<b>1 Security Mode.....</b>	<b>1</b>
1.1 Description.....	1
1.2 Obtaining Sample Projects from Huawei Mirrors.....	1
1.3 Sample Projects of MRS Components.....	5
1.4 Security Authentication.....	14
1.4.1 Security Authentication Principles and Mechanisms.....	14
1.4.2 Preparing a Developer Account.....	18
1.4.3 Handling an Authentication Failure.....	25
1.5 ClickHouse Development Guide.....	27
1.5.1 Overview.....	27
1.5.1.1 Introduction to ClickHouse.....	27
1.5.1.2 Basic Concepts.....	28
1.5.1.3 Development Process.....	28
1.5.2 Environment Preparations.....	30
1.5.2.1 Preparing the Development and Operating Environment.....	30
1.5.2.2 Configuring and Importing a Sample Project.....	33
1.5.2.3 Configuring and Importing a Transaction Sample Project.....	38
1.5.2.4 Configuring and Importing the Spring Boot Sample Project.....	41
1.5.3 Application Development.....	42
1.5.3.1 Typical Application Scenario.....	42
1.5.3.2 Development Guideline.....	43
1.5.4 Sample Code.....	43
1.5.4.1 Setting Properties.....	43
1.5.4.2 Establishing a Connection.....	43
1.5.4.3 Creating a Database.....	44
1.5.4.4 Creating a Table.....	44
1.5.4.5 Inserting Data.....	44
1.5.4.6 Querying Data.....	45
1.5.4.7 Deleting a Table.....	45
1.5.4.8 Using BalanceDataSource.....	45
1.5.5 Connecting the Python Driver to the ClickHouse in Security Mode.....	48
1.5.6 Application Commissioning.....	54
1.5.6.1 Commissioning Applications on Windows.....	54

1.5.6.2 Commissioning Applications on Linux.....	59
1.5.6.3 Commissioning the Spring Boot Sample Project.....	64
1.5.6.3.1 Commissioning the Spring Boot Project in Windows.....	64
1.5.6.3.2 Commissioning the Spring Boot Project in Linux.....	68
1.6 Doris Development Guide.....	69
1.6.1 Overview.....	69
1.6.1.1 Doris Introduction.....	69
1.6.1.2 Common Concepts.....	70
1.6.1.3 Development Process.....	72
1.6.1.4 Doris Sample Project Introduction.....	75
1.6.2 Environment Preparation.....	76
1.6.2.1 Preparing for Development Environment.....	76
1.6.2.2 Preparing the Configuration Files for Connecting to the Cluster.....	78
1.6.2.3 Configuring and Importing JDBC or Stream Load Sample Projects.....	80
1.6.2.4 Configuring and Importing SpringBoot Sample Projects.....	83
1.6.3 Doris Application Development.....	85
1.6.3.1 Using Doris Through JDBC or DBalancer.....	85
1.6.3.1.1 Service Scenario Description.....	85
1.6.3.1.2 Application Development Approach.....	85
1.6.3.1.3 Setting Up a Connection.....	86
1.6.3.1.4 Creating a Database.....	87
1.6.3.1.5 Creating a Table.....	87
1.6.3.1.6 Inserting Data.....	87
1.6.3.1.7 Querying Data.....	88
1.6.3.1.8 Deleting a Table.....	88
1.6.3.1.9 Deleting a Database.....	88
1.6.3.2 Loading Data to a Doris Table with Stream Load.....	89
1.6.4 Application Commissioning.....	91
1.6.4.1 Commissioning an Application in Windows.....	91
1.6.4.1.1 Compiling and Running an Application.....	91
1.6.4.1.2 Viewing Windows Commissioning Results.....	98
1.6.4.2 Commissioning an Application in Linux.....	101
1.6.4.2.1 Compiling and Running Applications.....	101
1.6.4.2.2 Viewing Linux Commissioning Results.....	104
1.7 Elasticsearch Development Guide .....	107
1.7.1 Overview.....	107
1.7.1.1 Application Development Overview.....	107
1.7.1.2 Concepts.....	107
1.7.1.3 Application Development Process.....	108
1.7.2 Environment Preparation.....	110
1.7.2.1 Preparing Development and Operating Environment.....	110
1.7.2.2 Configuring and Importing Sample Projects.....	113

1.7.2.2.1 Overview.....	114
1.7.2.2.2 Importing a RestClient Sample Project.....	114
1.7.2.2.3 Importing a SpringBoot Sample Project.....	116
1.7.2.3 Preparing for Security Authentication.....	118
1.7.3 Development Process.....	119
1.7.3.1 Typical Application Scenarios.....	119
1.7.3.2 Low Level Rest Client Sample Code.....	119
1.7.3.2.1 Connecting the Elasticsearch Client to an Elasticsearch Cluster.....	120
1.7.3.2.2 Querying Cluster Information.....	120
1.7.3.2.3 Checking Whether the Specified Index Exists.....	121
1.7.3.2.4 Creating an Index with the Desired Number of Shards.....	121
1.7.3.2.5 Writing Index Data.....	122
1.7.3.2.6 Writing Data in Batches.....	123
1.7.3.2.7 Batch write data to specified routes.....	123
1.7.3.2.8 Querying Index Information.....	124
1.7.3.2.9 Deleting an Index.....	125
1.7.3.2.10 Deleting Some Documents in the Index.....	125
1.7.3.2.11 Deleting All Documents in the Index.....	126
1.7.3.2.12 Refreshing an Index.....	126
1.7.3.2.13 Multi-Thread Example.....	127
1.7.3.2.14 Pre-sorting Indices.....	128
1.7.3.3 High Level Rest Client Sample Code.....	130
1.7.3.3.1 Connecting the Client to a Cluster.....	130
1.7.3.3.2 Querying Cluster Status Information.....	131
1.7.3.3.3 Writing Index Data.....	131
1.7.3.3.4 Operations in Batches.....	133
1.7.3.3.5 Batch write data to specified routes.....	133
1.7.3.3.6 Updating Index Information.....	134
1.7.3.3.7 Querying Index Information.....	135
1.7.3.3.8 Searching for Document Information.....	135
1.7.3.3.9 Searching for Document Information by Using a Cursor.....	136
1.7.3.3.10 Clearing a Cursor.....	136
1.7.3.3.11 Deleting an Index.....	137
1.7.3.3.12 Multi-Thread Request.....	137
1.7.3.3.13 BulkProcessor Batch Import Example.....	138
1.7.3.3.14 Pre-sorting Indices.....	139
1.7.3.4 OpenDistro JDBC Sample Code.....	141
1.7.3.4.1 Connecting the Client to a Cluster.....	141
1.7.3.4.2 Querying an Index.....	142
1.7.3.4.3 Deleting Index Information.....	143
1.7.3.4.4 Functions.....	144
1.7.4 Commissioning Process.....	150

1.7.4.1 Commissioning Applications on Windows.....	150
1.7.4.1.1 Commissioning a RestClient Application.....	150
1.7.4.1.2 Commissioning a SpringBoot Program.....	159
1.7.4.2 Commissioning Applications in Linux.....	162
1.7.4.2.1 Commissioning a RestClient Application.....	162
1.7.4.2.2 Commissioning a SpringBoot Program.....	169
1.8 Flink Development Guide.....	172
1.8.1 Overview.....	172
1.8.1.1 Application Development.....	172
1.8.1.2 Basic Concepts.....	174
1.8.1.3 Development Process.....	175
1.8.2 Environment Preparation.....	176
1.8.2.1 Preparing Development and Operating Environment.....	177
1.8.2.2 Configuring and Importing Sample Projects.....	180
1.8.2.3 Creating a Project (Optional).....	199
1.8.2.4 Preparing for Security Authentication.....	202
1.8.2.5 Configuring a Spring Boot Sample Project.....	209
1.8.3 Developing an Application.....	213
1.8.3.1 DataStream Application.....	213
1.8.3.1.1 Scenarios.....	213
1.8.3.1.2 Java Sample Code.....	214
1.8.3.1.3 Scala Sample Code.....	217
1.8.3.2 Interconnecting with Kafka.....	219
1.8.3.2.1 Scenario Description.....	219
1.8.3.2.2 Java Sample Code.....	222
1.8.3.2.3 Scala Sample Code.....	224
1.8.3.3 Asynchronous Checkpoint Mechanism.....	226
1.8.3.3.1 Scenarios.....	226
1.8.3.3.2 Java Sample Code.....	227
1.8.3.3.3 Scala Sample Code.....	230
1.8.3.4 Job Pipeline Program.....	232
1.8.3.4.1 Scenario.....	232
1.8.3.4.2 Java Sample Code.....	234
1.8.3.4.3 Scala Sample Code.....	237
1.8.3.5 JOIN Operation between Configuration Tables and Streams.....	239
1.8.3.5.1 Scenario Description.....	239
1.8.3.5.2 Java Sample Code.....	242
1.8.3.5.3 Scala Sample Code.....	252
1.8.3.6 Stream SQL Join Program.....	260
1.8.3.6.1 Scenario.....	260
1.8.3.6.2 Java Sample Code.....	261
1.8.3.6.3 Scala Sample Code.....	263

1.8.3.7 Submitting a SQL Job Using Flink Jar.....	266
1.8.3.7.1 Scenario Description.....	266
1.8.3.7.2 Java Sample Code.....	266
1.8.3.8 FlinkServer REST API JavaExample.....	267
1.8.3.8.1 Scenario Description.....	267
1.8.3.8.2 Java Sample Code.....	267
1.8.3.8.3 Accessing Flinkserver RESTful API as a Proxy User.....	268
1.8.3.9 Flink Reading Data from and Writing Data to HBase.....	269
1.8.3.9.1 Scenario Description.....	269
1.8.3.9.2 Java Sample Code.....	269
1.8.3.10 Flink Reading Data from and Writing Data to Hudi.....	274
1.8.3.10.1 Scenario Description.....	274
1.8.3.10.2 Java Sample Code.....	275
1.8.3.11 Python Development Examples.....	277
1.8.3.11.1 Submitting a Regular Job Using Python.....	277
1.8.3.11.2 Submitting a SQL Job Using Python.....	281
1.8.4 Debugging the Application.....	284
1.8.4.1 Compiling and Running the Application.....	284
1.8.4.2 Viewing the Debugging Result.....	294
1.8.4.3 Running a Spring Boot Sample Project and Viewing Results.....	300
1.8.5 More Information.....	301
1.8.5.1 Introduction to Common APIs.....	301
1.8.5.1.1 Java.....	301
1.8.5.1.2 Scala.....	318
1.8.5.2 Overview of RESTful APIs.....	332
1.8.5.3 Overview of Savepoints CLI.....	335
1.8.5.4 Introduction to Flink Client CLI.....	337
1.8.5.5 FAQ.....	338
1.8.5.5.1 Savepoints-related Problems.....	338
1.8.5.5.2 What If the Chrome Browser Cannot Display the Title.....	339
1.8.5.5.3 What If the Page Is Displayed Abnormally on Internet Explorer 10/11.....	340
1.8.5.5.4 What If Checkpoint Is Executed Slowly in RocksDBStateBackend Mode When the Data Amount Is Large.....	341
1.8.5.5.5 What If yarn-session Start Fails When blob.storage.directory Is Set to /home.....	343
1.8.5.5.6 Why Does Non-static KafkaPartitioner Class Object Fail to Construct FlinkKafkaProducer010?.....	344
1.8.5.5.7 When I Use a Newly Created Flink User to Submit Tasks, Why Does the Task Submission Fail and a Message Indicating Insufficient Permission on ZooKeeper Directory Is Displayed?.....	345
1.8.5.5.8 Why Cannot I Access the Apache Flink Dashboard?.....	345
1.8.5.5.9 How Do I View the Debugging Information Printed Using System.out.println or Export the Debugging Information to a Specified File?.....	346
1.8.5.5.10 Incorrect GLIBC Version.....	347
1.9 GraphBase Development Guide.....	348
1.9.1 Overview.....	348

1.9.1.1 Application Development Overview.....	348
1.9.1.2 Basic Concepts.....	349
1.9.1.3 Development Process.....	349
1.9.2 Environment Preparation.....	352
1.9.2.1 REST API Development Environment Preparation.....	352
1.9.2.1.1 Preparing Development and Operating Environment.....	352
1.9.2.1.2 Configuring and Importing Sample Projects.....	356
1.9.2.1.3 Preparing for Security Authentication.....	359
1.9.2.2 Gremlin API Development Environment Preparation.....	361
1.9.2.2.1 Preparing Development and Operating Environment.....	361
1.9.2.2.2 Configuring and Importing a Piece of Sample Code.....	364
1.9.2.2.3 Preparing for Security Authentication.....	364
1.9.3 Developing an Application.....	365
1.9.3.1 Typical Application Scenario.....	365
1.9.3.2 Preparing Data Files.....	368
1.9.3.2.1 Compiling a Schema File (XML).....	368
1.9.3.2.2 Compiling a Data File (CSV).....	371
1.9.3.2.3 Compiling a Data Description File (DESC).....	372
1.9.3.2.4 Compiling a Graph Mapping Rule File (.mapper).....	373
1.9.3.3 Importing Data.....	386
1.9.3.3.1 Importing Data in Batches Using Tools.....	387
1.9.3.3.2 Importing Data in Real Time Using Tool.....	389
1.9.3.3.3 Using the Hive Data Import Tool.....	394
1.9.3.3.4 Data Export.....	396
1.9.3.5 REST API Development.....	411
1.9.3.6 REST API Invocation Examples and Running Results.....	412
1.9.3.6.1 Example.....	412
1.9.3.6.2 Creating or Deleting a Graph.....	413
1.9.3.6.3 Creating a Schema by Uploading an XML File.....	414
1.9.3.6.4 Creating a Schema.....	414
1.9.3.6.5 Creating an Index.....	418
1.9.3.6.6 Creating and Querying a Vertex or an Edge.....	421
1.9.3.6.7 Performing a Full Graph Query.....	427
1.9.3.6.8 Performing a Path Query.....	430
1.9.3.6.9 Performing a Line Expansion Query.....	438
1.9.3.6.10 Analyzing the Typical Application Scenario.....	440
1.9.3.7 Gremlin Console.....	444
1.9.3.8 Gremlin Java.....	445
1.9.3.8.1 Connecting Gremlin Servers and Clients.....	445
1.9.3.8.2 Running Gremlin Java API Example Code.....	446
1.9.3.9 Gremlin Application Scenarios.....	446
1.9.3.9.1 Querying a Specified Graph Object.....	446

1.9.3.9.2 Queries One or More Properties.....	447
1.9.3.9.3 Traversing a Graph Object.....	447
1.9.3.9.4 Traversing a Path.....	448
1.9.3.9.5 Filtering by Condition.....	449
1.9.3.9.6 Sorting the Result.....	451
1.9.3.9.7 Displaying the Result in Multiple Pages.....	451
1.9.3.9.8 Calculating the Intersection Between Two Data Sets.....	451
1.9.3.9.9 Calculating the Union of Two Data Sets.....	451
1.9.3.9.10 Using Statistical Functions.....	451
1.9.4 Application Commissioning.....	452
1.9.4.1 Commissioning an Application in Windows.....	452
1.9.4.1.1 Compiling and Running an Application.....	452
1.9.4.1.2 Viewing Windows Commissioning Results.....	452
1.9.4.2 Commissioning an Application in Linux.....	453
1.9.4.2.1 Compiling and Running an Application.....	453
1.9.4.2.2 Viewing Linux Commissioning Results.....	455
1.9.5 More Information.....	456
1.9.5.1 Common APIs.....	456
1.9.5.1.1 REST API.....	456
1.9.5.1.2 Gremlin API.....	457
1.10 HBase Development Guide.....	457
1.10.1 Overview.....	457
1.10.1.1 Application Development Overview.....	457
1.10.1.2 Common Concepts.....	458
1.10.1.3 Development Process.....	458
1.10.1.4 HBase Sample Project Introduction.....	461
1.10.2 Environment Preparation.....	463
1.10.2.1 Preparing for Development Environment.....	463
1.10.2.2 Preparing the Connection Cluster Configuration File.....	465
1.10.2.3 Configuring and Importing Sample Projects.....	469
1.10.2.4 Preparing for Security Authentication.....	481
1.10.2.4.1 Security Authentication for HBase Data Read and Write and Global Secondary Index Example (Single-Cluster Scenario).....	481
1.10.2.4.2 Security Authentication for HBase Data Read and Write and Global Secondary Index Example (Mutual Trust Scenarios).....	483
1.10.2.4.3 Accessing HBase REST Service Security Authentication.....	485
1.10.2.4.4 Security Authentication for Accessing the ThriftServer Service.....	486
1.10.2.4.5 Security Authentication for Accessing Multiple ZooKeepers.....	488
1.10.2.4.6 Security Authentication for Interconnecting HBase/Phoenix with Spring Boot.....	489
1.10.3 Developing an Application.....	490
1.10.3.1 HBase Data Read/Write Sample Program.....	490
1.10.3.1.1 Service Scenario Description.....	490
1.10.3.1.2 Application Development Approach.....	491

1.10.3.1.3 Creating Configuration.....	492
1.10.3.1.4 Creating Connection.....	493
1.10.3.1.5 Creating a Table.....	493
1.10.3.1.6 Deleting a Table.....	495
1.10.3.1.7 Modifying a Table.....	496
1.10.3.1.8 Inserting Data.....	497
1.10.3.1.9 Deleting Data.....	498
1.10.3.1.10 Reading Data Using Get.....	499
1.10.3.1.11 Reading Data Using Scan.....	500
1.10.3.1.12 Filtering Data.....	501
1.10.3.1.13 Creating a Secondary Index.....	502
1.10.3.1.14 Deleting an Index.....	505
1.10.3.1.15 Secondary Index-based Query.....	505
1.10.3.1.16 Multi-Point Region Division.....	508
1.10.3.1.17 Creating a Phoenix Table.....	509
1.10.3.1.18 Writing Data to the PhoenixTable.....	510
1.10.3.1.19 Reading the PhoenixTable.....	511
1.10.3.1.20 Using HBase Dual-Read Capability.....	512
1.10.3.1.21 Configuring Log4j Log Output.....	515
1.10.3.2 HBase Global Secondary Index Sample Program.....	516
1.10.3.2.1 Service Scenario Description.....	516
1.10.3.2.2 Creating HBase Global Secondary Indexes.....	516
1.10.3.2.3 Querying Global Secondary Indexes.....	518
1.10.3.2.4 Querying Based on Global Secondary Indexes.....	518
1.10.3.2.5 Disabling Global Secondary Indexes.....	519
1.10.3.2.6 Deleting Global Secondary Indexes.....	520
1.10.3.3 Sample Program for Preloading Meta Tables When Request Concurrency Is High.....	520
1.10.3.3.1 Service Scenario Description.....	520
1.10.3.3.2 Preloading Meta Tables When Request Concurrency Is High.....	521
1.10.3.4 HBase Rest API Invoking Sample Program.....	523
1.10.3.4.1 Querying Cluster Information Using REST.....	523
1.10.3.4.2 Obtaining All Tables Using REST.....	523
1.10.3.4.3 Operate Namespaces Using REST.....	524
1.10.3.4.4 Operate Tables Using REST.....	525
1.10.3.5 Accessing the HBase ThriftServer Sample Program.....	526
1.10.3.5.1 Accessing the ThriftServer Operation Table.....	526
1.10.3.5.2 Accessing ThriftServer to Write Data.....	527
1.10.3.5.3 Accessing ThriftServer to Read Data.....	528
1.10.3.6 Sample Program for HBase to Access Multiple ZooKeepers.....	530
1.10.3.6.1 Accessing Multiple ZooKeepers.....	530
1.10.4 Application Commissioning.....	531
1.10.4.1 Commissioning an Application in Windows.....	531

1.10.4.1.1 Compiling and Running an Application.....	531
1.10.4.1.2 Viewing Windows Commissioning Results.....	536
1.10.4.2 Commissioning an Application in Linux.....	538
1.10.4.2.1 Compiling and Running an Application When a Client Is Installed.....	538
1.10.4.2.2 Compiling and Running an Application When No Client Is Installed.....	541
1.10.4.2.3 Viewing Linux Commissioning Results.....	542
1.10.5 More Information.....	543
1.10.5.1 SQL Query.....	543
1.10.5.2 HBase Dual-Read Configuration Items.....	545
1.10.5.3 External Interfaces.....	548
1.10.5.3.1 Shell.....	548
1.10.5.3.2 Java API.....	549
1.10.5.3.3 SQLLine.....	553
1.10.5.3.4 JDBC APIs.....	560
1.10.5.3.5 Web UI.....	560
1.10.5.4 Phoenix Command Line.....	563
1.10.5.5 FAQs.....	564
1.10.5.5.1 How to Rectify the Fault When an Exception Occurs During the Running of an HBase-developed Application and "org.apache.hadoop.hbase.ipc.controller.ServerRpcControllerFactory" Is Displayed in the Error Information?.....	564
1.10.5.5.2 What Are the Application Scenarios of the Bulkload and put Data-loading Modes?.....	565
1.10.5.5.3 An Error Occurred When Building a JAR Package.....	565
1.10.5.5.4 How to Rectify the Fault When an Exception Occurs During the Running of an HBase-developed Application and "java.lang.OutOfMemoryError: Direct buffer memory" Is Displayed in the Error Information?.....	566
1.10.5.5.5 Why Does the Error Information Contain "GSSEException" When an IBM JDK Is Used on a Client to Connect to an HBase Cluster?.....	566
1.11 HDFS Development Guide.....	567
1.11.1 Overview.....	567
1.11.1.1 Introduction to HDFS.....	567
1.11.1.2 Basic Concepts.....	568
1.11.1.3 Development Process.....	569
1.11.2 Environment Preparation.....	571
1.11.2.1 Preparing Development and Operating Environment.....	571
1.11.2.2 Configuring and Importing Sample Projects.....	574
1.11.2.3 Preparing the Authentication Mechanism.....	581
1.11.3 Developing the Project.....	583
1.11.3.1 Scenario.....	583
1.11.3.2 Development Idea.....	583
1.11.3.3 Declare the Example Codes.....	584
1.11.3.3.1 Initializing the HDFS.....	584
1.11.3.3.2 Creating Directories.....	586
1.11.3.3.3 Writing Data into a File.....	587
1.11.3.3.4 Appending Data to a File.....	588

1.11.3.3.5 Reading Data from a File.....	589
1.11.3.3.6 Deleting a File.....	589
1.11.3.3.7 Deleting Directories.....	590
1.11.3.3.8 Multi-Thread Tasks.....	591

1.21.3.5.3 Scala Example Code.....	1106
1.21.3.5.4 Python Example Code.....	1108
1.21.3.6 Reading Data from Hive and Write It to HBase.....	1109
1.21.3.6.1 Overview.....	1109
1.21.3.6.2 Java Sample Code.....	1112
1.21.3.6.3 Scala Example Code.....	1114
1.21.3.6.4 Python Example Code.....	1115
1.21.3.7 Streaming Connecting to Kafka0-10.....	1116
1.21.3.7.1 Overview.....	1116
1.21.3.7.2 Java Example Code.....	1119
1.21.3.7.3 Scala Example Code.....	1122
1.21.3.8 Structured Streaming Project.....	1124
1.21.3.8.1 Overview.....	1124
1.21.3.8.2 Java Sample Code.....	1127
1.21.3.8.3 Scala Sample Code.....	1128
1.21.3.8.4 Python Sample Code.....	1129
1.21.3.9 Structured Streaming Stream-Stream Join.....	1130
1.21.3.9.1 Overview.....	1130
1.21.3.9.2 Scala Example Code.....	1134
1.21.3.10 Spark on Elasticsearch.....	1136
1.21.3.10.1 Overview.....	1136
1.21.3.10.2 Java Sample Code.....	1140
1.21.3.10.3 Scala Sample Code.....	1141
1.21.3.10.4 Python Sample Code.....	1142
1.21.3.11 Spark on Solr.....	1143
1.21.3.11.1 Overview.....	1143
1.21.3.11.2 Java Sample Code.....	1145
1.21.3.11.3 Scala Sample Code.....	1146
1.21.3.11.4 Python Sample Code.....	1147
1.21.3.12 Structured Streaming Status Operation.....	1148
1.21.3.12.1 Overview.....	1148
1.21.3.12.2 Scala Sample Code.....	1151
1.21.3.13 Concurrent Access from Spark to HBase in Two Clusters.....	1153
1.21.3.13.1 Overview.....	1153

1.21.3.13.2 Scala Sample Code.....	1153
1.21.3.14 Synchronizing HBase Data from Spark to CarbonData.....	1154
1.21.3.14.1 Overview.....	1154
1.21.3.14.2 Java Example Code.....	1156
1.21.3.15 Using Spark to Perform Basic Hudi Operations.....	1157
1.21.3.15.1 Overview.....	1157
1.21.3.15.2 Java Example Code.....	1158
1.21.3.15.3 Scala Example Code.....	1159
1.21.3.15.4 Python Example Code.....	1160
1.21.3.16 Compiling User-defined Configuration Items for Hudi.....	1162
1.21.3.16.1 HoodieDeltaStreamer.....	1162
1.21.3.16.2 User-defined Partitioner.....	1163
1.21.3.17 Using Spark to Write Data to ClickHouse.....	1164
1.21.3.17.1 Overview.....	1164
1.21.3.17.2 Java Sample Code.....	1166
1.21.3.17.3 Scala Sample Code.....	1167
1.21.3.17.4 Python Sample Code.....	1169
1.21.3.17.5 SQL Example.....	1171
1.21.4 Commissioning the Application.....	1171
1.21.4.1 Commissioning Applications on Windows.....	1171
1.21.4.1.1 Compiling and Running Applications.....	1172
1.21.4.1.2 View Debugging Results.....	1174
1.21.4.2 Commissioning an Application in Linux.....	1174
1.21.4.2.1 Compiling and Running the Application.....	1175
1.21.4.2.2 Checking the Commissioning Result.....	1178
1.21.5 More Information.....	1179
1.21.5.1 Common APIs.....	1179
1.21.5.1.1 Java.....	1179
1.21.5.1.2 Scala.....	1184
1.21.5.1.3 Python.....	1190
1.21.5.1.4 REST API.....	1194
1.21.5.2 Common CLIs.....	1202
1.21.5.3 JDBCServer Interface.....	1203
1.21.5.4 Structured Streaming Functions and Reliability.....	1205
1.21.5.5 FAQ.....	1210
1.21.5.5.1 How to Add a User-Defined Library.....	1210
1.21.5.5.2 How to Automatically Load Jars Packages?.....	1213
1.21.5.5.3 Why the "Class Does not Exist" Error Is Reported While the SparkStresmingKafka Project Is Running?.....	1213
1.21.5.5.4 Privilege Control Mechanism of SparkSQL UDF Feature.....	1214
1.21.5.5.5 Why Does Kafka Fail to Receive the Data Written Back by SLog in to the node where the client is installed as the client installation user.park Streaming?.....	1214

1.21.5.5.6 Why a Spark Core Application Is Suspended Instead of Being Exited When Driver Memory Is Insufficient to Store Collected Intensive Data?.....	1215
1.21.5.5.7 Why the Name of the Spark Application Submitted in Yarn-Cluster Mode Does not Take Effect?.....	1217
1.21.5.5.8 How to Perform Remote Debugging Using IDEA?.....	1217
1.21.5.5.9 How to Submit the Spark Application Using Java Commands?.....	1220
1.21.5.5.10 A Message Stating "Problem performing GSS wrap" Is Displayed When IBM JDK Is Used... 1222	1222
1.21.5.5.11 Application Fails When ApplicationManager Is Terminated During Data Processing in the Cluster Mode of Structured Streaming.....	1223
1.21.5.5.12 Restrictions on Restoring the Spark Application from the checkpoint.....	1223
1.21.5.5.13 Support for Third-party JAR Packages on x86 and TaiShan Platforms.....	1224
1.21.5.5.14 What Should I Do If a Large Number of Directories Whose Names Start with blockmgr- or spark- Exist in the /tmp Directory on the Client Installation Node?.....	1226
1.21.5.5.15 Error Code 139 Is Reported When Python Pipeline Runs in the Arm Environment.....	1227
1.21.5.5.16 What Should I Do If the Structured Streaming Task Submission Way Is Changed?.....	1227
1.21.5.5.17 Migrating Spark Streaming's Interconnection from Kafka 0.8 to Kafka 0.10.....	1228
1.22 YARN Development Guide.....	1236
1.22.1 Overview.....	1237
1.22.2 Interfaces.....	1238
1.22.2.1 Command.....	1238
1.22.2.2 Java API.....	1244
1.22.2.3 REST API.....	1247
1.22.2.4 REST APIs of Superior Scheduler.....	1251

## **2 Normal Mode.....** **1267**

2.1 ClickHouse Development Guide.....	1267
2.1.1 Overview.....	1267
2.1.1.1 Introduction to ClickHouse.....	1267
2.1.1.2 Basic Concepts.....	1268
2.1.1.3 Development Process.....	1268
2.1.2 Environment Preparations.....	1270
2.1.2.1 Preparing the Development and Operating Environment.....	1270
2.1.2.2 Configuring and Importing a Sample Project.....	1273
2.1.2.3 Configuring and Importing a Transaction Sample Project.....	1278
2.1.2.4 Configuring and Importing the Spring Boot Sample Project.....	1281
2.1.3 Application Development.....	1282
2.1.3.1 Typical Application Scenario.....	1282
2.1.3.2 Development Guideline.....	1283
2.1.4 Sample Code.....	1283
2.1.4.1 Setting Properties.....	1283
2.1.4.2 Establishing a Connection.....	1283
2.1.4.3 Creating a Database.....	1284
2.1.4.4 Creating a Table.....	1284
2.1.4.5 Inserting Data.....	1284

2.1.4.6 Querying Data.....	1285
2.1.4.7 Deleting a Table.....	1285
2.1.4.8 Using BalanceDataSource.....	1285
2.1.5 Application Commissioning.....	1288
2.1.5.1 Commissioning Applications on Windows.....	1288
2.1.5.2 Commissioning Applications on Linux.....	1293
2.1.5.3 Commissioning the Spring Boot Sample Project.....	1297
2.1.5.3.1 Commissioning the Spring Boot Project in Windows.....	1297
2.1.5.3.2 Commissioning the Spring Boot Project in Linux.....	1301
2.2 Doris Development Guide.....	1303
2.2.1 Overview.....	1303
2.2.1.1 Doris Introduction.....	1303
2.2.1.2 Common Concepts.....	1303
2.2.1.3 Development Process.....	1305
2.2.1.4 Doris Sample Project Introduction.....	1308
2.2.2 Environment Preparation.....	1309
2.2.2.1 Preparing for Development Environment.....	1309
2.2.2.2 Preparing the Configuration Files for Connecting to the Cluster.....	1311
2.2.2.3 Configuring and Importing JDBC or Stream Load Sample Projects.....	1313
2.2.2.4 Configuring and Importing SpringBoot Sample Projects.....	1317
2.2.3 Doris Application Development.....	1318
2.2.3.1 Using Doris Through JDBC and DBalancer.....	1318
2.2.3.1.1 Service Scenario Description.....	1319
2.2.3.1.2 Application Development Approach.....	1319
2.2.3.1.3 Setting Up a Connection.....	1319
2.2.3.1.4 Creating a Database.....	1320
2.2.3.1.5 Creating a Table.....	1321
2.2.3.1.6 Inserting Data.....	1321
2.2.3.1.7 Querying Data.....	1321
2.2.3.1.8 Deleting a table.....	1322
2.2.3.1.9 Deleting a Database.....	1322
2.2.3.2 Loading Data to a Doris Table with Stream Load.....	1322
2.2.4 Application Commissioning.....	1324
2.2.4.1 Commissioning an Application in Windows.....	1325
2.2.4.1.1 Compiling and Running an Application.....	1325
2.2.4.1.2 Viewing Windows Commissioning Results.....	1332
2.2.4.2 Commissioning an Application in Linux.....	1335
2.2.4.2.1 Compiling and Running Applications.....	1335
2.2.4.2.2 Viewing Linux Commissioning Results.....	1338
2.3 Elasticsearch Development Guide .....	1341
2.3.1 Overview.....	1341
2.3.1.1 Application Development Overview.....	1341

2.3.1.2 Concepts.....	1341
2.3.1.3 Application Development Process.....	1342
2.3.2 Environment Preparation.....	1344
2.3.2.1 Preparing the Development Environment and Operating Environment.....	1344
2.3.2.2 Configuring and Importing Sample Projects.....	1347
2.3.2.2.1 Overview.....	1347
2.3.2.2.2 Importing a RestClient Sample Project.....	1348
2.3.2.2.3 Importing a SpringBoot Sample Project.....	1350
2.3.3 Development Process.....	1352
2.3.3.1 Typical Application Scenarios.....	1352
2.3.3.2 Low Level RestClient Sample Java Code.....	1353
2.3.3.2.1 Connecting the Elasticsearch Client to an Elasticsearch Cluster.....	1353
2.3.3.2.2 Querying the Health Status of an Elasticsearch Cluster.....	1353
2.3.3.2.3 Checking Whether the Specified Index Exists.....	1354
2.3.3.2.4 Creating an Index with the Desired Number of Shards.....	1354
2.3.3.2.5 Writing Index Data.....	1355
2.3.3.2.6 Writing Data in Batches.....	1356
2.3.3.2.7 Batch write data to specified routes.....	1357
2.3.3.2.8 Querying Index Information.....	1358
2.3.3.2.9 Deleting an Index.....	1358
2.3.3.2.10 Deleting Some Documents in the Index.....	1359
2.3.3.2.11 Deleting All Documents in the Index.....	1359
2.3.3.2.12 Refreshing an Index.....	1360
2.3.3.2.13 Multi-Thread Example.....	1361
2.3.3.2.14 Pre-sorting Indices.....	1362
2.3.3.3 High Level RestClient Sample Code.....	1363
2.3.3.3.1 Connecting the Client to a Cluster.....	1364
2.3.3.3.2 Querying Cluster Information.....	1364
2.3.3.3.3 Writing Index Data.....	1365
2.3.3.3.4 Operations in Batches.....	1366
2.3.3.3.5 Batch write data to specified routes.....	1367
2.3.3.3.6 Updating Index Information.....	1368
2.3.3.3.7 Querying Index Information.....	1368
2.3.3.3.8 Searching for Document Information.....	1368
2.3.3.3.9 Searching for Document Information by Using a Cursor.....	1369
2.3.3.3.10 Clearing a Cursor.....	1370
2.3.3.3.11 Deleting an Index.....	1370
2.3.3.3.12 Multi-Thread Request.....	1371
2.3.3.3.13 BulkProcessor Batch Import Example.....	1372
2.3.3.3.14 Pre-sorting Indices.....	1373
2.3.4 Commissioning Process.....	1374
2.3.4.1 Commissioning Applications on Windows.....	1374

