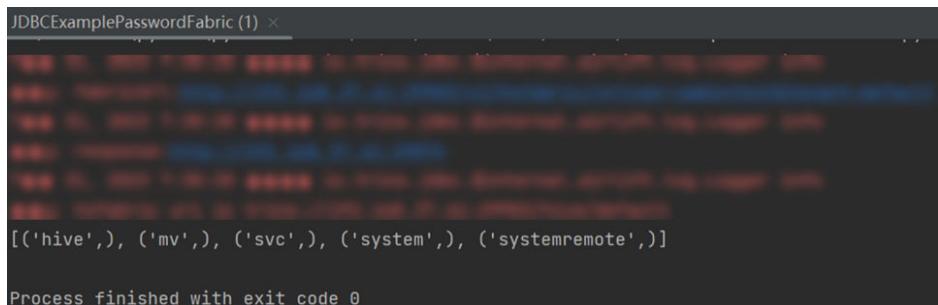

### Scenario

After the program code is written, you can commission the code in the Windows environment or upload the code to the Linux environment. If the local environment can communicate with the cluster service plane network, you can commission the program locally.

## Procedure

1. Refer to [Setting Up a Python3 Project](#) to obtain the sample code, obtain the **hetu-jdbc-XXX.jar** file, and copy it to the user-defined directory.

2. Edit the sample code, modify URLs and user information based on the cluster requirements, and modify **jdbc\_location** based on the actual path.
  - Example path in Windows: **D:\hetu-examples-python3\hetu-jdbc-XXX.jar**
  - Example path in Linux: **/opt/hetu-examples-python3/hetu-jdbc-XXX.jar**
3. Run the python3 sample code.
  - In Windows, run the **py** script through pycharm or Python IDLE.
  - To run the sample code on Linux, install Java first.  
Go to the sample code path and run the **py** script. An example of the sample code path is **/opt/hetu-examples-python3**.  
**cd /opt/hetu-examples-python3  
python3 JDBCExampleBroker.py**
4. View the command output.
  - In Windows, view the running result on the console.

**Figure 2-158** Running result

```
JDBCExamplePasswordFabric (1) ×
[('hive',), ('mv',), ('svc',), ('system',), ('systemremote',)]
Process finished with exit code 0
```

- The following is an example of the running result in Linux:  
...  
[ ('hive', ('mv'), ('svc'), ('system'), ('systemremote'))]

#### 2.8.4.4 Commissioning a Spring Boot Application

**Step 1** Configure the properties required for connecting the Spring Boot sample program to HetuEngine. Set the following parameters in the **springboot\hetu-examples\src\main\resources\application.yml** configuration file:

**Table 2-101** Configuring HetuEngine

Parameter	Mandatory	Description
host	Yes	HS Fabric address list of the HetuEngine service. The format is <i>HSFabric_IP1:HSFabric_Port,HSFabric_IP2:HSFabric_Port,HSFabric_IP3:HSFabric_Port</i> . Log in to FusionInsight Manager, choose <b>Cluster &gt; Services &gt; HetuEngine &gt; Instances</b> , and obtain the service IP addresses of all HSFabric instances. In the <b>Configurations</b> tab, search for <b>gateway.port</b> to obtain the HSFabric port.

Parameter	Mandatory	Description
catalog	Yes	Catalog name of the HetuEngine compute instance
schema	Yes	Schema name of the HetuEngine compute instance
user	Yes	Username for connecting to the HetuEngine compute instance
password	No	Password of the user for connecting to the HetuEngine compute instance in a cluster in security mode
ssl	Yes	Whether to use SSL to connect to the HetuEngine compute instance <ul style="list-style-type: none"> <li>● For a cluster in security mode, set this parameter to <b>true</b>.</li> <li>● For a cluster in normal mode, set this parameter to <b>false</b>.</li> </ul>

**Step 2** Click **Terminal** on the lower left part of the IDEA page to access the terminal. Run the following command to compile the file:

**mvn clean package**

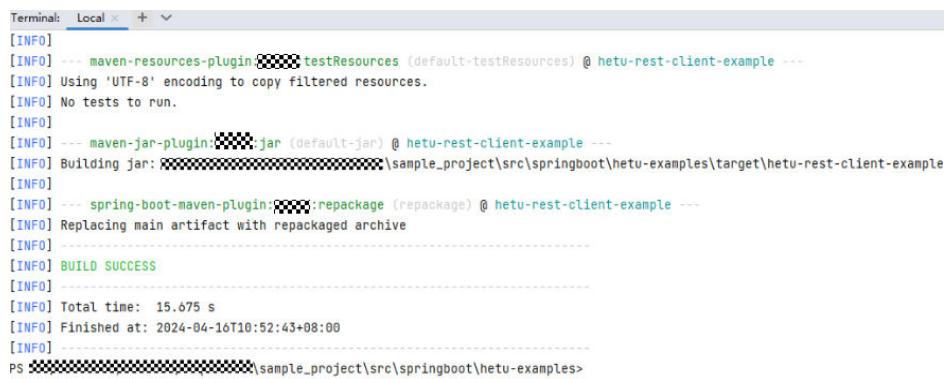

**Figure 2-159** Compile command

```
Terminal: Local + 
PowerShell
PS C:\sample_project\src\springboot\hetu-examples> mvn clean package
```

If "BUILD SUCCESS" is displayed, the compilation is successful. A JAR package containing the **hetu-rest-client-example** field is generated in the target directory of the sample project.

**Figure 2-160** Successful compilation

```
[INFO]
[INFO] --- maven-resources-plugin:testResources (default-testResources) @ hetu-rest-client-example ---
[INFO] Using 'UTF-8' encoding to copy filtered resources.
[INFO] No tests to run.
[INFO]
[INFO] --- maven-jar-plugin:jar (default-jar) @ hetu-rest-client-example ---
[INFO] Building jar: C:\sample_project\src\springboot\hetu-examples\target\hetu-rest-client-example.jar
[INFO]
[INFO] --- spring-boot-maven-plugin:repackage (repackage) @ hetu-rest-client-example ---
[INFO] Replacing main artifact with repackaged archive
[INFO]
[INFO] BUILD SUCCESS
[INFO]
[INFO] Total time: 15.675 s
[INFO] Finished at: 2024-04-16T10:52:43+08:00
[INFO]
PS C:\sample_project\src\springboot\hetu-examples>
```

**Step 3** Create a directory in the system as the run directory to save the JAR package that contains the **hetu-rest-client-example** field generated in **Step 2**.

- Create a directory on Windows, for example, D:\hetu-rest-client-example.
- Create a directory on Linux, for example, /opt/hetu-rest-client-example.

**Step 4** Run the following command to start the SpringBoot service:

- Commands for Windows:

```
cd /d d:\hetu-rest-client-example  
java -jar hetu-rest-client-example-*-.SNAPSHOT.jar
```

- Commands for Linux:

```
chmod +x /opt/hetu-rest-client-example -R  
cd /opt/hetu-rest-client-example  
java -jar hetu-rest-client-example-*-.SNAPSHOT.jar
```

#### NOTE

The preceding JAR package names are for reference only. Use the actual names.

**Step 5** Call a Spring Boot sample API of HetuEngine to run the sample code.

- For the Windows environment:

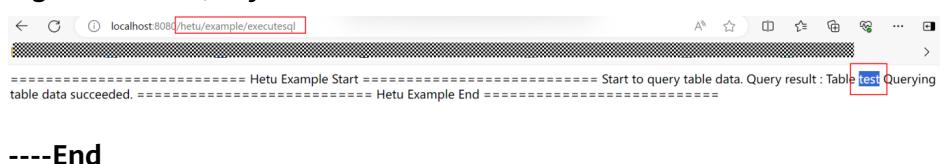

Open a browser and enter **http://localhost:8080/hetu/example/executesql** in the address box.

- For the Linux environment:

Run the **curl http://localhost:8080/hetu/example/executesql** command on the node where the JAR package is stored in **Step 3**.

**Step 6** View the query result of the SQL statement used in the sample code.

**Figure 2-161** Query results

## 2.9 Hive Development Guide

### 2.9.1 Overview

#### 2.9.1.1 Application Development Overview

##### Hive Introduction

Hive is an open-source data warehouse built on Hadoop. It stores structured data and provides basic data analysis services using the Hive query language (HQL), a language like the SQL. Hive converts HQL statements to MapReduce or Spark jobs for querying and analyzing massive data stored in Hadoop clusters.

Hive provides the following features:

- Extracts, transforms, and loads (ETL) data using HQL.
- Analyzes massive structured data using HQL.
- Supports flexible data storage formats, including JavaScript object notation (JSON), comma separated values (CSV), TextFile, RCFile, ORCFILE, and SequenceFile, and supports custom extensions.
- Multiple client connection modes. Interfaces, such as JDBC and Thrift interfaces are supported.

Hive applies to offline massive data analysis (such as log and cluster status analysis), large-scale data mining (such as user behavior analysis, interest region analysis, and region display), and other scenarios.

To ensure Hive high availability (HA), user data security, and service access security, MRS incorporates the following features based on Hive 3.1.0:

- Data file encryption

For Hive features in the Open Source Community, see <https://cwiki.apache.org/confluence/display/hive/designdocs>.

### 2.9.1.2 Common Concepts

- **Client**

Users can access the server from the client through the Java API and Thrift API to perform Hive-related operations.

- **HQL**

Similar to SQL

- **HCatalog**

HCatalog is a table information management layer created based on Hive metadata and absorbs DDL commands of Hive. HCatalog provides read/write interfaces for MapReduce and provides Hive command line interfaces (CLIs) for defining data and querying metadata. Hive and MapReduce development personnel can share metadata based on the HCatalog component of MRS, preventing intermediate conversion and adjustment and improving the data processing efficiency.

- **WebHCat**

WebHCat running users use Rest APIs to perform operations, such as running Hive DDL commands, submitting MapReduce tasks, and querying MapReduce task execution results.

### 2.9.1.3 Development Process

[Figure 2-162](#) and [Table 2-102](#) illustrates each phase of the development process.

Figure 2-162 Hive application development process

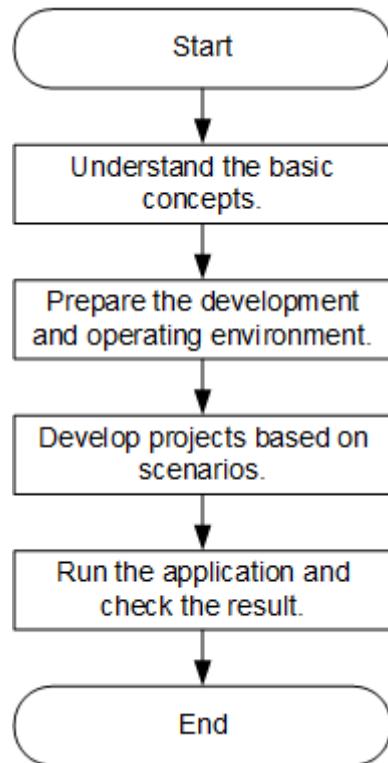

Table 2-102 Description of the Hive application development process

Phase	Description	Reference Document
Understand the basic concepts.	Before application development, understand common concepts about Hive.	<a href="#">Common Concepts</a>
Prepare the development and operating environment.	Hive applications support Java and Python development languages. You are advised to use the IntelliJ IDEA tool to configure the development environment based on the language.	<a href="#">Preparing the Environment</a>
Develop projects based on scenarios.	Provides example projects of the Java and Python languages as well as example projects covering table creation, data load, and data query.	<a href="#">Developing an Application</a>

Phase	Description	Reference Document
Run the application and view results.	Describes how to submit a developed application for compiling and view the result.	<a href="#">Commissioning Applications</a>

## 2.9.2 Preparing the Environment

### 2.9.2.1 Preparing Development and Operating Environment

#### Preparing Development Environment

Hive applications can be developed by using the JDBC/Metastore/Python/Python3 API. The following table describes the development and operating environment to be prepared.

**Table 2-103** JDBC/Metastore development environment

Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows OS. Windows 7 or later is supported.</li><li>• Operating environment: Windows OS or Linux OS If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul>

Item	Description
Installing JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>Tool used for developing Hive applications. Requirements are as follows:</p> <p>JDK 1.8 is used. IntelliJ IDEA 2019.1 or other compatible versions are used.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li></ul>
Installation of Maven	Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development.
7-zip	Used to decompress <b>.zip</b> and <b>.rar</b> packages. 7-Zip 16.04 is supported.

**Table 2-104** Python development environment

Item	Description
OS	Development and operating environment: Linux OS
Python installation	Python is a tool used to develop Hive applications. Its version must be 2.6.6 or later but should not be later than 2.7.13.
setuptools installation	Basic configuration for the Python development environment. The version must be 5.0 or later.

 NOTE

For details about how to install and configure the Python development tool, see the [Configuring the Python Sample Project](#).

**Table 2-105** Python3 development environment

Item	Description
OS	Development and operating environment: Linux OS
Python3 installation	Python3 is a tool used to develop Hive applications. Its version must be 3.6 or later but should not be later than 3.9.
setuptools installation	Basic configuration for the Python3 development environment. The version must be 47.3.1.

 NOTE

For details about how to install and configure the Python3 development tool, see the [Configuring the Python3 Sample Project](#).

## Preparing an Operating Environment

During application development, you need to prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. Log in to the FusionInsight Manager, click **Download Client** in the upper right corner of the Homepage, set **Select Client Type** to **Configuration Files Only** and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain

**FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** file.

Then, decompress

**FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** file to the D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles directory on the local PC. The directory name cannot contain spaces.

- b. Go to the client decompression path

**FusionInsight\_Cluster\_1\_Services\_ClientConfig\_Hive\config** and manually import the configuration file to the configuration file directory (usually the **resources** folder) of the Hive sample project.

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. **Table 2-106** describes the main configuration files.

**Table 2-106** Configuration file

Document Name	Function
hive metastore-site.xml	Configures Hive parameters.
hiveclient.properties	Configures Hive parameters.
user.keytab	Provides Hive user information for Kerberos security authentication.
krb5.conf	Contains Kerberos server configuration information.
core-site.xml	Configures Hive parameters.

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

#### NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
  - The local **hosts** file in a Windows environment is stored in, for example, C:\WINDOWS\system32\drivers\etc\hosts.
- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, the client installation directory is /opt/hadoopclient.  
Ensure that the difference between the client time and the cluster time is less than 5 minutes.  
For details about how to install a cluster client, see [Installing a Client](#).
  - b. [Accessing FusionInsight Manager of an MRS Cluster](#). Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**.

Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/Hive/config** directory to the **src/main/resources** directory where the compiled JAR package is stored for subsequent commissioning, for example, **/opt/hadoopclient/src/main/resources**.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Hive/config/* root@IP address of the client node:/opt/  
hadoopclient/src/main/resources
```

**Table 2-107** Configuration files

File	Function
hive metastore-site.xml	Configures Hive parameters.
hive-site.xml	Configures Hive parameters.

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

### 2.9.2.2 Configuring the JDBC Sample Project

#### Scenario

To run the JDBC API example codes of the Hive component of MRS, perform the following operations.

The following uses the development of an application for connecting the Hive service in JDBC mode on Windows as an example.

#### Procedure

- Step 1** Obtain the sample project folder **hive-jdbc-example** in the **src\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** Go to the client decompression path

**FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles\Hive\config** and manually import the **core-site.xml** and **hiveclient.properties** files to the **hive-jdbc-example\src\main\resources** directory of the sample project.

 NOTE

Hive allows you to add extension identifiers to JDBC connection strings. These extension identifiers are printed in HiveServer audit logs to distinguish SQL sources. If you need to configure an identifier, add the following content to the **hive-jdbc-example\src\main\resources\hiveclient.properties** file:

**auditAddition=xxx**

xxx is the custom identifier. The identifier can contain a maximum of 256 bytes and only letters, digits, underscores (\_), commas (,), and colons (:) are allowed.

After the SQL statement is executed, the configured extension identifier is printed in the HiveServer audit log **/var/log/Bigdata/audit/hive/hiveserver/hive-audit.log**. The following is an example.