2.3.4.1.1 Commissioning a RestClient Application.....	1374
2.3.4.1.2 Commissioning a SpringBoot Program.....	1383
2.3.4.2 Commissioning Applications in Linux.....	1386
2.3.4.2.1 Commissioning a RestClient Application.....	1386
2.3.4.2.2 Commissioning a SpringBoot Program.....	1391
2.4 Flink Development Guide.....	1393
2.4.1 Overview.....	1393
2.4.1.1 Application Development.....	1394
2.4.1.2 Basic Concepts.....	1396
2.4.1.3 Development Process.....	1397
2.4.2 Environment Preparation.....	1398
2.4.2.1 Preparing the Development and Operating Environment.....	1398
2.4.2.2 Configuring and Importing Sample Projects.....	1401
2.4.2.3 Creating a Project (Optional).....	1423
2.4.2.4 Configuring a Spring Boot Sample Project.....	1426
2.4.3 Developing an Application.....	1431
2.4.3.1 DataStream Application.....	1431
2.4.3.1.1 Scenarios.....	1431
2.4.3.1.2 Java Sample Code.....	1432
2.4.3.1.3 Scala Sample Code.....	1434
2.4.3.2 Interconnecting with Kafka.....	1436
2.4.3.2.1 Scenarios.....	1436
2.4.3.2.2 Java Sample Code.....	1437
2.4.3.2.3 Scala Sample Code.....	1439
2.4.3.3 Asynchronous Checkpoint Mechanism.....	1440
2.4.3.3.1 Scenarios.....	1440
2.4.3.3.2 Java Sample Code.....	1441
2.4.3.3.3 Scala Sample Code.....	1443
2.4.3.4 Job Pipeline Program.....	1446
2.4.3.4.1 Scenario.....	1446
2.4.3.4.2 Java Sample Code.....	1448
2.4.3.4.3 Scala Sample Code.....	1450
2.4.3.5 JOIN Operation between Configuration Tables and Streams.....	1452
2.4.3.5.1 Scenario Description.....	1452
2.4.3.5.2 Java Sample Code.....	1455
2.4.3.5.3 Scala Sample Code.....	1464
2.4.3.6 Stream SQL Join Program.....	1472
2.4.3.6.1 Scenario.....	1472
2.4.3.6.2 Java Sample Code.....	1473
2.4.3.6.3 Scala Sample Code.....	1475
2.4.3.7 Submitting a SQL Job Using Flink Jar.....	1477
2.4.3.7.1 Scenario Description.....	1478

2.4.3.7.2 Java Sample Code.....	1478
2.4.3.8 FlinkServer REST API JavaExample.....	1479
2.4.3.8.1 Scenario Description.....	1479
2.4.3.8.2 Java sample code for invoking the FlinkServer REST API to create a tenant.....	1479
2.4.3.8.3 Calling a FlinkServer REST API to Start a Job.....	1480
2.4.3.8.4 Accessing Flinkserver RESTful API as a Proxy User.....	1480
2.4.3.9 Flink Reading Data from and Writing Data to HBase.....	1481
2.4.3.9.1 Scenario Description.....	1481
2.4.3.9.2 Java Sample Code.....	1482
2.4.3.10 Flink Reading Data from and Writing Data to Hudi.....	1487
2.4.3.10.1 Scenario Description.....	1487
2.4.3.10.2 Java Sample Code.....	1487
2.4.3.11 Python Development Examples.....	1490
2.4.3.11.1 Submitting a Regular Job Using Python.....	1490
2.4.3.11.2 Submitting a SQL Job Using Python.....	1493
2.4.4 Debugging the Application.....	1497
2.4.4.1 Compiling and Running Applications.....	1497
2.4.4.2 Viewing the Debugging Result.....	1505
2.4.4.3 Running a Spring Boot Sample Project and Viewing Results.....	1511
2.4.5 More Information.....	1512
2.4.5.1 Introduction to Common APIs.....	1512
2.4.5.1.1 Java.....	1512
2.4.5.1.2 Scala.....	1529
2.4.5.2 Overview of RESTful APIs.....	1543
2.4.5.3 Overview of Savepoints CLI.....	1546
2.4.5.4 Introduction to Flink Client CLI.....	1548
2.4.5.5 FAQ.....	1549
2.4.5.5.1 Savepoints-related Problems.....	1549
2.4.5.5.2 What If the Chrome Browser Cannot Display the Title.....	1550
2.4.5.5.3 What If the Page Is Displayed Abnormally on Internet Explorer 10/11.....	1551
2.4.5.5.4 What If Checkpoint Is Executed Slowly in RocksDBStateBackend Mode When the Data Amount Is Large.....	1552
2.4.5.5.5 What If yarn-session Start Fails When blob.storage.directory Is Set to /home.....	1554
2.4.5.5.6 Why Does Non-static KafkaPartitioner Class Object Fail to Construct FlinkKafkaProducer010?.....	1555
2.4.5.5.7 When I Use a Newly Created Flink User to Submit Tasks, Why Does the Task Submission Fail and a Message Indicating Insufficient Permission on ZooKeeper Directory Is Displayed?.....	1556
2.4.5.5.8 Why Cannot I Access the Apache Flink Dashboard?.....	1556
2.4.5.5.9 How Do I View the Debugging Information Printed Using System.out.println or Export the Debugging Information to a Specified File?.....	1557
2.4.5.5.10 Incorrect GLIBC Version.....	1558
2.5 GraphBase Development Guide.....	1559
2.5.1 Overview.....	1559
2.5.1.1 Application Development Overview.....	1559

2.5.1.2 Basic Concepts.....	1560
2.5.1.3 Development Process.....	1560
2.5.2 Environment Preparation.....	1563
2.5.2.1 REST API Development Environment Preparation.....	1563
2.5.2.1.1 Preparing the Development and Operating Environment.....	1563
2.5.2.1.2 Configuring and Importing Sample Projects.....	1567
2.5.2.1.3 Preparing for Security Authentication.....	1570
2.5.2.2 Gremlin API Development Environment Preparation.....	1571
2.5.2.2.1 Preparing the Development and Operating Environment.....	1572
2.5.2.2.2 Configuring and Importing a Piece of Sample Code.....	1575
2.5.3 Developing an Application.....	1575
2.5.3.1 Typical Application Scenario.....	1575
2.5.3.2 Preparing Data Files.....	1578
2.5.3.2.1 Compiling a Schema File (XML).....	1578
2.5.3.2.2 Compiling a Data File (CSV).....	1581
2.5.3.2.3 Compiling a Data Description File (DESC).....	1582
2.5.3.2.4 Compiling a Graph Mapping Rule File (.mapper).....	1583
2.5.3.3 Importing Data.....	1596
2.5.3.3.1 Importing Data in Batches Using Tools.....	1597
2.5.3.3.2 Importing Data in Real Time Using Tool.....	1598
2.5.3.3.3 Using the Hive Data Import Tool.....	1603
2.5.3.4 Data Export.....	1605
2.5.3.5 REST API Development.....	1620
2.5.3.6 REST API Invocation Examples and Running Results.....	1620
2.5.3.6.1 Example.....	1620
2.5.3.6.2 Creating or Deleting a Graph.....	1622
2.5.3.6.3 Creating a Schema by Uploading an XML File.....	1623
2.5.3.6.4 Creating a Schema.....	1623
2.5.3.6.5 Creating an Index.....	1627
2.5.3.6.6 Creating and Querying a Vertex or an Edge.....	1630
2.5.3.6.7 Performing a Full Graph Query.....	1636
2.5.3.6.8 Performing a Path Query.....	1638
2.5.3.6.9 Performing a Line Expansion Query.....	1646
2.5.3.6.10 Analyzing the Typical Application Scenario.....	1648
2.5.3.7 Gremlin Console.....	1653
2.5.3.8 Gremlin Java.....	1654
2.5.3.8.1 Connecting Gremlin Servers and Clients.....	1654
2.5.3.8.2 Running Gremlin Java API Example Code.....	1655
2.5.3.9 Gremlin Application Scenarios.....	1655
2.5.3.9.1 Querying a Specified Graph Object.....	1655
2.5.3.9.2 Queries One or More Properties.....	1655
2.5.3.9.3 Traversing a Graph Object.....	1655

2.5.3.9.4 Traversing a Path.....	1657
2.5.3.9.5 Filtering by Condition.....	1657
2.5.3.9.6 Sorting the Result.....	1659
2.5.3.9.7 Displaying the Result in Multiple Pages.....	1659
2.5.3.9.8 Calculating the Intersection Between Two Data Sets.....	1659
2.5.3.9.9 Calculating the Union of Two Data Sets.....	1660
2.5.3.9.10 Using Statistical Functions.....	1660
2.5.4 Application Commissioning.....	1660
2.5.4.1 Commissioning an Application in Windows.....	1660
2.5.4.1.1 Compiling and Running an Application.....	1660
2.5.4.1.2 Viewing Windows Commissioning Results.....	1661
2.5.4.2 Commissioning an Application in Linux.....	1662
2.5.4.2.1 Compiling and Running an Application.....	1662
2.5.4.2.2 Viewing Linux Commissioning Results.....	1664
2.5.5 More Information.....	1665
2.5.5.1 Common APIs.....	1665
2.5.5.1.1 REST API.....	1665
2.5.5.1.2 Gremlin API.....	1665
2.6 HBase Development Guide.....	1666
2.6.1 Overview.....	1666
2.6.1.1 Application Development Overview.....	1666
2.6.1.2 Common Concepts.....	1667
2.6.1.3 Development Process.....	1667
2.6.1.4 HBase Sample Project Introduction.....	1669
2.6.2 Environment Preparation.....	1671
2.6.2.1 Preparing for Development and Operating Environment.....	1671
2.6.2.2 Preparing the Connection Cluster Configuration File.....	1673
2.6.2.3 Configuring and Importing Sample Projects.....	1676
2.6.3 Developing an Application.....	1687
2.6.3.1 HBase Data Read/Write Sample Program.....	1687
2.6.3.1.1 Service Scenario Description.....	1687
2.6.3.1.2 Application Development Approach.....	1688
2.6.3.1.3 Configuring Log4j Log Output.....	1689
2.6.3.1.4 Creating Configuration.....	1690
2.6.3.1.5 Creating Connection.....	1690
2.6.3.1.6 Creating a Table.....	1691
2.6.3.1.7 Deleting a Table.....	1693
2.6.3.1.8 Modifying a Table.....	1693
2.6.3.1.9 Inserting Data.....	1694
2.6.3.1.10 Deleting Data.....	1696
2.6.3.1.11 Reading Data Using Get.....	1697
2.6.3.1.12 Reading Data Using Scan.....	1697

2.6.3.1.13 Filtering Data.....	1699
2.6.3.1.14 Creating a Secondary Index.....	1700
2.6.3.1.15 Deleting an Index.....	1702

# 1 Security Mode

## 1.1 Description

### Overview

This document describes the application development process, sample projects, and code of components in the big data cluster. It also provides FAQs and development specifications for developers with Java development experience to develop applications.

### Preparations

- The cluster has been installed and is running properly.
- You have a basic understanding of components in the big data cluster.
- You have a basic understanding of Java.
- You have learned about MRS development components and how to use the Elastic Cloud Server (ECS).
- You have a basic understanding about how to use Maven.

### Obtaining Sample Projects

Log in to GitHub to obtain the files related to the component sample projects. Download the dependency JAR files of the sample projects from Huawei Mirrors, and download the rest open source dependency JAR files from the Maven central repository.

The MRS sample code library provides sample projects of basic functions of each component for users. You can import a sample project for compilation and running based on the Kerberos authentication mode of the cluster.

## 1.2 Obtaining Sample Projects from Huawei Mirrors

### Procedure

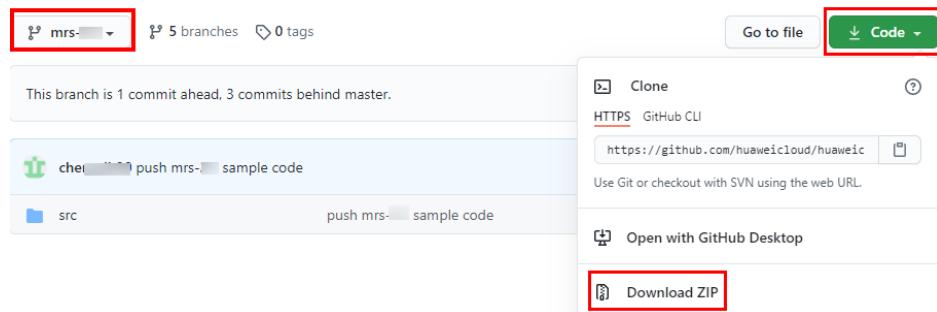

Building a sample project includes the following operations:

1. Download the Maven project source code and configuration files of the sample project. For details, see [Obtaining Sample Projects](#).
2. Configure the Maven mirror repository of the SDK in Huawei Mirrors. For details, see [Configuring Huawei Open-Source Mirrors](#).
3. Build a complete Maven project based on user requirements.

## Obtaining Sample Projects

You can download MRS sample projects at <https://github.com/huaweicloud/huaweicloud-mrs-example>.

**Figure 1-1** Downloading sample code

**Switch the branch to the version that matches the MRS cluster**, download the package to a local directory, and decompress the package to obtain the sample code project of each component. For details about the sample projects of each component of the current version, see [Sample Projects of MRS Components](#).

## Configuring Huawei Open-Source Mirrors

Huawei provides Huawei Mirrors for you to download all dependency JAR files of sample projects. However, you need to download the rest dependency open-source JAR files from the Maven central repository or other custom repository address.

### NOTE

Before using a development tool to download the dependency JAR files in the local environment, ensure that the following conditions are met:

- The local network is normal.  
Uses a browser and visit Huawei Mirrors to check whether the website can be accessed. If the access is abnormal, connect the local network.
- The proxy is disabled for the development tool.

Take the IntelliJ IDEA development tool of version 2020.2 as an example. Choose **File > Settings > Appearance & Behavior > System Settings > HTTP Proxy**, select **No proxy**, and click **OK** to save the configuration.

Perform the following steps to configure the open-source mirror warehouse.

**Step 1** Check that JDK 1.8 or later and Maven 3.0 or later have been installed.

**Step 2** Configure the Maven configuration file.

- To overwrite the Maven configuration file, choose **Huawei SDK > HuaweiCloud SDK** at Huawei Mirrors, download the **settings.xml** file, and

overwrite the < Maven installation directory >/**conf/settings.xml** file with the downloaded file.

- (Optional) If you do not want to overwrite the Maven configuration file, manually modify the **settings.xml** configuration file or the **pom.xml** file of the component sample project to configure the mirror repository address. The configuration methods are as follows:

- **Configuration method 1:** Modify the **settings.xml** configuration file.

Add the following open-source mirror repository address to **mirrors** in the **settings.xml** configuration file.

```
<mirror>
  <id>repo2</id>
  <mirrorOf>central</mirrorOf>
  <url>https://repo1.maven.org/maven2/</url>
</mirror>
```

Add the following mirror repository address to **profiles** in the **settings.xml** configuration file.

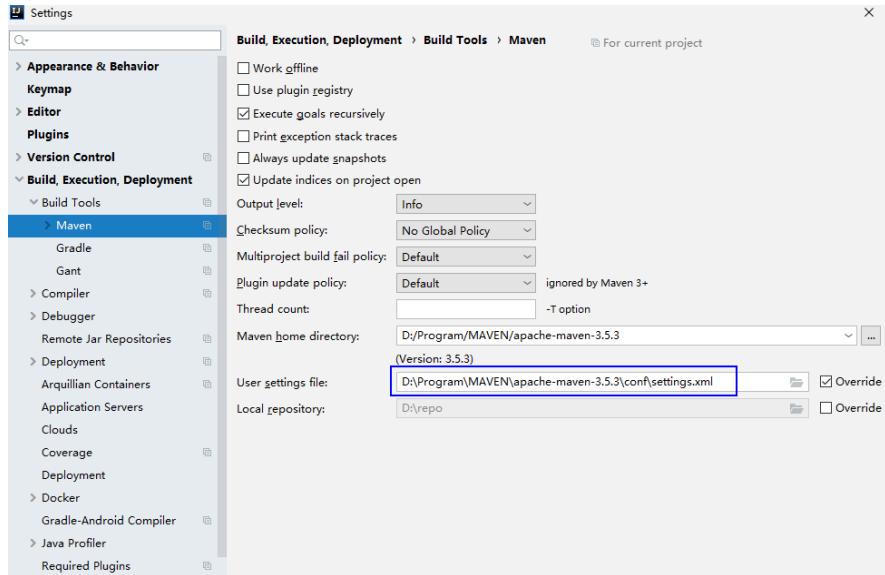

```
<profile>
  <id>huaweicloudsdk</id>
  <repositories>
    <repository>
      <id>huaweicloudsdk</id>
      <url>https://repo.huaweicloud.com/repository/maven/huaweicloudsdk/</url>
      <releases><enabled>true</enabled></releases>
      <snapshots><enabled>true</enabled></snapshots>
    </repository>
  </repositories>
</profile>
```

Add the following mirror repository address to the **activeProfiles** node in the **settings.xml** file.

```
<activeProfile>huaweicloudsdk</activeProfile>
```

 NOTE

- Huawei Mirrors does not provide third-party open-source JAR files. After configuring Huawei open-source mirrors, you need to separately configure third-party Maven mirror repository address.
- When using the IntelliJ IDEA development tool, you can choose **File > Settings > Build, Execution, Deployment > Build Tools > Maven** to view the directory where the **settings.xml** file is stored.

- **Configuration method 2: Modify the `pom.xml` configuration file.**

Add the following mirror repository address directly to the **pom.xml** file in the secondary development sample project.

```
<repositories>

    <repository>
        <id>huaweicloudsdk</id>
        <url>https://mirrors.huaweicloud.com/repository/maven/huaweicloudsdk/</url>
        <releases><enabled>true</enabled></releases>
        <snapshots><enabled>true</enabled></snapshots>
    </repository>

    <repository>
        <id>central</id>
        <name>Maven Central</name>
        <url>https://repo1.maven.org/maven2/</url>
    </repository>

</repositories>
```

**Step 3** Configure the default Maven code and JDK. Add the following information to **profiles** in the **settings.xml** configuration file:

```
<profile>
<id>JDK1.8</id>
<activation>
<activeByDefault>true</activeByDefault>
<jdk>1.8</jdk>
</activation>
<properties>
<project.build.sourceEncoding>UTF-8</project.build.sourceEncoding>
<project.reporting.outputEncoding>UTF-8</project.reporting.outputEncoding>
<maven.compiler.encoding>UTF-8</maven.compiler.encoding>
<maven.compiler.source>1.8</maven.compiler.source>
```

```
<maven.compiler.target>1.8</maven.compiler.target>
<maven.compiler.compilerVersion>1.8</maven.compiler.compilerVersion>
</properties>
</profile>
```

----End

## 1.3 Sample Projects of MRS Components

The MRS sample code library provides sample projects of basic functions of each component for users. See [Table 1-1](#) for details about the sample projects of each component of the current version.

For details about how to obtain a sample project, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Table 1-1** Sample projects of each component

Component	Project Name	Project Description
ClickHouse	clickhouse-examples	As an independent DBMS system, ClickHouse allows you to use the SQL language to perform common operations. This sample project describes the implementation of the following common operations: creating connections, databases, and tables, setting attributes, inserting and querying data, and deleting tables.
Elasticsearch	elasticsearch-rest-client-example	Sample code of the Elasticsearch REST APIs. An application is developed to search for all library information, provide information about books related to search keywords, and grade the books by score. The search function can be implemented by Elasticsearch.
Flink (normal/ security)	FlinkCheckpointJavaExample	Sample project of the asynchronous checkpoint mechanism application.
	FlinkCheckpointScalaExample	Assume that you want to collect data volume in a 4-second time window every other second and the status of operators must be strictly consistent. That is, if an application recovers from a failure, the status of all operators must be the same.

Component	Project Name	Project Description
	FlinkConfigtable-JavaExample	Assume that there is a log text file about dwell durations of netizens for shopping online at weekends and a CSV table of netizen information, and you need to develop a Flink application that achieves following functions:
	FlinkConfigtableScalaExample	<ul style="list-style-type: none"> <li>Collect statistics on female netizens who spend more than two hours in total for online shopping in real time. The name fields in the log file and the CSV table can be used as keywords, based on which the two files are joined.</li> <li>The first column in the log file records names, the second column records genders, and the third column records the dwell durations in the unit of minute. Three columns are separated by comma (,).</li> </ul>
	FlinkKafkaJavaExample	Sample code for developing an application to produce and consume data in Kafka.
	FlinkKafkaScalaExample	Assume that a Flink service receives one message record every second. A Flink application is developed to output prefixed message content in real time based on service requirements.
	FlinkPipelineJavaExample	In this sample project, the publisher job generates 10,000 pieces of data each second. Data is sent by the NettySink operator from the publisher job to downstream jobs. The other two jobs are used as subscribers and each of them subscribes a piece of data.
	FlinkPipelineScalaExample	
	FlinkStreamJavaExample	Assume that you need to develop a DataStream application of Flink to perform the following operations on logs about dwell durations of netizens for shopping online at weekends:
	FlinkStreamScalaExample	<ul style="list-style-type: none"> <li>Collect statistics on female netizens who dwell on online shopping for more than two hours in real time.</li> <li>The first column in the log file records names, the second column records genders, and the third column records the dwell durations in the unit of minute. Three columns are separated by comma (,).</li> </ul>

Component	Project Name	Project Description
	FlinkStreamSqlJoinExample	<p>Assume that a Flink service receives a message every second. The message records the basic information about a user, including the name, gender, and age. Another Flink service (service 2) receives a message irregularly, and the message records the name and career information about the user.</p> <p>To meet the requirements of some services, a Flink application is developed to achieve the following function: using the username recorded in the message received by service 2 as a keyword to jointly query service data.</p>
	FlinkHBaseJavaExample	<p>Reads and writes HBase data through Flink API jobs.</p> <ol style="list-style-type: none"><li>1. Writes data to HBase:<ol style="list-style-type: none"><li>a. Specify the parent directory of the <b>hbase-site.xml</b> file. Flink Sink can obtain the HBase connection.</li><li>b. Use the connection to determine whether a table exists. If it does not, create one.</li><li>c. Convert received data into Put objects and writes the Put objects to HBase.</li></ol></li><li>2. Reads data from HBase:<ol style="list-style-type: none"><li>a. Specify the parent directory of the <b>hbase-site.xml</b> file. Flink Source can obtain the HBase connection.</li><li>b. Use the connection to determine whether a table exists. If it does not, the job fails. In this case, you need to create a table in HBase shell or an upstream job.</li><li>c. Read data from HBase, converts result data into Row objects, and sends the Row objects to downstream operators.</li></ol></li></ol>

Component	Project Name	Project Description
	FlinkHudiJavaExample	<p>The job generates one data record per second, writes the data to the Hudi table, and reads and prints the data in the Hudi table.</p> <ol style="list-style-type: none"> <li>1. Write data to Hudi:             <ol style="list-style-type: none"> <li>a. Generate data through a random data generation class.</li> <li>b. Convert the generated data into <b>DataStream&lt;RowData&gt;</b>.</li> <li>c. Write data to the Hudi table.</li> </ol> </li> <li>2. Read data from Hudi:             <ol style="list-style-type: none"> <li>a. Read data from the Hudi table.</li> <li>b. Combine the read data into the JSON format and print the data.</li> </ol> </li> </ol>
	pyflink-example	Uses Python to read and write Kafka and submit SQL jobs.
HBase	hbase-example	Assume that you need to develop an application to manage information about users of service A in an enterprise and provide the following functions: creating user information tables, adding the educational background and title of users to the tables, querying user names and addresses based on user IDs, and collecting and deleting data.
	hbase-rest-example	Sample code for accessing the HBase service using REST APIs.
	hbase-thrift-example	Sample code for accessing the HBase service using Thrift APIs.
	hbase-zk-example	Sample code for connecting to the FusionInsight ZooKeeper and the third-party ZooKeeper to process HBase services.
HDFS	hdfs-example-normal	Service operation objects of HDFS are files. File operations covered in the sample code include creating a folder, writing data to a file, appending file content, reading a file, and deleting a file or folder. Other operations on HDFS include setting file access permissions.
	hdfs-example-security	

Component	Project Name	Project Description
HetuEngine	hetu-examples-normal	Assume that you need to join table A of the Hive data source and table B of the MPPDB data source to develop an application for querying data of the Hive data source using HetuEngine. The process is as follows: connecting to the HetuEngine JDBC Server, assembling SQL statements, running the statements, analyzing results, and disabling the connection.
	hetu-examples-security	
	hetu-examples-python3	
Hive	hcatalog-example	Sample code for obtaining Hive metadata information from MRS.  A Hive data analysis application is developed to manage employee information of an enterprise by analyzing the data in the employee information table and employee contact information table.
	hive-jdbc-example	Sample code for connecting to HiveServer using JDBC.
	hive-jdbc-example-multizk	Sample code for connecting to HiveServer with multiple ZooKeeper IP addresses using JDBC.
	python-examples	Sample code for connecting to HiveServer using Python 2.
	python3-examples	Sample code for connecting to HiveServer using Python 3.
IoTDB	iotdb-flink-example	Sample code for sending data from a Flink job to an IoTDB server. <ul style="list-style-type: none"> <li>A simulated source SensorSource generates a data point every second.</li> <li>Flink uses IoTDBSink to consume produced data and write the data into IoTDB.</li> </ul> Session object parameters include the IP address, port number, username, and password of the node where the IoTDBServer is located.
	iotdb-jdbc-example	Sample code for running IoTDB SQL statements in JDBC connection mode.
	iotdb-session-example	Sample code for running IoTDB SQL statements in Session connection mode.

Component	Project Name	Project Description
Kafka	kafka-examples	Kafka is a distributed message system, in which messages can be published or subscribed. A Producer is developed to send a message to a topic of a Kafka cluster every second, and a Consumer is implemented to ensure that the topic is subscribed and that messages of the topic are consumed in real time.
Manager	manager-examples	Assume that you need to work with FusionInsight Manager in non-GUI mode. An HTTP basic authentication-based application is required to provide the following functions: <ul style="list-style-type: none"><li>• Log in to FusionInsight Manager.</li><li>• Log in to FusionInsight Manager for data querying, adding, or deleting.</li></ul>
MapReduce	mapreduce-example-normal	The sample project describes the MapReduce statistics sample application and the sample application for MapReduce to access multiple components.
	mapreduce-example-security	
Oozie (normal/ security)	OozieMapReduceExample	The sample project describes how to submit MapReduce jobs and query job status using Java APIs. The sample code involves only MapReduce jobs.
	OozieSparkHBaseExample	Sample code for scheduling Spark to access HBase and Hive using Oozie.
	OozieSparkHiveExample	
Redis	redis-examples	The service operation object of Redis is key. Operations covered by the sample code include access operations for keys of the String, List, Hash, Set, and Sorted Set types.
RTD (normal/ security)	rtd-example	This example describes how to customize event source plug-ins and decision engine configuration sets.

Component	Project Name	Project Description
Solr	solr-example	<p>An application is developed to manage employees and search for their personal information. Solr can provide the searching service.</p> <p>Operations involved in the sample code include establishing a connection with the Solr server, querying a collection, deleting a collection, creating a collection, adding one or more documents, performing simple search, and deleting a document.</p>
Spark (normal/ security)	SparkHbaseToCarbonJavaExample	<p>Data is written to HBase in real time for point query services and is synchronized to CarbonData tables in batches at a specified interval for analytical query services.</p>
	SparkHbaseToHbaseJavaExample	<p>Assume that table1 of HBase stores a user's consumption amount on the current day and table2 stores the user's history consumption amount.</p> <p>In table1, the <b>key=1,cf:cid=100</b> record indicates that user1's consumption amount on the current day is CNY 100.</p>
	SparkHbaseToHbasePythonExample	<p>In table2, the <b>key=1,cf:cid=1000</b> record indicates that user1's history consumption amount is CNY 1000.</p> <p>Based on some service requirements, a Spark application is developed to implement the following functions:</p> <p>Calculate a user's history consumption amount based on the user name, that is, the user's total consumption amount = CNY 100 (consumption amount of the current day) + CNY 1000 (history consumption amount).</p> <p>In the preceding example, the application run result is that in table2, the total consumption amount of user1 (<b>key=1</b>) is CNY 1100 (<b>cf:cid=1100</b>).</p>
	SparkOnClickHouseJavaExample SparkOnClickHousePythonExample SparkOnClickHouseScalaExample	<p>In Spark applications, the native APIs of ClickHouse JDBC and the Spark JDBC driver can be used to create, query, and insert ClickHouse databases and tables.</p>

Component	Project Name	Project Description
	SparkHivetoHbase JavaExample	Assume that <b>person</b> table of Hive stores a user's consumption amount on the current day and HBase table2 stores the user's history consumption amount data. In the <b>person</b> table, the <b>name=1,account=100</b> record indicates that user1's consumption amount on the current day is CNY 100.
	SparkHivetoHbase PythonExample	In the <b>person</b> table, the <b>name=1,account=100</b> record indicates that user1's consumption amount on the current day is CNY 100.
	SparkHivetoHbase ScalaExample	In table2, the <b>key=1,cf:cid=1000</b> record indicates that user1's history consumption amount is CNY 1000. Based on some service requirements, a Spark application is developed to implement the following functions: Calculate a user's history consumption amount based on the user name, that is, the user's total consumption amount = CNY 100 (consumption amount of the current day) + CNY 1000 (history consumption amount). In the preceding example, the application run result is that in table2, the total consumption amount of user1 ( <b>key=1</b> ) is CNY 1100 ( <b>cf:cid=1100</b> ).
	SparkJavaExample	A Spark application is developed to perform the following operations on logs about netizens' dwell time for online shopping at weekends.
	SparkPythonExample	<ul style="list-style-type: none"><li>Collect statistics on female netizens who dwell on online shopping for more than two hours at weekends.</li><li>The first column in the log file records names, the second column records genders, and the third column records the dwell durations in the unit of minute. Three columns are separated by comma (,).</li></ul>
	SparkLauncherJavaExample	Sample code for submitting Spark applications using the <b>org.apache.spark.launcher.SparkLauncher</b> class through Java commands.
	SparkLauncherScalaExample	Sample code for submitting Spark applications using the <b>org.apache.spark.launcher.SparkLauncher</b> class through Scala commands.

Component	Project Name	Project Description
	SparkOnEsJavaExample	In Spark, you can read, write, and collect statistics on the data in Elasticsearch using Elasticsearch native APIs and the APIs provided by elasticsearch-spark.
	SparkOnEsPythonExample	
	SparkOnEsScalaExample	
	SparkOnHbaseJavaExample	HBase can be used as data sources in Spark applications. In this sample project, data is stored in HBase in Avro format. Data is read from the HBase, and the read data is filtered.
	SparkOnHbasePythonExample	
	SparkOnHbaseScalaExample	
	SparkOnHudiJavaExample	Spark is used to perform operations such as data insertion, query, update, incremental query, query at a specific time point, and data deletion on Hudi.
	SparkOnHudiPythonExample	
	SparkOnHudiScalaExample	
	SparkOnMultiHbaseScalaExample	Sample code for concurrent access from Spark to HBase in two clusters.
	SparkOnSolrJavaExample	In the Spark application, Solr client APIs are used to create indexes, insert data, and search for data.
	SparkOnSolrPythonExample	
	SparkOnSolrScalaExample	
	SparkSQLJavaExample	A Spark application is developed to perform the following operations on logs about netizens' dwell time for online shopping at weekends.
	SparkSQLPythonExample	<ul style="list-style-type: none"><li>Collect statistics on female netizens who dwell on online shopping for more than two hours at weekends.</li></ul>
	SparkSQLScalaExample	<ul style="list-style-type: none"><li>The first column in the log file records names, the second column records genders, and the third column records the dwell durations in the unit of minute. Three columns are separated by comma (,).</li></ul>

Component	Project Name	Project Description
	SparkStreamingKafka010JavaExample	Assume that Kafka receives one word record every second in a service. Based on some service requirements, a Spark application is developed to implement the following function: Calculate the total number of records of each word in real time.
	SparkStreamingKafka010ScalaExample	
	SparkStructuredStreamingJavaExample	In Spark applications, Structured Streaming is used to call Kafka APIs to obtain word records. Word records are classified to obtain the number of records of each word.
	SparkStructuredStreamingPythonExample	
	SparkStructuredStreamingScalaExample	
	SparkThriftServerJavaExample	On the custom JDBCServer client, JDBC connection is used to load, query, and delete data, create tables, and the JDBC APIs are used to submit data analysis tasks and return results.
	SparkThriftServerScalaExample	
	StructuredStreamingADScalaExample	Structured Streaming is used to read advertisement request data, display data, and click data from Kafka, obtain effective display statistics and click statistics in real time, and write the statistics to Kafka.
	StructuredStreamingStateScalaExample	In the Spark structure flow application, the number of events in each session and the start and end timestamp of the sessions are collected in different batches. At the same time, the system exports the sessions that are in the updated state in this batch.

## 1.4 Security Authentication

### 1.4.1 Security Authentication Principles and Mechanisms

#### Function

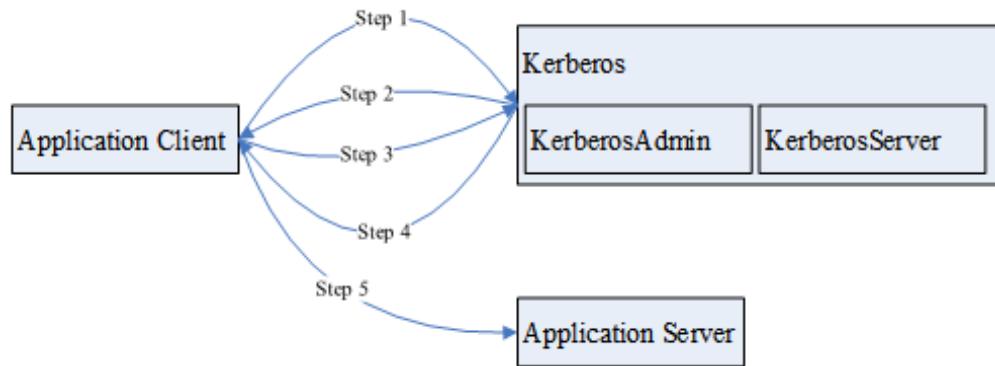

For clusters in security mode with Kerberos authentication enabled, security authentication is required during application development.

Kerberos, named after the ferocious three-headed guard dog of Hades from Greek mythology, is now used to a concept in authentication. The Kerberos protocol adopts a client-server model and cryptographic algorithms such as AES (Advanced Encryption Standard). It provides mutual authentication, that is, both the client and the server can verify each other's identity. Kerberos is used to prevent interception and replay attacks and protect data integrity. It is a system that manages keys by using a symmetric key mechanism.

## Architecture

Kerberos architecture is shown in [Figure 1-2](#) and module description in [Table 1-2](#).

**Figure 1-2** Kerberos architecture

**Table 1-2** Module description

Module	Description
Application Client	An application client, which is usually an application that submits tasks or jobs
Application Server	An application server, which is usually an application that an application client accesses
Kerberos	A service that provides security authentication
KerberosAdmin	A process that provides authentication user management
KerberosServer	A process that provides authentication ticket distribution

The process and principle are described as follows:

An application client can be a service in a cluster or a secondary development application of the customer. An application client can submit tasks or jobs to an application service.

1. Before submitting a task or job, the application client needs to apply for a ticket granting ticket (TGT) from the Kerberos service to establish a secure session with the Kerberos server.
2. After receiving the TGT request, the Kerberos service resolves parameters in the request to generate a TGT, and uses the key of the username specified by the client to encrypt the response.
3. After receiving the TGT response, the application client (based on the underlying RPC) resolves the response and obtains the TGT, and then applies for a server ticket (ST) of the application server from the Kerberos service.
4. After receiving the ST request, the Kerberos service verifies the TGT validity in the request and generates an ST of the application service, and then uses the application service key to encrypt the response.
5. After receiving the ST response, the application client packages the ST into a request and sends the request to the application server.
6. After receiving the request, the application server uses its local application service key to resolve the ST. After successful verification, the request becomes valid.

## Basic Concepts

The following concepts can help users learn the Kerberos architecture quickly and understand the Kerberos service better. The following uses security authentication for HDFS as an example.

### TGT

A TGT is generated by the Kerberos service and used to establish a secure session between an application and the Kerberos server. The validity period of a TGT is 24 hours. After 24 hours, the TGT expires automatically.

The following describes how to apply for a TGT (HDFS is used as an example):

1. Obtain a TGT through an API provided by HDFS.

```
/*
 * login Kerberos to get TGT, if the cluster is in security mode
 * @throws IOException if login is failed
 */
private void login() throws IOException {
    // not security mode, just return
    if (! "kerberos".equalsIgnoreCase(conf.get("hadoop.security.authentication"))) {
        return;
    }

    //security mode
    System.setProperty("java.security.krb5.conf", PATH_TO_KRB5_CONF);

    UserGroupInformation.setConfiguration(conf);
    UserGroupInformation.loginUserFromKeytab(PRINCIPAL_NAME, PATH_TO_KEYTAB);
}
```

2. Run shell commands on the client in kinit mode. For details about how to use shell commands, see *Shell O&M Command Description*.

### ST

An ST is generated by the Kerberos service and used to establish a secure session between an application and application service. An ST is valid only once.

In FusionInsight products, the generation of an ST is based on the Hadoop-RPC communication. The underlying RPC submits a request to the Kerberos server and the Kerberos server generates an ST.

## Sample Authentication Code

```
package com.huawei.bigdata.hdfs.examples;

import java.io.IOException;

import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.fs.FileStatus;
import org.apache.hadoop.fs.FileSystem;
import org.apache.hadoop.fs.Path;
import org.apache.hadoop.security.UserGroupInformation;

public class KerberosTest {
    private static String PATH_TO_HDFS_SITE_XML = KerberosTest.class.getClassLoader().getResource("hdfs-site.xml")
        .getPath();
    private static String PATH_TO_CORE_SITE_XML = KerberosTest.class.getClassLoader().getResource("core-site.xml")
        .getPath();
    private static String PATH_TO_KEYTAB =
        KerberosTest.class.getClassLoader().getResource("user.keytab").getPath();
    private static String PATH_TO_KRB5_CONF =
        KerberosTest.class.getClassLoader().getResource("krb5.conf").getPath();
    private static String PRINCIPAL_NAME = "develop";
    private FileSystem fs;
    private Configuration conf;

    /**
     * initialize Configuration
     */
    private void initConf() {
        conf = new Configuration();

        // add configuration files
        conf.addResource(new Path(PATH_TO_HDFS_SITE_XML));
        conf.addResource(new Path(PATH_TO_CORE_SITE_XML));
    }

    /**
     * login Kerberos to get TGT, if the cluster is in security mode
     * @throws IOException if login is failed
     */
    private void login() throws IOException {
        // not security mode, just return
        if (! "kerberos".equalsIgnoreCase(conf.get("hadoop.security.authentication"))) {
            return;
        }

        //security mode
        System.setProperty("java.security.krb5.conf", PATH_TO_KRB5_CONF);

        UserGroupInformation.setConfiguration(conf);
        UserGroupInformation.loginUserFromKeytab(PRINCIPAL_NAME, PATH_TO_KEYTAB);
    }

    /**
     * initialize FileSystem, and get ST from Kerberos
     * @throws IOException
     */
    private void initFileSystem() throws IOException {
        fs = FileSystem.get(conf);
    }

    /**
```

```
* An example to access the HDFS
* @throws IOException
*/
private void doSth() throws IOException {
    Path path = new Path("/tmp");
    FileStatus fStatus = fs.getFileStatus(path);
    System.out.println("Status of " + path + " is " + fStatus);
    //other thing
}

public static void main(String[] args) throws Exception {
    KerberosTest test = new KerberosTest();
    test.initConf();
    test.login();
    test.initFileSystem();
    test.doSth();
}
}
```

#### NOTE

1. During Kerberos authentication, you need to configure the file parameters required for configuring the Kerberos authentication, including the keytab path, Kerberos authentication username, and the **krb5.conf** configuration file of the client for Kerberos authentication.
2. Method **login()** indicates calling the Hadoop API to perform Kerberos authentication and generating a TGT.
3. Method **doSth** indicates calling the Hadoop API to access the file system. In this situation, the underlying RPC automatically carries the TGT to Kerberos for verification and then an ST is generated.
4. The preceding code can be used to create **KerberosTest.java** in the HDFS secondary development sample project in security mode and run and view the commissioning result. For details, see [HDFS Development Guide](#).

## 1.4.2 Preparing a Developer Account

### Scenario

A developer account is used to run the sample project. When developing components for different services, you need to assign different user permissions.

### Procedure

**Step 1** Log in to FusionInsight Manager.

**Step 2** Choose **System > Permission > Role > Create Role**.

1. Enter a role name, for example, **developrole**.
2. Check whether Ranger authentication is enabled. For details, see "How Do I Determine Whether the Ranger Authentication Is Used for a Service?" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.
  - If yes, go to **Step 3**.
  - If no, edit the role to add the permissions required for service development based on the permission control type of the service. For details, see [Table 1-3](#).

**Table 1-3** List of permissions

Service	Permissions to Be Granted
HDFS	In <b>Configure Resource Permission</b> , choose <i>Name of the desired cluster</i> > <b>HDFS</b> > <b>File System</b> , select <b>Read</b> , <b>Write</b> , and <b>Execute</b> for <b>hdfs://hacluster</b> , and click <b>OK</b> .
MapReduce/ Yarn	<ol style="list-style-type: none"><li>1. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>HDFS</b> &gt; <b>File System</b> &gt; <b>hdfs://hacluster/</b>, and select <b>Read</b>, <b>Write</b>, and <b>Execute</b> for the user. Choose <i>Name of the desired cluster</i> &gt; <b>HDFS</b> &gt; <b>File System</b> &gt; <b>hdfs://hacluster/</b> &gt; <b>user</b>, select <b>Read</b>, <b>Write</b>, and <b>Execute</b> for <b>mapred</b>. To execute multiple component cases, perform the following operations: Choose <i>Name of the desired cluster</i> &gt; <b>HBase</b> &gt; <b>HBase Scope</b> &gt; <b>global</b> and select the <b>default</b> option <b>create</b>. Choose <i>Name of the desired cluster</i> &gt; <b>HBase</b> &gt; <b>HBase Scope</b> &gt; <b>global</b> &gt; <b>hbase</b>, select <b>hbase:meta</b>, and click <b>Execute</b>. Choose <i>Name of the desired cluster</i> &gt; <b>HDFS</b> &gt; <b>File System</b> &gt; <b>hdfs://hacluster/</b> &gt; <b>user</b>, and select <b>Read</b>, <b>Write</b>, and <b>Execute</b> for <b>Hive</b>. Choose <i>Name of the desired cluster</i> &gt; <b>HDFS</b> &gt; <b>File System</b> &gt; <b>hdfs://hacluster/</b> &gt; <b>user</b> &gt; <b>hive</b>, and select <b>Read</b>, <b>Write</b>, and <b>Execute</b> for <b>warehouse</b>. Choose <i>Name of the desired cluster</i> &gt; <b>HDFS</b> &gt; <b>File System</b> &gt; <b>hdfs://hacluster/</b> &gt; <b>tmp</b>, and select <b>Read</b>, <b>Write</b> and <b>Execute</b> for <b>hive-scratch</b>. If examples exist, select <b>Read</b>, <b>Write</b>, <b>Execute</b>, and <b>recursion</b> for <b>example</b>. Choose <i>Name of the desired cluster</i> &gt; <b>Hive</b> &gt; <b>Hive Read Write Privileges</b> and select <b>Query</b>, <b>Insert</b>, <b>Create</b> and <b>recursion</b> for <b>default</b>. Click <b>OK</b>.</li><li>2. Edit the role. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>Yarn</b> &gt; <b>Scheduler Queue</b> &gt; <b>root</b>, select the default option <b>Submit</b>, and click <b>OK</b>.</li></ol>
HBase	In <b>Configure Resource Permission</b> , choose <i>Name of the desired cluster</i> > <b>HBase</b> > <b>HBase Scope</b> > <b>global</b> , select the <b>admin</b> , <b>create</b> , <b>read</b> , <b>write</b> , and <b>execute</b> permissions, and click <b>OK</b> .

Service	Permissions to Be Granted
Spark	<ol style="list-style-type: none"> <li>(Configure this parameter if HBase is installed.) In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>HBase</b> &gt; <b>HBase Scope</b> &gt; <b>global</b>, select the default option <b>create</b>, and click <b>OK</b>.</li> <li>(Configure this parameter if HBase is installed.) Edit the role. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>HBase</b> &gt; <b>HBase Scope</b> &gt; <b>global</b> &gt; <b>hbase</b>, select <b>execute</b> for <b>hbase:meta</b>, and click <b>OK</b>.</li> <li>Edit the role. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>HDFS</b> &gt; <b>File System</b> &gt; <b>hdfs://hacluster/</b> &gt; <b>user</b>, select <b>Execute</b> for <b>hive</b>, and click <b>OK</b>.</li> <li>Edit the role. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>HDFS</b> &gt; <b>File System</b> &gt; <b>hdfs://hacluster/</b> &gt; <b>user</b> &gt; <b>hive</b>, select <b>Read</b>, <b>Write</b>, and <b>Execute</b> for <b>warehouse</b>, and click <b>OK</b>.</li> <li>Edit the role. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>Hive</b> &gt; <b>Hive Read Write Privileges</b>, select the default option <b>Create</b>, and click <b>OK</b>.</li> <li>Edit the role. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>Yarn</b> &gt; <b>Scheduler Queue</b> &gt; <b>root</b>, select the default option <b>Submit</b>, and click <b>OK</b>.</li> </ol>
Hive	<p>In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>Yarn</b> &gt; <b>Scheduler Queue</b> &gt; <b>root</b>, select the default option <b>Submit</b> and <b>Admin</b>, and click <b>OK</b>.</p> <p><b>NOTE</b> Extra operation permissions required for Hive application development must be obtained from the system administrator.</p>
ClickHouse	<p>In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>ClickHouse</b> &gt; <b>ClickHouse Scope</b> and select <b>Create Privilege</b> for the target database Click the database name, select the read and write permissions of the corresponding table based on the task scenario, and click <b>OK</b>.</p>

Service	Permissions to Be Granted
IoTDB	<ol style="list-style-type: none"><li>In the <b>Configure Resource Permission</b> table, choose <i>Name of the desired cluster</i> &gt; <b>IoTDB</b> &gt; <b>Common User Permission</b>, select <b>Set Database</b> for the <b>root</b> directory, and click <b>OK</b>.</li><li>In the <b>Configure Resource Permission</b> table, choose <i>Name of the desired cluster</i> &gt; <b>IoTDB</b> &gt; <b>Common User Permission</b> &gt; <b>root</b>, select the corresponding storage group, select the <b>Create</b>, <b>Modify</b>, <b>Write</b>, <b>Read</b>, or <b>Delete</b> permission based on the task scenario, and click <b>OK</b>.</li></ol>
HetuEngine	<ol style="list-style-type: none"><li>In the <b>Configure Resource Permission</b> table, choose <i>Name of the desired cluster</i> &gt; <b>Hive</b> and select <b>Hive Admin Privilege</b>.</li><li>In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>Hive</b> &gt; <b>Hive Read Write Privileges</b>, select permissions based on task scenarios, and click <b>OK</b>.</li></ol> <p><b>NOTE</b> Scenario<ul style="list-style-type: none"><li>○ In the default database, select <b>Query</b> to query the tables of other users.</li><li>○ In the default database, select <b>Delete</b> and <b>Insert</b> to import data to tables of other users.</li></ul></p>
Flink	<ol style="list-style-type: none"><li>In the <b>Configure Resource Permission</b> table, choose <i>Name of the desired cluster</i> &gt; <b>HDFS</b> &gt; <b>File System</b> &gt; <b>hdfs://hacluster/</b> &gt; <b>flink</b>, select <b>Read</b>, <b>Write</b>, and <b>Execute</b>, and click <b>Service</b> in the <b>Configure Resource Permission</b> table to return.</li><li>In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>Yarn</b> &gt; <b>Scheduler Queue</b> &gt; <b>root</b>, select the default option <b>Submit</b>, and click <b>OK</b>.</li></ol> <p><b>NOTE</b> If <b>state backend</b> is set to a path on HDFS, for example, <b>hdfs://hacluster/flink-checkpoint</b>, configure the read, write, and execute permissions on the <b>hdfs://hacluster/flink-checkpoint</b> directory.</p>
Solr	-
Elasticsearch	-
GraphBase	-
Kafka	-
Redis	In <b>Configure Resource Permission</b> , choose <i>Name of the desired cluster</i> > <b>Redis</b> > <b>Redis Access Manage</b> , select <b>Read</b> , <b>Write</b> , and <b>Management</b> , and click <b>OK</b> .

Service	Permissions to Be Granted
Oozie	<ol style="list-style-type: none"><li>1. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>Oozie</b> &gt; <b>Common User Privileges</b>, and click <b>OK</b>.</li><li>2. Edit the role. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>HDFS</b> &gt; <b>File System</b>, select <b>Read</b>, <b>Write</b>, and <b>Execute</b> for <code>hdfs://hacluster</code>, and click <b>OK</b>.</li><li>3. Edit the role. In <b>Configure Resource Permission</b>, choose <i>Name of the desired cluster</i> &gt; <b>Yarn</b>, select <b>Cluster Admin Operations</b>, and click <b>OK</b>.</li></ol>

**Step 3** Choose **System > Permission > User Group > Create User Group** to create a user group for the sample project, for example, **developgroup**.

**Step 4** Choose **System > Permission > User > Create** to create a user for the sample project.

**Step 5** Enter a username, for example, **developuser**, select a user type and user group to which the user is to be added according to [Table 1-4](#), bind the role **developrole** obtain permissions, and click **OK**.

**Table 1-4** User type and user group list

Service	User Type	User Group
HDFS	Machine-Machine	Join the <b>developgroup</b> and <b>supergroup</b> groups. Set the primary group to <b>supergroup</b> .
MapReduce/Yarn	Machine-Machine	Join the <b>developgroup</b> group.
HBase	Machine-Machine	Join the <b>hadoop</b> group.

Service	User Type	User Group
Spark	Machine-Machine/Human-Machine	<p>Join the <b>developgroup</b> group.</p> <p>If the user needs to interconnect with Kafka, add the <b>Kafkaadmin</b> user group.</p> <p>If you need to connect to Elasticsearch, create a <b>Human-Machine</b> user and join the <b>elasticsearch</b> group.</p>
Hive	Machine-Machine/Human-Machine	Join the <b>hive</b> group.
Solr	Machine-Machine	Join the <b>solr</b> group.
Elasticsearch	Machine-Machine	<p>Join the <b>elasticsearch</b> group.</p> <p>To execute the OpenDistro JDBC sample of Elasticsearch, you need to join the <b>supergroup</b> group and set it as the primary group.</p>
Kafka	Machine-Machine	Join the <b>kafkaadmin</b> group.

Service	User Type	User Group
HetuEngine	<b>Human-Machine</b>	Join the <b>hive</b> group. Set the primary group to <b>hive</b> .
Redis	<b>Machine-Machine</b>	Join the <b>developgroup</b> group.
ClickHouse	<b>Machine-Machine/Human-Machine</b>	Join the <b>developgroup</b> and <b>supergroup</b> (primary) groups and add a role with the ClickHouse permission.
Oozie	<b>Human-Machine</b>	Join the <b>hadoop</b> , <b>supergroup</b> , and <b>hive</b> groups If the multi-instance function is enabled for Hive, the user must belong to a specific Hive instance group, for example, <b>hive3</b> .
GraphBase	<b>Human-Machine</b>	Join the <b>graphbaseadmin</b> , <b>graphbasedeveloper</b> , or <b>graphbaseoperator</b> group.
Flink	<b>Human-Machine</b>	Join the <b>developgroup</b> and <b>hadoop</b> groups. Set the primary group to <b>developgroup</b> . <b>NOTE</b> If a user wants to interconnect with Kafka, a hybrid cluster with Flink and Kafka components is required, or cross-cluster mutual trust needs to be configured for the cluster with Flink and the cluster with Kafka components. Additionally, the created Flink user is added to the <b>kafkaadmin</b> user group.

Service	User Type	User Group
IoTDB	Machine-Machine	Join the <b>iotdbgroup</b> group.

- Step 6** If Ranger authentication is enabled for the service, in addition to the permissions of the default user group and role, grant required permissions to the user or its role or user group on the Ranger web UI after the user is created. For details, see "Component Operation Guide" > "Using Ranger" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.
- Step 7** On the homepage of FusionInsight Manager, choose **System** > **Permission** > **User**. Select **developuser** from the user list and click **More** > **Download Authentication Credential** to download authentication credentials. Save the downloaded package and decompress the file to obtain **user.keytab** and **krb5.conf** files. These files are used for security authentication during the sample project. For details, see the corresponding service development guide.

#### NOTE

If the user type is human-machine, you need to change the initial password before downloading the authentication credential file. Otherwise, **Password has expired - change password to reset** is displayed when you use the authentication credential file. As a result, security authentication fails.

----End

### 1.4.3 Handling an Authentication Failure

#### Symptom

An authentication failure occurs during the commissioning and running of an example project.

#### Troubleshooting Process

There are many reasons that will cause an authentication failure. You are advised to perform the following steps for troubleshooting in different scenarios:

- Step 1** Check whether the network connection between the device where this application runs and the cluster is normal, and check whether the TCP and UDP ports required by Kerberos authentication can be accessed.
- Step 2** Check whether each configuration file is correctly read and stored in a correct directory.

- Step 3** Ensure that the username and keytab file are obtained according to the operation guide.
- Step 4** Check whether the configuration information is properly set before initiating an authentication.
- Step 5** Check whether multiple authentication requests are initiated in the same process. That is, check whether the **login()** method is called repeatedly.
- Step 6** If the problem persists, contact Huawei engineers for further analysis.

----End

## Authentication Failure Examples

"clock skew too great" is displayed during authentication.

- Step 1** Check the cluster time.
- Step 2** Check the time of the machine where the development environment is located. The difference between the machine time and the cluster time must be less than 5 minutes.

----End

"(Receive time out) can not connect to kdc server" is displayed during authentication.

- Step 1** Check whether the content of the **krb5.conf** file is correct. That is, check whether the file content is the same as the service IP address configuration of KerberosServer in the cluster.
- Step 2** Check whether the Kerberos service is running properly.
- Step 3** Check whether the firewall is disabled.

----End

An exception occurs when a client application submits a task to the Hadoop cluster, and the message "Failed to find any Kerberos tgt" or "No valid credentials provided" is displayed.

- Step 1** Check whether the **kinit** command is executed. If no, perform kinit authentication before submitting the task.
- Step 2** In the multi-thread scenario, when the process starts, call the **loginFromKeytab** function provided by Hadoop to log in to KDC to obtain TGT. Before submitting tasks, call the **reloginFromKeytab** function to update the TGT.

```
// After the first login succeeds, set user group information.  
UserGroupInformation.loginUserFromKeytab(this.userPrincipal, this.keytabFile);  
// Before the thread submits the task:  
UserGroupInformation.getLoginUser().reloginFromKeytab();
```
- Step 3** If multiple scripts use the **kinit** command to authenticate the same user, run the **export KRB5CCNAME=keytab\_path** command before running the **kinit** command in each script to ensure that the path specified by **KRB5CCNAME** in each script process is inconsistent.

----End

# 1.5 ClickHouse Development Guide

## 1.5.1 Overview

### 1.5.1.1 Introduction to ClickHouse

#### ClickHouse

ClickHouse is a column-based database oriented to online analysis and processing. It supports SQL query and provides good query performance. The aggregation analysis and query performance based on large and wide tables is excellent, which is one order of magnitude faster than other analytical databases.

Advantages for ClickHouse:

- High data compression ratio
- Multi-core parallel computing
- Vectorized computing engine
- Supporting nested data structure
- Supporting sparse indexes
- Supporting INSERT and UPDATE

**ClickHouse application scenarios:**

- Real-time data warehouse

The streaming computing engine (such as Flink) is used to write real-time data to ClickHouse. With the excellent query performance of ClickHouse, Multi-dimensional and multi-mode real-time query and analysis requests can be responded within subseconds.

- Offline query

Large-scale service data is imported to ClickHouse and constructs a large wide table with hundreds of millions to tens of billions of records and hundreds of dimensions. It supports personalized statistics collection and continuous exploratory query and analysis at any time to assist business decision-making and provides excellent query experience.

#### Introduction to the ClickHouse Development Interface

ClickHouse is developed using C++ and positioned as a DBMS. It supports HTTP and Native TCP network interface protocols and multiple driver modes such as JDBC and ODBC. You are advised to use [clickhouse-jdbc](#) of the community version for application development.

### 1.5.1.2 Basic Concepts

#### Concepts

- **cluster**

Cluster: Cluster is a logical concept in ClickHouse. It can be defined by users as required, which is different from the general understanding of cluster. Multiple ClickHouse nodes are loosely coupled and exist independently.

- **shards**

Shard: A shard is a horizontal division of a cluster. A cluster can consist of multiple shards.

- **replicas**

Replica: One shard can contain multiple replicas.

- **partition**

Partition: A partition is used for local replicas and can be considered as a vertical division.

- **MergeTree**

ClickHouse has a huge table engine system. As the basic table engine of the family system, MergeTree provides functions such as data partitioning, primary indexes, and secondary indexes. When creating a table, you need to specify the table engine. Different table engines determine the final character of a data table, for example, the features of a data table, the form how data is stored, and how data is loaded.

### 1.5.1.3 Development Process

[Figure 1-3](#) and [Table 1-5](#) describe the phases in the development process.

Figure 1-3 ClickHouse application development process

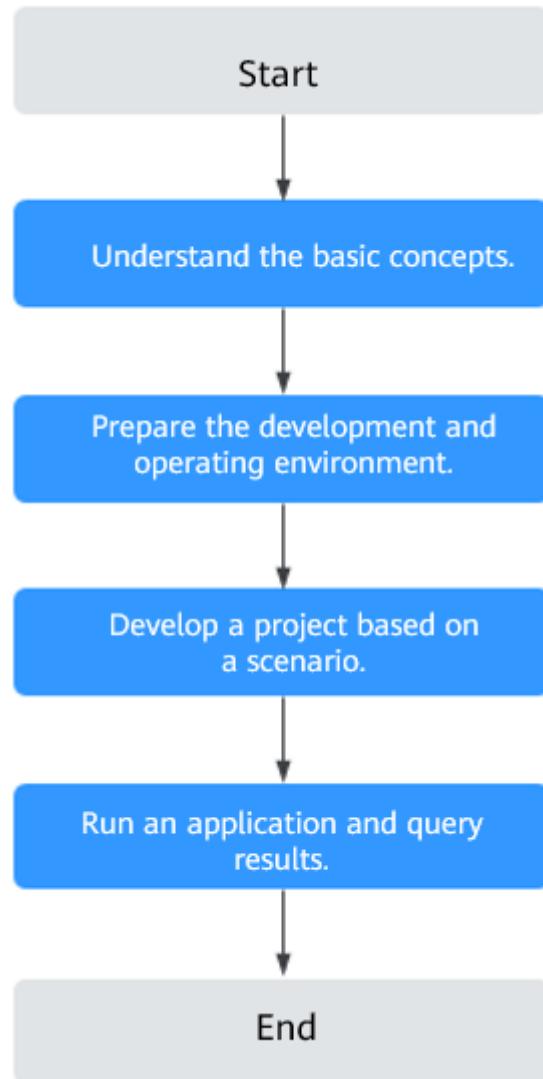

Table 1-5 Description of the ClickHouse application development process

Phase	Description	Reference
Understand the basic concepts.	Before application development, you need to understand basic concepts of ClickHouse.	<a href="#">Concepts</a>
Prepare the development and operating environment.	ClickHouse applications can be developed in multiple languages, mainly Java. The IntelliJ IDEA tool is recommended. Configure the development environment based on the guide.	<a href="#">Preparing the Development and Operating Environment</a>

Phase	Description	Reference
Develop a project based on a scenario.	Sample projects are provided to help you quickly understand APIs of ClickHouse components.	<a href="#">Configuring and Importing a Sample Project</a>
Run application and query results.	You can check the application running status from the running results.	<a href="#">Commissioning Applications on Windows</a> <a href="#">Commissioning Applications on Linux</a>

## 1.5.2 Environment Preparations

### 1.5.2.1 Preparing the Development and Operating Environment

#### Preparing the Development Environment

[Table 1-6](#) describes the environment required for application development.

**Table 1-6** Development environment

Item	Description
Operating System (OS)	<ul style="list-style-type: none"><li>• Development environment: Windows 7 or later.</li><li>• Operating environment: Linux</li></ul> If the program needs to be commissioned locally, the operating environment must be able to communicate with network on the cluster service plane.

Item	Description
JDK installation	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– Oracle JDK 1.8</li><li>– IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>– BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
Installing and configuring IntelliJ IDEA	<p>Basic configuration of the development environment. You are advised to use version 2019.1 or other compatible versions.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you use IBM JDK, ensure that the JDK configured in IntelliJ IDEA is IBM JDK.</li><li>• If you use Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is Oracle JDK.</li><li>• If you use Open JDK, ensure that the JDK configured in IntelliJ IDEA is Open JDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>

Item	Description
Apache Maven installation	Basic configuration of the development environment. This operation is used for project management throughout the lifecycle of software development.
Developer account preparation	Prepare a cluster user for application development and grant permissions to the user. For details, see <a href="#">Preparing a Developer Account</a> .
7-zip	This tool is used to decompress *.zip and *.rar files. <b>7-Zip 16.04</b> is supported.

## Preparing the Operating Environment

During application development, you need to prepare the environment for code running and commissioning to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning application; configure the network connection, and commission the application in Windows.
  - a. **Accessing FusionInsight Manager of an MRS Cluster.** In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Configuration Files Only**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar**. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles** directory on the local PC. The directory name cannot contain spaces.
  - b. Copy all items from the hosts file in the decompression directory to the hosts file on the node where the client is installed. Ensure that the network communication between the local PC and hosts listed in the hosts file in the decompression directory is normal.

### NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.

- If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client in a directory, for example, `/opt/hadoopclient`, on the node.  
Ensure that the difference between the client time and the cluster time is less than 5 minutes.  
For details about how to install a cluster client, see [Installing a Client](#).
  - b. Check the network connection of the client node.  
During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the `/etc/hosts` file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides. Ensure that the local host can communicate with each host in the cluster on the network.

### 1.5.2.2 Configuring and Importing a Sample Project

#### Context

Obtain the ClickHouse development sample project and import the project to IntelliJ IDEA to learn the sample project.

#### Prerequisites

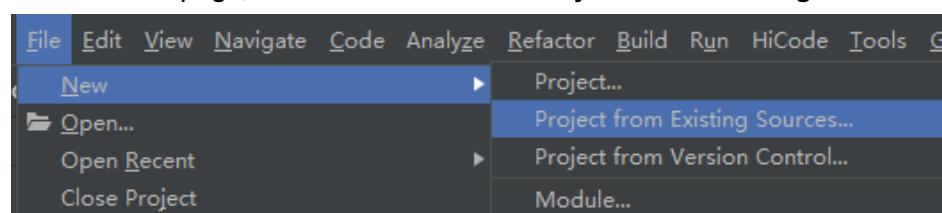

Ensure that the difference between the local PC time and the cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the time of the cluster in the lower-right corner on the FusionInsight Manager page.

#### Scenarios

ClickHouse provides sample projects for multiple scenarios to help you quickly learn ClickHouse projects.

#### Procedure

- Step 1** Obtain the sample project folder **clickhouse-examples** and Maven configurations in the `src` directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.
  1. On the IDEA page, choose **File > New > Project from Existing Sources**.

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **clickhouse-examples/ClickHouseJDBCJavaExample** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.
4. Select the recommended JDK version and click **Finish**.

**Step 3** After the project is imported, modify the **clickhouse-example.properties** file in the **conf** directory of the sample project based on the actual environment information.

```
loadBalancerIPList=
sslUsed=false
loadBalancerHttpPort=21425
loadBalancerHttpsPort=21426
CLICKHOUSE_SECURITY_ENABLED=true
user=
# Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or
environment variables.
password=
isMachineUser=false
isSupportMachineUser=false
clusterName=default_cluster
databaseName=testdb
tableName=testtb
batchRows=10000
batchNum=10
clickhouse_dataSource_ip_list=
native_dataSource_ip_list=
```

**Table 1-7** Configuration description

Parameter	Default Value	Definition
loadBalancerIPList	-	<p>Mandatory. Set this parameter to the IP address list of LoadBalance.</p> <ul style="list-style-type: none"><li>• Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Instance</b> and check the service IP addresses of all ClickHouseBalancer instances.</li><li>• Use commas (,) to separate multiple IP addresses, for example, <b>10.10.10.100,10.10.10.101</b>.</li><li>• If the IP address is an IPv6 address, convert it, for example, from <b>192:168:0:0:0:158:2</b> to <b>192:168::158:2</b>.</li></ul>

Parameter	Default Value	Definition
sslUsed	true	<p>Whether to enable SSL encryption. You are advised to set this parameter to <b>true</b> for clusters in security mode.</p> <p><b>Note:</b> If this parameter is set to <b>false</b>, non-SSL connections are used. Security clusters use SSL connections by default. If non-SSL connections are required, log in to FusionInsight Manager, choose <b>Cluster &gt; Services &gt; ClickHouse</b>, click the <b>Configuration</b> tab then the <b>All Configurations</b> sub-tab. On the page that is displayed, search for the <b>SSL_NONESSL_BOTH_ENABLE</b> configuration item, change its value to <b>true</b>, and restart all ClickHouse service instances.</p>
loadBalancerHttpPort	21425	<p>HTTP port number of LoadBalance. If <b>sslUsed</b> is set to <b>false</b>, this parameter cannot be left blank.</p> <p>Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Port</b> in the <b>HTTP Balancer Port</b> column.</p>
loadBalancerHttpsPort	21426	<p>HTTPS port number of LoadBalance. If <b>sslUsed</b> is set to <b>true</b>, this parameter cannot be left blank.</p> <p>Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Ssl Port</b> in the <b>HTTP Balancer Port</b> column.</p>
CLICKHOUSE_SECURITY_ENABLED	true	Whether to enable the security mode for ClickHouse. This parameter has a fixed value of <b>true</b> for a cluster in security mode.
user	N/A	Developer user name prepared in <a href="#">Table 1-3</a> .
password	N/A	<p>Password of a human-machine user. Leave this parameter blank if a machine-machine user is used.</p> <p>Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or environment variables.</p> <p><b>NOTE</b> If the human-machine user is created on FusionInsight Manager, you need to change the initial password upon the first login.</p>

Parameter	Default Value	Definition
isMachineUser	false	<p>Set this parameter to <b>true</b> if a machine-machine user is used for authentication.</p> <p>If this parameter is set to <b>true</b>, the values of <b>user</b> and <b>password</b> are the username and password of the machine-machine user.</p>
isSupportMachineUser	true	<p>Whether to support machine-machine user authentication. Value options are as follows:</p> <p><b>true</b>: Machine-machine user authentication is supported.</p> <p><b>false</b>: Machine-machine user authentication is not supported.</p> <p>To set this parameter, perform the following operations:</p> <p>Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Configuration</b> then <b>All Configurations</b>. In the navigation pane on the left, choose <b>ClickHouseServer(Role) &gt; Security</b>. On the page that is displayed, check the value of <b>SUPPORT_MACHINE_USER</b>.</p>
clusterName	default_c_luster	ClickHouse logical cluster name. Use the actual one.
databaseName	testdb	Name of the database to be created in the sample code project. You can change the database name based on the site requirements.
tableName	testtb	Name of the table to be created in the sample code project. You can change the table name based on the site requirements.
batchRows	10000	Number of data records written in a batch.
batchNum	10	Total number of batches in which data is written.