```
2024-02-27 11:55:56,501 | INFO  | HiveServer2-Handler-Pool: Thread-402 | UserName=test  UserID=192.168.64.230  Time=2024/02/27 11:55:56      Operation=OpenSession Result= Data

```

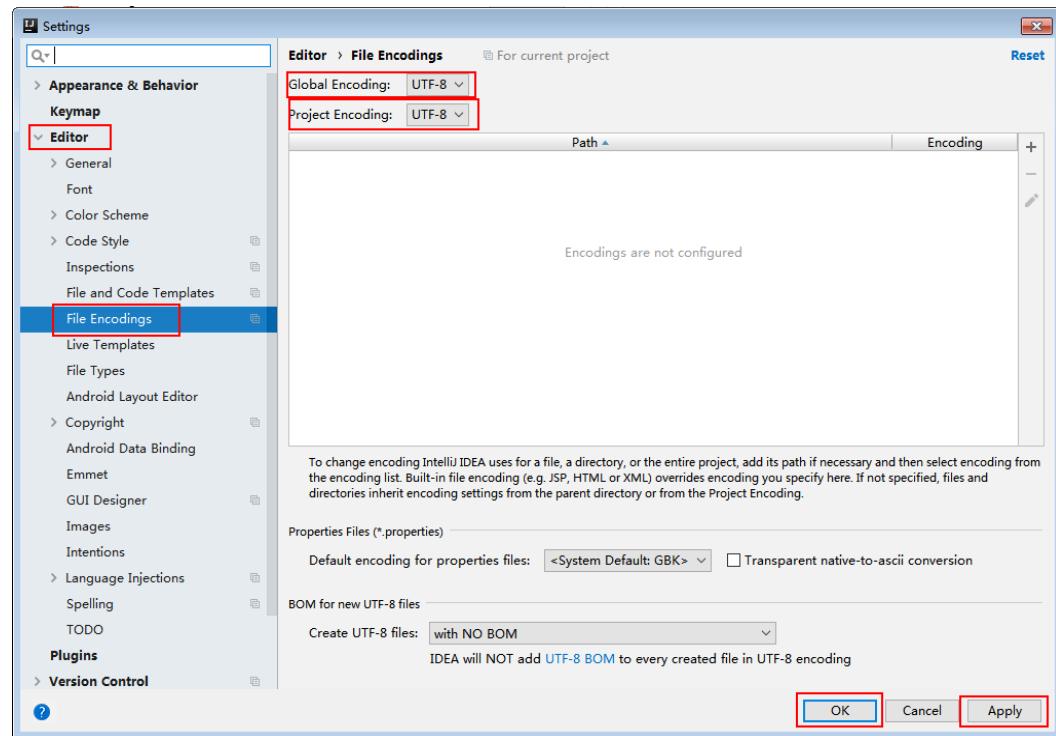

**Step 3** Import the example project to the IntelliJ IDEA development environment.

1. On the IntelliJ IDEA menu bar, choose **File > Open....** The **Open File or Project** window is displayed.
2. In the displayed window, select the folder **hive-jdbc-example**, and click **OK**. On Windows, the path cannot contain any space.

**Step 4** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

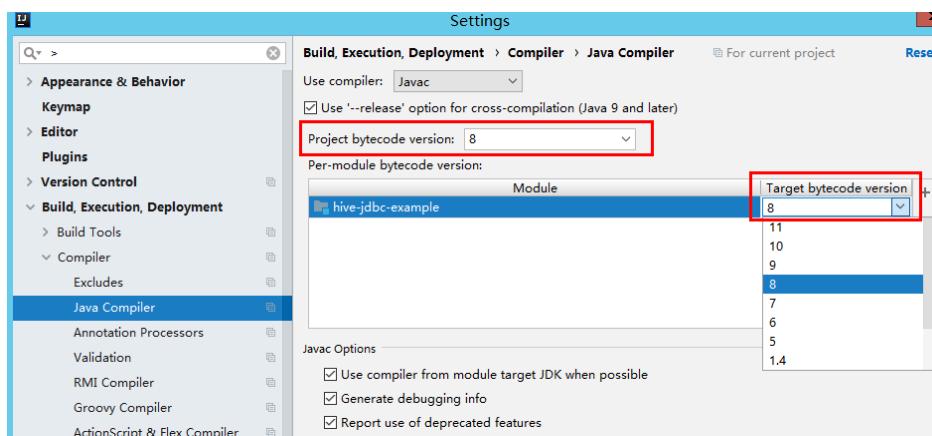

1. On the IntelliJ IDEA menu bar, choose **File > Settings**. The **Settings** window is displayed.
2. In the navigating tree on the left, choose **Editor > File Encodings**. In the **Project Encoding** area and **Global Encoding** area, set the value to **UTF-8**, and click **Apply** and **OK**, as shown in [Figure 2-163](#).

Figure 2-163 Setting the IntelliJ IDEA coding format

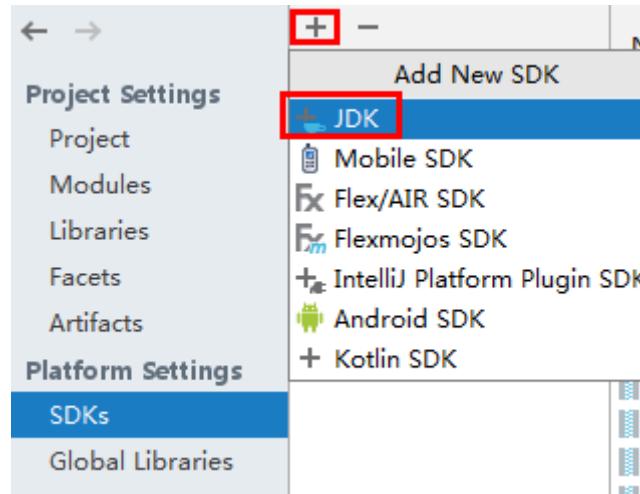

**Step 5** Set the JDK of the project.

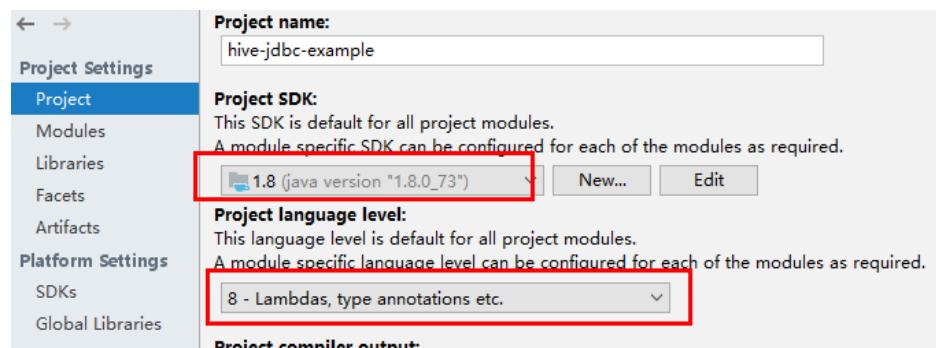

1. On the IntelliJ IDEA menu bar, choose **File > Settings....** The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler**, select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** to **8** for **hive-jdbc-example**.

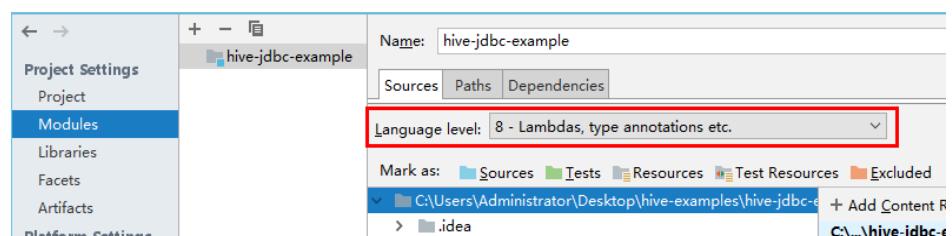

3. Click **Apply** and **OK**.
4. On the IntelliJ IDEA menu bar, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Select **SDKs**, click the plus sign (+), and select **JDK**.

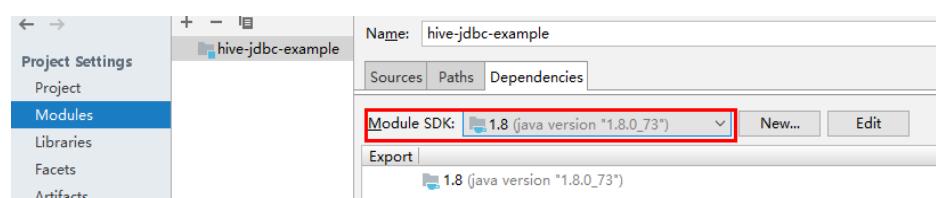

6. On the **Select Home Directory for JDK** page that is displayed, select the **JDK** directory and click **OK**.
7. After selecting the JDK, click **Apply**.
8. Select **Project**, select the JDK added in SDKs from the **Project SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Project language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Source** page, change the value of **Language level** to **8 - Lambdas, type annotations etc.**

On the **Dependencies** page, change the value of **Module SDK** to the JDK added in SDKs.

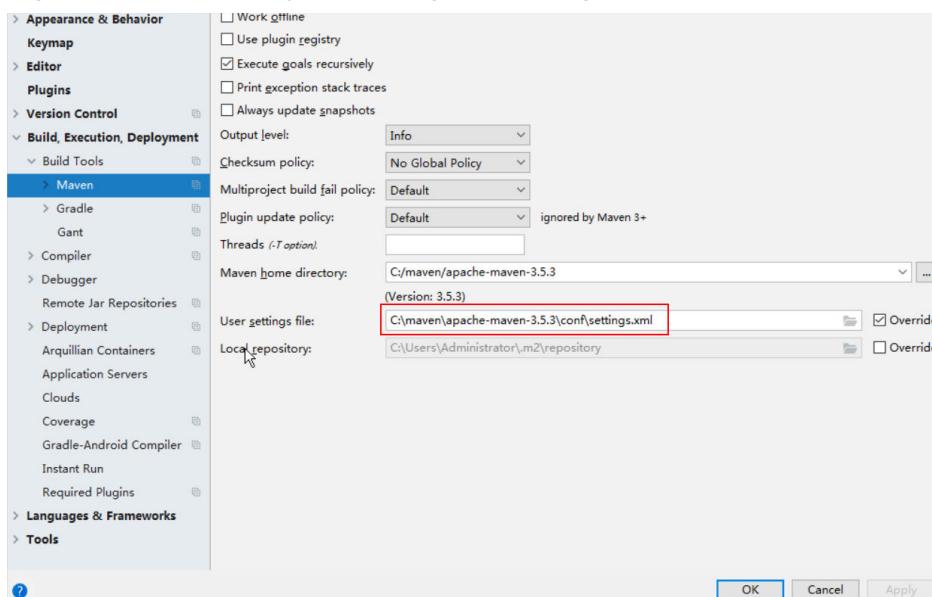

11. Click **Apply** and **OK**.

**Step 6** Configure Maven.

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, select **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is *<Local Maven installation directory>\conf\settings.xml*.

**Figure 2-164** Directory for storing the **settings.xml** file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply**, and then click **OK**.

----End

### 2.9.2.3 Configuring the Hcatalog Sample Project

#### Scenario

To run the HCatalog interface example codes of the Hive component of MRS, perform the following operations.

#### NOTE

The following uses the development of an application for connecting the Hive service in HCatalog mode on Windows as an example.

## Procedure

**Step 1** Obtain the sample project folder **hcatalog-example** in the **src\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

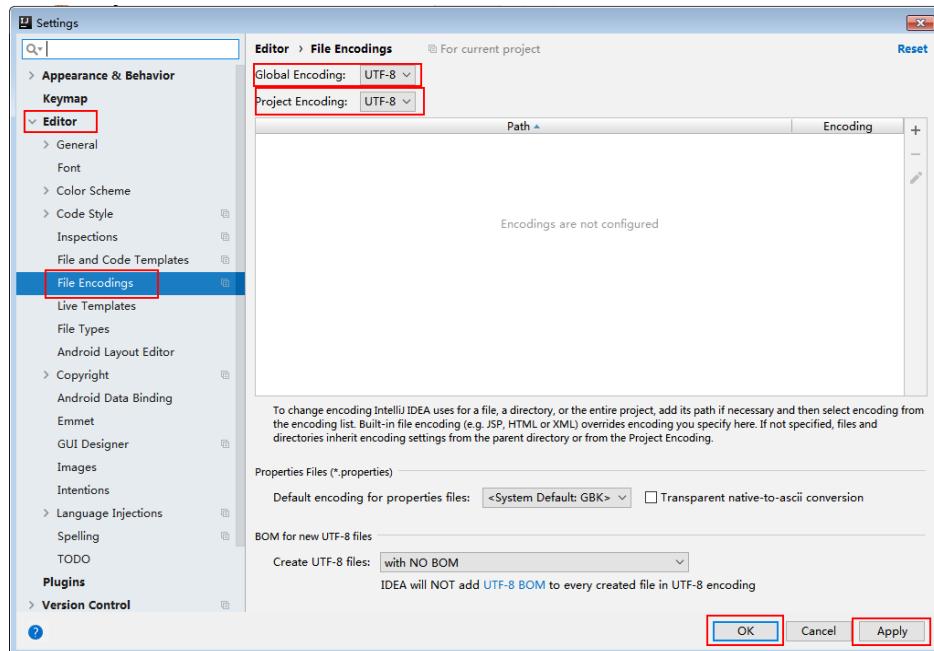

**Step 2** Import the example project to the IntelliJ IDEA development environment.

1. On the IntelliJ IDEA menu bar, choose **File > Open....** The **Open File or Project** window is displayed.
2. In the displayed window, select the folder **hcatalog-example**, and click **OK**. On Windows, the path cannot contain any space.

**Step 3** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

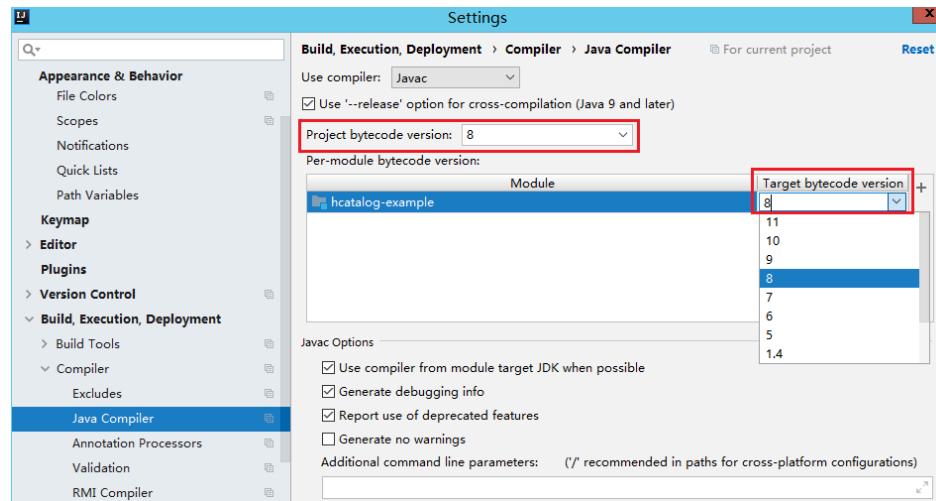

1. On the IntelliJ IDEA menu bar, choose **File > Settings**. The **Settings** window is displayed.
2. Choose **Editor > File Encodings** from the navigation tree. In the **Project Encoding** area and **Global Encoding** area, set the value to **UTF-8**, click **Apply**, and click **OK**, as shown in [Figure 2-165](#).

**Figure 2-165** Setting the IntelliJ IDEA coding format

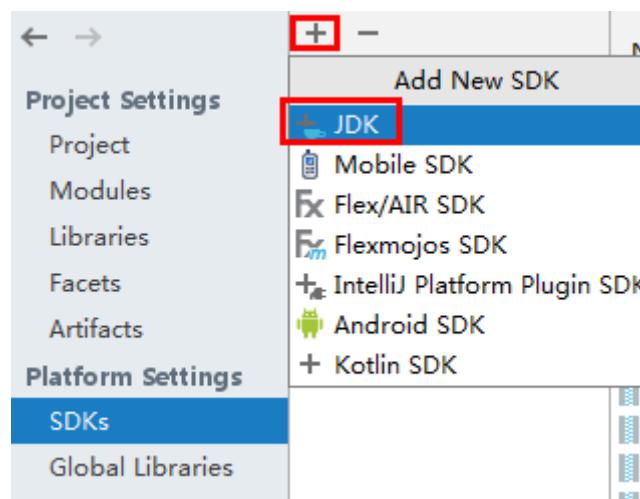

**Step 4** Set the JDK of the project.

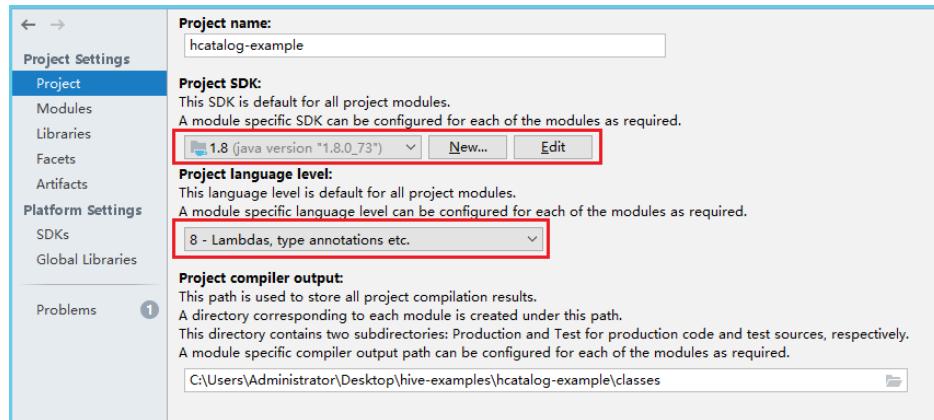

1. On the IntelliJ IDEA menu bar, choose **File > Settings....** The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler**, select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** to **8** for **hive-jdbc-example**.

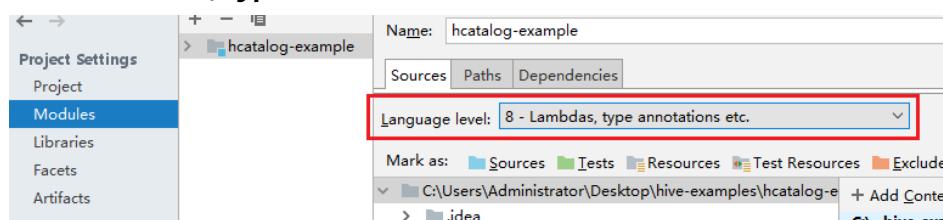

3. Click **Apply** and **OK**.
4. On the IntelliJ IDEA menu bar, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Select **SDKs**, click the plus sign (+), and select **JDK**.

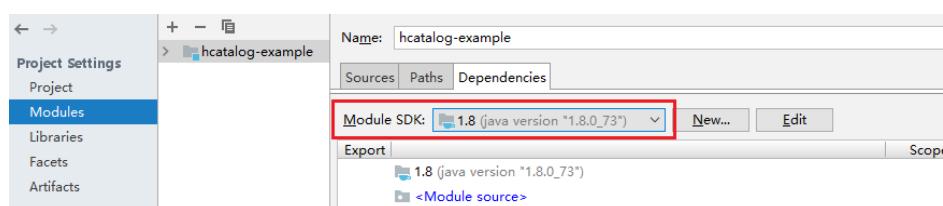

6. On the **Select Home Directory for JDK** page that is displayed, select the **JDK** directory and click **OK**.
7. After selecting the JDK, click **Apply**.
8. Select **Project**, select the JDK added in SDKs from the **Project SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Project language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Source** page, change the value of **Language level** to **8 - Lambdas, type annotations etc.**

11. On the **Dependencies** page, change the value of **Module SDK** to the JDK added in **SDKs**.

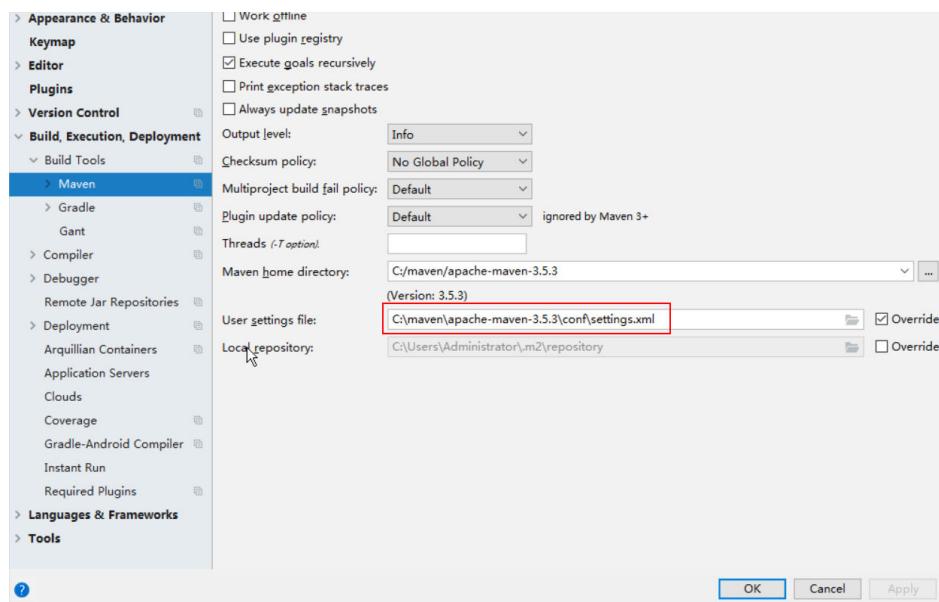

12. Click **Apply** and **OK**.

#### Step 5 Configure Maven.

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, select **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is **<Local Maven installation directory>\conf\settings.xml**.

Figure 2-166 Directory for storing the **settings.xml** file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply**, and then click **OK**.

----End

#### 2.9.2.4 Configuring the Python Sample Project

##### Scenario

To run the Python interface example codes of the Hive component of MRS, perform the following operations.

##### Procedure

**Step 1** Python of 2.6.6 or a higher version has been installed on a client. The Python version cannot be higher than 2.7.13.

The Python version can be viewed by running the **python** command on the command-line interface (CLI) of the client. The following information indicates that the Python version is 2.6.6.