Parameter	Default Value	Definition
clickhouse_dataSource_ip_list	-	<p>Mandatory. Set this parameter to the IP address list and HTTP port number of the ClickHouseBalancer instance.</p> <ul style="list-style-type: none"> <li>• Use commas (,) to separate multiple IP addresses. The format is as follows: <i>ip:port,ip:port,ip:port</i>.</li> <li>• IP address: Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Instance</b> and check the service IP addresses of all ClickHouseBalancer instances.</li> <li>• Port: Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Ssl Port</b> in the <b>HTTP Balancer Port</b> column.</li> <li>• If the IP address is an IPv6 address, convert it to the IP address + Port number format. 192:168:0:0:0:158:2:21425 &gt; [192:168::158:2]:21425</li> </ul>
native_dataSource_ip_list	-	<p>Mandatory. Set this parameter to the IP address list and TCP port number of the ClickHouseBalancer instance.</p> <ul style="list-style-type: none"> <li>• Use commas (,) to separate multiple IP addresses. The format is as follows: <i>ip:port,ip:port,ip:port</i>.</li> <li>• IP address: Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Instance</b> and check the service IP addresses of all ClickHouseBalancer instances.</li> <li>• Port: Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Port</b> in the <b>TCP Balancer Port</b> column.</li> <li>• If the IP address is an IPv6 address, convert it to the IP address + Port number format. 192:168:0:0:0:158:2:21424 &gt; [192:168::158:2]:21424</li> </ul>

 NOTE

ClickHouse uses the LoadBalance-based deployment architecture to automatically distribute user access traffic to multiple backend nodes, expanding service capabilities to external systems and improving fault tolerance. When a client application requests a cluster, Nginx-based ClickHouseBalancer is used to distribute traffic. In this way, data read/write load and high availability of application access are guaranteed.

- Step 4** (Optional) If machine-machine user authentication is used, download the **user.keytab** and **krb5.conf** authentication credential files of the machine-machine user by referring to [Step 7](#), and upload the files to the **conf** directory of the sample project.

----End

### 1.5.2.3 Configuring and Importing a Transaction Sample Project

#### Context

Obtain the ClickHouse development sample project and import the project to IntelliJ IDEA to learn the sample project.

#### Prerequisites

Ensure that the difference between the local PC time and the cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the time of the cluster in the lower-right corner on the FusionInsight Manager page.

#### Scenarios

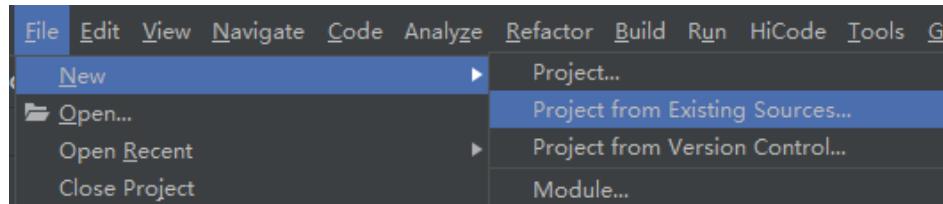

ClickHouse provides sample projects for multiple scenarios to help you quickly learn ClickHouse projects.

#### Procedure

- Step 1** Obtain the sample project folder **clickhouse-examples** and Maven configurations in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

- Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.

1. On the IDEA page, choose **File > New > Project from Existing Sources**.

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **clickhouse-examples/ClickHouseJDBC-Transaction-JavaExample** folder and click **OK**.

3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.
4. Select the recommended JDK version and click **Finish**.

**Step 3** After the project is imported, modify the **clickhouse-example.properties** file in the **conf** directory of the sample project based on the actual environment information.

```
loadBalancerIPList=
sslUsed=true
loadBalancerHttpPort=21425
loadBalancerHttpsPort=21426
CLICKHOUSE_SECURITY_ENABLED=true
user=
# Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or
environment variables.
password=
#Whether to use transactions.
useTransaction=true
#Whether to automatically submit SQL statements. The options are true (automatic) and false (manual).
Automatic submission is recommended. Due to the session forwarding mechanism of Balance, SQL
statements cannot be manually submitted by connecting to Balance.
autoCommit=true
clusterName=default_cluster
databaseName=testdb
tableName=testtb
batchRows=10000
batchNum=10
```

**Table 1-8** Parameter description

Parameter	Default Value	Description
loadBalancerIPList	-	<p>Mandatory. Set this parameter to the IP address list of LoadBalance.</p> <ul style="list-style-type: none"><li>• Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Instance</b> and check the service IP addresses of all ClickHouseBalancer instances.</li><li>• Use commas (,) to separate multiple IP addresses, for example, <b>10.10.10.100,10.10.10.101</b>.</li><li>• If the IP address is an IPv6 address, convert it, for example, from <b>192:168:0:0:0:158:2</b> to <b>192:168::158:2</b>.</li></ul>

Parameter	Default Value	Description
sslUsed	true	<p>Whether to enable SSL encryption. You are advised to set this parameter to <b>true</b> for clusters in security mode.</p> <p><b>Note:</b> If this parameter is set to <b>false</b>, non-SSL connections are used. Security clusters use SSL connections by default. If non-SSL connections are required, log in to FusionInsight Manager, choose <b>Cluster &gt; Services &gt; ClickHouse</b>, click the <b>Configuration</b> tab then the <b>All Configurations</b> sub-tab. On the page that is displayed, search for the <b>SSL_NONESSL_BOTH_ENABLE</b> configuration item, change its value to <b>true</b>, and restart all ClickHouse service instances.</p>
loadBalancerHttpPort	21425	<p>HTTP port number of LoadBalance. If <b>sslUsed</b> is set to <b>false</b>, this parameter cannot be left blank.</p> <p>Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Port</b> in the <b>HTTP Balancer Port</b> column.</p>
loadBalancerHttpsPort	21426	<p>HTTPS port number of LoadBalance. If <b>sslUsed</b> is set to <b>true</b>, this parameter cannot be left blank.</p> <p>Log in to FusionInsight Manager and choose <b>Cluster &gt; Services &gt; ClickHouse</b>. Click <b>Logical Cluster</b>, locate the row containing the desired logical cluster, and view <b>Ssl Port</b> in the <b>HTTP Balancer Port</b> column.</p>
CLICKHOUSE_SECURITY_ENABLED	true	Whether to enable the security mode for ClickHouse. This parameter has a fixed value of <b>true</b> for a cluster in security mode.
user	N/A	Developer user name prepared in <a href="#">Table 1-3</a> .
password	N/A	<p>Password of a human-machine user. This parameter is left blank if a machine-machine user is used.</p> <p>Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or environment variables.</p> <p><b>NOTE</b> If the human-machine user is created on FusionInsight Manager, you need to change the initial password upon the first login.</p>

Parameter	Default Value	Description
useTransaction	true	Whether to use transactions. Set this parameter to <b>true</b> . If this parameter is set to <b>true</b> , SQL statements use transactions.
autoCommit	true	Whether to submit data automatically. The available values are: <b>true</b> : The transactions are automatically submitted, which is equivalent to using implicit transactions. <b>false</b> : The transactions are manually submitted.
clusterName	default_c_luster	ClickHouse logical cluster name. Use the actual one.
databaseName	testdb	Name of the database to be created in the sample code project. You can change the database name based on the site requirements.
tableName	testtb	Name of the table to be created in the sample code project. You can change the table name based on the site requirements.
batchRows	10000	Number of data records written in a batch.
batchNum	10	Total number of batches in which data is written.

#### NOTE

ClickHouse uses the LoadBalance-based deployment architecture to automatically distribute user access traffic to multiple backend nodes, expanding service capabilities to external systems and improving fault tolerance. When a client application requests a cluster, Nginx-based ClickHouseBalancer is used to distribute traffic. In this way, data read/write load and high availability of application access are guaranteed.

- Step 4** (Optional) If machine-machine user authentication is used, download the **user.keytab** and **krb5.conf** authentication credential files of the machine-machine user by referring to [Step 7](#), and upload the files to the **conf** directory of the sample project.

----End

### 1.5.2.4 Configuring and Importing the Spring Boot Sample Project

#### Scenarios

To run the Spring Boot interface sample code of the ClickHouse component of MRS, perform the following operations.

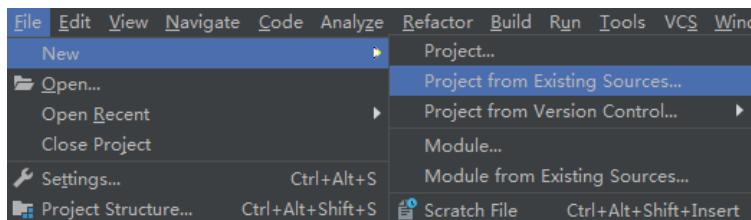

In the following example, an application is developed by compiling a Spring Boot project to connect to ClickHouse in Windows.

## Procedure

**Step 1** Obtain the sample project folder **clickhouse-rest-client-example** in the **src/springboot/clickhouse-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.

1. Choose **File > New > Project from Existing Sources....**

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **clickhouse-rest-client-example** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.

Select the recommended JDK version and click **Finish**.

**Step 3** In the IntelliJ IDEA development environment, open the **clickhouse-example.properties** file in the **conf** directory of the sample project, and change the values of the parameters listed in [Table 1-7](#).

**Step 4** (Optional) If machine-machine user authentication is used, download the **user.keytab** and **krb5.conf** authentication credential files of the machine-machine user by referring to [Step 7](#), and upload the files to the **conf** directory of the sample project.

----End

## 1.5.3 Application Development

### 1.5.3.1 Typical Application Scenario

This section describes the application development in a typical scenario, helping you quickly learn and master the ClickHouse development process and know key functions.

#### Scenario

ClickHouse enables you to perform common service operations by executing SQL statements. The SQL operations involved in sample codes include creating a database, creating a table, inserting data into a table, querying table data, and deleting a table.

Sample codes are described in the following sequence:

1. Setting properties
2. Establishing a connection
3. Creating a database
4. Creating a table
5. Inserting data into a table
6. Querying data
7. Deleting a table

### 1.5.3.2 Development Guideline

#### Development Guideline

As an independent DBMS system, ClickHouse allows you to use the SQL language to perform common operations. In the development program example, the clickhouse-jdbc API is used for description. The development process consists of the following parts:

- Setting properties: Sets the parameters for connecting to a ClickHouse service instance.
- Establishing a connection: Establishes a connection to the ClickHouse service instance.
- Creating a database: Creates a ClickHouse database.
- Creating a table: Creates a table in the ClickHouse database.
- Inserting data: Inserts data into a ClickHouse table.
- Querying data: Queries data in ClickHouse tables.
- Deleting a table: Deletes a ClickHouse table.

### 1.5.4 Sample Code

#### 1.5.4.1 Setting Properties

Set connection properties in the examples of creating connections in the **ClickhouseJDBCHaDemo**, **Demo**, **NativeJDBCHaDemo**, and **Util** files. The following code sets the socket timeout interval to 60 seconds:

```
Properties clickHouseProperties = new Properties();
clickHouseProperties.setProperty(ClickHouseClientOption.CONNECTION_TIMEOUT.getKey(),
Integer.toString(60000));
clickHouseProperties.setProperty(ClickHouseClientOption.SSL.getKey(), Boolean.toString(true));
clickHouseProperties.setProperty(ClickHouseClientOption.SSL_MODE.getKey(), "none");
```

If **sslUsed** in the **clickhouse-example.properties** configuration file in [Configuring and Importing a Sample Project](#) is set to **true**, set the following connection properties in the examples for creating connections in the **ClickhouseJDBCHaDemo**, **Demo**, **NativeJDBCHaDemo**, and **Util** files:

```
clickHouseProperties.setSsl(true);
clickHouseProperties.setSslMode("none");
```

#### 1.5.4.2 Establishing a Connection

The following code snippets are provided in the **initConnection** method of the **ClickhouseJDBCHaDemo** class. During connection creation, the user and password configured in [Table 1-7](#) are used as authentication credentials. ClickHouse performs security authentication on the server with the user and password.

```
clickHouseProperties.setProperty(ClickHouseDefaults.USER.getKey(), userName);
clickHouseProperties.setProperty(ClickHouseDefaults.PASSWORD.getKey(), userPass);
try {
    clickHouseProperties.setProperty(ClickHouseClientOption.FAILOVER.getKey(), "21");
    clickHouseProperties.setProperty(ClickHouseClientOption.LOAD_BALANCING_POLICY.getKey(),
"roundRobin");
    balancedClickhouseDataSource = new ClickHouseDataSource(JDBC_PREFIX + UriList,
clickHouseProperties);
} catch (Exception e) {
    LOG.error("Failed to create balancedClickHouseProperties.");
    throw e;
}
```

### 1.5.4.3 Creating a Database

Run the **on cluster** statement to create a database whose name is the value of **databaseName** in [Table 1-7](#) in the cluster.

```
private void createDatabase(String databaseName, String clusterName) throws Exception {
    String createDbSql = "create database if not exists " + databaseName + " on cluster " + clusterName;
    util.exeSql(createDbSql);
}
```

### 1.5.4.4 Creating a Table

Run the **on cluster** statement to create the ReplicatedMerge and Distributed tables whose names are the same as the values of **tableName** in [Table 1-7](#).

#### NOTE

If multiple ClickHouse services are installed in the cluster, for example, **clickhouse-1**, the ZooKeeper path is **/clickhouse-1/tables/{shard}/**.

```
private void createTable(String databaseName, String tableName, String clusterName) throws Exception {
    String createSql = "create table " + databaseName + "." + tableName + " on cluster " + clusterName +
" (name String, age UInt8, date Date)engine=ReplicatedMergeTree('/clickhouse/tables/{shard}/' +
databaseName + "." + tableName + "", "+ "{replica}") partition by toYYYYMM(date) order by age";
    String createDisSql = "create table " + databaseName + "." + tableName + "_all" + " on cluster " +
clusterName + " as " + databaseName + "." + tableName + " ENGINE = Distributed(default_cluster," +
databaseName + "," + tableName + ", rand());" ; ArrayList<String> sqlList = new ArrayList<String>();
    sqlList.add(createSql);
    sqlList.add(createDisSql);
    util.exeSql(sqlList);
}
```

### 1.5.4.5 Inserting Data

The table created in [Creating a Table](#) has three fields of the String, UInt8, and Date types.

```
String insertSql = "insert into " + databaseName + "." + tableName + " values (?, ?, ?)";
PreparedStatement preparedStatement = connection.prepareStatement(insertSql);
long allBatchBegin = System.currentTimeMillis();
for (int j = 0; j < batchNum; j++) {
    for (int i = 0; i < batchRows; i++) {
        preparedStatement.setString(1, "huawei_" + (i + j * 10));
        preparedStatement.setInt(2, ((int) (Math.random() * 100)));
        preparedStatement.setDate(3, generateRandomDate("2018-01-01", "2021-12-31"));
        preparedStatement.addBatch();
    }
}
```

```
        }
        long begin = System.currentTimeMillis();
        preparedStatement.executeBatch();
        long end = System.currentTimeMillis();
        log.info("Inert batch time is {} ms", end - begin);
    }
long allBatchEnd = System.currentTimeMillis();
log.info("Inert all batch time is {} ms", allBatchEnd - allBatchBegin);
```

#### 1.5.4.6 Querying Data

Query statement 1 **querySql1** queries any 10 records in the **tableName** table created in [Creating a Table](#). Query statement 2 **querySql2** uses a built-in function to combine the year and month fields in the **tableName** table created in [Creating a Table](#).

```
private void queryData(String databaseName, String tableName) throws Exception {
    String querySql1 = "select * from " + databaseName + "." + tableName + "_all" + " order by age limit 10";
    String querySql2 = "select toYYYYMM(date),count(1) from " + databaseName + "." + tableName + "_all"
+ " group by toYYYYMM(date) order by count(1) DESC limit 10";
    ArrayList<String> sqlList = new ArrayList<String>();
    sqlList.add(querySql1);
    sqlList.add(querySql2);
    ArrayList<ArrayList<ArrayList<String>>> result = util.exeSql(sqlList);
    for (ArrayList<ArrayList<String>> singleResult : result) {
        for (ArrayList<String> strings : singleResult) {
            StringBuilder stringBuilder = new StringBuilder();
            for (String string : strings) {
                stringBuilder.append(string).append("\t");
            }
            log.info(stringBuilder.toString());
        }
    }
}
```

#### 1.5.4.7 Deleting a Table

Delete the replica table and distributed table created in [Creating a Table](#).

```
private void dropTable(String databaseName, String tableName, String clusterName) throws Exception {
    String dropLocalTableSql = "drop table if exists " + databaseName + "." + tableName + " on cluster " +
clusterName;
    String dropDisTableSql = "drop table if exists " + databaseName + "." + tableName + "_all" + " on cluster "
+ clusterName;
    ArrayList<String> sqlList = new ArrayList<String>();
    sqlList.add(dropLocalTableSql);
    sqlList.add(dropDisTableSql);
    util.exeSql(sqlList);
}
```

#### 1.5.4.8 Using BalanceDataSource

BalanceDataSource provides high-availability access connection APIs for applications. When detecting that a ClickHouseBalancer service is abnormal, applications can access the service by using other normal service instances. The following sample code provides examples of ClickHouse JDBC and Native JDBC using BalanceDataSource.

### NOTE

- ClickHouse JDBC uses HTTP to access ClickHouse, and Native JDBC uses TCP to access ClickHouse. For details about the access configurations, see the configuration description of [clickhouse.dataSource\\_ip\\_list](#) and [native.dataSource\\_ip\\_list](#) in [Configuring and Importing a Sample Project](#).
- Native JDBC does not support SSL-encrypted access.

## ClickHouse JDBC Example

Initial configuration and connection.

```
public void initConnection() throws Exception {
    Properties properties = new Properties();
    String proPath = System.getProperty("user.dir") + File.separator + "conf"
        + File.separator + "clickhouse-example.properties";
    try {
        properties.load(new FileInputStream(proPath));
    } catch (IOException e) {
        LOG.error("Failed to load properties file.");
        throw e;
    }
    Properties clickHouseProperties = new Properties();
    boolean isSec = Boolean.parseBoolean(properties.getProperty("CLICKHOUSE_SECURITY_ENABLED"));
    String UriList = properties.getProperty("clickhouse.dataSource_ip_list");
    String userName = properties.getProperty("user");
    boolean isMachineUser = Boolean.parseBoolean(properties.getProperty("isMachineUser"));
    if (isSec) {
        if (isMachineUser) {
            clickHouseProperties.setProperty("isMachineUser", "true");
            clickHouseProperties.setProperty("keytabPath", System.getProperty("user.dir") + File.separator +
                "conf" + File.separator + "user.keytab");
        }
        String userPass = properties.getProperty("password");
        clickHouseProperties.setProperty(ClickHouseDefaults.PASSWORD.getKey(), userPass);
        clickHouseProperties.setProperty(ClickHouseClientOption.SSL.getKey(), Boolean.toString(true));
        clickHouseProperties.setProperty(ClickHouseClientOption.SSL_MODE.getKey(), "none");
    }
    clickHouseProperties.setProperty(ClickHouseDefaults.USER.getKey(), userName);
    try {
        clickHouseProperties.setProperty(ClickHouseClientOption.FAILOVER.getKey(), "21");
        clickHouseProperties.setProperty(ClickHouseClientOption.LOAD_BALANCING_POLICY.getKey(),
            "roundRobin");
        balancedClickhouseDataSource = new ClickHouseDataSource(JDBC_PREFIX + UriList,
        clickHouseProperties);
    } catch (Exception e) {
        LOG.error("Failed to create balancedClickHouseProperties.");
        throw e;
    }
}
```

Obtain the connection and send an SQL request.

```
public void queryData(String databaseName, String tableName) {
    String querySql1 = "select name,age from " + databaseName + "." + tableName + "_all" + " order by age
limit 10";
    try (ClickHouseConnection connection = balancedClickhouseDataSource.getConnection();
        ClickHouseStatement statement = connection.createStatement();
        ResultSet set = statement.executeQuery(querySql1)){
        while (set.next()) {
            LOG.info("Name is: " + set.getString(1) + ", age is: " + set.getString(2));
        }
    } catch (SQLException e) {
        //If the return code is 210, the LB server may be disconnected. Check whether the connection is
        available and try again.
        if (e.getErrorCode() == ClickHouseErrorCode.NETWORK_ERROR.code) {
            balancedClickhouseDataSource.actualize();
            try (ClickHouseConnection con = balancedClickhouseDataSource.getConnection());

```

```
        ClickHouseStatement st = con.createStatement();
        ResultSet rs = st.executeQuery(querySql1)) {
        while (rs.next()) {
            LOG.info("Name is: " + rs.getString(1) + ", age is: " + rs.getString(2));
        }
    } catch (SQLException exception) {
        LOG.error("Query data failed.");
    }
} else {
    LOG.error("Query data failed.", e);
}
}
```

## Native JDBC Example

Initial configuration and connection.

```
public void initConnection() throws IOException {
    Properties properties = new Properties();
    String proPath = System.getProperty("user.dir") + File.separator + "conf"
        + File.separator + "clickhouse-example.properties";
    try {
        properties.load(new FileInputStream(proPath));
    } catch (IOException e) {
        LOG.error("Failed to load properties file.");
        throw e;
    }
    String UriList = properties.getProperty("native.dataSource.ip.List");
    //Whether to check connection availability during connection initialization.
    properties.put("is_check_connection", "true");
    balancedClickhouseDataSource = new BalancedClickhouseDataSource(JDBC_PREFIX + UriList, properties)
        //This method periodically checks whether the connection is available in the background and
        maintains a list of available connections. The following configuration indicates that the check is performed
        every 30 seconds.
        .scheduleActualization(30, TimeUnit.SECONDS);
}
```

Obtain the connection and send an SQL request.

```
public void queryData(String databaseName, String tableName) {
    String querySql1 = "select name,age from " + databaseName + "." + tableName + "_all" + " order by age
limit 10";
    try (ClickHouseConnection connection = balancedClickhouseDataSource.getConnection();
        ClickHouseStatement statement = connection.createStatement();
        ResultSet set = statement.executeQuery(querySql1)){
        while (set.next()) {
            LOG.info("Name is: " + set.getString(1) + ", age is: " + set.getString(2));
        }
    } catch (SQLException e) {
        //If the return code is 210, the LB server may be disconnected. Check whether the connection is
        available and try again.
        if (e.getErrorCode() == ClickHouseErrCode.NETWORK_ERROR.code()) {
            balancedClickhouseDataSource.actualize();
            try (Connection con = balancedClickhouseDataSource.getConnection();
                Statement statement = con.createStatement();
                ResultSet rs = st.executeQuery(querySql1)) {
                while (rs.next()) {
                    LOG.info("Name is: " + rs.getString(1) + ", age is: " + rs.getString(2));
                }
            } catch (SQLException exception) {
                LOG.error("Query data failed.");
            }
        } else {
            LOG.error("Query data failed.", e);
        }
    }
}
```

## 1.5.5 Connecting the Python Driver to the ClickHouse in Security Mode

### Overview

This topic describes how to use the open-source Python driver to connect to ClickHouse in security mode.

Machine-machine users and Kerberos authentication are available in ClickHouse for secure access. ClickHouse is also compatible with the human-machine user authentication of the open-source driver.

- Human-Machine Users  
You can simply use the username and password to connect to ClickHouse in security mode.
- Machine-Machine Users  
You need to adapt the Kerberos authentication to machine-machine users based on the source code of the open-source driver to connect to ClickHouse in security mode.

### Driver Adaptation

#### Driver Source Code

To support machine-machine users and be compatible with open-source capabilities, add the optional parameter **X-ClickHouse-MachineUser** to the header of the message sent from the driver source code to the ClickHouse server. The data type of the value is string.

The options are as follows:

**true**: A machine-machine user is used and needs to be authenticated.

**false** or not added: A human-machine user is used and needs to be authenticated.

#### Driver Usage

- Initialize the connection.

To use a human-machine user, use it in the same way as using the open-source driver, or set **X-ClickHouse-MachineUser** to **false**.

To use a machine-machine user, set **X-ClickHouse-MachineUser** to **true**.

- Password

For a human-machine user, use the password set when the user is created.

For a machine-machine user, parse the keytab file, obtain the file content, and pass it as the password.

### Prerequisites

- A ClickHouse user, for example, **cksuser** has been created on FusionInsight Manager. For details, see [Preparing the Development and Operating Environment](#). The authentication file of the user has been downloaded. For details, see [Step 7](#).

- If you are using an HTTP port, log in to FusionInsight Manager, choose **Cluster > Services > ClickHouse > Configurations > All Configurations > ClickHouse > Network**, and set **SSL\_NONESSL\_BOTH\_ENABLE** to **true**, save the configuration and restart the ClickHouse service to apply the changes.
- Python3 has been deployed in the running environment.
- You have prepared the ClickHouse open-source Python driver package. You can download the package from <https://github.com/ClickHouse/clickhouse-connect/archive/refs/tags/v0.6.21.zip>.
- You have prepared and installed the dependent package related to the Python driver.

You can run the following command to install the dependency package:

**pip3 install certifi lz4 pytz urllib3 zstandard**

 NOTE

- If the versions of dependency packages do not match, install the matched versions, for example:

**pip3 install urllib3==1.26.6**

- You can also manually download the dependency packages, upload them to the runtime environment of the Python driver, and install them. The dependency packages and their versions are as follows:

certifi-2020.4.5.1

lz4-3.1.3

pytz-2020.1

urllib3-1.26.6

zstandard-0.21.0

## Procedure

The following uses the **clickhouse-connect-0.6.21** driver as an example to describe how to perform source code adaptation and connect to ClickHouse in security mode through HTTP.

### Modifying Driver Source Code

**Step 1** Add the **support\_machine\_user** parameter to the initialization function of **clickhouse-connect-0.6.21\clickhouse\_connect\driver\httpclient.py**. The parameter is optional and its value is a string. The default value is **None**. During initialization, the value is saved to the **self.support\_machine\_user** variable.

```
apply_server_timezone: Optional[Union[str, bool]] = True,  
support_machine_user: Optional[str] = None):
```

```

46     # pylint: disable=too-many-arguments,too-many-locals,too-many-branches,too-many-statements,
47     def __init__(self,
48         interface: str,
49         host: str,
50         port: int,
51         username: str,
52         password: str,
53         database: str,
54         compress: Union[bool, str] = True,
55         query_limit: int = 0,
56         query_retries: int = 2,
57         connect_timeout: int = 10,
58         send_receive_timeout: int = 300,
59         client_name: Optional[str] = None,
60         verify: bool = True,
61         ca_cert: Optional[str] = None,
62         client_cert: Optional[str] = None,
63         client_cert_key: Optional[str] = None,
64         session_id: Optional[str] = None,
65         settings: Optional[Dict[str, Any]] = None,
66         pool_mgr: Optional[PoolManager] = None,
67         http_proxy: Optional[str] = None,
68         https_proxy: Optional[str] = None,
69         server_host_name: Optional[str] = None,
70         apply_server_timezone: Optional[Union[str, bool]] = True,
71         support_machine_user: Optional[str] = None):
72     """
73     Create an HTTP ClickHouse Connect client
74     See clickhouse_connect.get_client for parameters

```

```

self.support_machine_user = None
if support_machine_user:
    self.support_machine_user = support_machine_user

```

```

124
125     if session_id:
126         ch_settings['session_id'] = session_id
127     elif 'session_id' not in ch_settings and common.get_setting('autogenerate_session_id'):
128         ch_settings['session_id'] = str(uuid.uuid4())
129
130     self.support_machine_user = None
131     if support_machine_user:
132         self.support_machine_user = support_machine_user
133
134     if coerce_bool(compress):
135         compression = '.'.join(available_compression)
136         self.write_compression = available_compression[0]
137     elif compress and compress not in ('False', 'false', '0'):

```

**Step 2** In the SQL command execution function of `clickhouse-connect-0.6.21\clickhouse_connect\driver\httpclient.py`, check whether the `self.support_machine_user` parameter is empty. If this parameter is not left blank, the `X-ClickHouse-MachineUser` parameter must be contained in the message header.

```

if self.support_machine_user:
    headers['X-ClickHouse-MachineUser'] = self.support_machine_user

```

```

177     def _query_with_context(self, context: QueryContext) -> QueryResult:
178         headers = {}
179         params = {}
180         if self.database:
181             params['database'] = self.database
182         if self.protocol_version:

```

----End

## Using the Driver

Modify the main function code of the **clickhouse-connect-0.6.21\examples\insert\_examples.py** sample to verify the use of the human-machine and machine-machine, respectively.

**Step 1** Add the driver package path to the beginning of **insert\_examples.py**.

```

import sys
sys.path.append('..')
import base64

```

**Step 2** Human-machine user: Create a client. Same as using the open-source driver, you do not need to specify the **support\_machine\_user** parameter. Set other parameters based on your environment. Verify the process of creating a connection, deleting a table, creating a table, inserting data, and querying data.

Use the following sample code to replace all code in the red box of the main function:

```

71     usage
72     def main():
73         global client # pylint: disable=global-statement
74         client = clickhouse_connect.get_client()
75         print('Nested example flatten_nested = 1 (Default)')
76         inserted_nested_flat()
77         print('\n\nNested example flatten_nested = 0')
78         insert_nested_not_flat()

```

The sample code is as follows:

```

global client # pylint: disable=global-statement
print('start test demo')

```

```
client = clickhouse_connect.get_client(host='xx.xx.xx.xx', port=xxx, username='xxx', password='xxx')
client.command('DROP TABLE IF EXISTS default.test')
client.command(
    """
    CREATE TABLE default.test
    (
        `key` UInt32,
        `value` String
    )
    ENGINE = MergeTree
    ORDER BY key
    """
)
result = client.query('insert into default.test values(1,\'test\')')
result = client.query('select * from default.test')
print(result.column_names[0:2])
print(result.result_columns[0:2])
```

### NOTE

Refer to the following to configure the parameters:

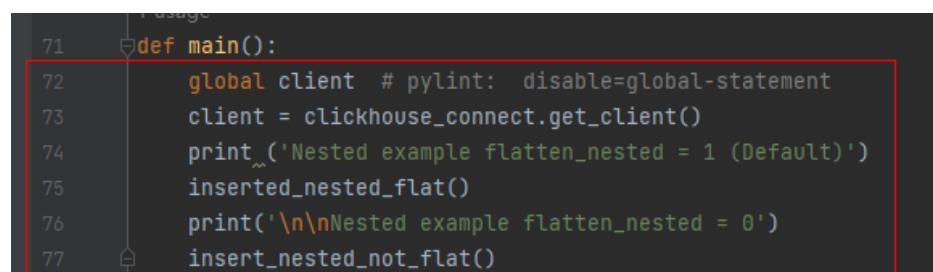

- **host**: IP address of the ClickHouse instance. To obtain the service IP address of the ClickHouseServer instance, log in to FusionInsight Manager, choose **Cluster > Services > ClickHouse**, and click the **Instances** tab.
- **port**: HTTP port of the ClickHouse server. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Services > ClickHouse > Configurations > All Configurations > ClickHouseServer > Network**, and check the value of **http\_port**.
- **username**: human-machine username created on FusionInsight Manager
- **password**: password set when the human-machine user is created on FusionInsight Manager

If the sample code contains authentication passwords, there are security risks. Delete the information about the passwords after using the code or store them securely.

### Step 3 Machine-machine user:

1. Parse the keytab file and obtain the content.
2. When the client is initialized, the **support\_machine\_user** parameter is passed and set to **true**. The user password is the file content parsed in step 1.
3. Verify the process of creating a connection, deleting a table, creating a table, inserting data, and querying data.

Use the following sample code to replace all code in the red box of the main function:

```
71 def main():
72     global client # pylint: disable=global-statement
73     client = clickhouse_connect.get_client()
74     print('Nested example flatten_nested = 1 (Default)')
75     inserted_nested_flat()
76     print('\n\nNested example flatten_nested = 0')
77     insert_nested_not_flat()
```

The sample code is as follows:

```
global client # pylint: disable=global-statement
print('start test demo')
file = open('user.keytab', 'rb')
byte_array = file.read()
b64_str = base64.b64encode(byte_array)
b64_str = b64_str.decode('utf8')

client = clickhouse_connect.get_client(host='xx.xx.xx.xx', port=xxx,username='xxx', password=b64_str,
support_machine_user='true')
```

```
client.command('DROP TABLE IF EXISTS default.test')
client.command(
    """
CREATE TABLE default.test
(
    `key` UInt32,
    `value` String
)
ENGINE = MergeTree
ORDER BY key
""")
result = client.query('insert into default.test values(1,\'test\')')
result = client.query('select * from default.test')
print(result.column_names[0:2])
print(result.result_columns[0:2])
```

#### NOTE

- Parse the keytab file. **user.keytab** is the keytab file of the user downloaded from FusionInsight Manager. Replace it with the one you need.
- Create a connection and configure the parameters by referring the following:
  - **host**: IP address of the ClickHouse instance. To obtain the service IP address of the ClickHouseServer instance, log in to FusionInsight Manager, choose **Cluster > Services > ClickHouse**, and click the **Instances** tab.
  - **port**: HTTP port of the ClickHouse server. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Services > ClickHouse > Configurations > All Configurations > ClickHouseServer > Network**, and check the value of **http\_port**.
  - **username**: machine-machine username created on FusionInsight Manager
  - **password**: variable for storing the keytab file content
  - **support\_machine\_user**: whether the user is a machine-machine user. The value is **true**.

----End

## Commissioning

**Step 1** Upload the modified driver code on the server, for example, to the **/opt/tmp** directory.

**Step 2** For a machine-machine user, upload the keytab file downloaded from to the **/opt/tmp/clickhouse-connect-0.6.21/examples** directory.

**Step 3** Run the following command to go to the example path:

```
cd /opt/tmp/clickhouse-connect-0.6.21/examples
```

**Step 4** Run the following command to execute the sample code:

```
python3 insert_examples.py
```

The result is as follows.

```
[root@XXXXXX examples]# python3 insert_examples.py
Unable to connect optimized C data functions [No module named 'clickhouse_connect.driverc.buffer'], falling back to pure Python
start test demo
('key', 'value')
[[1], ['test']]
```

----End

## 1.5.6 Application Commissioning

### 1.5.6.1 Commissioning Applications on Windows

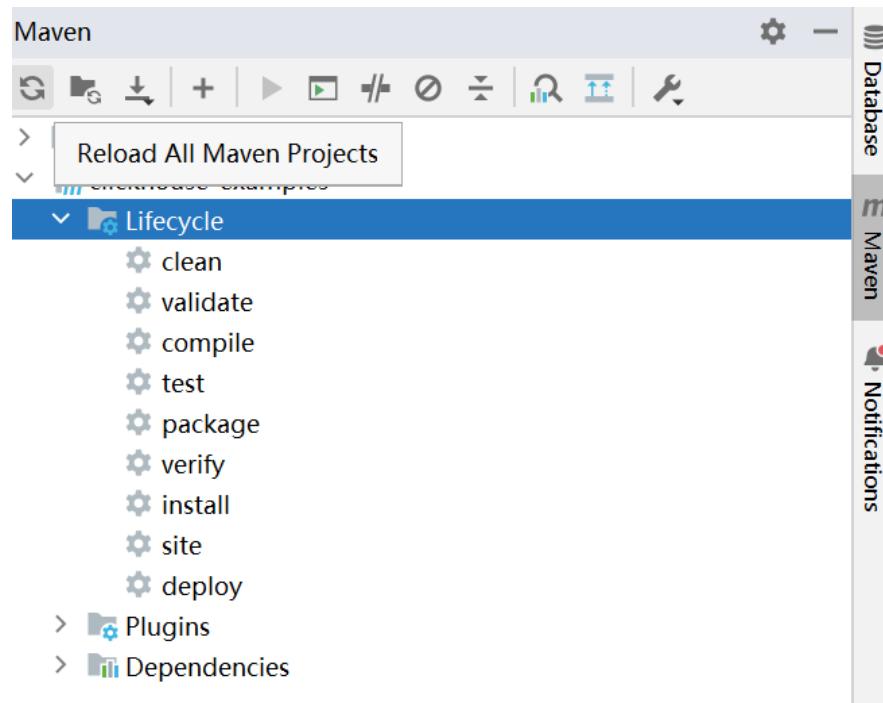

#### Writing and Running An Application

You can run an application in the Windows environment after application code development is complete. If the local and cluster service planes can communicate with each other, you can perform the commissioning on the local host.

#### Procedure

- Step 1** Click **Reload All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

**Figure 1-4** reload projects

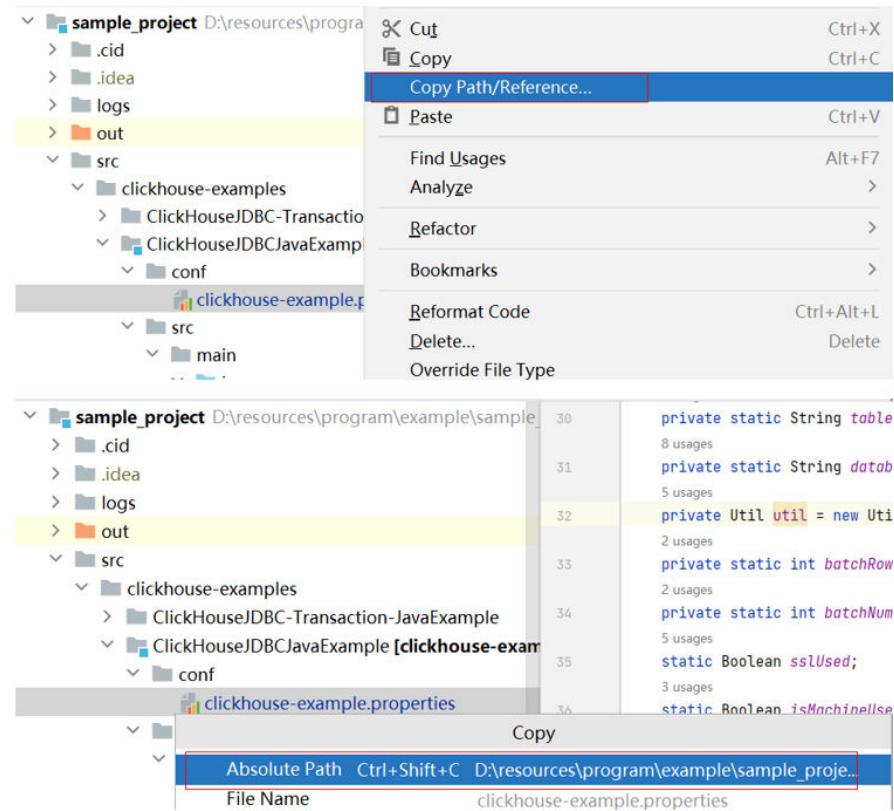

- Step 2** Copy the **clickhouse-example.properties** path on the IDEA page. Right-click **clickhouse-example.properties** and choose **Copy Path/Reference > Absolute Path** from the shortcut menu.

**NOTE**

Skip this step if you are commissioning the transaction sample project.

**Figure 1-5** Copying absolute path of the configuration file

**Step 3** In **Demo.java**, replace the path of **proPath** in the **getProperties()** method with **clickhouse-example.properties**.

**Figure 1-6** Replacing the path

```
private void getProperties() throws Exception {
    Properties properties = new Properties();
    String proPath = "D:\\resources\\program\\example\\sample_project\\src\\clickhouse-examples\\ClickHouseJDBCJavaExample\\conf\\clickhouse-example.properties";
    try {
        properties.load(new FileInputStream(new File(proPath)));
    } catch (IOException e) {
        log.error("Failed to load properties file.");
        throw e;
    }
}
```

**Step 4** In **ClickhouseJDBCHaDemo.java**, replace the path of **proPath** in the **initConnection()** method with **clickhouse-example.properties**.

#### NOTE

Skip this step if you are commissioning the transaction sample project.

**Figure 1-7** Replacing the path

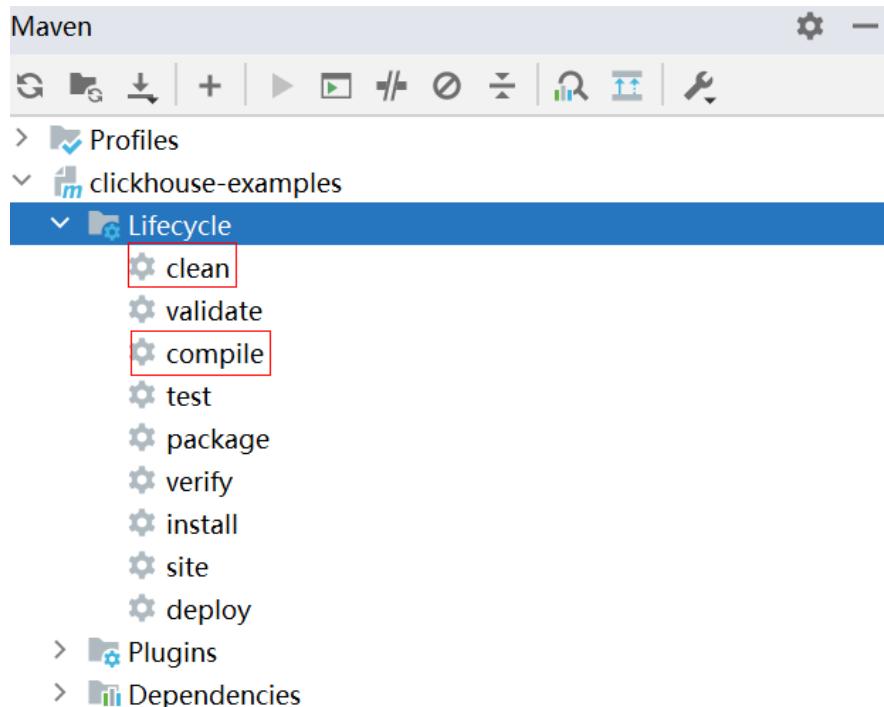

```
public void initConnection() throws Exception {
    Properties properties = new Properties();
    String proPath = "D:\\resources\\program\\example\\sample_project\\src\\clickhouse-examples\\ClickHouseJDBCJavaExample\\conf\\clickhouse-example.properties";
    try {
        properties.load(new FileInputStream(proPath));
    } catch (IOException e) {
        LOG.error("Failed to load properties file.");
        throw e;
    }
}
```

**Step 5** Compile the application.

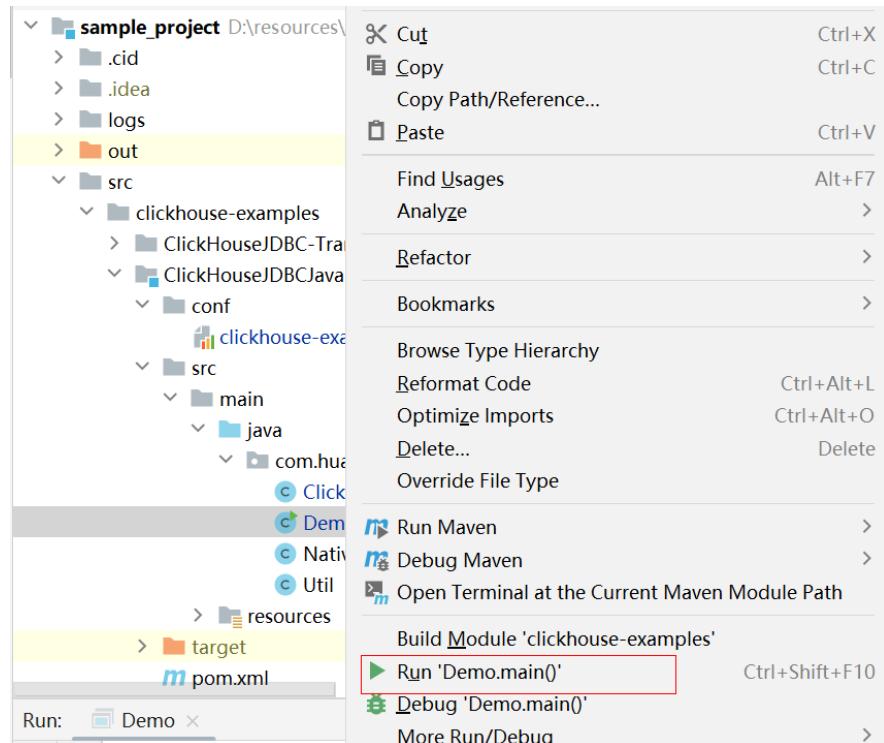

- Select **Maven > clickhouse-examples > Lifecycle > clean** and double-click **clean** to run the **clean** command of Maven.

- Select **Maven > clickhouse-examples > Lifecycle > compile** and double-click **compile** to run the **compile** command of Maven.

**Figure 1-8** Maven commands clean and compile

**Step 6** Click `Run'Demo.main()'` to run the application.

**Figure 1-9** Running the program

----End

## Viewing the Commissioning Result

After a ClickHouse application finishes running, you can use one of the following methods to view the running result:

- Viewing the command output
- View the **clickhouse-example.log** file in the **logs** directory to obtain the application running status.

After the complete sample of the **clickhouse-examples** finishes running, the following information is displayed on the console:

```

### 1.5.6.2 Commissioning Applications on Linux

ClickHouse applications can run in a Linux environment. After the application code is developed, you can upload the JAR file to the prepared Linux environment.

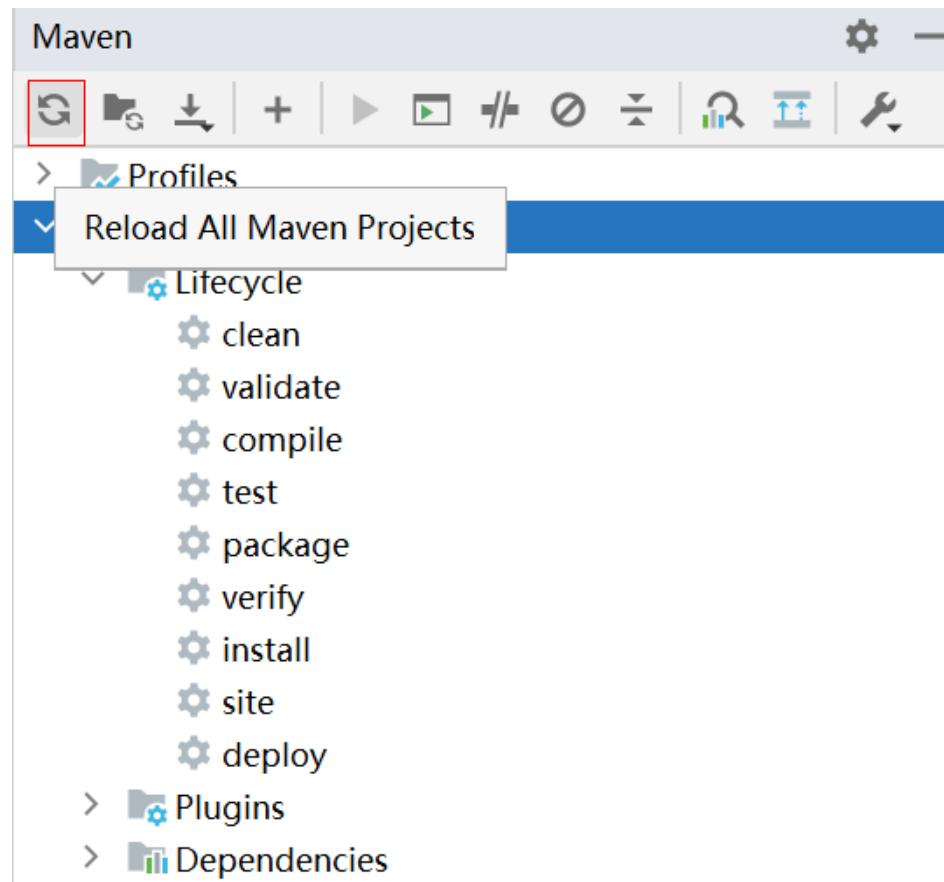

#### Prerequisites

JDK has been installed on Linux. The version must be the same as JDK version of the JAR file exported from IntelliJ IDEA. Java environment variables have been set.

#### Compile and run applications.

**Step 1** Click **Reload All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

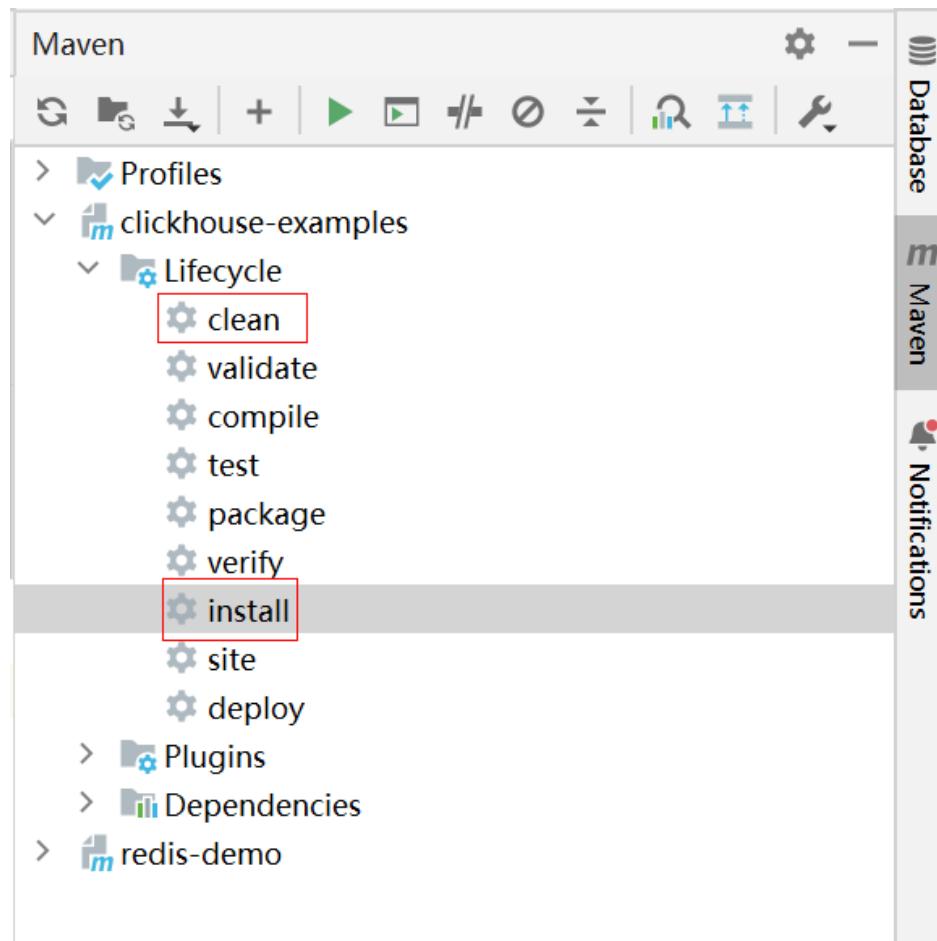

Figure 1-10 reload projects

**Step 2** Exporting the JAR file

- Select **Maven > clickhouse-examples > Lifecycle > clean** and double-click **clean** to run the **clean** command of Maven.
- Select **Maven > clickhouse-examples > Lifecycle > install** and double-click **install** to run the **install** command of Maven.

Figure 1-11 Maven clean and install commands

- Step 3** Copy the **clickhouse-examples-\*jar** file from the **target** directory and the **conf** folder from the **clickhouse-examples** directory to the ClickHouse client installation directory, for example, *Client installation directory/JDBC* or *Client installation directory/JDBCTransaction*.

NOTE

The *Client installation directory/JDBC* directory is used to commission JDBC secondary samples.

The *Client installation directory/JDBCTransaction* directory is used to commission secondary transaction samples.

- Step 4** Log in to the client node, go to the directory where the JAR file is uploaded, and change the file permission to 700.

**cd** *Client installation directory/JDBC*

Or **cd** *Client installation directory/JDBCTransaction*

**chmod 700 clickhouse-examples-\*jar**

- Step 5** In the client directory where **clickhouse-examples-\*jar** is stored, run the following commands to run the JAR file:

**source** *Client installation directory/bigdata\_env*

**cd** *Client installation directory/JDBC*

Or **cd Client installation directory/JDBCTransaction**

**java -jar clickhouse-examples-\*.jar**

----End

## Viewing Commissioning Results

After a ClickHouse application is run, you can use one of the following methods to view the running result:

- Viewing the command output
- Viewing ClickHouse logs

View the **logs clickhouse-example.log** file in the directory where the current JAR file is located, for example, *Client installation directory/JDBC/logs/ clickhouse-example.log* or *Client installation directory/JDBCTransaction/ logs/ clickhouse-example.log*.

The execution result of the JAR file is as follows:

```
2023-09-21 09:08:38,944 | INFO | main | loadBalancerIPList is 192.168.5.132, loadBalancerHttpPort is 21422, user is ck_user, clusterName is default_cluster, isSec is true, password is xxx. | com.huawei.clickhouse.examples.Demo.main(Demo.java:42)

### 1.5.6.3 Commissioning the Spring Boot Sample Project

### 1.5.6.3.1 Commissioning the Spring Boot Project in Windows

# Compiling and Running Applications

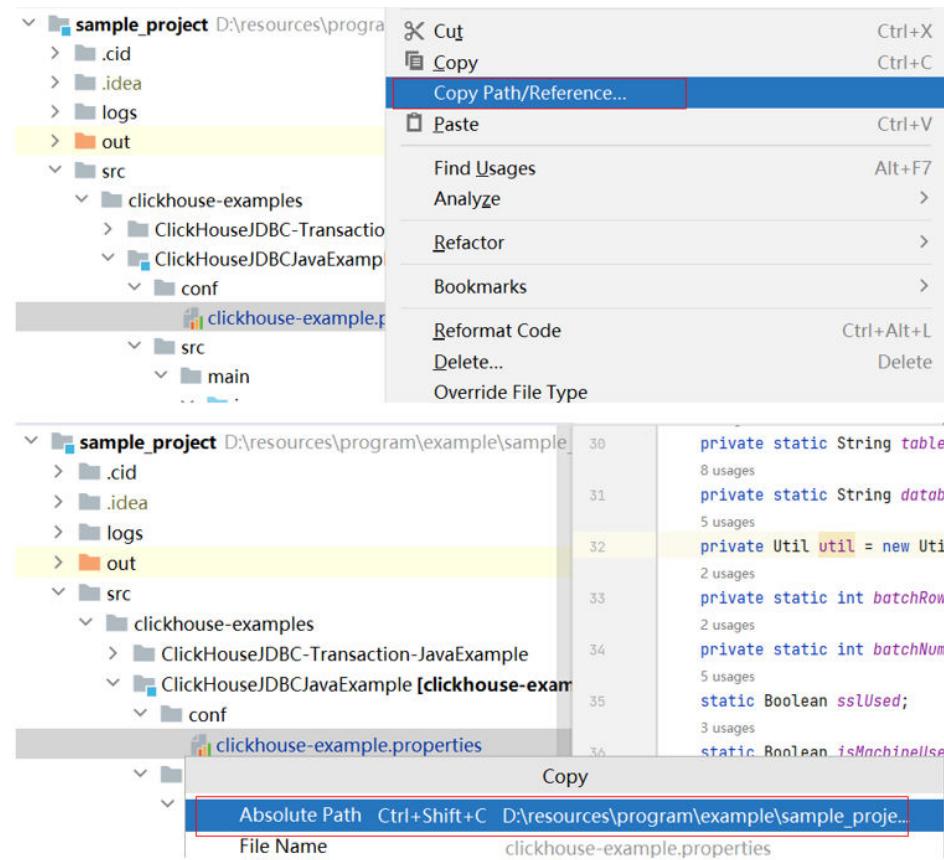

You can run applications in the Windows environment after application code development is complete. If the local and cluster service planes can communicate with each other, you can perform the commissioning on the local host. Right-click **ClickHouseApplication** in IntelliJ IDEA project **clickhouse-rest-client-examples** in the development environment, and then choose **Run ClickHouseApplication** from the shortcut menu to run the application project.

## Procedure

- Step 1** Copy the `clickhouse-example.properties` path on the IDEA page. Right-click `clickhouse-example.properties` and choose **Copy Path/Reference > Absolute Path** from the shortcut menu.

**Figure 1-12** Copying absolute path of the configuration file

**Step 2** In `ClickHouseFunc.java`, replace the path of `proPath` in the `getProperties()` method with `clickhouse-example.properties`.

**Figure 1-13** Replacing the path

----End

## Viewing Commissioning Results

- After the ClickHouse Spring Boot service is started, the ClickHouse sample interface is used to trigger the running of the sample code. Enter the link of the specific operation to be performed in the address box of the browser, for example, <http://localhost:8080/clickhouse/executeQuery>. The following result is returned:  
ClickHouse springboot client runs normally.
- View the `clickhouse-springboot-example.log` file to obtain the application running status.

After the `clickhouse-springboot` sample is run, the following information is displayed on the console:

```
.\clickhouse-springboot-example
((()__))|_|_|_|`V`|\\\\\\
```

```
\W ____| |_)| | | | | |(| | ) ) )
' |____| .|_| | \_ | \_, | | | |

### 1.5.6.3.2 Commissioning the Spring Boot Project in Linux

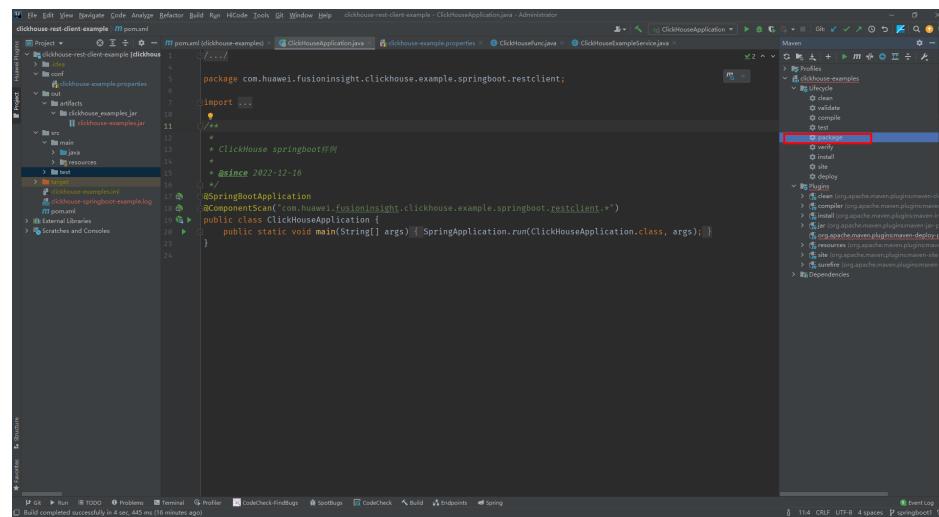

The ClickHouse Spring Boot applications can run in a Linux environment. After the application code is developed, you can upload the JAR file to the prepared Linux environment.

#### Prerequisites

JDK has been installed on Linux. The version must be the same as JDK version of the JAR file exported from IntelliJ IDEA. Java environment variables have been set.

### Compiling and Running Applications

- Step 1** Click **Maven** on the right of IDEA, expand **Lifecycle**, and double-click **package** to package the current project.

- Step 2** Log in to the ClickHouse client node as user **root**, create a running directory, for example, **/opt/test**, and obtain the JAR package whose name contains **-with-dependencies** from the **target** directory of IDEA. Upload the JAR package and the **conf** folder in the IDEA to the **/opt/test** directory, as shown in the following figure.

```
[root@host-192-168-6-24 test]# 
[root@host-192-168-6-24 test]# pwd
/opt/test
[root@host-192-168-6-24 test]# ll
total 25048
-rw-r--r-- 1 root root 25644916 Feb  6 19:24 clickhouse-examples-1.0-SNAPSHOT-jar-with-dependencies.jar
drwxr-xr-x 2 root root     4096 Feb  6 18:03 conf
[root@host-192-168-6-24 test]# 
```

- Step 3** Run the following commands to set environment variables and run the JAR package:

**cd** *Client installation path*

**source** *bigdata\_env*

**cd** */opt/test*

**java -jar** *clickhouse-examples-1.0-SNAPSHOT-jar-with-dependencies.jar*

The command output is displayed as follows:

```
[root@host-192-168-6-24 test]# java -jar clickhouse-examples-1.0-SNAPSHOT-jar-with-dependencies.jar
2023-02-06 19:42:02.200 INFO 42496 --- [main] c.h.f.c.e.s.r.ClickHouseApplication : Starting ClickHouseApplication using Java 1.8.0_332 on host-192-168-6-24 with PID 24296 [/opt/test	clickhouse-examples-1.0-SNAPSHOT-jar-with-dependencies.jar started by root in /opt/test]
2023-02-06 19:42:02.203 INFO 42496 --- [main] c.h.f.c.e.s.r.ClickHouseApplication : No active profile set, falling back to 1 default profile: "default"
2023-02-06 19:42:03.396 INFO 42496 --- [main] o.s.b.w.embedded.tomcat.TomcatWebServer : Tomcat initialized with port(s): 8080 (http)
2023-02-06 19:42:03.400 INFO 42496 --- [main] o.s.b.w.embedded.tomcat.StandardService : Starting service [Tomcat]

2023-02-06 19:42:04.074 INFO 42496 --- [main] o.s.b.w.embedded.tomcat.TomcatWebServer : Tomcat started on port(s): 8080 (http) with context path ''
2023-02-06 19:42:04.079 INFO 42496 --- [main] c.h.f.c.e.s.r.ClickHouseApplication : Started ClickHouseApplication in 2.718 seconds (JVM running for 3.07)
```

#### Step 4 Call the Spring Boot sample API of ClickHouse to trigger running the sample code.

- Running method in Windows:

Open the browser, enter **http://IP address of the ClickHouse client node:8080/clickhouse/executeQuery** in the address box, and check the returned information.

ClickHouse springboot client runs normally.

- Running method in Linux:

Log in to the ClickHouse client node and run the following command to view shell logs and log files in Linux:

**curl http://localhost:8080/clickhouse/executeQuery**  
**vi clickhouse-springboot-example.log**

```
[root@host-192-168-6-24 test]# ll
total 25660

## 1.6 Doris Development Guide

### 1.6.1 Overview

#### 1.6.1.1 Doris Introduction

Doris is a high-performance and real-time analytical database based on the MPP architecture. Doris is well known for its high speed and ease of use. It can return query results in massive data in sub-second response time and supports high-concurrency point query scenarios. It also supports complex analysis scenarios with high throughput. Based on this, Apache Doris can meet the requirements of report analysis, ad hoc query, unified data warehouse construction, and data lake federated query acceleration. Users can build applications such as user behavior

analysis, A/B experiment platform, log retrieval analysis, user profile analysis, and order analysis.

Doris uses the MPP model, which is executed concurrently between nodes and within nodes. It is applicable to the distributed join of multiple large tables. Supports the vectorized query engine, adaptive query execution (AQE), optimization policy that combines CBO and RBO, and hot data cache query.

### 1.6.1.2 Common Concepts

In Doris, data is logically described in the form of tables.

- **Row&Column**

A table consists of rows and columns:

- Row: indicates a row of user data.
- Column: describes different fields in a row of data.

Columns can be divided into two categories: Key and Value. From the business perspective, Key and Value can correspond to the dimension column and indicator column respectively. From the point of view of the aggregation model, rows with the same key column are aggregated into one row. The aggregation mode of the Value column is specified by the user when creating a table.

- **Tablet&Partition**

In the storage engine of Doris, user data is horizontally divided into several data fragments (tablets, also called data buckets). Each Tablet contains several rows of data. Tablet data has no intersection and is physically stored independently.

Multiple tablets belong to different partitions logically. A tablet belongs to only one partition, and a partition contains several tablets. Because tablets are physically independent, partitions can be considered as physically independent. A tablet is the smallest physical storage unit for operations such as data movement and replication.

Multiple partitions form a table. A partition can be considered as the smallest logical management unit. Data can be imported and deleted only for one partition.

- **Data model**

Doris data models are classified into three types: Aggregate, Unique, and Duplicate.

- **Aggregate model**

When data is imported, rows with the same Key column are aggregated into one row, and the Value column is aggregated based on the AggregationType parameter. Currently, the AggregationType supports the following aggregation modes:

- SUM: Sum of values in multiple lines.
- Replace: Replace the value in the next batch of data.
- MAX: retain the maximum value.

- MIN: minimum value.

- **Unique model**

In some multidimensional analysis scenarios, users focus more on how to ensure the uniqueness of keys, that is, how to obtain the uniqueness constraint of the primary key. Therefore, the Unique data model is introduced.

- **Read-on-Merge**

The read-on-merge implementation of the Unique model can be completely replaced by the Replace mode in the Aggregate model. Its internal implementation and data storage are exactly the same.

- **Combine on write**

The unique model is implemented by combining data on write. The query performance of the unique model is closer to that of the duplicate model. Compared with the aggregate model, the unique model has higher query performance than the aggregate model in scenarios where primary key constraints are required, especially in aggregate queries and queries where a large amount of data needs to be filtered by indexes.

In the Unique table with the merge-on-write option enabled, the overwritten and updated data is marked and deleted during the import phase, and new data is written to a new file. During query, all data marked for deletion is filtered out at the file level, and the read data is the latest data. This eliminates the data aggregation process during read merge and supports pushdown of multiple predicates in many cases. Therefore, the performance can be greatly improved in many scenarios, especially in the case of aggregated queries.

- **Duplicate model**

In some multidimensional analysis scenarios, data has neither primary keys nor aggregation requirements. The Duplicate data model can be introduced to meet such requirements.

This data model is different from the Aggregate and Unique models. The data is stored exactly as the data in the import file, and there is no aggregation. Even if the two rows of data are identical, they are retained. The DUPLICATE KEY specified in the table creation statement is only used to specify the columns by which the underlying data is sorted.

- **Data Model Selection Suggestions**

The data model is determined when the table is created and cannot be modified. Therefore, it is important to choose a suitable data model.

- i. The Aggregate model greatly reduces the amount of data to be scanned and the amount of query calculation during aggregation query through pre-aggregation. It is suitable for the report query scenario with fixed mode. However, this model is not friendly to count(\*) queries. In addition, the aggregation mode of the Value column is fixed. Therefore, the semantic correctness needs to be considered when performing other types of aggregation queries.
- ii. The Unique model ensures the uniqueness of primary key constraints in scenarios where unique primary key constraints are required.

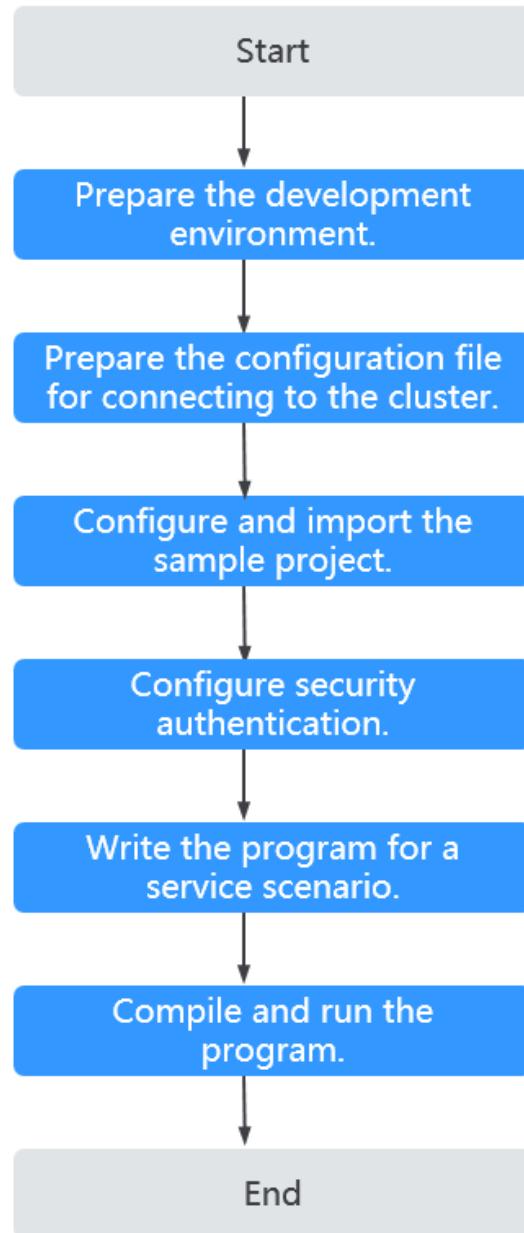

However, the query advantages of pre-aggregation such as ROLLUP cannot be taken advantage of.

- 1) For users who have high performance requirements for aggregated queries, the merge-on-write implementation introduced in version 1.2 is recommended.
- 2) The Unique model supports only the entire row update. If the unique primary key constraint and some columns need to be updated, (e.g., importing multiple source tables into a Doris table), you can use the Aggregate model and set the aggregation type of the non-primary key column to Replaced\_IF\_NOT\_NULL.
- 3) Duplicate is applicable to Ad-hoc queries in any dimension. Although the pre-aggregation feature cannot be used, it is not restricted by the aggregation model and can take advantage of the column-store model. (Only the relevant columns are read, not all the Key columns).