```
Python 2.6.6 (r266:84292, Oct 12 2012, 14:23:48)
[GCC 4.4.6 20120305 (Red Hat 4.4.6-4)] on linux2
Type "help", "copyright", "credits" or "license" for more information.
```

**Step 2** Setuptools of 5.0 or a higher version has been installed on a client. The setuptools version cannot be higher than 36.8.0.

To obtain the software, visit the official website.

<https://pypi.org/project/setuptools/#files>

Copy the downloaded setuptools package to the client, decompress the package, go to the decompressed directory, and run the **python setup.py install** command in the CLI of the client.

The following information indicates that setuptools 5.7 is installed successfully.

Finished processing dependencies for setuptools==5.7

**Step 3** Install Python on the client.

1. Obtain the sample project folder **python-examples** in the **src\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
2. Go to the **python-examples** folder.
3. Run the **python setup.py install** command in the CLI.

The following information indicates that Python is installed successfully.

Finished processing dependencies for pyhs2==0.5.0

**Step 4** After the installation is successful, the following files are generated. **python-examples/pyCLI\_nosec.py** is the Python client example codes. **python-examples/pyhs2/haconnection.py** is the Python client API. Run **hive\_python\_client** scripts to execute the SQL functions, for example, **sh hive\_python\_client 'show tables'**. This function applies to only simple SQL statements and depends on the ZooKeeper client.

----End

### 2.9.2.5 Configuring the Python3 Sample Project

#### Scenario

To run the Python3 interface example codes of the Hive component of FusionInsight MRS, perform the following operations.

#### Procedure

**Step 1** Python3 of 3.6 or a higher version has been installed on a client. The Python3 version cannot be higher than 3.9.

The Python version can be viewed by running the **python3** command on the command-line interface (CLI) of the client. The following information indicates that the Python version is 3.8.2.

Python 3.8.2 (default, Jun 23 2020, 10:26:03)  
[GCC 4.8.5 20150623 (Red Hat 4.8.5-36)] on linux  
Type "help", "copyright", "credits" or "license" for more information.

**Step 2** Setuptools of 47.3.1 version has been installed on a client.

To obtain the software, visit the official website.

<https://pypi.org/project/setuptools/#files>

Copy the downloaded setuptools package to the client, decompress the package, go to the decompressed directory, and run the **python3 setup.py install** command in the CLI of the client.

The following information indicates that setuptools 47.3.1 is installed successfully.

Finished processing dependencies for setuptools==47.3.1

 NOTE

If the system displays a message indicating that the installation of setuptools of 47.3.1 fails, check whether the environment is faulty or whether the problem is caused by Python.

**Step 3** Install Python on the client.

1. Obtain the sample project folder **python3-examples** in the **src\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
2. Go to the **python3-examples** folder.
3. Go to the **dependency\_python3.6**, **dependency\_python3.7**, or **dependency\_python3.8**, or **dependency\_python3.9** folder based on the Python3 version.
4. Run the **whereis easy\_install** command to find the path of the **easy\_install** program. If there are multiple paths, run the **easy\_install --version** command to select the **easy\_install** path corresponding to the **setuptools** version, for example, **/usr/local/bin/easy\_install**.
5. Run the **easy\_install** command to install the egg files in the **dependency\_python3.x** folder. If the egg file has dependencies, you can use wildcards to install the egg file. For example:
  - **dependency\_python3.6** directory:  
**/usr/local/bin/easy\_install future\*egg six\*egg python\*egg sasl-\*linux-\$uname -p.egg thrift-\*egg thrift\_sasl\*egg**
  - **dependency\_python3.7** directory:  
**/usr/local/bin/easy\_install future\*egg six\*egg sasl-\*linux-\$uname -p.egg thrift-\*egg thrift\_sasl\*egg**
  - **dependency\_python3.8** directory:  
**/usr/local/bin/easy\_install future\*egg six\*egg python\*egg sasl-\*linux-\$uname -p.egg thrift-\*linux-\$uname -p.egg thrift\_sasl\*egg**
  - **dependency\_python3.9** directory:  
**/usr/local/bin/easy\_install future\*egg six\*egg sasl-\*linux-\$uname -p.egg six-\*egg thrift-\*linux-\$uname -p.egg thrift\_sasl\*egg**

If the following information is displayed for each egg file, the installation is successful:

Finished processing dependencies for \*\*\*

**Step 4** After the installation is successful, the following files are generated. **python3-examples/pyCLI\_sec.py** is the Python client example codes. **python3-examples/pyhive/hive.py** is the Python client API.

----End

### 2.9.2.6 Configuring a Spring Boot Sample Project

#### Scenario

Run the Spring Boot interface sample code of MRS Hive.

In the following example, an application is developed by compiling a Spring Boot project to connect to Hive in Windows.

## Procedure

- Step 1** Obtain the sample project folder **hive-rest-client-example** in the `src\springboot\hive-examples` directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Go to the client decompression path `FusionInsight_Cluster_1_Services_ClientConfig\Hive\config` and copy the `core-site.xml` and `hiveclient.properties` files to the `hive-jdbc-example\src\main\resources` directory of the sample project.

Hive allows you to add extension identifiers to JDBC connection strings. These extension identifiers are printed in HiveServer audit logs to distinguish SQL sources. If you need to configure an identifier, add the following content to the `hive-jdbc-example\src\main\resources\hiveclient.properties` file:

```
auditAddition=xxx
```

`xxx` is the custom identifier. The identifier can contain a maximum of 256 bytes and only letters, digits, underscores (\_), commas (,), and colons (:) are allowed.

After the SQL statement is executed, the configured extension identifier is printed in the HiveServer audit log `/var/log/Bigdata/audit/hive/hiveserver/hive-audit.log`. The following is an example.

```
2024-02-27 11:55:56,501 | INFO | HiveServer2-Handler-Pool: Thread-402 | UserName=test UserIP=192.168.64.230 Time=2024/02/27 11:55:56 Operation=OpenSession Result= Data

2024-02-27 11:55:56,501 | INFO | HiveServer2-Handler-Pool: Thread-402 | UserName=test UserIP=192.168.64.230 Time=2024/02/27 11:55:56 Operation=OpenSession Result=SUCCE
SS
2024-02-27 11:55:59,336 | INFO | HiveServer2-Handler-Pool: Thread-402 | UserName=test UserIP=192.168.64.230 Time=2024/02/27 11:55:59 Operation=ExecuteStatement stat
=(show tables) Result= Details=Addition=xxx | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:512)
2024-02-27 11:55:59,336 | INFO | HiveServer2-Handler-Pool: Thread-402 | OperationId=7187e0c-b8d1-42f0-80d3-76babf5282ef UserName=test UserIP=192.168.64.230 Time=2024/02
/27 11:55:59 Operation=ExecuteStatement: stat=(show tables) Result=SUCCESS Detail= Addition=xxx | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:512)
```

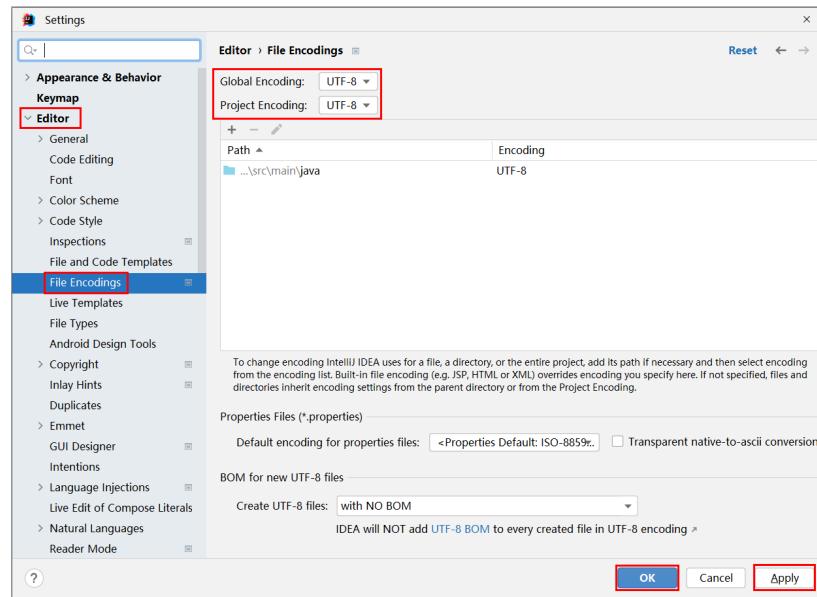

- Step 3** Import the sample project to the IntelliJ IDEA development environment.

- On the menu bar of IntelliJ IDEA, choose **File > Open....**
- In the **Open File or Project** dialog box that is displayed, select the **hive-rest-client-example** folder and click **OK**. In Windows, the folder path cannot contain any space.

- Step 4** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

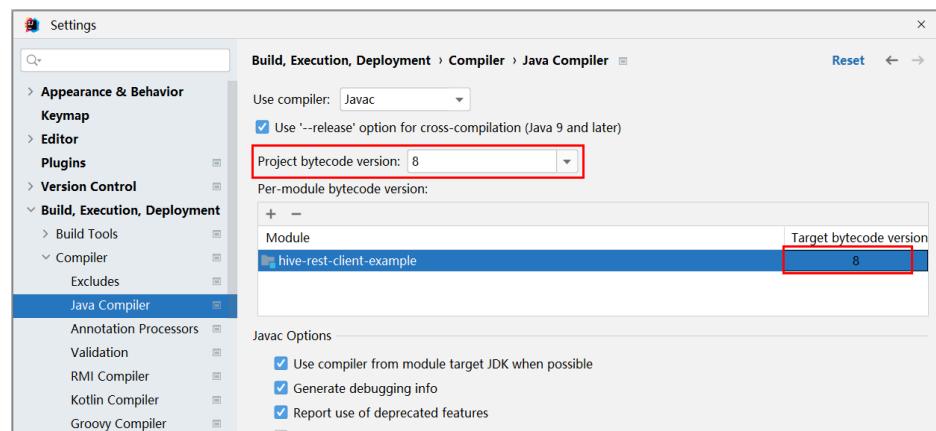

- On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
- In the left navigation pane, choose **Editor > File Encodings**. In the **Project Encoding** and **Global Encoding** areas, set the parameter to **UTF-8**. Click **Apply** and **OK**.

Figure 2-167 Setting the IntelliJ IDEA coding format

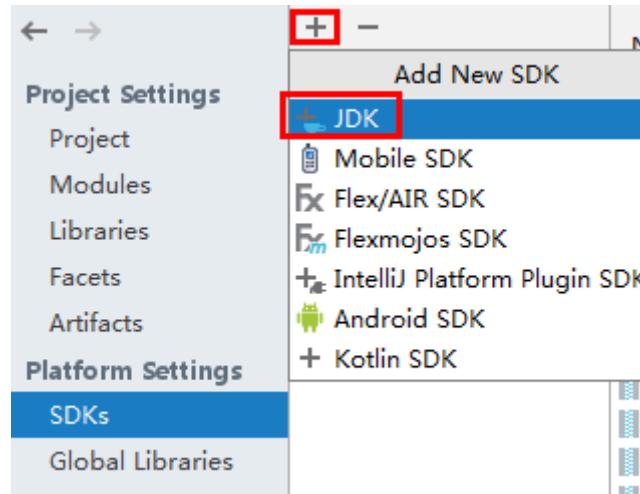

**Step 5** Set the JDK of the project.

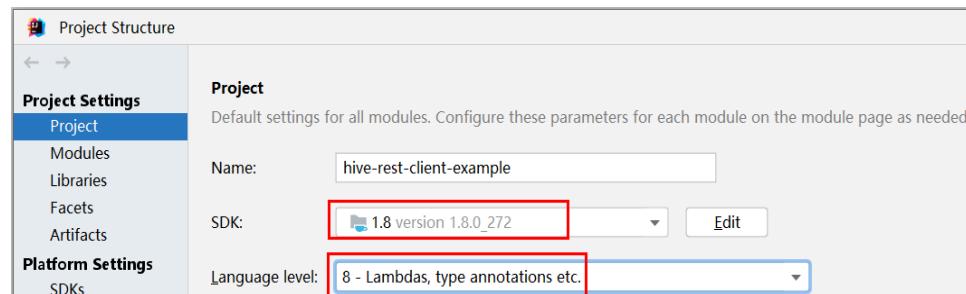

1. On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler** and select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** in **hive-rest-client-example** to **8**.

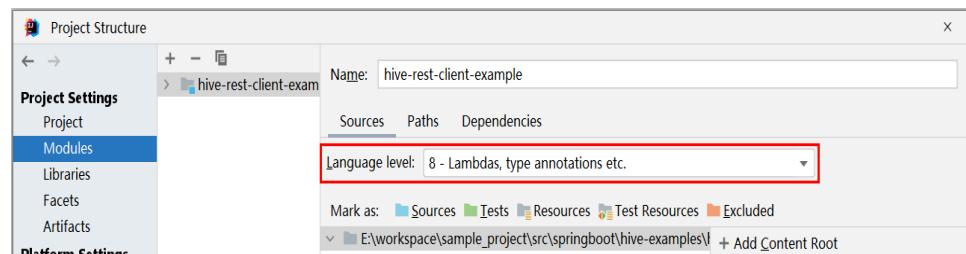

3. Click **Apply** then **OK**.
4. On the menu bar of IntelliJ IDEA, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Choose **SDKs**, click the plus sign (+), and select **JDK**.

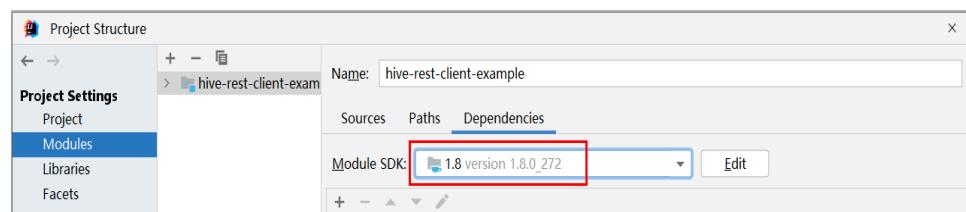

6. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.
7. Click **Apply**.
8. Select **Project**, select the JDK added in **SDKs** from the **SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Sources** tab page, change the value of **Language level** to **8 - Lambdas, type annotations etc..**

On the **Dependencies** tab page, change the value of **Module SDK** to the JDK added in **SDKs**.

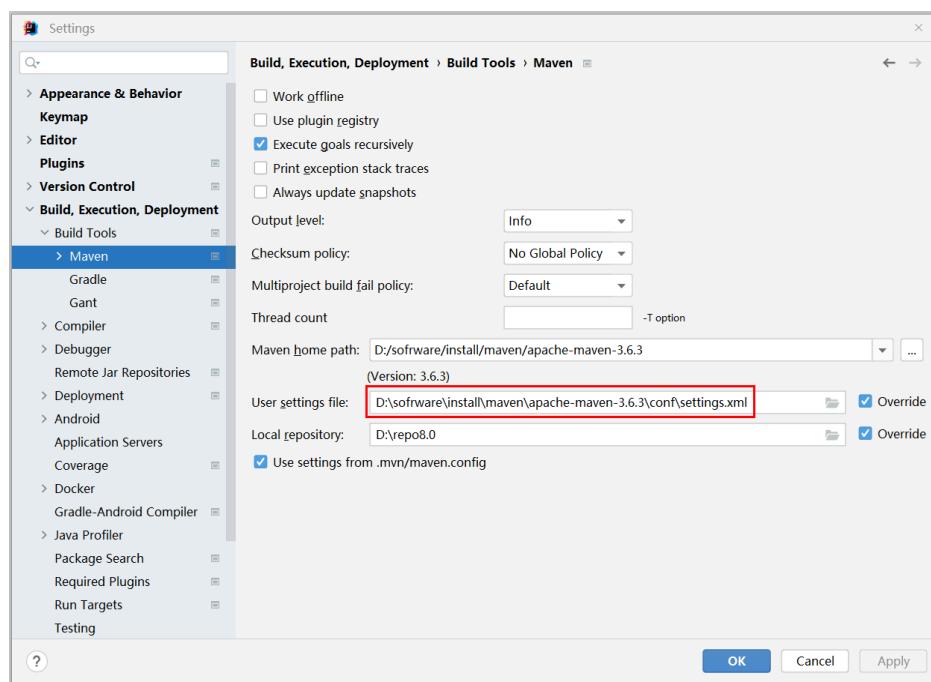

11. Click **Apply** then **OK**.

### Step 6 Configure Maven.

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, choose **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is *<Local Maven installation directory>\conf\settings.xml*.

Figure 2-168 Directory for storing the settings.xml file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply** then **OK**.

----End

## 2.9.3 Developing an Application

### 2.9.3.1 Typical Scenario Description

#### Scenarios

A user develops a Hive data analysis application for managing employee information described in [Table 2-108](#) and [Table 2-109](#).

#### Procedure

##### Step 1 Prepare data.

1. Create three tables: employee information table **employees\_info**, contact table **employees\_contact**, and extended employee information table **employees\_info\_extended**.
  - Fields in the **employees\_info** table include the employee ID, name, salary currency, salary, tax category, work place, and hiring date. **R** indicates RMB, and **D** indicates USD.
  - Fields in the **employees\_contact** table include the employee ID, mobile phone number, and e-mail address.
  - Fields in the **employees\_info\_extended** table include the employee ID, name, mobile phone number, e-mail address, salary currency, salary, tax category, and work place. The partition field is the hiring date.

For table creation codes, see [Creating a Table](#).

2. Load employee information to **employees\_info**.

For data loading codes, see [Loading Data](#).

**Table 2-108** describes employee information.

**Table 2-108** Employee information

ID	Name	Salary Currency	Salary	Tax Category	Work Place	Hiring Date
1	Wang	R	8000.01	personal income tax&0.05	Country 1:City1	2014
3	Tom	D	12000.02	personal income tax&0.09	Country 2:City2	2014
4	Jack	D	24000.03	personal income tax&0.09	Country 3:City3	2014
6	Linda	D	36000.04	personal income tax&0.09	Country 4:City4	2014
8	Zhang	R	9000.05	personal income tax&0.05	Country 5:City5	2014

3. Load employee contact information to **employees\_contact**.

**Table 2-109** describes employee contact information.

**Table 2-109** Employee contact information

ID	Mobile Phone Number	E-mail Address
1	135 XXXX XXXX	xxxx@xx.com

ID	Mobile Phone Number	E-mail Address
3	159 XXXX XXXX	xxxxx@xx.com.cn
4	186 XXXX XXXX	xxxx@xx.org
6	189 XXXX XXXX	xxxx@xxx.cn
8	134 XXXX XXXX	xxxx@xxxx.cn

4. Load extended employee information to **employees\_info\_extended**.

**Table 2-110** describes the extended employee information.

**Table 2-110** Extended employee information

ID	Name	Mobile Phone Number	E-mail Address	Salary Currency	Salary	Tax Category	Work Place	Hiring Date
1	Wa ng	135 XXXX XXXX	xxxx@x x.com	R	8000 .01	personal income tax&0.0 5	Country1 :City1	201 4
3	To m	159 XXXX XXXX	xxxxx@ xx.com. cn	D	1200 0.02	personal income tax&0.0 9	Country2 :City2	201 4
4	Jack	186 XXXX XXXX	xxxx@x x.org	D	2400 0.03	personal income tax&0.0 9	Country3 :City3	201 4
6	Lin da	189 XXXX XXXX	xxxx@x x.cn	D	3600 0.04	personal income tax&0.0 9	Country4 :City4	201 4
8	Zha ng	134 XXXX XXXX	xxxx@x xx.cn	R	9000 .05	personal income tax&0.0 5	Country5 :City5	201 4

## Step 2 Analyze data.

For data analysis codes, see [Querying Data](#).

- Query contact information of employees whose salaries are paid in USD.
- Query the IDs and names of employees who were hired in 2014, and load query results to the partition with the hiring time of 2014 in **employees\_info\_extended**.

- Collect statistics for the number of records in the employees\_info table.
- Query information about employees whose email addresses end with "cn".

**Step 3** Submit a data analysis task to collect statistics for the number of records in the employees\_info table.

For details about the implementation, see [Example Program Guide](#).

----End

### 2.9.3.2 Example Codes

#### 2.9.3.2.1 Creating a Table

##### Function

This topic describes how to use Hive Query Language (HQL) to create internal and external tables. You can create a table in three modes:

- Define the table structure, and use the key word EXTERNAL to differentiate between internal and external tables.
  - If all data is to be processed by Hive, create an internal table. When an internal table is deleted, the metadata and data in the table are deleted.
  - If data is to be processed by multiple tools, create an external table. When an external table is deleted, only the metadata is deleted.
- Create a table based on existing tables. Use CREATE LIKE to fully copy the original table structure, including the storage format.
- Create a table based on query results using CREATE AS SELECT.  
In this mode, you can specify which fields are to be copied when copying the original table structure. The storage format is not copied.

Both the table name and field name can contain a maximum of 128 bytes. Both the field comment and value can contain a maximum of 4000 bytes. The key in **WITH SERDEPROPERTIES** can contain a maximum of 256 bytes.

### Example Codes