### 1.6.1.3 Development Process

The following figure shows the phases in the development process.

Figure 1-14 Doris application development process

**Table 1-9** HBase application development process description

Phase	Description	Reference Document
Prepare the development environment.	Before developing an application, you need to prepare the development environment. You are advised to use the Java language and IntelliJ IDEA tool for development. In addition, you need to complete the initial configuration of the JDK and Maven.	<a href="#">Preparing for Development Environment</a>
Prepare the Configuration File for Connecting to the Cluster.	During application development or running, you need to connect to the MRS cluster through cluster configuration files. The configuration file contains user files used for security authentication. You can obtain related content from the created MRS cluster.  Nodes used for program commissioning or running must be able to communicate with nodes in the MRS cluster and the hosts domain name must be configured.	<a href="#">Preparing the Configuration Files for Connecting to the Cluster</a>
Configure and import the sample project.	Doris provides multiple sample programs in different scenarios. You can obtain sample projects and import them to the local development environment for program learning.	<a href="#">Configuring and Importing JDBC or Stream Load Sample Projects</a> <a href="#">Configuring and Importing SpringBoot Sample Projects</a>

Phase	Description	Reference Document
Configure security authentication.	When using the JDBC or Spring Boot interface to connect to Doris, you need to configure a user with Doris administrator rights for security authentication.	<a href="#">Configuring and Importing JDBC or Stream Load Sample Projects</a> <a href="#">Configuring and Importing SpringBoot Sample Projects</a>
Develop programs based on business scenarios.	Develop programs based on actual service scenarios and invoke component interfaces to implement corresponding functions.	<a href="#">Using Doris Through JDBC or DBalancer</a>
Compile and run the application.	You can commission and run the program in the local Windows development environment, or compile the program into a JAR package and submit it to the Linux node for running.	<a href="#">Application Commissioning</a>

#### 1.6.1.4 Doris Sample Project Introduction

To obtain the MRS sample project, visit <https://github.com/huaweicloud/huaweicloud-mrs-example>. Switch to the version branch that matches the MRS cluster, download the package to the local PC, and decompress the package to obtain the sample code project of each component.

Currently, MRS provides the following Doris-related sample projects:

**Table 1-10** Doris-related sample projects

Sample Project Location	Function Description
doris-examples/doris-jdbc-example	Application development example of Doris data read and write operations. You can invoke Doris APIs to create user tables, insert data into tables, query table data, and delete tables. For details, see <a href="#">Using Doris Through JDBC or DBalancer</a> .

Sample Project Location	Function Description
springboot/doris-examples	SpringBoot application development example for Doris data read and write operations. This section provides an example for connecting Doris to SpringBoot. For details, see <a href="#">Configuring and Importing SpringBoot Sample Projects</a> .
doris-examples/doris-stream-load-example	Application development example of the Doris Stream Load API for importing local CSV files. This section provides an example of using the Stream Load API to import data from a local CSV file to a Doris table. For details about the example, see <a href="#">Loading Data to a Doris Table with Stream Load</a> .

## 1.6.2 Environment Preparation

### 1.6.2.1 Preparing for Development Environment

[Table 1-11](#) describes the environment required for secondary development.

**Table 1-11** Development environment

Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows OS. Windows 7 or later is supported.</li><li>• Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul>

Item	Description
Installing JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>Tool used for developing HBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>
JUnit plug-in installation	Basic configuration for the development environment.

Item	Description
Installation of Maven	Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development.  Huawei provides Huawei Mirrors for you to download all dependency JAR files of sample projects. However, you need to download the rest dependency open-source JAR files from the Maven central repository or other custom repository address. For details, see <a href="#">Configuring Huawei Open-Source Mirrors</a> .
7-zip	Used to decompress .zip and .rar packages. The 7-Zip 16.04 is supported.

### 1.6.2.2 Preparing the Configuration Files for Connecting to the Cluster

#### Preparing for User Authentication

For an MRS cluster with Kerberos authentication enabled, you need to prepare a user who has the operation permission on related components for program authentication.

The following Doris permission configuration example is for reference only. You can modify the configuration as you need.

**Step 1** Log in to FusionInsight Manager.

**Step 2** Choose **System > Permission > Role**. On the displayed page, click **Create Role**.

1. Enter a role name, for example, **dorisrole**.
2. In the **Configure Resource Permission** area, select *Desired cluster > Doris*, select **Doris Adm Permission**, and click **OK**.

**Step 3** Choose **User**, and click **Create**. On the displayed page, create a human-machine user, for example, **developuser**, and associate the user to the role created in [Step 2](#).

**Step 4** Log in to FusionInsight Manager again as the **developuser** user and change the initial password of the user.

----End

#### Configuring the Network of the Running Environment

Nodes used for program debugging or running must be able to communicate with nodes within the MRS cluster, and the host domain names must be configured.

- Scenario 1: Configure the network connection between the local Windows environment and MRS cluster nodes.
  - a. Log in to FusionInsight Manager, click **Download Client** in the upper right corner of **Homepage**, select **Configuration Files Only** for **Select**

**Client Type**, and click **OK**. After the client file package is generated, download the client to the local PC as prompted and decompress it.

For example, if the client configuration file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar**. Then, continue to decompress this file.

- b. Copy the **hosts** file content from the decompression directory to the **hosts** file of the local PC.

 NOTE

- If you need to debug the application in the local Windows environment, ensure that the local PC can communicate with the hosts listed in the **hosts** file.
- The local **hosts** file in a Windows environment is stored, for example, in **C:\WINDOWS\system32\drivers\etc\hosts**.
- When configuring IPv6 hosts on the local PC running Windows, add **%** and the interface index of the network interface card (NIC) to the end of the IPv6 address. The interface index can be obtained by running the **ipconfig** command.

The following is an example:

`fec1:0:0:e505:8:99:5:1%10`

- Scenario 2: Configure the network communication between the Linux environment and MRS cluster nodes.
  - a. Install the MRS cluster client on nodes.  
For example, the client installation directory can be **/opt/hadoopclient**.
  - b. Obtain the configuration files.
    - i. Log in to FusionInsight Manager, click **Download Client** in the upper right corner of **Homepage**. Set **Select Client Type** to **Configuration Files Only**, select **Save to Path**, and click **OK** to download the client configuration file to the active OMS node of the cluster.
    - ii. Log in to the active OMS node as user **root** and go to the directory where the client configuration file is stored. The default directory is **/tmp/FusionInsight-Client/**.  
For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:  
`cd /tmp/FusionInsight-Client`  
`tar -xvf FusionInsight_Cluster_1_Services_Client.tar`  
`tar -xvf FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles.tar`  
`cd FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles`
  - c. Check the network connection of the client node.  
During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If they are not contained, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client is deployed.

### 1.6.2.3 Configuring and Importing JDBC or Stream Load Sample Projects

#### Background

To run the JDBC or Stream Load API sample code of the Doris component, perform the following operations.

#### Procedure

**Step 1** Obtain the sample project folder **doris-jdbc-example** or **doris-stream-load-example** in the **src\doris-examples** directory in the sample code decompression directory by referring to [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** Import the sample project to the IntelliJ IDEA development environment.

1. On the menu bar of IntelliJ IDEA, choose **File > Open...** to display the Open File or Project dialog box.
2. In the displayed dialog box, select the **doris-jdbc-example** or **doris-stream-load-example** folder and click **OK**. In Windows, the full path of the folder does not contain spaces.

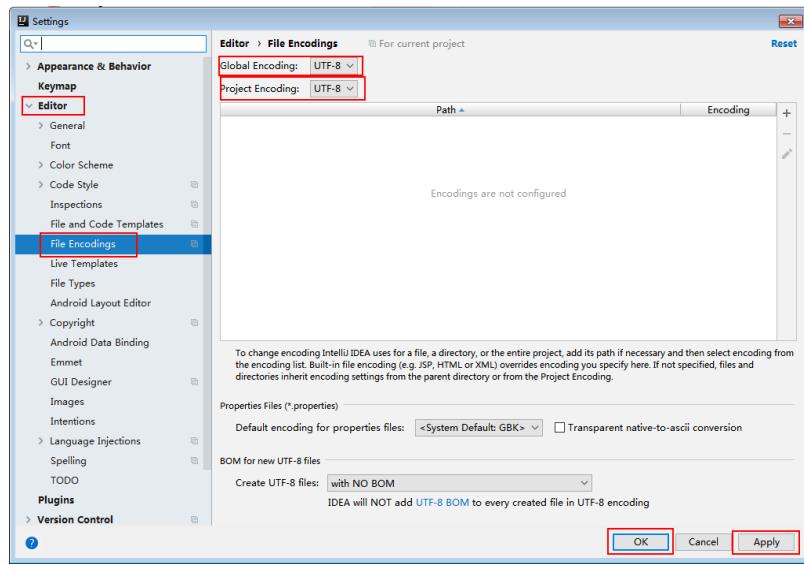

##### NOTE

- This section describes how to develop an application that connects to the Doris service in JDBC mode in Windows.
- Set the **DORIS\_MY\_USER** and **DORIS\_MY\_PASSWORD** environment variables in the local environment variables. Store the environment variables in ciphertext and decrypt the environment variables to ensure security.
  - **DORIS\_MY\_USER** indicates the user name for logging in to the Doris.
  - **DORIS\_MY\_PASSWORD** indicates the password for logging in to the Doris.If the error message "Could not connect to *IP address of the FE instance*.MySQL protocol query connection port" is displayed during the execution of the sample program, the configured local environment variables may not take effect. In this case, restart the computer for the settings to take effect.
- After the **jdb-example** sample project is imported, modify the following parameters:
  - In the code, change *xxx* in **HOST = "xxx"** to the IP address of the master FE node of the Doris. To obtain the IP address of the master FE node, choose **Cluster > Services > Doris** on Manager and view the **Host Where Leader Locates**.
  - In the code, change *xxx* where **PORT = "xxx"** to the MySQL query connection port of Doris. The default port is 29982. To obtain the port, log in to FusionInsight Manager, choose Cluster > Services > Doris > Configurations, and search for **query\_port**.

**Step 3** Set the encoding format of the IntelliJ IDEA text file to solve the problem of garbled characters.

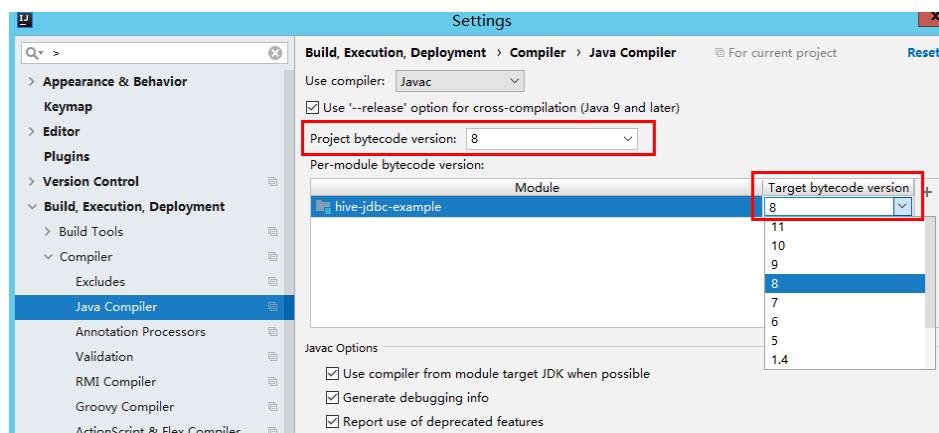

1. Choose **File > Settings...** from the main menu of IntelliJ IDEA. The Settings window is displayed.
2. In the navigation tree on the left, choose **Editor > File Encodings**. In the **Project Encoding** and **Global Encoding** areas, set the parameter value to **UTF-8**, click **Apply**, and click **OK**, as shown in [Figure 1-15](#).

**Figure 1-15 Setting the Encoding Format of IntelliJ IDEA**

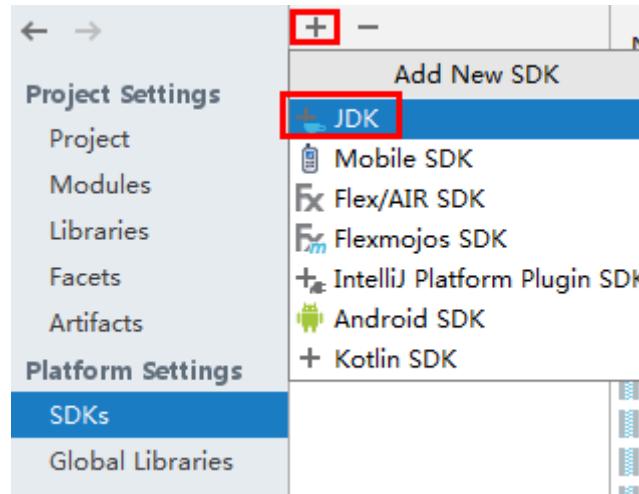

**Step 4** Set the JDK of the project.

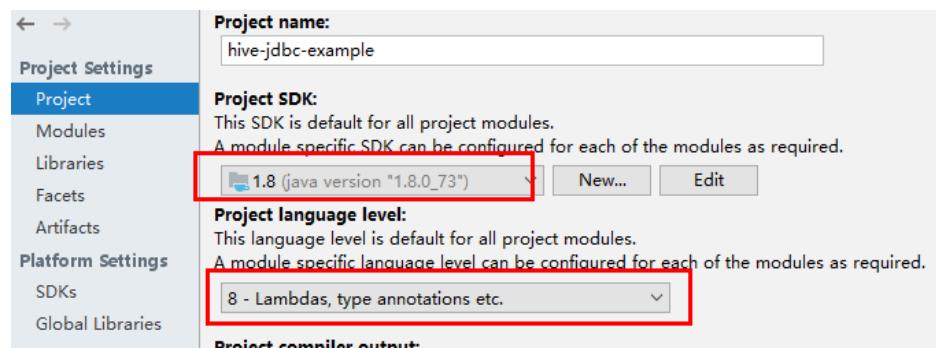

1. On the IntelliJ IDEA menu bar, choose **File > Settings....** The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler**, select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** to **8** for **doris-jdbc-example**.

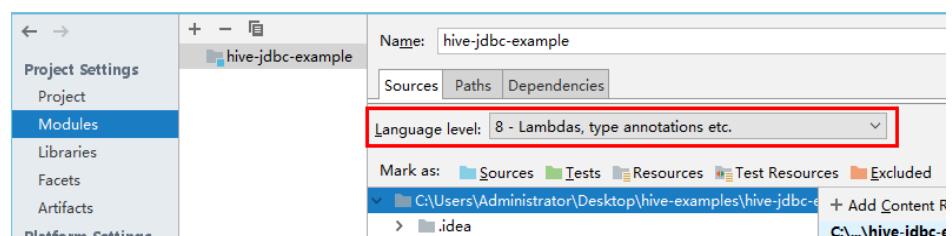

3. Click **Apply** and **OK**.
4. On the IntelliJ IDEA menu bar, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Select **SDKs**, click the plus sign (+), and select **JDK**.

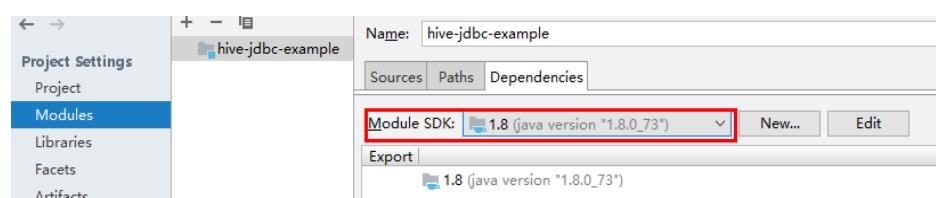

6. On the **Select Home Directory for JDK** page that is displayed, select the **JDK** directory and click **OK**.
7. After selecting the JDK, click **Apply**.
8. Select **Project**, select the JDK added in SDKs from the **Project SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Project language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Source** page, change the value of **Language level** to **8 - Lambdas, type annotations etc.**

On the **Dependencies** page, change the value of **Module SDK** to the JDK added in SDKs.

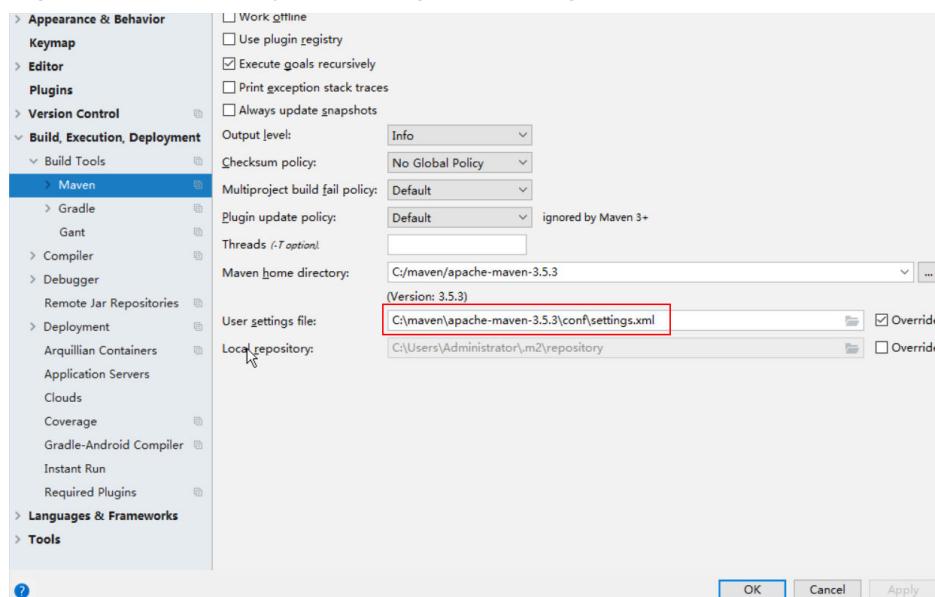

11. Click **Apply** and **OK**.

**Step 5** Configure Maven.

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, select **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is **<Local Maven installation directory>\conf\settings.xml**.

**Figure 1-16** Directory for storing the **settings.xml** file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply**, and then click **OK**.

----End

#### 1.6.2.4 Configuring and Importing SpringBoot Sample Projects

##### Background

To run the SpringBoot API sample code of the Doris component of MRS, perform the following operations:

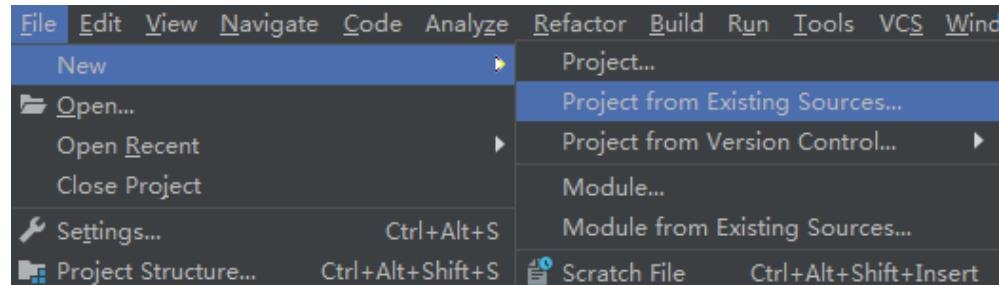

This section describes how to develop an application that connects to the Doris service in SpringBoot mode in Windows.

##### Procedure

- Step 1** Obtain the sample project folder **doris-rest-client-example** in the **src/springboot/doris-examples** directory in the sample code decompression directory by referring to [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.

1. Choose **File > New > Project from Existing Sources**.

2. In the **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **doris-rest-client-example** folder and click **OK**.
3. Confirm the subsequent configuration and click **Next**. If there is no special requirement, use the default value.

Select the recommended JDK version and click **Finish**.

**NOTE**

- This section describes how to develop an application that connects to the Doris service in SpringBoot mode in Windows.
- Set the **DORIS\_MY\_USER** and **DORIS\_MY\_PASSWORD** environment variables in the local environment variables. Store the environment variables in ciphertext and decrypt the environment variables to ensure security.
  - **DORIS\_MY\_USER** indicates the user name for logging in to the Doris.
  - **DORIS\_MY\_PASSWORD** indicates the password for logging in to the Doris.If the error message "Could not connect to *IP address of the FE instance*.MySQL protocol query connection port" is displayed during the execution of the sample program, the configured local environment variables may not take effect. In this case, restart the computer for the settings to take effect.
- After the **doris-rest-client-example** sample project is imported, modify the following parameters:
  - In the code, change *xxx* in **HOST = "xxx"** to the IP address of the master FE node of the Doris. To obtain the IP address of the master FE node, choose **Cluster > Services > Doris** on Manager and view the **Host Where Leader Locates**.
  - In the code, change *xxx* where **PORT = "xxx"** to the MySQL query connection port of Doris. The default port is 29982. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and search for **query\_port**.

----End

 NOTE

- This section describes how to develop an application that connects to the Doris service in JDBC mode in Windows.
- After the jdbc-example sample project is imported, modify the following parameters:
- Change the value of xxx under USER = "xxx" in the code to the actual development user, for example, developer.
- Change the value of xxx under PASSWD = "xxx" in the code to the actual password of the development user.
- In the code, change xxx in HOST = "xxx" to the IP address of the master FE node of the Doris. You can obtain the IP address of the master FE node by choosing Cluster > Service > Doris on FusionInsight Manager and checking the host where the leader resides.
- In the code, change xxx where PORT = "xxx" to the MySQL query connection port of Doris. The default port is 29982. To obtain the port, log in to FusionInsight Manager, choose Cluster > Service > Doris > Configuration, and search for query\_port.

## 1.6.3 Doris Application Development

### 1.6.3.1 Using Doris Through JDBC or DBalancer

#### 1.6.3.1.1 Service Scenario Description

This section describes how to quickly learn the Doris development process and understand key interface functions.

#### Scenario

Doris can use SQL statements to perform common service operations. The SQL operations involved in the code example include creating a database, creating a table, inserting table data, querying table data, deleting a table, and deleting a database (DBalancer).

The code sample operation process is as follows:

1. Connect to Doris using JDBC or DBalancer.
2. Create a database.
3. Create a table in the database.
4. Inserts data into a table.
5. Query table data.
6. Delete the table.
7. Delete a database. (DBalancer)

#### 1.6.3.1.2 Application Development Approach

#### Function Decomposition

Doris is compatible with the MySQL protocol. Common operations can be performed by using the SQL language.

The development process consists of the following parts:

- Establish a connection: Establish a connection to the Doris service instance.
- Create Library: Create a Doris database.
- Create Table: Create a table in the Doris database.
- Insert Data: Insert data into the Doris table.
- Querying data: Query the Doris table data.
- Deleting a table: You can delete a created Doris table.
- Deleting a database (DBalancer): You can delete a created Doris database.

### 1.6.3.1.3 Setting Up a Connection

## Connecting Doris Using JDBC

The following code snippet uses the **createConnection** method of the **JDBCExample** class in the **com/huawei/bigdata/doris/example** package.

```
private static Connection createConnection() throws Exception {
    Connection connection = null;
    try {
        Class.forName(JDBC_DRIVER);
        String dbUrl = String.format(DB_URL_PATTERN, HOST, PORT);
        connection = DriverManager.getConnection(dbUrl, USER, PASSWD);
    } catch (Exception e) {
        logger.error("Init doris connection failed.", e);
        throw new Exception(e);
    }
    return connection;
}
```

In the preceding code snippet, HOST and PORT indicate the IP address of the master FE node and the MySQL query connection port for Doris, respectively.

- To obtain the IP address of the master FE node, log in to FusionInsight Manager, choose **Cluster > Services > Doris**, and check the **Host Where Leader Locates**.
- The default MySQL query connection port is 29982. To obtain the port number, log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and search for **query\_port**.

```
private static final String HOST = "192.168.67.78";
private static final int PORT = 29982;
```

## Connecting Doris Using DBalancer

The following code snippet uses the **createConnection** method on the **DBalancerJDBCExample** class in the **com/huawei/bigdata/doris/example** package.

```
private static Connection createConnection() throws Exception {
    Connection connection = null;
    try {
        Class.forName(JDBC_DRIVER);
        String dbUrl = String.format(DB_URL_PATTERN, HOST, PORT);
        connection = DriverManager.getConnection(dbUrl, USER, PASSWD);
    } catch (Exception e) {
        logger.error("Init doris connection failed.", e);
        throw new Exception(e);
    }
    return connection;
}
```

In the preceding code snippet, HOST and PORT indicate the IP address of the DBalancer node and DBalancer TCP access port set in the following example.

- To obtain the IP address of the DBalancer node, log in to FusionInsight Manager and choose **Cluster > Services > Doris > Instances**.
- The default TCP access port of DBalancer is 29992. To obtain the port number, log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and search for **balancer\_tcp\_port**.

```
private static final String HOST = "192.168.20.37";
private static final int PORT = 29992;
```

#### 1.6.3.1.4 Creating a Database

Run the SQL statement in Java JDBC or Java DBalancer mode to create the database corresponding to the *dbName* variable in the cluster.

```
String createDatabaseSql = "create database if not exists dbName";
public static void execDDL(Connection connection, String sql) throws Exception {
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.execute();
    } catch (Exception e) {
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

#### 1.6.3.1.5 Creating a Table

Run the SQL statement in Java JDBC or Java DBalancer mode to create the table corresponding to *tableName* in the database corresponding to the *dbName* variable in the cluster.

```
String createTableSql = "create table if not exists " + dbName + "." + tableName + " (\n" +
    "c1 int not null,\n" +
    "c2 int not null,\n" +
    "c3 string not null\n" +
    ") engine=olap\n" +
    "unique key(c1, c2)\n" +
    "distributed by hash(c1) buckets 1";
public static void execDDL(Connection connection, String sql) throws Exception {
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.execute();
    } catch (Exception e) {
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

#### 1.6.3.1.6 Inserting Data

Run the following SQL statement in Java JDBC or Java DBalancer mode to insert data into the *dbName.tableName* table of the cluster.

```
String insertTableSql = "insert into " + dbName + "." + tableName + " values(?, ?, ?)";
private static void insert(Connection connection, String sql) throws Exception {
    int INSERT_BATCH_SIZE = 10;
    try(PreparedStatement stmt = connection.prepareStatement(sql)) {
        for (int i =0; i < INSERT_BATCH_SIZE; i++) {
            stmt.setInt(1, i);
            stmt.setInt(2, i * 10);
            stmt.setString(3, String.valueOf(i * 100));
            stmt.addBatch();
        }
        stmt.executeBatch();
    } catch (Exception e) {
```

```
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

### 1.6.3.1.7 Querying Data

Use Java JDBC or Java DBalancer to run SQL statements to query data in the *dbName.tableName* table in the cluster.

```
String querySql = "select * from " + dbName + "." + tableName + " limit 10";
private static void query(Connection connection, String sql) throws Exception {
    try (Statement stmt = connection.createStatement()) {
        ResultSet resultSet = stmt.executeQuery(sql) {
            ResultSetMetaData md = resultSet.getMetaData();
            int columnCount = md.getColumnCount();
            StringBuffer stringBuffer = new StringBuffer();
            logger.info("Start to print query result.");
            for (int i = 1; i <= columnCount; i++) {
                stringBuffer.append(md.getColumnName(i));
                stringBuffer.append(" ");
            }
            logger.info(stringBuffer.toString());

            while (resultSet.next()) {
                stringBuffer = new StringBuffer();
                for (int i = 1; i <= columnCount; i++) {
                    stringBuffer.append(resultSet.getObject(i));
                    stringBuffer.append(" ");
                }
                logger.info(stringBuffer.toString());
            }
        } catch (Exception e) {
            logger.error("Execute sql {} failed.", sql, e);
            throw new Exception(e);
        }
    }
}
```

### 1.6.3.1.8 Deleting a Table

Run the SQL statement in Java JDBC or Java DBalancer mode to delete the *dbName.tableName* table from the cluster.

```
String dropSql = "drop table " + dbName + "." + tableName;
public static void execDDL(Connection connection, String sql) throws Exception {
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.execute();
    } catch (Exception e) {
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

### 1.6.3.1.9 Deleting a Database

Run the SQL statement using Java DBalancer to delete the *dbName* database from the cluster.

```
String dropDb = "drop database " + dbName;
public static void execDDL(Connection connection, String sql) throws Exception {
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.execute();
    } catch (Exception e) {
        logger.error("Execute sql {} failed.", sql, e);
        throw new Exception(e);
    }
}
```

### 1.6.3.2 Loading Data to a Doris Table with Stream Load

The Doris Stream Load sample program imports local CSV file data to a Doris table.

#### Example Code

Modify the following parameters in the sample code based on the site requirements:

- **HOST**: IP address of the master FE node of Doris. To obtain the IP address of the master FE node, log in to FusionInsight Manager, choose **Cluster > Services > Doris**, and check **Host Where Leader Locates**.
- **PORT**: HTTPS port of the Doris FE service. The default value is **29991**. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Services > Doris**, click **Configurations**, and search for **https\_port**.
- **JDBC\_PORT**: The value is the MySQL protocol query connection port of the Doris. The default port is **29982**. To obtain the port, log in to FusionInsight Manager, choose **Cluster > Services > Doris > Configurations**, and search for **query\_port**.
- **DATABASE**: database of the table storing imported data
- **TABLE**: name of the Doris table that stores imported data
- **getHttpPost**: path of the CSV file to be imported

```
public class DorisStreamLoader {  
  
    // FE IP Address  
    private final static String HOST = "192.168.13.178";  
    // If Kerberos authentication is enabled for the cluster (the cluster is in security mode), FE port is the value  
    // of https_port; If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), FE port  
    // is the value of http_port.  
    private final static int PORT = 29991;  
  
    private final static int JDBC_PORT = 29982;  
    // db name  
    private final static String DATABASE = "test_2";  
    // table name  
    private final static String TABLE = "doris_test_sink";  
  
    private static final String JDBC_DRIVER = "com.mysql.cj.jdbc.Driver";  
    private static final String DB_URL_PATTERN = "jdbc:mysql://%s:%d?rewriteBatchedStatements=true";  
  
    private static final String USER = System.getenv("DORIS_MY_USER");  
    private static final String PASSWD = System.getenv("DORIS_MY_PASSWORD");  
  
    // If Kerberos authentication is enabled for the cluster (the cluster is in security mode), Start the url with  
    // https; If Kerberos authentication is disabled for the cluster (the cluster is in normal mode), start the url  
    // with http.  
    private final static String loadUrl = String.format("https://%s:%s/api/%s/%s/_stream_load",  
        HOST, PORT, DATABASE, TABLE);  
  
    //Call the Curl method.  
    public static String execCurl(String[] cmd) {  
        ProcessBuilder process = new ProcessBuilder(cmd);  
        Process p;  
        try {  
            p = process.start();  
            BufferedReader reader = new BufferedReader(new InputStreamReader(p.getInputStream()));  
            StringBuilder builder = new StringBuilder();  
            String line;  
            while ((line = reader.readLine()) != null) {  
                System.out.println(line);  
            }  
        } catch (IOException e) {  
            e.printStackTrace();  
        }  
    }  
}
```

```
builder.append(line);
builder.append(System.getProperty("line.separator"));
}
return builder.toString();

} catch (Exception e) {
System.out.print("error");
}
return null;
}

public static void initTable(){
String createDatabaseSql = "create database if not exists "+DATABASE;

String createTableSql = "create table if not exists " + DATABASE + "." + TABLE + " (\n" +
" `id` int NULL COMMENT '\"',\n" +
" `number` int NULL COMMENT '\"',\n" +
" `price` DECIMAL(12,2) NULL COMMENT '\"',\n" +
" `skuname` varchar(40) NULL COMMENT '\"',\n" +
" `skudesc` varchar(200) NULL COMMENT '\"'\n" +
" ) ENGINE=OLAP\n" +

" \"in_memory\" = \"false\",\n" +
" \"storage_format\" = \"V2\"\n" +
" );";
try (Connection connection = createConnection()) {
// Create a database.
System.out.println("Start create database.");
execDDL(connection, createDatabaseSql);
System.out.println("Database created successfully.");
// Create a table.
System.out.println("Start create table.");
execDDL(connection, createTableSql);
System.out.println("Table created successfully.");
} catch (Exception e) {
System.out.println("Execute doris operation failed.");
}
}

private static Connection createConnection() throws Exception {
Connection connection = null;
try {
Class.forName(JDBC_DRIVER);
String dbUrl = String.format(DB_URL_PATTERN, HOST, JDBC_PORT);
connection = DriverManager.getConnection(dbUrl, USER, PASSWD);
} catch (Exception e) {
System.out.println("Init doris connection failed.");
throw new Exception(e);
}
return connection;
}

public static void execDDL(Connection connection, String sql) throws Exception {
try (PreparedStatement statement = connection.prepareStatement(sql)) {
statement.execute();
} catch (Exception e) {
System.out.println("Execute sql {} failed.");
throw new Exception(e);
}
}

// Call the API.
public static String getHttpPost(String csvPath) {

String[] cmdList = {"curl", "-k", "--location-trusted", "-u" + USER + ":" + PASSWD, "-H", "expect:100-
```

```
continue", "-H", "column_separator:", "-T",
csvPath,

// In the Linux scenario, upload the test.csv file in the resource directory to the Linux background and
// specify the file path in getPost.
getPost(filePath);
}
}
```

## 1.6.4 Application Commissioning

### 1.6.4.1 Commissioning an Application in Windows

#### 1.6.4.1.1 Compiling and Running an Application

##### Scenario

After the code development is complete, you can run the application in the Windows development environment.