```
-- Create an external table employees_info.  
CREATE EXTERNAL TABLE IF NOT EXISTS employees_info  
(  
id INT,  
name STRING,  
usd_flag STRING,  
salary DOUBLE,  
deductions MAP<STRING, DOUBLE>,  
address STRING,  
entrytime STRING  
)  
-- Specify the field delimiter. Use delimited fields terminated by to specify the delimiter between columns to a comma (,).  
-- Use MAP KEYS TERMINATED BY to specify the delimiter between map keys to &  
ROW FORMAT delimited fields terminated by '' MAP KEYS TERMINATED BY '&'  
-- Set the storage format to TEXTFILE.  
STORED AS TEXTFILE;  
  
-- Create an external table employees_contact.
```

```
CREATE EXTERNAL TABLE IF NOT EXISTS employees_contact
(
    id INT,
    tel_phone STRING,
    email STRING
)
ROW FORMAT delimited fields terminated by ','
STORED AS TEXTFILE;

-- Create an external table employees_info_extended.
CREATE EXTERNAL TABLE IF NOT EXISTS employees_info_extended(id INT, name STRING, usd_flag STRING,
salary DOUBLE, deductions MAP<STRING, DOUBLE>, address STRING)
-- A table may have one or multiple partitions. Each partition is saved as an independent folder in the table
directory. Partitions help minimize the query scope, accelerate data query, and allow users to manage data
based on certain criteria.
-- Use PARTITIONED BY to specify the column name and data type of the partition.
PARTITIONED BY(entrytime STRING)
ROW FORMAT delimited fields terminated by ',' MAP KEYS TERMINATED BY '&
STORED AS TEXTFILE;
-- After a table is created, you can use ALTER TABLE to add or delete fields to or from the table, modify
table attributes, and add partitions.
-- Add the tel_phone and email fields to the employees_info_extended table.
ALTER TABLE employees_info_extended ADD COLUMNS (tel_phone STRING, email STRING);
```

### 2.9.3.2.2 Loading Data

#### Function

This topic describes how to use Hive Query Language (HQL) to load data to the existing **employees\_info** table. You can learn how to load data from a local file system and MRS cluster. LOCAL is used to differentiate between local and non-local data sources.

#### Example Codes

```
-- Load the employee_info.txt file from the /opt/hive_examples_data/ directory of the local file system to
the employees_info table.
---- Overwrite the original data using the new data
LOAD DATA LOCAL INPATH '/opt/hive_examples_data/employee_info.txt' OVERWRITE INTO TABLE
employees_info;
---- Retain the original data and add the new data to the table.
LOAD DATA LOCAL INPATH '/opt/hive_examples_data/employee_info.txt' INTO TABLE employees_info;

-- Load /user/hive_examples_data/employee_info.txt from HDFS to the employees_info table.
---- Overwrite the original data using the new data
LOAD DATA INPATH '/user/hive_examples_data/employee_info.txt' OVERWRITE INTO TABLE
employees_info;
---- Retain the original data and add the new data to the table.
LOAD DATA INPATH '/user/hive_examples_data/employee_info.txt' INTO TABLE employees_info;
```

Loading data is to copy data to a specified table in the Hadoop distributed file system (HDFS).

#### Sample Data

Data in **employees\_info** is as follows:

```
1,Wang,R,8000.01,person&personal^Btype&income^Btax&0.05,Country1:City1,2014
3,Tom,D,12000.02,person&personal^Btype&income^Btax&0.09,Country2:City2,2014
4,Jack,D,24000.03,person&personal^Btype&income^Btax&0.05,Country3:City3,2014
6,Linda,D,36000.04,person&personal^Btype&income^Btax&0.05,Country4:City4,2014
8,Zhang,R,9000.05,person&personal^Btype&income^Btax&0.05,Country5:City5,2014
```

Data in **employees\_contact** is as follows:

```
1,135 XXXX XXXX,xxxx@xx.com  
3,159 XXXX XXXX,xxxx@xx.com.cn  
4,186 XXXX XXXX,xxxx@xx.org  
6,189 XXXX XXXX,xxxx@xxx.cn  
8,134 XXXX XXXX,xxxx@xxxx.cn
```

Data in **employees\_info\_extended** is as follows:

```
1,Wang,135 XXXX  
XXXX,xxxx@xx.com,R,8000.01,person&personal^Btype&income^Btax&0.05,Country1:City1,2014  
3,Tom,159 XXXX  
XXXX,xxxx@xx.com.cn,D,12000.02,person&personal^Btype&income^Btax&0.09,Country2:City2,2014  
4,Jack,186 XXXX

```

### 2.9.3.2.3 Querying Data

#### Function

This topic describes how to use Hive Query Language (HQL) to query and analyze data. You can query and analyze data using the following methods:

- Use common features for SELECT query, such as JOIN.
- Load data to a specified partition.
- Use Hive-provided functions.
- Query and analyze data using user-defined functions (UDFs). For details about how to create and define UDFs, see [UDF](#).

#### Example Codes

```
-- Query the contact information of employees whose salaries are paid in USD.  
SELECT  
a.name,  
b.tel_phone,  
b.email  
FROM employees_info a JOIN employees_contact b ON(a.id = b.id) WHERE usd_flag='D';  
  
-- Query the IDs and names of employees who were hired in 2014, and load query results to the partition  
with the hiring time of 2014 in the employees_info_extended table.  
INSERT OVERWRITE TABLE employees_info_extended PARTITION (entrytime = '2014')  
SELECT  
a.id,  
a.name,  
a.usd_flag,  
a.salary,  
a.deductions,  
a.address,  
b.tel_phone,  
b.email  
FROM employees_info a JOIN employees_contact b ON (a.id = b.id) WHERE a.entrytime = '2014';  
  
-- Use the existing Hive function COUNT() to count the number of records in the employees_info table.  
SELECT COUNT(*) FROM employees_info;  
  
-- Query information about employees whose email addresses end with "cn".  
SELECT a.name, b.tel_phone FROM employees_info a JOIN employees_contact b ON (a.id = b.id) WHERE  
b.email like '%cn';
```

## Extensions

- Configure intermediate Hive data encryption.  
Set the table format to RCFile (recommended) or SequenceFile, and the encryption algorithm to ARC4Codec. SequenceFile is a unique Hadoop file format, and RCFile is a Hive file format with optimized column storage. When a big table is queried, RCFile provides higher performance than SequenceFile.