If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

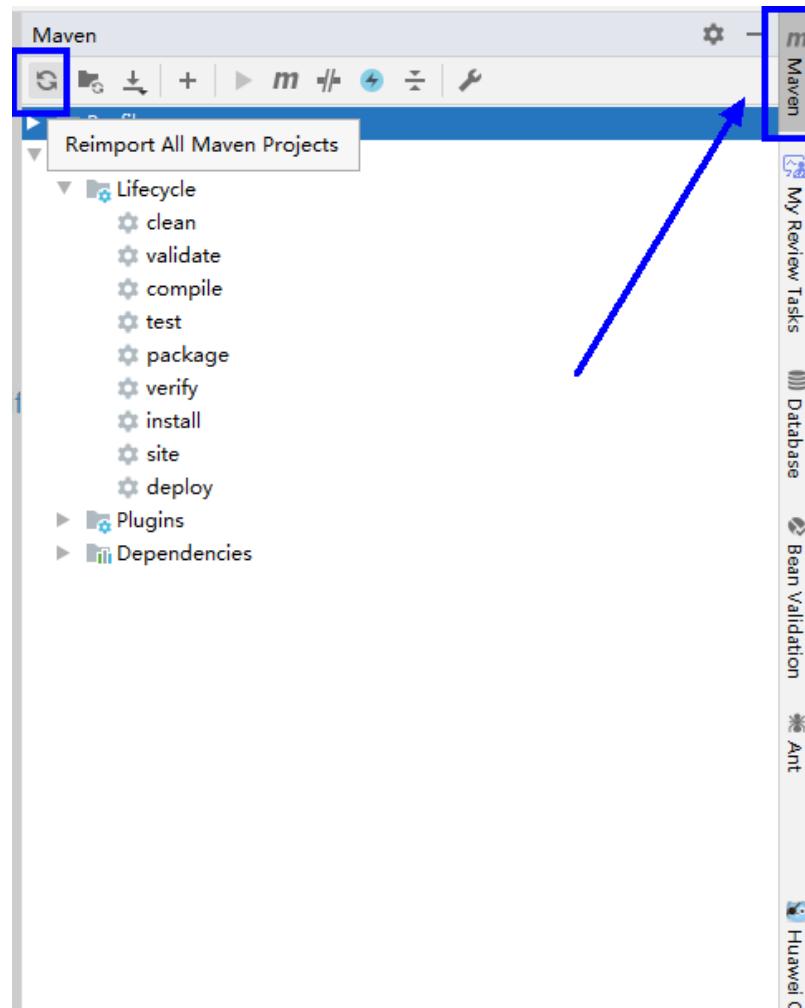

##### NOTE

- If IBM JDK is used in the Windows development environment, the application cannot be run in the Windows environment.
- You need to set the mapping between the host names and IP addresses of the access nodes in the hosts file on the local host where the sample code is run. The host names and IP addresses must be mapped one by one.

##### Procedure

**Step 1** Click **Reimport All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

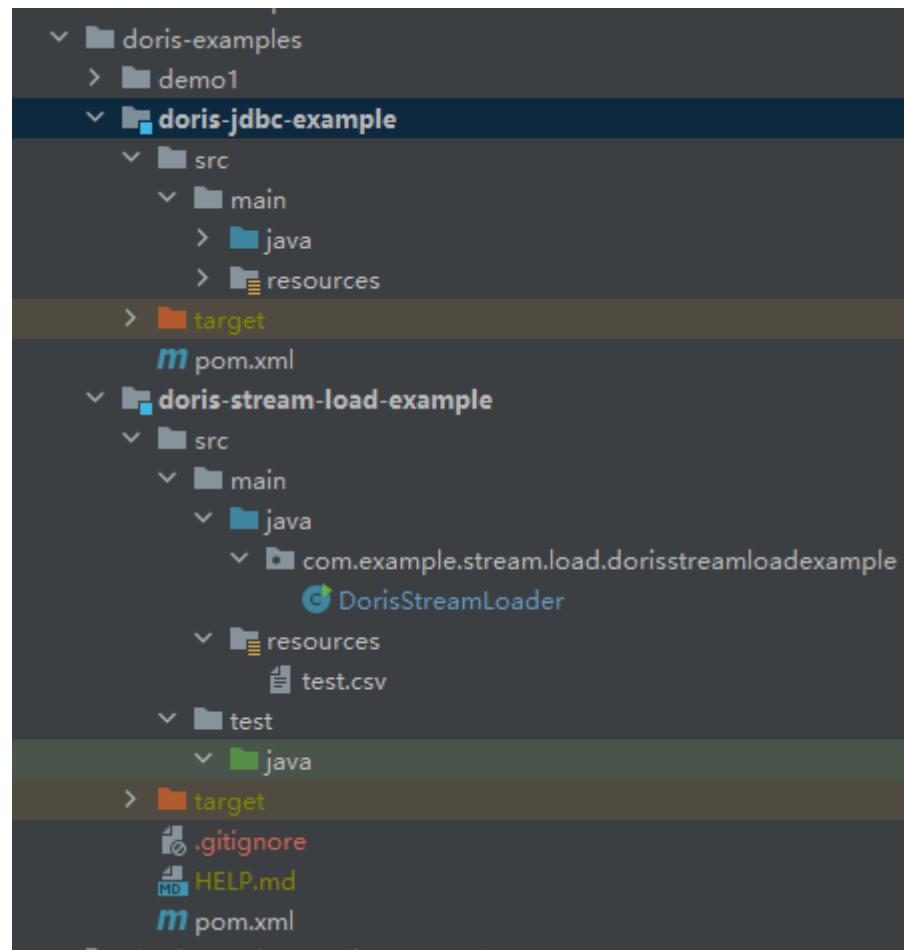

Figure 1-17 reimport projects

**Step 2** Compile and run an application.

Place the configuration file directory and modify the code to match the login user.  
See [Figure 1-18](#).

Figure 1-18 Directory list of Doris to be compiled

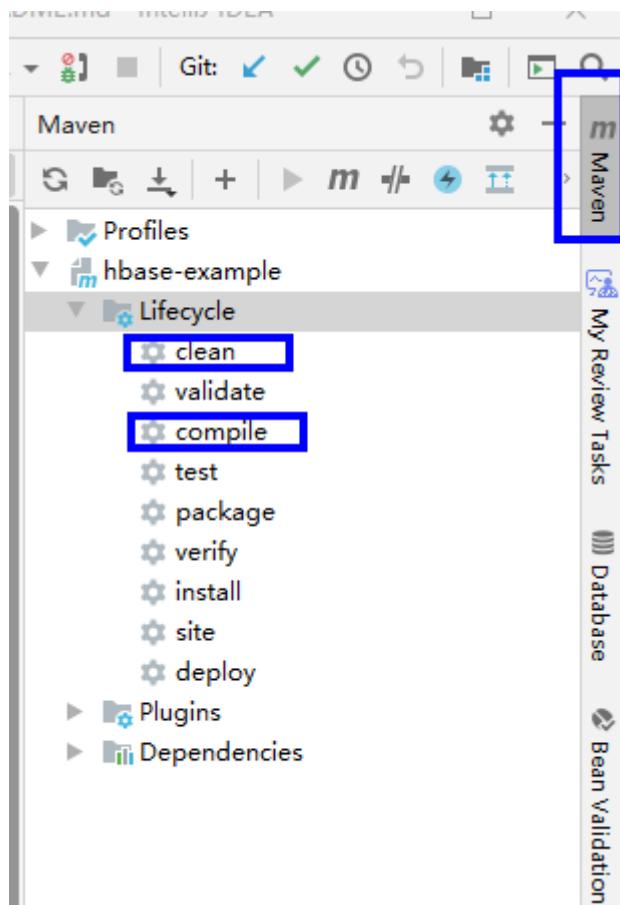

1. Compile an application.

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean** and double-click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **compile**, double click **compile** to run the **compile** command of Maven.

Figure 1-19 clean and compile tools of Maven

- Method 2:

Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean compile** command to compile the **pom.xml** file.

When the compilation is complete, the **Build Success** message is printed and the target directory is generated.

Figure 1-20 doris-jdbc-example compiled

```
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 1.241 s

[INFO] -----
[INFO] Total time:  0.190 s
[INFO] Finished at: 2024-06-12T11:26:09+08:00
[INFO] -----
```

 NOTE

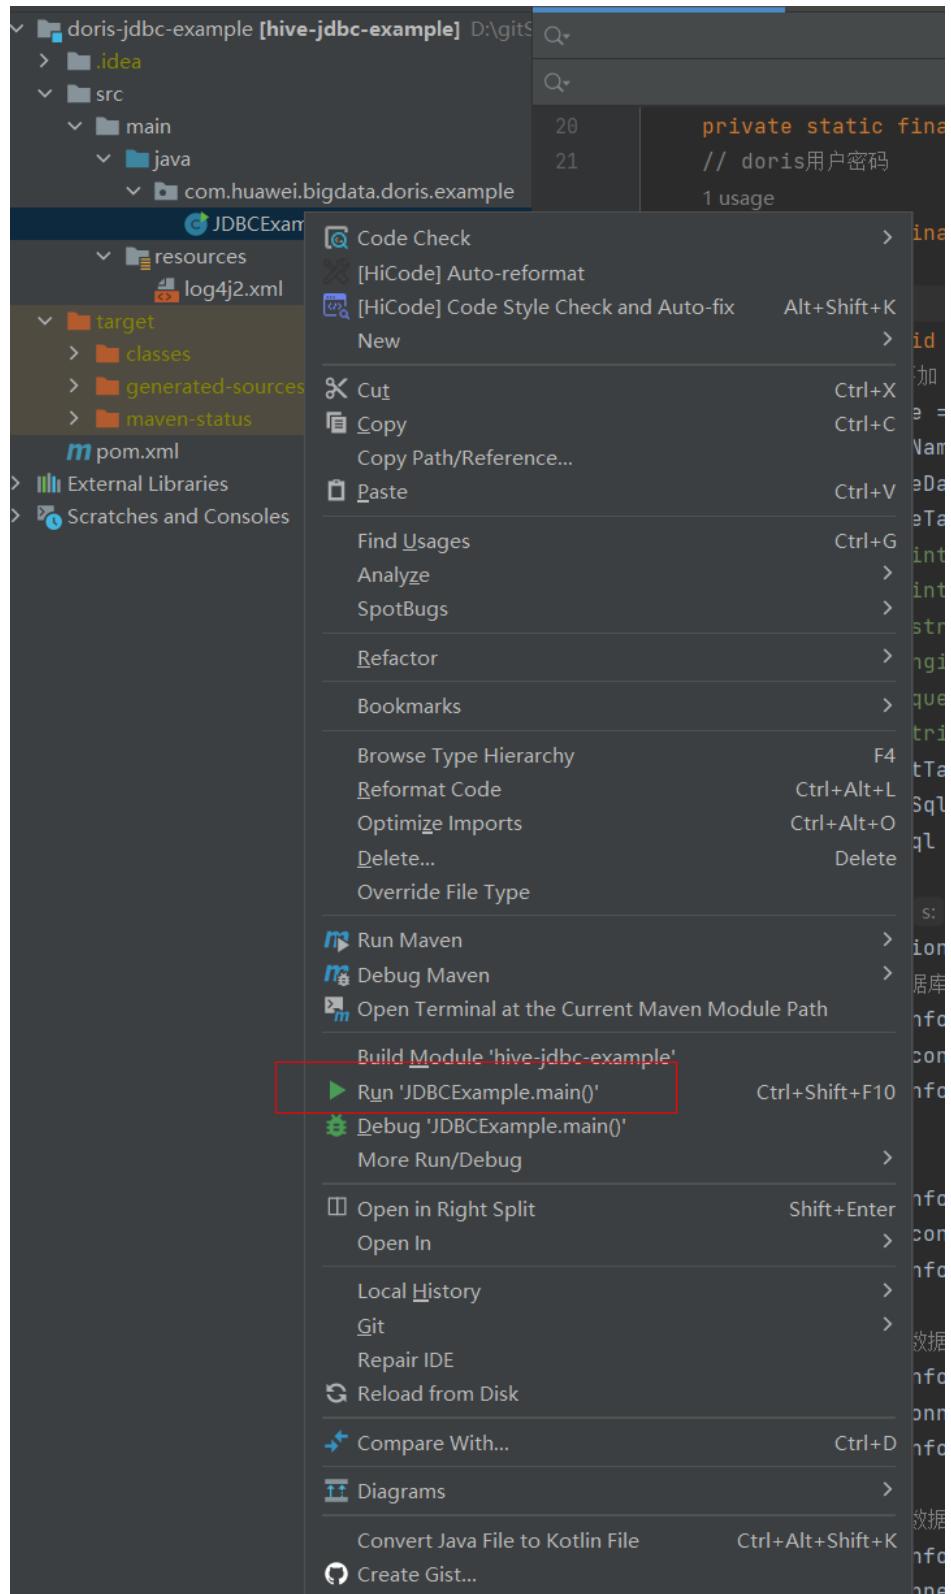

If the error message "Please use -source 7 or later to enable try-with-resources" is displayed during compilation, add the following content to the **properties** tag in the **pom.xml** configuration file:

```
<maven.compiler.source>8</maven.compiler.source>
<maven.compiler.target>8</maven.compiler.target>
```

2. Run the program.

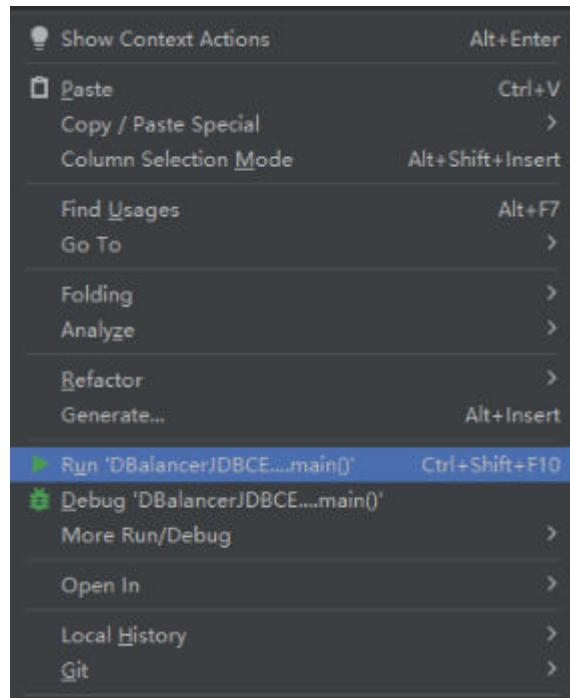

- Right-click the **JDBCExample.java** file and choose **Run 'JDBCExample.main()'**.

Figure 1-22 Run the Doris application.

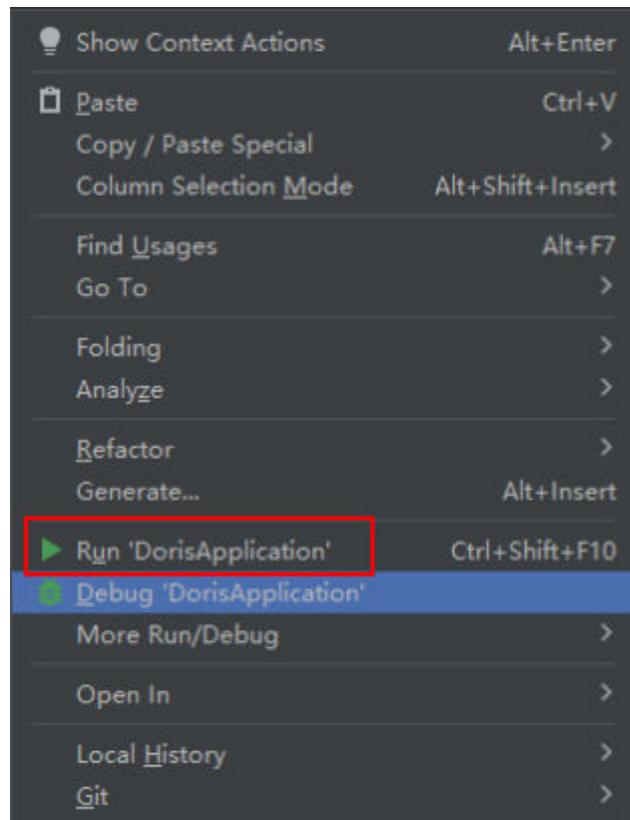

- Right-click the **DBalancerJDBCExample.java** file and choose **Run 'DBalancerJDBCExample.main()'**.

Figure 1-23 Run the DorisDBalancer application.

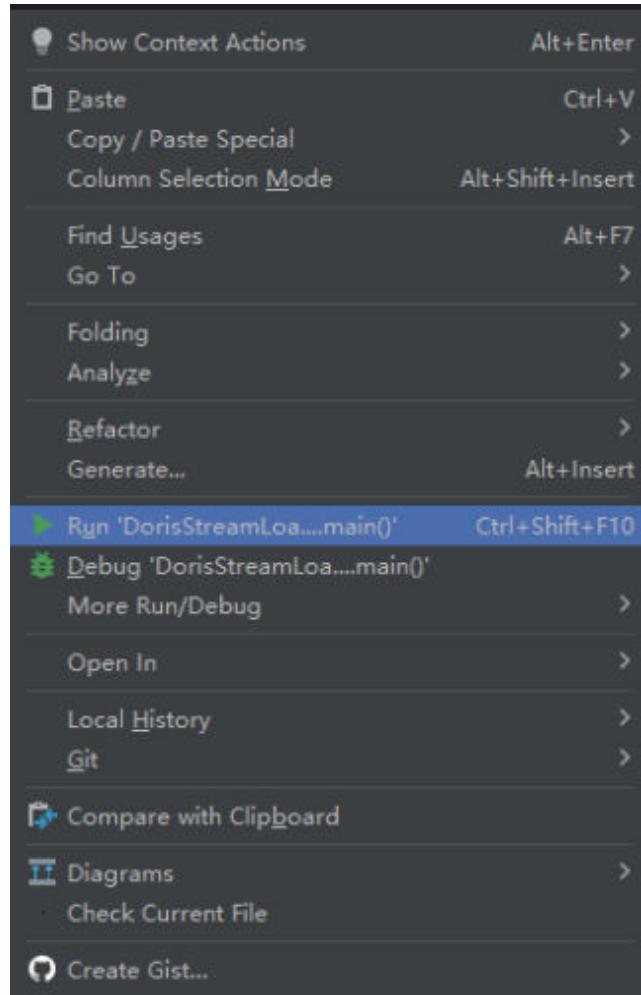

- Right-click the **DorisApplication.java** file and choose **Run 'DorisApplication'**.

Figure 1-24 Run the Doris SpringBoot application.

- Right-click the **DorisStreamLoader.java** file and choose **Run 'DorisStreamLoader.main()'**.

Figure 1-25 Run the Doris Stream Load application.

----End

#### 1.6.4.1.2 Viewing Windows Commissioning Results

##### Operation Scenario

After a Doris application finishes running, you can use one of the following methods to view the running result:

- Check the IntelliJ IDEA.
- Check the Doris log.

##### Procedure

- After the **JDBCExample.java** of **doris-jdbc-example** sample is successfully executed, the following information is displayed:

```
2023-08-17 23:13:13,473 | INFO | main | Start execute doris example. |

## 1.6.4.2 Commissioning an Application in Linux

### 1.6.4.2.1 Compiling and Running Applications

#### Scenario

After application code development is complete, you can upload a JAR file to the Linux environment to run applications.

#### Prerequisites

- You have installed a JDK in the Linux environment. The version of the JDK must be consistent with that of the JDK used by IntelliJ IDEA to export the JAR file.
- If the host where the Linux environment is deployed is not a node in the cluster, the mapping between the host name and the IP address must be set in the **hosts** file on the node where the Linux environment is deployed. The host names and IP addresses must be mapped one on one.

## Compiling and Running JDBC, DBalancer and SpringBoot Programs

### Step 1 Export a JAR file.

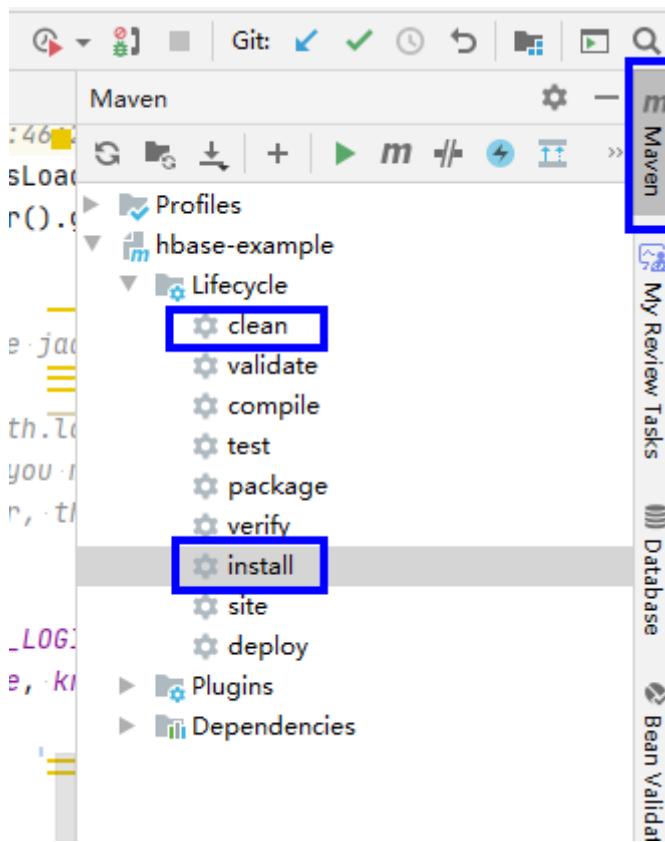

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven**, locate the target project name, and double-click **clean** under **Lifecycle** to run the **clean** command of Maven.

Choose **Maven**, locate the target project name, and double-click **install** under **Lifecycle** to run the **install** command of Maven.

Figure 1-28 Maven clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window of IDEA, and run the **mvn clean install** command to build the file.

After the build is complete, message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

**Step 2** Decide whether to run Doris to connect to SpringBoots.

- If yes, perform the following steps to run the sample:
  - Create a running directory in the Linux environment and save the **doris-rest-client-example-\*jar** file in the **target** directory to this directory.
  - Switch to the running directory and run the following command to run the JAR package:  
**java -jar doris-rest-client-example-\*jar-with-dependencies.jar**
- If no, go to **Step 4**.

**Step 3** Export the JAR package on which the sample project depends.

Go to the directory where the **pom.xml** file is stored in the **Terminal** window at the bottom of the IDEA or in other command line tools. Run the following command:

**mvn dependency:copy-dependencies -DoutputDirectory=lib**

The **lib** folder is generated in the directory where the **pom.xml** file is stored. The **lib** folder contains the JAR packages on which the sample project depends.

**Step 4** Prepare the dependency JAR file and configuration file.

1. In the Linux environment, create a directory, for example, **/opt/test**, and create the subdirectory **lib**. Export the JAR package on which the sample project depends, and upload the JAR package generated in **Step 1** and JAR package generated in **Step 3** to the **lib** directory of the Linux operating system.
2. In the **/opt/test** root directory, create the **run.sh** script, modify the following content, and save the file:

```
#!/bin/sh  
BASEDIR=`cd $(dirname $0);pwd`  
cd ${BASEDIR}  
for file in ${BASEDIR}/lib/*.jar  
do  
i_cp=$i_cp:$file  
echo "$file"  
done  
  
java -cp ${i_cp} com.huawei.bigdata.doris.example.JDBCExample
```

**com.huawei.bigdata.doris.example.JDBCExample** is used as an example. Replace it with the actual code.

**Step 5** Configure the environment variables **DORIS\_MY\_USER** and **DORIS\_MY\_PASSWORD**.

1. Add the following content to the **/etc/profile** file and save the file:  
*DORIS\_MY\_USER=Username for accessing Doris*  
*DORIS\_MY\_PASSWORD=Password for accessing Doris*
2. Run the following command to apply the environment variables:  
**source /etc/profile**

**Step 6** Go to **/opt/test** and run the following command to run the JAR file:

**sh run.sh**

----End

## Compiling and Running the Stream Load Program

- Step 1** Create a directory in the Linux environment, for example, **/opt/test**, and upload the **/src/main/resources/test.csv** file prepared in the **doris-stream-load-example** sample project obtained in **Step 1** to the directory.
- Step 2** Change the value of **getHttpPost** in the **doris-stream-load-example** sample code to **/opt/test/test.csv**.
- Step 3** Export a JAR file.

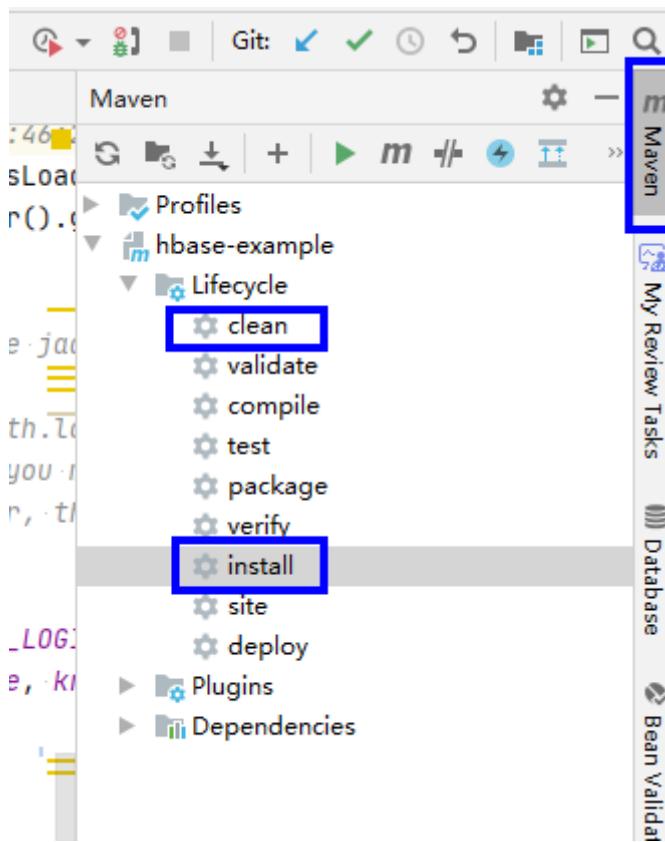

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven**, locate the target project name, and double-click **clean** under **Lifecycle** to run the **clean** command of Maven.

Choose **Maven**, locate the target project name, and double-click **install** under **Lifecycle** to run the **install** command of Maven.

Figure 1-29 Maven clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window of IDEA, and run the **mvn clean install** command to build the file.

After the build is complete, message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

**Step 4** Place **doris-stream-load-example-\*jar** in the **target** directory to the directory created in **Step 1**, for example, **/opt/test**.

**Step 5** Switch to the JDK directory and run the JAR package.

```
java -jar doris-stream-load-example-*jar-with-dependencies.jar
```

----End

#### 1.6.4.2.2 Viewing Linux Commissioning Results

- After the **JDBCExample.java** of **doris-jdbc-example** sample is successfully executed, the following information is displayed:

```

## 1.7 Elasticsearch Development Guide

### 1.7.1 Overview

#### 1.7.1.1 Application Development Overview

##### Introduction to Elasticsearch

Elasticsearch, a Lucene-powered search server, provides a distributed full-text search and analysis engine with multi-user capabilities. Designed for big data scenarios, Elasticsearch is easy to install and use and supports stable, fast, and reliable real-time search and analysis.

In addition to the basic functions, such as timestamp-based filtering and exact match provided by traditional relational databases, Elasticsearch can perform full-text search, process synonyms, score documents based on the correlation, and generate analysis and aggregation results based on the same data. Data can be processed in real time if a large number of working processes do not exist.

#### 1.7.1.2 Concepts

##### Basic Concepts

- **cluster**

There are multiple nodes in a cluster, one of which is the master node and the others are the slave nodes. Master node and slave node are defined within a cluster. In Elasticsearch, decentralization is posed. That is, there is no "central node" of the Elasticsearch cluster to external systems. Nodes in an Elasticsearch cluster can be logically considered as an entity. In this way, communication with any node in Elasticsearch is equivalent to the communication with the Elasticsearch cluster.

- **shards**

Indicates the index shard. Elasticsearch can divide a complete index into multiple shards. In this way, a large index can be split into multiple shards and distributed to different nodes, implementing distributed search. The number of shards can only be specified before the index is created and cannot be changed after the index is created.

- **replicas**

Indicates the index replica. Elasticsearch allows you to set multiple replicas for an index. Replication is to improve the fault tolerance of the system. When a shard of a node is damaged or lost, the system can restore it using its replica. In addition, replication is to improve the query efficiency of Elasticsearch. Elasticsearch automatically balances the search requests.

- **recovery**

Indicates data restoration or data redistribution. When a node is added or deleted, Elasticsearch redistributes index shards based on the load of the corresponding physical server. When a faulty node is restarted, data restoration is also performed.

- **river**

Indicates a data source of Elasticsearch. It is also a method of synchronizing data from other storage modes (such as the database) to Elasticsearch. **river** is a plug-in Elasticsearch service. The river plug-in reads data from a river data source and indexes it to Elasticsearch. Official rivers include those from CouchDB, RabbitMQ, Twitter, and Wikipedia.

- **gateway**

Indicates the storage mode of an Elasticsearch index snapshot. By default, Elasticsearch stores an index in the memory. When the memory is full, Elasticsearch persistently saves the index to the local hard disk. A gateway stores index snapshots. When the corresponding Elasticsearch cluster is stopped and then restarted, the index backup data is read from the gateway. Elasticsearch supports multiple types of gateways, including local file systems (default), distributed file systems, and Hadoop HDFS.

- **discovery.zen**

Indicates the automatic node discovery mechanism of Elasticsearch. Elasticsearch is a P2P system. It searches for existing nodes through broadcast and then communicates with nodes through multicast protocols. Elasticsearch supports P2P interaction.

- **Index**

Indicates the data storage mode of Elasticsearch and is similar to a table in relational database .

- **Document**

Is similar to the row of a relational database. Each document of the same index has a unique ID.

- **Field**

Is similar to the column in a relational database, which is the smallest unit of Elasticsearch data storage.

### 1.7.1.3 Application Development Process

[Figure 1-32](#) shows the Elasticsearch application development process.

Figure 1-32 Elasticsearch application development process

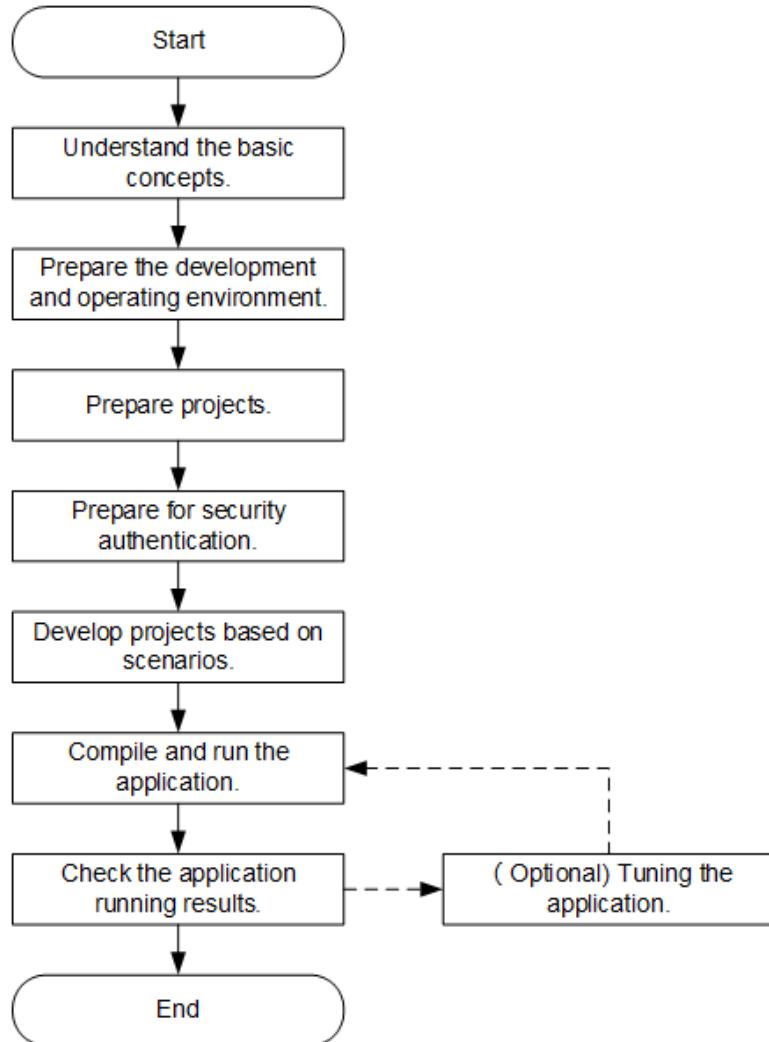

Table 1-12 Description of the Elasticsearch application development process

| Phase                                             | Description                                                                                                                                                                                                                                            | Reference                                                       |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| Understand basic concepts.                        | Before application development, learn basic concepts of Elasticsearch and understand scenario requirements.                                                                                                                                            | <a href="#">Concepts</a>                                        |
| Development Environment and Operating Environment | Elasticsearch applications support RESTful development using Java. You are advised to use the IDEA tool to configure development environments. Elasticsearch runs on an Elasticsearch client. Install and configure the client according to the guide. | <a href="#">Preparing Development and Operating Environment</a> |

| Phase                                    | Description                                                                                                                                                                                    | Reference                                                 |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| Prepare a project.                       | Elasticsearch provides sample projects for different scenarios. You can import a sample project to learn the application. You can also create an Elasticsearch project according to the guide. | <a href="#">Configuring and Importing Sample Projects</a> |
| Develop a project based on the scenario. | Provide a sample project using Java language, covering an entire process for sample projects from query index to deletion index.                                                               | <a href="#">Development Process</a>                       |
| Compile and run applications .           | You can compile the developed application and submit it for running.                                                                                                                           | <a href="#">Commissioning Process</a>                     |
| View application running results.        | Application running results are stored under a user-defined path. You can also view the application running status on the UI.                                                                  | <a href="#">Commissioning Process</a>                     |

## 1.7.2 Environment Preparation

### 1.7.2.1 Preparing Development and Operating Environment

#### Preparing Development Environment

**Table 1-13** describes the development environment and operating environment required for application development.

**Table 1-13** Development environment

| Item | Description                                                                                                                                                                                                                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OS   | <ul style="list-style-type: none"><li>• Development environment: Windows (Windows 7 or later is supported.)</li><li>• Operating environment: Windows or Linux. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul> |

| Item                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Installation of Maven        | Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development. |
| User development preparation | See <a href="#">Preparing a Developer Account</a> for configuration.                                                                         |
| 7-zip                        | It is a tool used to decompress *.zip and *.rar files. The 7-Zip 16.04 is supported.                                                         |

## Preparing an Operating Environment

During application development, you need to prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#) and choose **Homepage > Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.
  - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Elasticsearch\config** and manually import the configuration file to the configuration file directory (usually the **conf** folder) of the Elasticsearch sample project. The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory.
  - c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.  
Ensure that the difference between the client time and the cluster time is less than 5 minutes.  
For details about how to install a cluster client, see [Installing a Client](#).
  - b. **Accessing FusionInsight Manager of an MRS Cluster**. Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig\ Elasticsearch\config** directory to the **conf** directory where the compiled JAR package is stored for subsequent commissioning, for example, **/opt/hadoopclient/conf**.  
For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Elasticsearch/config/* root@IP address of the client node:/opt/hadoopclient/conf
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory.
  - c. Check the network connection of the client node.  
During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

### 1.7.2.2 Configuring and Importing Sample Projects

### 1.7.2.2.1 Overview

#### Background

Obtain the Elasticsearch development sample project. Import the project to IntelliJ IDEA for learning.