```
set hive.exec.compress.output=true;
set hive.exec.compress.intermediate=true;
set hive.intermediate.compression.codec=org.apache.hadoop.io.encryption.arc4.ARC4Codec;
```
- For details about UDFs, see [UDF](#).

### 2.9.3.2.4 UDF

When internal functions of Hive cannot meet requirements, you can compile user-defined functions (UDFs) and use them for query.

According to implementation methods, UDFs are classified as follows:

- Common UDFs: used to perform operations on a single data row and export a single data row.
- User-defined aggregating functions (UDAFs): used to input multiple data rows and export a single data row.
- User-defined table-generating functions (UDTFs): used to perform operations on a single data row and export multiple data rows.

According to usage methods, UDFs are classified as follows:

- Temporary functions: used only in the current session and must be recreated after a session restarts.
- Permanent function: used in multiple sessions and do not have to be created every time a session restarts.

The following uses AddDoublesUDF as an example to describe how to compile and use UDFs.

## Function

AddDoublesUDF is used to add two or multiple floating point values. The following example describes how to compile and use UDFs.

### NOTE

- The normal UDF must be originated from `org.apache.hadoop.hive.ql.exec.UDF`.
- The normal UDF must implement at least one `evaluate()`. The `evaluate` function supports overloading.
- To develop a customized function, you need to add the `hive-exec-3.1.0.jar` dependency package to the project. The package can be obtained from the Hive installation directory.

## Example Codes

The following is a UDF example:

```
package com.huawei.bigdata.hive.example.udf;
import org.apache.hadoop.hive.ql.exec.UDF;
```

```
public class AddDoublesUDF extends UDF {  
    public Double evaluate(Double... a) {  
        Double total = 0.0;  
        // Processing logic  
        for (int i = 0; i < a.length; i++)  
            if (a[i] != null)  
                total += a[i];  
        return total;  
    }  
}
```

## How to Use

- Step 1** Package the preceding program into **AddDoublesUDF.jar**, and upload it to a directory on the HDFS (such as `/user/hive_examples_jars/`). The user who creates the UDF and the user who uses the UDF function must have read right on this JAR file. Example statements:

```
hdfs dfs -put ./hive_examples_jars /user/hive_examples_jars
```

```
hdfs dfs -chmod 777 /user/hive_examples_jars
```

- Step 2** Run the following command:

```
beeline -n Hive service user
```

- Step 3** Define the function in Hive Server. Run the following SQL statement to create a permanent function:

```
CREATE FUNCTION addDoubles AS  
'com.huawei.bigdata.hive.example.udf.AddDoublesUDF' using jar 'hdfs://  
hacluster/user/hive_examples_jars/AddDoublesUDF.jar';
```

*addDoubles* indicates the function alias that is used for SELECT query.

Run the following statement to create a temporary function:

```
CREATE TEMPORARY FUNCTION addDoubles AS  
'com.huawei.bigdata.hive.example.udf.AddDoublesUDF' using jar 'hdfs://  
hacluster/user/hive_examples_jars/AddDoublesUDF.jar';
```

- *addDoubles* indicates the function alias that is used for SELECT query.
- TEMPORARY indicates that the function is used only in the current session with the Hive server.

- Step 4** Run the following SQL statement to use the function in the Hive server:

```
SELECT addDoubles(1,2,3);
```

If an **[Error 10011]** error is displayed when you log in to the client again, run the **reload function;** command and then use this function.

- Step 5** Run the following SQL statement to delete the function from the Hive server:

```
DROP FUNCTION addDoubles;
```

----End

## Extensions

None

### 2.9.3.2.5 Example Program Guide

## Function

This section describes how to use an example program to complete an analysis task. An example program can submit a task by using the following methods:

- Submitting a data analysis task by using JDBC interfaces
- Submitting a data analysis task by using Python

## Example Codes

- Submit a data analysis task using the Hive Java database connectivity (JDBC) interface, that is, JDBCExample.java.

- Read the **property** file of the HiveServer client. The **hiveclient.properties** file is saved in the **resources** directory of the JDBC example program provided by Hive.

```
Properties clientInfo = null;
String userdir = System.getProperty("user.dir") + File.separator
+ "conf" + File.separator;
InputStream fileInputStream = null;
try{
    clientInfo = new Properties();
    //hiveclient.properties indicates the client configuration file. If the multiple instances feature is used, the file must be replaced with the hiveclient.properties file on the instance client.
    //hiveclient.properties is located under the config directory of the directory where the instance client installation package is decompressed.
    String hiveclientProp = userdir + "hiveclient.properties" ;
    File propertiesFile = new File(hiveclientProp);
    fileInputStream = new FileInputStream(propertiesFile);
    clientInfo.load(fileInputStream);
} catch (Exception e) {
    throw new IOException(e);
} finally{
    if(fileInputStream != null){
        fileInputStream.close();
        fileInputStream = null;
    }
}
```

- Obtain the IP address and port list of ZooKeeper, the cluster authentication mode, the SASL configuration of HiveServers, node names of HiveServers in ZooKeeper, the discovery mode from the client to the server, and the principal server process for user authentication. You can read all these configurations from the **hiveclient.properties** file.

```
//The format of zkQuorum is
xxx.xxx.xxx.xxx:24002,xxx.xxx.xxx:24002,xxx.xxx.xxx:24002;
//xxx.xxx.xxx.xxx is the IP address of the node where ZooKeeper resides. The default port is
24002.
zkQuorum = clientInfo.getProperty("zk.quorum");
auth = clientInfo.getProperty("auth");
sasl_qop = clientInfo.getProperty("sasl.qop");
zooKeeperNamespace = clientInfo.getProperty("zooKeeperNamespace");
serviceDiscoveryMode = clientInfo.getProperty("serviceDiscoveryMode");
principal = clientInfo.getProperty("principal");
auditAddition = clientInfo.getProperty("auditAddition");
```

- In security mode, the kerberos user and keytab file path are required for login authentication. For details about how to obtain **USER\_NAME**,

**USER\_KEYTAB\_FILE**, and **KRB5\_FILE**, see [Running JDBC and Viewing Results](#).

```
// Set the userName of new user.  
USER_NAME = "xxx";  
// Set the keytab and krb5 files location of client.  
String userdir = System.getProperty("user.dir") + File.separator  
+ "conf" + File.separator;  
USER_KEYTAB_FILE = userdir + "user.keytab";  
KRB5_FILE = userdir + "krb5.conf";
```

- d. Define HQL. HQL must be a single statement and cannot contain semicolons (;).

```
// Define HQL. HQL cannot contain ";"  
String[] sqls = {"CREATE TABLE IF NOT EXISTS employees_info(id INT,name STRING)",  
"SELECT COUNT(*) FROM employees_info", "DROP TABLE employees_info"};
```

- e. Build JDBC URL.

 **NOTE**

You can also implement pre-authentication without the need of providing the account and keytab file path. For details, see JDBC code example 2 in [Examples](#). If IBM JDK is used to run Hive applications, pre-authentication in JDBC sample code 2 must be implemented.

The following is an example of the JDBC URL composed of code snippets:

```
jdbc:hive2://  
xxx.xxx.xxx:24002,xxx.xxx.xxx:24002,xxx.xxx.xxx:24002;/serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=hiveserver2;sasl.qop=auth-conf;auth=KERBEROS;principal=hive/hadoop.<system domain name>@<system domain name>;
```

You can login in to FusionInsight Manager, choose **System > Permission > Domain and Mutual Trust**, and check the value of **Local Domain**, which is the current system domain name.

**hive/hadoop.<system domain name>** is the user name. All letters in the system domain name contained in the user name of the system are lowercase letters. For example, if **Local domain** is set to **9427068F-6EFA-4833-B43E-60CB641E5B6C.COM**, the user is **hive/hadoop.9427068f-6efa-4833-b43e-60cb641e5b6c.com**.

```
// Concat JDBC URL  
StringBuilder sBuilder = new StringBuilder(  
"jdbc:hive2://"").append(zkQuorum).append("/");  
  
if ("KERBEROS".equalsIgnoreCase(auth)) {  
    sBuilder.append(";serviceDiscoveryMode=")  
        .append(serviceDiscoveryMode)  
        .append(";zooKeeperNamespace=")  
        .append(zooKeeperNamespace)  
        .append(";sasl.qop=")  
        .append(sasl_qop)  
        .append(";auth=")  
        .append(auth)  
        .append(";principal=")  
        .append(principal)  
        .append(";user.principal=")  
        .append(USER_NAME)  
        .append(";user.keytab=")  
        .append(USER_KEYTAB_FILE);  
  
} else {  
    // Normal mode  
    sBuilder.append(";serviceDiscoveryMode=")  
        .append(serviceDiscoveryMode)  
        .append(";zooKeeperNamespace=")  
        .append(zooKeeperNamespace)  
        .append(";auth=none;");
```

```
        }
        if (auditAddition != null && !auditAddition.isEmpty()) {
            strBuilder.append(";auditAddition=").append(auditAddition);
        }
        String url = sBuilder.toString();
```

- f. Load the Hive JDBC driver.

```
// Load the Hive JDBC driver.  
Class.forName(HIVE_DRIVER);
```

- g. Obtain the JDBC connection, confirm the HQL type (DDL/DML), call ports to run the HQL statement, return the queried column name and results to the console, and close the JDBC connection.

```
Connection connection = null;  
try {  
    // Obtain the JDBC connection.  
    // If the normal mode is used, the second parameter needs to be set to a correct username.  
    // Otherwise, the anonymous user will be used for login.  
    connection = DriverManager.getConnection(url, "", "");  
  
    // Create a table  
    // To import data to a table after the table is created, you can use the LOAD statement. For  
    // example, import data from the HDFS to the table.  
    //load data inpath '/tmp/employees.txt' overwrite into table employees_info;  
    execDDL(connection,sqls[0]);  
    System.out.println("Create table success!");  
  
    // Query  
    execDML(connection,sqls[1]);  
  
    // Delete the table  
    execDDL(connection,sqls[2]);  
    System.out.println("Delete table success!");  
}  
finally {  
    // Close the JDBC connection.  
    if (null != connection) {  
        connection.close();  
    }  
  
public static void execDDL(Connection connection, String sql)  
throws SQLException {  
    PreparedStatement statement = null;  
    try {  
        statement = connection.prepareStatement(sql);  
        statement.execute();  
    }  
    finally {  
        if (null != statement) {  
            statement.close();  
        }  
    }  
}  
  
public static void execDML(Connection connection, String sql) throws SQLException {  
    PreparedStatement statement = null;  
    ResultSet resultSet = null;  
    ResultSetMetaData resultMetaData = null;  
  
    try {  
        // Run the HQL statement.  
        statement = connection.prepareStatement(sql);  
        resultSet = statement.executeQuery();  
  
        // Return the queried column name to the console.  
        resultMetaData = resultSet.getMetaData();  
        int columnCount = resultMetaData.getColumnCount();  
    }
```

```
for (int i = 1; i <= columnCount; i++) {  
    System.out.print(resultMetaData.getColumnLabel(i) + '\t');  
}  
System.out.println();  
  
// Return the results to the console.  
while (resultSet.next()) {  
    for (int i = 1; i <= columnCount; i++) {  
        System.out.print(resultSet.getString(i) + '\t');  
    }  
    System.out.println();  
}  
finally {  
    if (null != resultSet) {  
        resultSet.close();  
    }  
  
    if (null != statement) {  
        statement.close();  
    }  
}
```

- Submit a data analysis task using the Python interface, that is, **python-examples/pyCLI\_nosec.py**.

- Import the HAConnection class.

```
from pyhs2.haconnection import HAConnection
```

- Declare the HiveServer IP address list. In this example, **hosts** indicate the nodes of HiveServer, and **xxx.xxx.xxx.xxx** indicates the business IP address.

```
hosts = ["xxx.xxx.xxx.xxx", "xxx.xxx.xxx.xxx"]
```

#### NOTE

- If the HiveServer instance is migrated, the original sample program is invalid. You need to update the IP address of the HiveServer after the migration of the HiveServer instance used in the sample program.
- If multiple Hive instances are used, update the IP address based on the address of the instance that is actually connected.
- Set the third parameter of the **HAConnection** constructor to a correct username. The password can be left empty. Create a connection, run the HQL statement, and return the queried column name and results to the console.

```
try:  
    with HAConnection(hosts = hosts,  
                      port = 21066,  
                      authMechanism = "PLAIN",  
                      user='user1',  
                      password='*****') as haConn:  
        with haConn.getConnection() as conn:  
            with conn.cursor() as cur:  
                # Show databases  
                print cur.getDatabases()  
                # Execute query  
                cur.execute("show tables")  
                # Return column info from query  
                print cur.getSchema()  
                # Fetch table results  
                for i in cur.fetch():  
                    print i
```

```
except Exception, e:  
    print e
```

#### NOTE

If multiple Hive instances are used, you need to modify hosts according to the description in **b** and change the port number based on to the actual port number. The default ports of Hive to Hive4 are 21066 to 21070, respectively.

### 2.9.3.2.6 Accessing Multiple ZooKeepers

#### Description

This section describes how to access both FusionInsight ZooKeeper and the third-party ZooKeeper in the same client process using the `testConnectHive` and `testConnectApacheZK` methods respectively.

In the `JDBCExample` class of the `hive-jdbc-example-multizk` package, the code structure of the main method is as follows:

```
public static void main(String[] args) throws InstantiationException, IllegalAccessException,  
ClassNotFoundException, SQLException, IOException{  
    testConnectHive(); // Method of accessing FusionInsight ZooKeeper  
    testConnectApacheZk(); // Method of accessing the open-source ZooKeeper  
}
```

#### Accessing FusionInsight ZooKeeper

If only the method of accessing FusionInsight ZooKeeper needs to be executed, comment out the `testConnectApacheZk` method in the `main` function.

Before using the `testConnectHive` method to access FusionInsight ZooKeeper, perform the following operations:

- Step 1** Change the value of `USER_NAME` in the `init` method in `JDBCExample`.  
`USER_NAME` indicates the user that is used to access FusionInsight ZooKeeper and has permissions of the FusionInsight Hive and Hadoop common user groups.
  - Step 2** Go to the client decompression path  
`FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles\Hive\config` and manually import the `core-site.xml` and `hiveclient.properties` files to the `hive-jdbc-example-multizk\src\main\resources` directory of the sample project.
  - Step 3** Check and change the values of `zk.port` and `zk.quorum` in the `hiveclient.properties` file in the `resources` directory.
    - `zk.port`: indicates the port for accessing FusionInsight ZooKeeper. Generally, the default value is used. Change the value as required.
    - `zk.quorum`: indicates the IP address for accessing ZooKeeper quorumpeer. Set it to the IP address of the cluster deployed with the FusionInsight ZooKeeper service.
- End

#### Accessing Open-Source ZooKeeper

To use `testConnectApacheZk` to connect to the open-source ZooKeeper code, change `xxx.xxx.xxx.xxx` in the following code to the IP address of the open-source

ZooKeeper to be connected. Change the port number as required. After the connection is used, run the try statement in try-with-resources mode to automatically close the ZooKeeper connection. If only the sample for accessing the third-party ZooKeeper needs to be executed, comment out the **testConnectHive** method in the **main** function.

```
private static void testConnectApacheZk() {  
    //After the try statement is executed, the ZooKeeper connection is automatically disabled to prevent  
    //connection leakage.  
    try (org.apache.zookeeper.ZooKeeper digestZk =  
        new org.apache.zookeeper.ZooKeeper("xxx.xxx.xxx:port", 600000, null)) {  
        while (true) {  
            if (digestZk.getState().isConnected()) {  
                List<String> nodes = digestZk.getChildren("/", null);  
                logger.info("digest root path:{}", nodes);  
                for (String node : nodes) {  
                    List<String> subNodes = digestZk.getChildren="/" + node, null);  
                    logger.info("{} child path:{}", node, subNodes);  
                    for (String subNode : subNodes) {  
                        logger.info(  
                            "child patch:{}", subNode, digestZk.getChildren="/" + node + "/" + subNode, null));  
                    }  
                }  
                break;  
            }  
            Thread.sleep(1000);  
        }  
    } catch (IOException | KeeperException | InterruptedException e) {  
        logger.error("failed to connect zookeeper", e);  
    }  
}
```

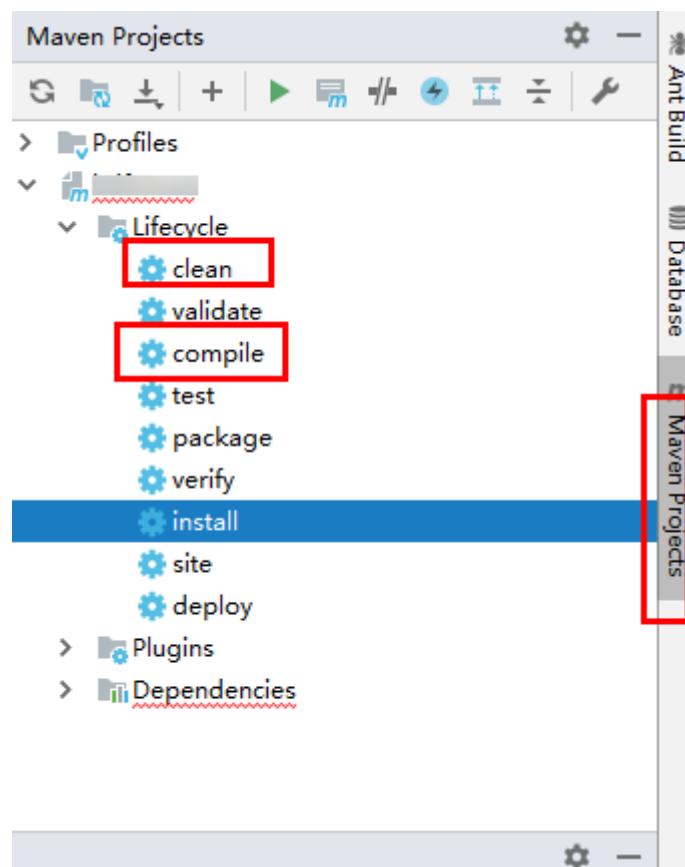

## 2.9.4 Commissioning Applications

### 2.9.4.1 Running JDBC and Viewing Results

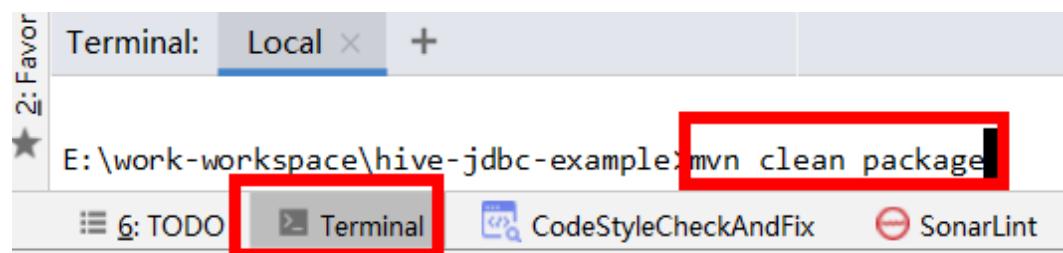

#### Running JDBC in CLI Mode

**Step 1** On the right of the IntelliJ IDEA home page, click **Maven Projects**. On the **Maven Projects** page, choose *Project name* > **Lifecycle** and run the **clean** and **compile** scripts.

Figure 2-169 Maven Projects page

**Step 2** In the lower left corner of the IDEA page, click **Terminal** to access the terminal. Run the **mvn clean package** command to compile the package.

If **BUILD SUCCESS** is displayed, the compilation is successful, as shown in the following figure. A JAR file containing the **-with-dependencies** field is generated in the **target** directory of the sample project.

```
Terminal: Local +  
[INFO] com/ already added, skipping  
[INFO] com/huawei/ already added, skipping  
[INFO] com/huawei/bigdata/ already added, skipping  
[INFO] META-INF/maven/ already added, skipping  
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 32.933 s  
[INFO] Finished at: 2020-11-23T16:18:08+08:00  
[INFO] -----
```

**Step 3** Create a directory on Windows or Linux as the running directory, for example, **D:\jdbc\_example** (Windows) or **/opt/jdbc\_example** (Linux). Place the JAR file whose name contains **-with-dependencies** in the **target** directory generated in **Step 2** to this directory. Create the **src/main/resources** subdirectory in the directory. Copy all files in the **resources** directory of the **jdbc-examples** project to the **resources** directory.

**Step 4** In Windows, run the following command:

```
cd /d d:\jdbc_example  
java -jar hive-jdbc-example-1.0-SNAPSHOT-jar-with-dependencies.jar
```

In Linux, run the following command:

```
chmod +x /opt/jdbc_example -R  
cd /opt/jdbc_example  
java -jar hive-jdbc-example-1.0-SNAPSHOT-jar-with-dependencies.jar
```

#### NOTE

The preceding JAR file names are for reference only. The actual names may vary.

**Step 5** In the CLI, view the HQL query results in the example codes.

The following information is displayed if the sample project is successful in Windows:

```
Create table success!  
_c0  
0  
Delete table success!
```

The following information is displayed if the sample project is successful in Linux:

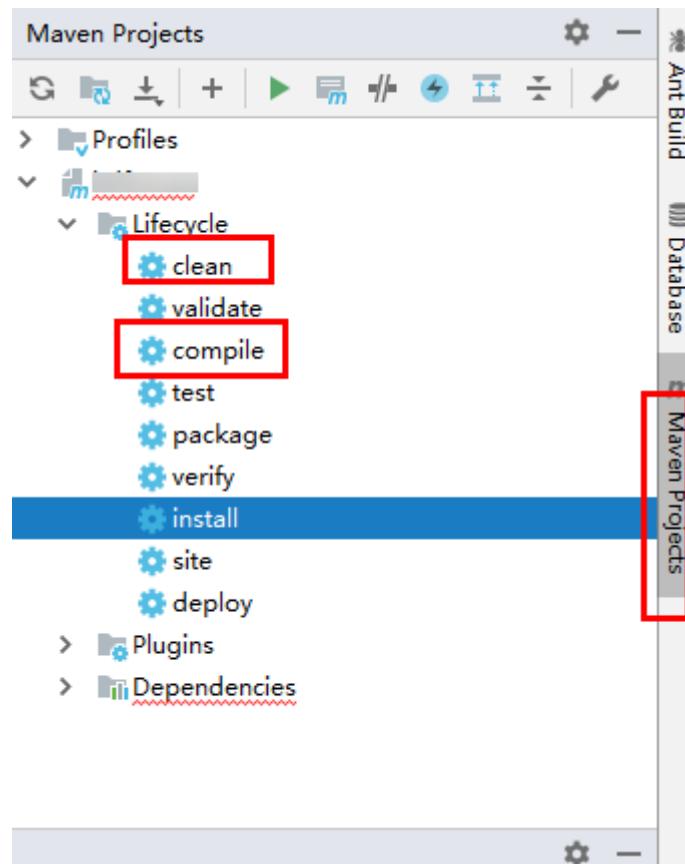

```
Create table success!  
_c0  
0  
Delete table success!
```

----End

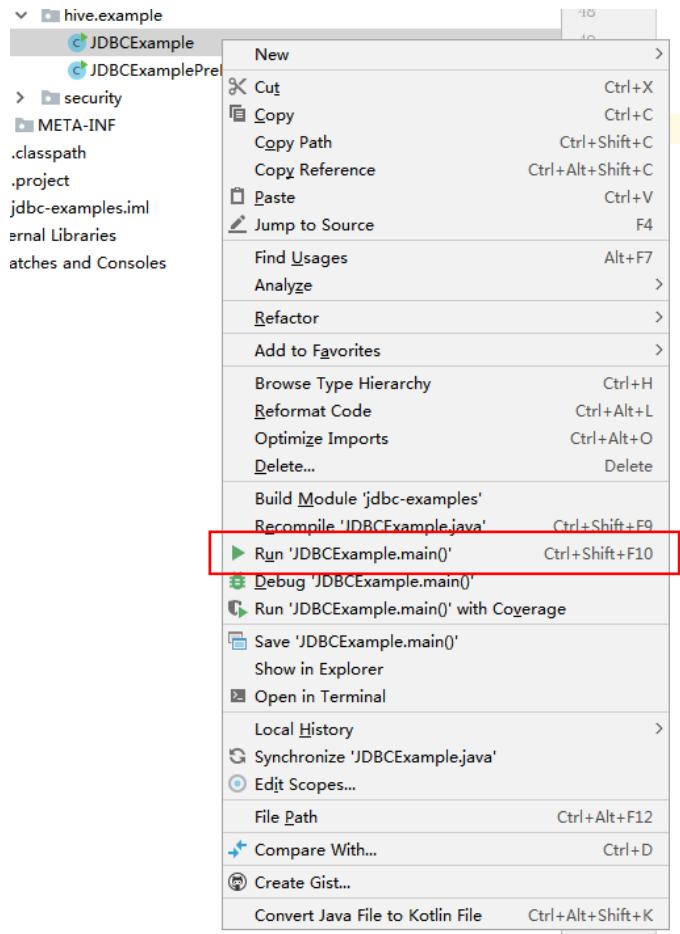

## Running JDBC in IntelliJ IDEA Mode

**Step 1** On the right of the IntelliJ IDEA home page, click **Maven Projects**. On the **Maven Projects** page, choose *Project name* > **Lifecycle** and run the **clean** and **compile** scripts.

Figure 2-170 Maven Projects page

**Step 2** Right-click the JDBCExample class in the IntelliJ IDEA jdbc-examples project, and choose **Run JDBCExample.main()** from the shortcut menu. As shown in the following figure.

**Step 3** In the IntelliJ IDEA output window, view the HQL query results in the example codes.

```
Create table success!
_c0
0
Delete table success!
```

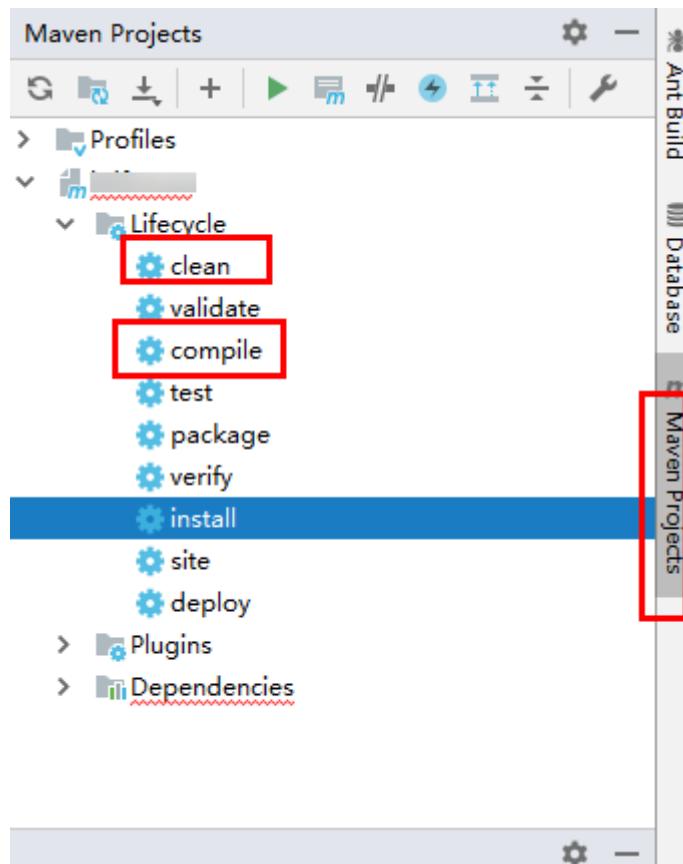

----End

#### 2.9.4.2 Running HCatalog and Viewing Results

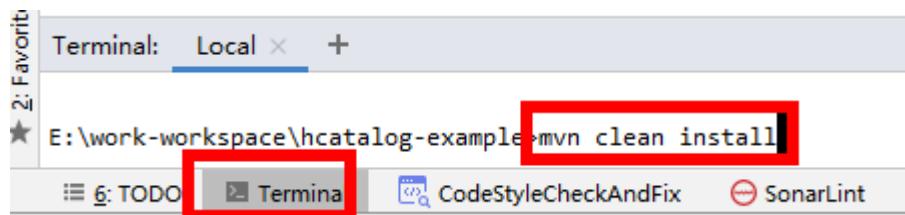

##### Running HCatalog Example Projects

**Step 1** On the right of the IntelliJ IDEA home page, click **Maven Projects**. On the **Maven Projects** page, choose *Project name > Lifecycle* and run the **clean** and **compile** scripts.

Figure 2-171 Maven Projects page

**Step 2** In the lower left corner of the IDEA page, click **Terminal** to access the terminal. Run the **mvn clean install** command to compile the package.

If **BUILD SUCCESS** is displayed, the compilation is successful, as shown in the following figure. The **hcatalog-example-\*jar** package is generated in the **target** directory of the sample project.

```
Terminal: Local × +  
[INFO] --- maven-jar-plugin:2.4:jar (default-jar) @ hcatalog-example ---  
[INFO] Building jar: E:\other-workspase\sample_project\src\hive-examples\hcatalog-example\target\hcatalog-example-1.0-SNAPSHOT.jar  
[INFO]  
[INFO] --- maven-install-plugin:2.4:install (default-install) @ hcatalog-example ---

```

#### NOTE

The preceding JAR file names are for reference only. The actual names may vary.

- Step 3** Upload the **hcatalog-example-\*.jar** file generated in the **target** directory in the previous step to the specified directory on Linux, for example, **/opt/hive\_client**, marked as **\$HCAT\_CLIENT**, and ensure that the Hive and YARN clients have been installed. Execute environment variables for the HCAT\_CLIENT to take effect.

```
export HCAT_CLIENT=/opt/hive_client
```

- Step 4** Run the following command to configure environment parameters (client installation path **/opt/hadoopclient** is used as an example):

```
export HADOOP_HOME=/opt/hadoopclient/HDFS/hadoop  
export HIVE_HOME=/opt/hadoopclient/Hive/Beeline  
export HCAT_HOME=$HIVE_HOME/../HCatalog  
export LIB_JARS=$HCAT_HOME/lib/hive-hcatalog-core-xxx.jar,$HCAT_HOME/lib/hive-metastore-xxx.jar,$HCAT_HOME/lib/hive-standalone-metastore-xxx.jar,$HIVE_HOME/lib/hive-exec-xxx.jar,$HCAT_HOME/lib/libfb303-xxx.jar,$HCAT_HOME/lib/slf4j-api-xxx.jar,$HCAT_HOME/lib/jdo-api-xxx.jar,$HCAT_HOME/lib/antlr-runtime-xxx.jar,$HCAT_HOME/lib/datanucleus-api-jdo-xxx.jar,$HCAT_HOME/lib/datanucleus-core-xxx.jar,$HCAT_HOME/lib/datanucleus-rdbms-fic-xxx.jar,$HCAT_HOME/lib/log4j-api-xxx.jar,$HCAT_HOME/lib/log4j-core-xxx.jar,$HIVE_HOME/lib/commons-lang-xxx.jar,$HIVE_HOME/lib/hive-exec-xxx.jar  
export HADOOP_CLASSPATH=$HCAT_HOME/lib/hive-hcatalog-core-xxx.jar:$HCAT_HOME/lib/hive-metastore-xxx.jar:$HCAT_HOME/lib/hive-standalone-metastore-xxx.jar:$HIVE_HOME/lib/hive-exec-xxx.jar:$HCAT_HOME/lib/libfb303-xxx.jar:$HADOOP_HOME/etc/hadoop:$HCAT_HOME/conf:$HCAT_HOME/lib/slf4j-api-xxx.jar:$HCAT_HOME/lib/jdo-api-xxx.jar:$HCAT_HOME/lib/antlr-runtime-xxx.jar:$HCAT_HOME/lib/datanucleus-api-jdo-xxx.jar:$HCAT_HOME/lib/datanucleus-core-xxx.jar:$HCAT_HOME/lib/datanucleus-rdbms-fic-xxx.jar:$HCAT_HOME/lib/log4j-api-xxx.jar:$HCAT_HOME/lib/log4j-core-xxx.jar:$HIVE_HOME/lib/commons-lang-xxx.jar:$HIVE_HOME/lib/hive-exec-xxx.jar
```

#### NOTE

- xxx: Indicates the version number of the JAR package. **Change the version numbers of the JAR files specified in LIB\_JARS and HADOOP\_CLASSPATH based on the actual environment.**
- If the multi-instance function is enabled for Hive, perform the configuration in **export HIVE\_HOME=/opt/hadoopclient/Hive/Beeline**. For example, if Hive 1 is used, ensure that the Hive 1 client has been installed before using it. Change the value of **export HIVE\_HOME** to **/opt/hadoopclient/Hive1/Beeline**.

- Step 5** Prepare for the running:

1. Use the Hive client to create source table t1 in beeline: **create table t1(col1 int);**

Insert the following data into t1:

t1.col1
1
1
1
2
2
3

2. Create destination table t2: **create table t2(col1 int,col2 int);**

**Step 6** Use the Yarn client to submit tasks:

```
yarn --config $SHADOOP_HOME/etc/hadoop jar $HCAT_CLIENT/hcatalog-example-1.0-SNAPSHOT.jar com.huawei.bigdata.HCatalogExample -libjars $LIB_JARS t1 t2
```

**Step 7** View the running result. The data in t2 is as follows:

```
0: jdbc:hive2://192.168.1.18:24002,192.168.1.18:24002> select * from t2;
+-----+-----+
| t2.col1 | t2.col2 |
+-----+-----+
| 1       | 3       |
| 2       | 2       |
| 3       | 1       |
+-----+-----+
```

----End

### 2.9.4.3 Running Python and Viewing Results

#### Running Python in CLI Mode

**Step 1** Grant the execution permission for the script of **python-examples** folder. Run the following command in the CLI:

```
chmod +x python-examples -R
```

**Step 2** Enter the service plane IP address of the node where HiveServer is installed in the hosts array of **python-examples/pyCLI\_nosec.py**.

When the multi-instance is enabled: In **python-examples/pyCLI\_nosec.py** the hosts array must be modified. In addition, the port must be set according to the used instance. The port (`hive.server2.thrift.port`) is used for Hive to provide the Thrift service. For example, if the Hive 1 instance is used, port must be set to 21067. (The default ports of Hive to Hive 4 is 21066 to 21070, respectively).

**Step 3** Run the following command:

```
cd python-examples
```

```
python pyCLI_nosec.py
```

**Step 4** In the CLI, view the HQL query results in the example codes.

For example:

```
[['default', '']]  
[{'comment': 'from deserializer', 'columnName': 'tab_name', 'type': 'STRING_TYPE'}]  
['xx']
```

If the following exception occurs:

```
importError: libsasl2.so.2: cannot open shared object file: No such file or directory
```

You can handle the problem as follows:

1. Run the following command to check the LibSASL version in the installed operating system.

```
ldconfig -p|grep sasl
```

If the following is displayed, the current operating system only has the 3.x version.

```
libsasl2.so.3 (libc6,x86-64) => /usr/lib64/libsasl2.so.3  
libsasl2.so.3 (libc6) => /usr/lib/libsasl2.so.3
```

2. If only the 3.x version exists, run the following command to create a soft link.  

```
ln -s /usr/lib64/libsasl2.so.3.0.0 /usr/lib64/libsasl2.so.2
```

----End

#### 2.9.4.4 Running Python3 and Viewing Results

##### Running Python in CLI Mode

**Step 1** Grant the execution permission for the script of **python3-examples** folder. Run the following command in the CLI:

```
chmod +x python3-examples -R.
```

**Step 2** In **python3-examples/pyCLI\_nosec.py**, change the value of host to the service plane IP address of the node where HiveServer is installed, and change the value of port to the port (**hive.server2.thrift.port**) used by Hive to provide the Thrift service. The default value is 21066.

When the multi-instance is enabled: In **python3-examples/pyCLI\_nosec.py**, the hosts must be modified. In addition, the port must be set according to the used instance. The port (**hive.server2.thrift.port**) is used for Hive to provide the Thrift service. For example, if the Hive 1 instance is used, port must be set to 21067. (The default ports of Hive to Hive 4 is 21066 to 21070, respectively).

**Step 3** Run the following commands to start the Python3 client:

```
cd python3-examples
```

```
python pyCLI_nosec.py
```

**Step 4** In the CLI, view the HQL query results in the example codes. For example:

```
('table_name1',)  
(('table_name2',)  
(('table_name3',)  
(('table_name4',)  
(('table_name5',)
```

In the preceding command, **table\_nameX** indicates the actual table name.

----End

## 2.9.4.5 Running a Spring Boot Sample Project and Viewing Results

### Running the Spring Boot Sample Project in CLI

- Step 1** Click **Terminal** in the lower left corner of the IDEA page to access the terminal. Run the **mvn clean package** command to perform compilation.

```
PS E:\workspace\sample_project\src\springboot\hive-examples\hive-rest-client-example> mvn clean package
```

If "BUILD SUCCESS" is displayed, the compilation is successful. A JAR file containing the **-with-dependencies** field is generated in the **target** directory of the sample project.

```
Terminal: Local +  
[INFO] com/ already added, skipping  
[INFO] com/huawei/ already added, skipping  
[INFO] com/huawei/bigdata/ already added, skipping  
[INFO] META-INF/maven/ already added, skipping  
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 32.933 s  
[INFO] Finished at: 2020-11-23T16:18:08+08:00  
[INFO] -----
```

- Step 2** Create a directory on Windows or Linux as the running directory, for example, **D:\hive-rest-client-example** (Windows) or **/opt/hive-rest-client-example** (Linux). Place the JAR file in **Step 1** to this directory, and create the **src/main/resources** subdirectory in the directory. Copy all files in the **resources** directory of the **hive-rest-client-example** project to **resources**.

- Step 3** Run the following commands to start the Spring Boot service:

- Commands for Windows:

```
cd /d D:\hive-rest-client-example
```

```
java -jar hive-rest-client-example-8.3.1-3.3.1-SNAPSHOT-jar-with-dependencies.jar
```

- Commands for Linux:

```
chmod +x /opt/hive-rest-client-example -R
```

```
cd /opt/hive-rest-client-example
```

```
java -jar hive-rest-client-example-8.3.1-3.3.1-SNAPSHOT-jar-with-dependencies.jar
```

#### NOTE

The preceding JAR file name is for reference only. Replace it with the actual one.

**Step 4** Call the Spring Boot sample API of Hive to trigger running the sample code.

- Running method in Windows:

Open the browser and enter <http://localhost:8080/hive/example/executesql> in the address box.

- Running method in Linux:

Run the `curl http://localhost:8080/hive/example/executesql` command on the node where the JAR file is stored in [Step 2](#).

 **NOTE**

The following information may be printed in the log when the sample code is executed. Although the log level is ERROR, the execution result is not affected.

```
ERROR 51320 --- [c-8-EventThread] o.a.c.framework.imps.EnsembleTracker : Invalid config event received: {version=100000000, server.48=IP address of the ZooKeeper node.ZooKeeper port number.ZooKeeper port number:participant...}
```

**Step 5** View the HQL query results in the sample code.

- The following information is displayed if the sample project is successful in Windows:

```
===== Hive Example Start =====
Start create table.
Table created successfully.
Start to insert data into the table.
Inserting data to the table succeeded.
Start to query table data.
Query result :
employees_infoa.id    employees_infoa.age    employees_infoa.name
1      31      SJK