#### Prerequisites

Ensure that the time difference between the local PC and the cluster is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. Time of the cluster can be viewed in the lower-right corner on FusionInsight Manager.

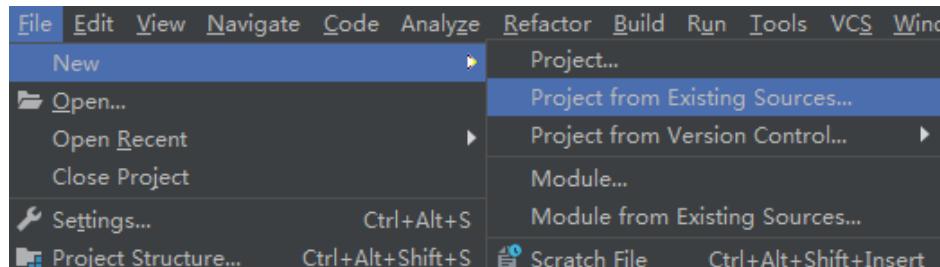

### 1.7.2.2 Importing a RestClient Sample Project

#### Procedure

**Step 1** Obtain the sample project folder **elasticsearch-rest-client-example** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.

1. Choose **File > New > Project from Existing Sources**.

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **elasticsearch-rest-client-example** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.
4. Select the recommended JDK version and click **Finish**.

**Step 3** Obtain the authentication credential file of the new user. Obtain the **user.keytab** and **krb5.conf** files during [Preparing a Developer Account](#) and copy them to the **conf** directory of the sample project for security authentication in the sample project.

**Step 4** Find the configuration file **es-rest-client-example.properties** exists in the client folder **Elasticsearch\config** directory. Copy the parameter values in the file to the **esParams.properties** file in the **conf** directory of the sample project.

**Step 5** In the IntelliJ IDEA development environment, open the **esParams.properties** file in the **conf** directory of the sample project, and change the values of the parameters listed in [Table 1-14](#) as required.

**Table 1-14** Configuration table

| Parameter                | Default Value                                     | Description                                                                                                                                                                                                                                                    |
|--------------------------|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| esServerHost             | Examples:<br>ip1:port1,ip2:port2<br>,ip3:port3... | Specifies the list of combinations of the IP addresses of nodes in the Elasticsearch cluster and the HTTP ports of the Elasticsearch instances installed on the nodes, except EsMaster instances.                                                              |
| connectTimeout           | 5000                                              | Specifies the timeout interval of the connection between the client and the server, in milliseconds.                                                                                                                                                           |
| socketTimeout            | 60,000                                            | Specifies the server response obtaining timeout interval of the client, in milliseconds.                                                                                                                                                                       |
| connectionRequestTimeout | 100000                                            | Indicates that the connection timeout interval is obtained from the connection pool, in milliseconds.                                                                                                                                                          |
| maxConnPerRoute          | 100                                               | Maximum number of connections per route.                                                                                                                                                                                                                       |
| maxConnTotal             | 1000                                              | Maximum number of connections                                                                                                                                                                                                                                  |
| isSecureMode             | true                                              | Indicates whether the client is in security mode. The value <b>true</b> indicates that the security mode is enabled, and the value <b>false</b> indicates that the normal mode is enabled.                                                                     |
| sslEnabled               | true                                              | Indicates whether SSL encryption is enabled on the client. The value <b>true</b> indicates that SSL encryption is enabled, and the value <b>false</b> indicates that SSL encryption is disabled. The value must be the same as that configured in the cluster. |
| principal                | esuser                                            | Specifies the authentication subject. The recommended format is "username". You can also use the format of "username@system domain name".                                                                                                                      |
| snifferEnable            | true                                              | Indicates whether the Rest client enables the sniffing function. The value <b>true</b> indicates that the sniffing function is enabled, and the value <b>false</b> indicates that the sniffing function is disabled.                                           |
| customJaasPath           | null                                              | User-defined path of the <b>jaas.conf</b> file, which must contain specific file name. If this parameter is not set, the system automatically generates a path.                                                                                                |

**Step 6** Set **isSecureMode** in the **esParams.properties** file in the **conf** directory of the sample project to **true** and enable the security mode.

 NOTE

- If an error is reported during sample code importing, use a later IntelliJ IDEA version.
- The HTTP request function of the EsMaster instance is disabled. The value of the **esServerHost** parameter does not contain the EsMaster instance, that is, the 24148 port. Otherwise, the request fails.
- Set **esServerHost** to the list of combinations. The combinations contain the IP addresses of all nodes in the Elasticsearch cluster and the HTTP ports of all Elasticsearch instances installed on the nodes, for example, ip1: Port1, ip2:port2, ip3:port3. You can query the port number as follows: On FusionInsight Manager, choose **Cluster > Name of the desired cluster > Services > Elasticsearch > Configurations > All Configurations**. Click **Port** of the corresponding instance and check the value of **SERVER\_PORT**.
- To check whether the Elasticsearch cluster is in security mode or normal mode, log in to FusionInsight Manager, choose **Cluster > Name of the desired cluster > Services > Elasticsearch > Configurations > All Configurations**, and search for **ELASTICSEARCH\_SECURITY\_ENABLE** parameter. If this parameter can be queried and its value is **true**, the Elasticsearch cluster is in security mode. If this parameter is not found or its value is **false**, the Elasticsearch cluster is in normal mode.
- You can log in to the Manager, choose **System > Permission > Domain and Mutual Trust**, and check the value of **Local Domain**, which is the current system domain name. For example, if the cluster domain name is **9427068F-6EFA-4833-B43E-60CB641E5B6C.COM**, the value of **principal** is **esuser@9427068F-6EFA-4833-B43E-60CB641E5B6C.COM**.
- You can customize the file path of **jaas.conf** by setting the **customJaasPath** parameter. If there is no such requirement, you can leave this parameter empty. The system automatically generates a path.

----End

### 1.7.2.2.3 Importing a SpringBoot Sample Project

#### Scenario

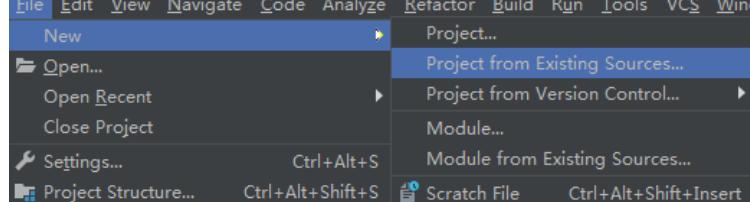

To run the SpringBoot interface sample code of the Elasticsearch component of MRS, perform the following operations.

The following example develops an application that uses SpringBoot to connect to Impala in the Windows environment.

#### Procedure

- Step 1** Obtain the sample project folder **elasticsearch-rest-client-example** in the **src/springboot/elasticsearch-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Import the sample project to the IntelliJ IDEA development environment in the application development environment.

1. Choose **File > New > Project from Existing Sources....**

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **elasticsearch-rest-client-example** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.

Select the recommended JDK version and click **Finish**.

- Step 3** Obtain the authentication credential file of the new user. Obtain the **user.keytab** and **krb5.conf** files obtained during [Preparing a Developer Account](#) and copy them to the **conf** directory of the sample project for security authentication.
- Step 4** Find configuration file **es-rest-client-example.properties** in the **Elasticsearch \config** directory of the client folder. Copy the parameter values in the file to the **esParams.properties** file in the **conf** directory of the sample project.
- Step 5** In the IntelliJ IDEA development environment, open the **esParams.properties** file in the **conf** directory of the sample project, and change the values of the parameters listed in [Table 1-15](#).

**Table 1-15** Configuration table

| Parameter                | Default Value                    | Description                                                                                                                                                                                                             |
|--------------------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| esServerHost             | ip1:port1,ip2:port2,ip3:port3... | List of combinations of the IP addresses of nodes in the Elasticsearch cluster and the HTTP ports of the Elasticsearch instances installed on the nodes, except EsMaster instances.                                     |
| connectTimeout           | 5000                             | Timeout interval of the connection between the client and the server, in milliseconds.                                                                                                                                  |
| socketTimeout            | 60000                            | Server response obtaining timeout interval of the client, in milliseconds.                                                                                                                                              |
| connectionRequestTimeout | 100000                           | Connection timeout interval is obtained from the connection pool, in milliseconds.                                                                                                                                      |
| maxConnPerRoute          | 100                              | Maximum number of connections on each route                                                                                                                                                                             |
| maxConnTotal             | 1000                             | Maximum number of connections                                                                                                                                                                                           |
| isSecureMode             | true                             | Whether the client is in security mode. The value <b>true</b> indicates that the security mode is enabled, and the value <b>false</b> indicates that the normal mode is enabled.                                        |
| sslEnabled               | true                             | Whether to enable SSL encryption on the client. <b>true</b> indicates that encryption is enabled, and <b>false</b> indicates that encryption is disabled. The value must be the same as that configured in the cluster. |

| Parameter      | Default Value | Description                                                                                                                                                                                                |
|----------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| principal      | esuser        | Authentication subject. The options are as follows: <ul style="list-style-type: none"><li>• <b>Username</b> (recommended)</li><li>• <i>Username@System domain name</i></li></ul>                           |
| snifferEnable  | true          | Whether the REST Client enables the sniffing function. The value <b>true</b> indicates that the sniffing function is enabled, and the value <b>false</b> indicates that the sniffing function is disabled. |
| customJaasPath | N/A           | User-defined path of the <b>jaas.conf</b> file, which must contain specific file name. If this parameter is not set, the system automatically generates a path.                                            |

**Step 6** Set **isSecureMode** in the **esParams.properties** file in the **conf** directory of the sample project to **true** and enable the security mode.

 **NOTE**

- If an error is reported during sample code importing, use IntelliJ IDEA of a later version.
- The HTTP request function of the EsMaster instance is disabled. The value of the **esServerHost** parameter does not contain the EsMaster instance, that is, the 24148 port. Otherwise, the request fails.
- Set **esServerHost** to a list of combinations of IP addresses of nodes in the installed Elasticsearch cluster and HTTP ports of Elasticsearch instances installed on the nodes, for example, *ip1:port1,ip2:port2,ip3:port3...*. To query the port number, choose **Cluster > Services > Elasticsearch** on FusionInsight Manager, click **Configuration**, click **All Configurations**, click **Port** of the corresponding instance, and check the value of **SERVER\_PORT**.
- To check whether the current Elasticsearch cluster is in security mode or common mode, log in to FusionInsight Manager, choose **Cluster > Services > Elasticsearch**, click **Configuration**, click **All Configurations**, and search for the **ELASTICSEARCH\_SECURITY\_ENABLE** parameter. If the parameter can be queried and its value is **true**, the Elasticsearch cluster is in security mode. If this parameter cannot be queried or the value of this parameter is **false**, the Elasticsearch cluster is in normal mode.
- *System domain name*: log in to FusionInsight Manager, choose **System > Permission > Domain and Mutual Trust**, and check the value of **Local Domain**. For example, if **Local Domain** is set to *XXX.COM*, the value of **principal** is **esuser@XXX.COM**.
- You can set the **customJaasPath** parameter to customize the path of the **jaas.conf** file. Leave this parameter blank if it is not required, and the system automatically generates a path.

----End

### 1.7.2.3 Preparing for Security Authentication

#### Scenarios

In a security cluster environment, the components must be mutually authenticated before communicating with each other to ensure communication

security. Spnego security authentication is required for Elasticsearch application development. Spnego authentication is a security protocol expending Kerberos and using GSS-API authentication mechanism. Security authentication is typically code-based. The **krb5.conf**, and **user.keytab** files are used together to support the Oracle Java and IBM Java platforms.

**krb5.conf** and **user.keytab** are obtained in **Preparing a Development Account** and are stored in the **conf** directory of the sample project.

 NOTE

On the RestClient client, change the value of **principal** in the **esParams.properties** file in the **conf** directory of the sample project to *new username@<system domain name>*.

## 1.7.3 Development Process

### 1.7.3.1 Typical Application Scenarios

You can quickly learn and master the Elasticsearch development process and know key API functions in a typical application scenario.

#### Scenario Description

Assume that you want to develop an application to search for all library information, provide information about books related to search keywords, and grade the books by score. The search function can be implemented by Elasticsearch. The search process is as follows:

1. Connecting the client to a cluster
2. Querying the health status
3. Checking whether a specified index exists
4. Creating an index for specifying the number of shards
5. Writing index data
6. Writing data in batches
7. Batch write data to specified routes
8. Querying index information
9. Deleting an index
10. Deleting documents in an index
11. Refreshing an index
12. Using a multi-thread sample for query
13. Pre-sorting indices

### 1.7.3.2 Low Level Rest Client Sample Code

### 1.7.3.2.1 Connecting the Elasticsearch Client to an Elasticsearch Cluster

#### Function Description

Before using APIs provided by Elasticsearch, you need to obtain the Elasticsearch client. Connect the Elasticsearch client to the desired Elasticsearch cluster by setting the IP address and port number of the cluster.

##### NOTE

Call **RestClient.close()** to close requested resources after the Elasticsearch operation is complete.

```
public static void main(String[] args) {
    HwRestClient hwRestClient = new HwRestClient();
    RestClient restClient = hwRestClient.getRestClient();
    try {
        /...
    } catch (Exception e) {
        LOG.error("There are exceptions occurred.", e);
    } finally {
        if (restClient != null) {
            try {
                restClient.close();
                LOG.info("Close the client successful.");
            } catch (Exception e1) {
                LOG.error("Close the client failed.", e1);
            }
        }
    }
}
```

##### NOTE

- By default, the HwRestClient reads the following configuration files from the **conf** directory in the code running path: **esParams.properties**, **krb5.conf**, and **user.keytab**.
- The configuration file path can be customized. For example, if the code runs in the Windows operating system, and the configuration files are stored in the root directory of drive D, you can set **HwRestClient hwRestClient** to **new HwRestClient("D:\\")**.

### 1.7.3.2.2 Querying Cluster Information

#### Function

**QueryClusterInfo.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/cluster** directory is used to query information about the Elasticsearch cluster.

```
/*
 * Query the cluster's information
 */
public static void queryClusterInfo(RestClient restClientTest) {

    Response response;
    try {
        Request request=new Request("GET", "/_cluster/health");
        //Process the returned result to display it more intuitively
        request.addParameter("pretty", "true");
        response = restClientTest.performRequest(request);
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
            LOG.info("QueryClusterInfo successful.");
        } else {
            LOG.error("QueryClusterInfo failed.");
        }
    }
```

```
        }
        LOG.info("QueryClusterInfo response entity is : {}. ",EntityUtils.toString(response.getEntity()));
    } catch (Exception e) {
        LOG.error("QueryClusterInfo failed, exception occurred.", e);
    }
}
```

### 1.7.3.2.3 Checking Whether the Specified Index Exists

#### Function

**IndexExist.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/exist** directory is used to check whether the specified index exists in the Elasticsearch cluster.

```
/*
 * Check the existence of the index or not.
 */
public static void boolean(RestClient restClientTest, String index) {

    Response response;
    try {
        Request request = new Request("HEAD", "/" + index);
        response = restClientTest.performRequest(request);
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
            LOG.info("***** Check index successful,index is exist : " + index + " *****");
        }
        if (HttpStatus.SC_NOT_FOUND == response.getStatusLine().getStatusCode()) {
            LOG.info("Check index successful,index is exist : {}.");
        }
        return true;
    }
    if (HttpStatus.SC_NOT_FOUND == response.getStatusLine().getStatusCode()) {
        LOG.info("Index is not exist : {}.");
    }
    return false;
} catch (Exception e) {
    LOG.error("Check index failed, exception occurred.", e);
}
return false;
}
```

### 1.7.3.2.4 Creating an Index with the Desired Number of Shards

#### Function

**CreateIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/index** directory is used to create an index of numbers of specified primary shards and replica shards.

Set variables *shardNum* and *replicaNum* in the following code, that is, the number of primary shards and the number of replica shards.

```
/*
 * Create one index with customized shard number and replica number.
 */
public static void createIndexWithShardNum(RestClient restClientTest, String index) {

    Response rsp;
    int shardNum = 3;
    int replicaNum = 1;
```

```

String jsonString =
    "{" + "\"settings\":{\":" + "\"number_of_shards\":\"" + shardNum + "\",\"" + "\"number_of_replicas\":\""
+ replicaNum + "\"}}";
    HttpEntity entity = new NStringEntity(jsonString, ContentType.APPLICATION_JSON);
try {
    Request request = new Request("PUT", "/" + index);
    request.addParameter("pretty", "true");
    request.setEntity(entity);
    rsp = restClientTest.performRequest(request);
    if (HttpStatus.SC_OK == rsp.getStatusLine().getStatusCode()) {
        LOG.info("CreateIndexWithShardNum successful.");
    } else {
        LOG.error("CreateIndexWithShardNum failed.");
    }
    LOG.info("CreateIndexWithShardNum response entity is : {}.", EntityUtils.toString(rsp.getEntity()));
} catch (Exception e) {
    LOG.error("CreateIndexWithShardNum failed, exception occurred.", e);
}
}

```

### 1.7.3.2.5 Writing Index Data

#### Function

**PutData.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/index** directory is used to insert data into a specified index, to update the index.

Variable **jsonString** of **String** indicates the data to be inserted. The value is user-defined.

```

/**
 * Write one document into the index
 */
public static void putData(RestClient restClientTest, String index, String type, String id) {

    Gson gson = new Gson();
    Map<String, Object> esMap = new HashMap<>();
    esMap.put("name", "Happy");
    esMap.put("author", "Alex Yang");
    esMap.put("pubinfo", "Beijing,China");
    esMap.put("pubtime", "2020-01-01");
    esMap.put("description", "Elasticsearch is a highly scalable open-source full-text search and analytics
engine.");
    String jsonString = gson.toJson(esMap);

    HttpEntity entity = new NStringEntity(jsonString, ContentType.APPLICATION_JSON);
    Response rsp;

    try {
        Request request = new Request("POST", "/" + index + "/" + type + "/" + id);
        request.addParameter("pretty", "true");
        request.setEntity(entity);
        rsp = restClientTest.performRequest(request);
        if (HttpStatus.SC_OK == rsp.getStatusLine().getStatusCode() || HttpStatus.SC_CREATED ==
rsp.getStatusLine().getStatusCode()) {
            LOG.info("PutData successful.");
        } else {
            LOG.error("PutData failed.");
        }
        LOG.info("PutData response entity is : {}.", EntityUtils.toString(rsp.getEntity()));
    } catch (Exception e) {
        LOG.error("PutData failed, exception occurred.", e);
    }
}

```

### 1.7.3.2.6 Writing Data in Batches

#### Function

**Bulk.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/bulk` directory is used to insert data into a specified index in batches.

**totalRecordNumber** indicates the total number of documents to be inserted, and **oneCommit** indicates the number of documents to be inserted at a time. Data added to **esMap** is the data to be written into the index.

```
/*
 * Send a bulk request
 */
private static void bulk(RestClient restClientTest, String index) {
    //Total number of documents to be written
    long totalRecordNum = 10000;
    //Number of documents written in a bulk
    long oneCommit = 1000;
    long circleNumber = totalRecordNum / oneCommit;
    StringEntity entity;
    Gson gson = new Gson();
    Map<String, Object> esMap = new HashMap<>();
    String str = "{ \"index\" : { \"_index\" : \"\" + index + "\" } }";
    for (int i = 1; i <= circleNumber; i++) {
        StringBuilder builder = new StringBuilder();
        for (int j = 1; j <= oneCommit; j++) {
            esMap.clear();
            esMap.put("name", "Linda");
            esMap.put("age", ThreadLocalRandom.current().nextInt(18, 100));
            esMap.put("height", (float)ThreadLocalRandom.current().nextInt(140, 220));
            esMap.put("weight", (float)ThreadLocalRandom.current().nextInt(70, 200));
            esMap.put("cur_time", System.currentTimeMillis());
            String strJson = gson.toJson(esMap);
            builder.append(str).append("\n");
            builder.append(strJson).append("\n");
        }
        entity = new StringEntity(builder.toString(), ContentType.APPLICATION_JSON);
        entity.setContentType("UTF-8");
        Response response;
        try {
            Request request = new Request("PUT", "/_bulk");
            request.addParameter("pretty", "true");
            request.setEntity(entity);
            response = restClientTest.performRequest(request);
            if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
                LOG.info("Already input documents : " + oneCommit * i);
            } else {
                LOG.error("Bulk failed.");
            }
            LOG.info("Bulk response entity is : " + EntityUtils.toString(response.getEntity()));
        } catch (Exception e) {
            LOG.error("Bulk failed, exception occurred.", e);
        }
    }
}
```

### 1.7.3.2.7 Batch write data to specified routes

#### Function

**BulkRoutingSample.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/bulk` directory

is used to set routing for each request in the bulk, route documents with the same routing to the same segment, and specify routing during query to narrow the query range and improve the query speed.

```
/*
 * Number of documents to be written.
 */
private static final int NUM_OF_DOC = 100;

/**
 * Use bulk to write data and specify routing.
 */
private static void bulkWithRouting(RestClient restClient, String indexName) {
    StringEntity entity;
    Gson gson = new Gson();
    Map<String, Object> esMap = new HashMap<>();
    String str = "{ \"index\" : { \"_index\" : \"\" + indexName + "\"}";
    StringBuilder sb = new StringBuilder();
    int age;
    for (int i = 1; i <= NUM_OF_DOC; i++) {
        esMap.clear();
        esMap.put("user", "Linda" + i);
        age = ThreadLocalRandom.current().nextInt(18, 100);
        esMap.put("age", age);
        esMap.put("postDate", "2020-01-01");
        esMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
        esMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
        String strJson = gson.toJson(esMap);
        // Route documents of the same age to the same shard based on the age.
        sb.append(str).append("\"routing\":\"").append(age).append("\"\")").append("\n");
        sb.append(strJson).append("\n");
    }
    entity = new StringEntity(sb.toString(), ContentType.APPLICATION_JSON);
    entity.setContentType("UTF-8");
    Response response;
    try {
        Request request = new Request("PUT", "_bulk");
        request.addParameter("pretty", "true");
        request.setEntity(entity);
        response = restClient.performRequest(request);
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
            LOG.info("Bulk routing is successful.");
        } else {
            LOG.error("Bulk routing is failed.");
        }
    } catch (IOException e) {
        LOG.error("Bulk routing is failed, exception occurred.", e);
    }
}
```

### 1.7.3.2.8 Querying Index Information

#### Function

**QueryData.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/search** directory is used to query information about a document with specified **index**, **type**, and **id**.

```
/*
 * Query all data of one index.
 */
public static void queryData(RestClient restClientTest, String index, String type, String id){

    Response response;
    try {
        Request request = new Request("GET", "/" + index + "/" + type + "/" + id);
        request.addParameter("pretty", "true");
    }
```

```
response = restClientTest.performRequest(request);
if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
    LOG.info("QueryData successful.");
} else {
    LOG.error("QueryData failed.");
}
LOG.info("QueryData response entity is : {}.", EntityUtils.toString(response.getEntity()));
} catch (Exception e) {
    LOG.error("QueryData failed, exception occurred.", e);
}
}
```

### 1.7.3.2.9 Deleting an Index

#### Function

**DeleteIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/delete** directory is used to delete a specified index.

```
/**
 * Delete one index
 */
public static void deleteIndex(RestClient restClientTest, String index) {

    Response response;
    try {
        Request request = new Request("DELETE", "/" + index + "?&pretty=true");
        response = restClientTest.performRequest(request);
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
            LOG.info("DeleteIndex successful.");
        } else {
            LOG.error("DeleteIndex failed.");
        }
        LOG.info("DeleteIndex response entity is : {}.", EntityUtils.toString(response.getEntity()));
    } catch (Exception e) {
        LOG.error("DeleteIndex failed, exception occurred.", e);
    }
}
```

### 1.7.3.2.10 Deleting Some Documents in the Index

#### Function

**DeleteSomeDocumentsInIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/delete** directory is used to refresh a specified index.

```
/**
 * Delete some documents by query in one index
 */
public static void deleteSomeDocumentsInIndex(RestClient restClientTest, String index, String field, String value) {
    String jsonString =
        "\n" +
        "  \"query\": {\n" +
        "    \"match\": { \"" + field + "\": \"" + value + "\"}\n" +
        "  }\n";
    Map<String, String> params = Collections.singletonMap("pretty", "true");
    HttpEntity entity = new NStringEntity(jsonString, ContentType.APPLICATION_JSON);
    Response rsp;
    try {
        rsp = restClientTest.performRequest("POST", "/" + index + "/_delete_by_query", params, entity);
        if (HttpStatus.SC_OK == rsp.getStatusLine().getStatusCode()) {
            LOG.info("DeleteSomeDocumentsInIndex successful.");
        }
    }
```

```
        else {
            LOG.error("DeleteSomeDocumentsInIndex failed.");
        }
        LOG.info("DeleteSomeDocumentsInIndex response entity is : " +
EntityUtils.toString(rsp.getEntity()));
    }
    catch (Exception e) {
        LOG.error("DeleteSomeDocumentsInIndex failed, exception occurred.", e);
    }
}
```

### 1.7.3.2.11 Deleting All Documents in the Index

#### Function

**DeleteAllDocumentsInIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/delete** directory is used to refresh a specified index.

```
/**
 * Delete all documents by query in one index
 */
public static void deleteAllDocumentsInIndex(RestClient restClientTest, String index) {

    String jsonString = "{\n" + " \\"query\\": {\n" + " \\"match_all\\": {}\n" + " }\n" + "}";

    HttpEntity entity = new NStringEntity(jsonString, ContentType.APPLICATION_JSON);
    Response response;
    try {
        response = restClientTest.performRequest("POST", "/" + index + "/_delete_by_query", params,
entity);
        if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
            LOG.info("DeleteAllDocumentsInIndex successful.");
        } else {
            LOG.error("DeleteAllDocumentsInIndex failed.");
        }
        LOG.info("DeleteAllDocumentsInIndex response entity is :
{}.", EntityUtils.toString(response.getEntity()));
    } catch (Exception e) {
        LOG.error("DeleteAllDocumentsInIndex failed, exception occurred.", e);
    }
}
```

### 1.7.3.2.12 Refreshing an Index

#### Refreshing a Single Index

**Flush.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/flush** directory is used to refresh a specified index.

```
/**
 * Flush one index data to storage and clearing the internal transaction log
 */
public static void flushOneIndex(RestClient restClientTest, String index) {

    Response flushRsp;
    try {
        Request request=new Request("POST", "/" + index + "/_flush");
        request.addParameter("pretty", "true");
        flushRsp = restClientTest.performRequest(request);
        LOG.info(EntityUtils.toString(flushRsp.getEntity()));
    }
}
```

```
if (HttpStatus.SC_OK == flushRsp.getStatusLine().getStatusCode()) {
    LOG.info("Flush one index successful.");
} else {
    LOG.error("Flush one index failed.");
}
LOG.info("Flush one index response entity is : {}", EntityUtils.toString(flushRsp.getEntity()));
} catch (Exception e) {
    LOG.error("Flush one index failed, exception occurred.", e);
}
```

## Refreshing all Indexes

**Flush.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/flush** directory is used to refresh all indexes.

```
/*
 * Flush all indexes data to storage and clearing the internal transaction log
 * The user who performs this operation must belong to the "supergroup" group.
 */
private static void flushAllIndexes(RestClient restClientTest) {
    Map<String, String> params = Collections.singletonMap("pretty", "true");
    Response flushRsp;
    try {
        flushRsp = restClientTest.performRequest("POST", "/_all/_flush", params);
        if (HttpStatus.SC_OK == flushRsp.getStatusLine().getStatusCode()) {
            LOG.info("Flush all indexes successful.");
        } else {
            LOG.error("Flush all indexes failed.");
        }
        LOG.info("Flush all indexes response entity is : " + EntityUtils.toString(flushRsp.getEntity()));
    } catch (Exception e) {
        LOG.error("Flush all indexes failed, exception occurred.", e);
    }
}
```

### 1.7.3.2.13 Multi-Thread Example

#### Function

**MultithreadRequest.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/multithread** directory is used to create a thread class **sendRequestThread**, rewrite a **run** method, implement a **bulk** request, and write data in batches.

```
/*
 * Thread that sends bulk request
 */
public static class sendRequestThread implements Runnable {
    private RestClient restClientTh;
    private HwRestClient hwRestClient;
    @Override
    public void run() {
        LOG.info("Thread begin.");
        try {
            hwRestClient = new HwRestClient();
            restClientTh = hwRestClient.getRestClient();
            LOG.info("Thread name: " + Thread.currentThread().getName());
            bulk(restClientTh, "huawei1", "type1");
        } catch (Exception e) {
            LOG.error("SendRequestThread has exception.", e);
        } finally {
            if (restClientTh != null) {
```

```
        try {
            restClientTh.close();
            LOG.info("Close the client successful in thread : " + Thread.currentThread().getName());
        } catch (IOException e) {
            LOG.error("Close the client failed.", e);
        }
    }
}
```

In the main method, the **fixedThreadPool** thread pool is created. By specifying **threadPoolSize** and **jobNumber**, multiple threads are supported to send **bulk** requests and data can be concurrently written in batches.

```
public static void main(String[] args) throws Exception {  
    LOG.info("Start to do multithread request !");  
    ExecutorService fixedThreadPool;  
    HwRestClient hwRestClient = new HwRestClient();  
    RestClient restClientThNew;  
    restClientThNew = hwRestClient.getRestClient();  
    int threadPoolSize = 2;  
    int jobNumber = 5;  
    try {  
        fixedThreadPool = Executors.newFixedThreadPool(threadPoolSize);  
        for (int i = 0; i < jobNumber; i++) {  
            fixedThreadPool.execute(new sendRequestThread());  
        }  
        fixedThreadPool.shutdown();  
    } catch (Exception e) {  
        LOG.error("There are exceptions in sendRequestThread.", e);  
    } finally {  
        if (restClientThNew != null) {  
            try {  
                restClientThNew.close();  
                LOG.info("Close the client successful.");  
            } catch (Exception e1) {  
                LOG.error("Close the client failed.", e1);  
            }  
        }  
    }  
}
```

#### 1.7.3.2.14 Pre-sorting Indices

## Function Description

The `IndexSorting.java` file in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/lowlevel/index` directory is used to configure the fields to be sorted when an index is created, implement the `bulk` request, write data in batches, and query the top N documents.

During index creation, specify the fields to be sorted and specify whether each field is sorted in descending or ascending order.

```
private static void createIndexWithSorting(RestClient restClient, String index) {  
    Response rsp;  
    String jsonString;  
    jsonString = "{\"settings\":{\"number_of_shards\":\"3\", \"number_of_replicas\":\"1\",  
        + \"sort.field\": [\"height\",\"weight\"],\"sort.order\": [\"desc\",\"asc\"]},\"mappings\":{  
        + \"properties\":{\"height\":{\"type\":\"float\"},\"weight\":{\"type\":\"float\"}}}}";  
    HttpEntity entity = new StringEntity(jsonString, ContentType.APPLICATION_JSON);  
    try {
```

```

Request request = new Request("PUT", "/" + index);
request.addParameter("pretty", "true");
request.setEntity(entity);
rsp = restClient.performRequest(request);
if (rsp.getStatusLine().getStatusCode() == HttpStatus.SC_OK) {
    LOG.info("Create index with sorting successfully.");
} else {
    LOG.error("Create index with sorting failed.");
}
LOG.info("Create index with sorting response entity is {}.", EntityUtils.toString(rsp.getEntity()));
} catch (IOException | ParseException e) {
    LOG.error("Failed to create index with sorting, exception occurred.", e);
}
}

```

Then, write data in batches.

```

public static void bulk(RestClient restClientTest, String index) {
    // Total number of documents to be written
    long totalRecordNum = 10000;
    // Number of documents written in each bulk. The recommended size is 5 MB to 15 MB.
    long oneCommit = 1000;
    long circleNumber = totalRecordNum / oneCommit;
    StringEntity entity;
    Gson gson = new Gson();
    Map<String, Object> esMap = new HashMap<>();
    String str = "{ \"index\" : { \"_index\" : \"" + index + "\" } }";

    for (int i = 1; i <= circleNumber; i++) {
        StringBuilder builder = new StringBuilder();
        for (int j = 1; j <= oneCommit; j++) {
            esMap.clear();
            esMap.put("name", "Linda");
            esMap.put("age", ThreadLocalRandom.current().nextInt(18, 100));
            esMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
            esMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
            esMap.put("cur_time", System.currentTimeMillis());

            String strJson = gson.toJson(esMap);
            builder.append(str).append(System.lineSeparator());
            builder.append(strJson).append(System.lineSeparator());
        }
        entity = new StringEntity(builder.toString(), ContentType.APPLICATION_JSON);
        entity.setContentEncoding("UTF-8");
        Response response;
        try {
            Request request = new Request("PUT", "/_bulk");
            request.addParameter("pretty", "true");
            request.setEntity(entity);
            response = restClientTest.performRequest(request);
            if (HttpStatus.SC_OK == response.getStatusLine().getStatusCode()) {
                LOG.info("Already input documents : {}.", oneCommit * i);
            } else {
                LOG.error("Bulk failed.");
            }
            LOG.info("Bulk response entity is : {}.", EntityUtils.toString(response.getEntity()));
        } catch (IOException | ParseException e) {
            LOG.error("Bulk failed, exception occurred.", e);
        }
    }
}

```

Perform the refresh operation so that the data can be queried after being written in batches.

```

private static void refresh(RestClient restClient, String index) {
    try {
        Map<String, String> params = Collections.singletonMap("pretty", Boolean.TRUE.toString());
        Response rsp = restClient.performRequest(buildRequest("POST", "/" + index + "/_refresh", params,
null));
        if (rsp.getStatusLine().getStatusCode() == HttpStatus.SC_OK) {

```

```
        LOG.info("Refresh sorting index successfully.");
    }
} catch (IOException e) {
    LOG.error("Failed to refresh sorting index, exception occurred.", e);
}
}
```

Then, you can query the sorting field. By default, the top 10 documents are obtained.

```
private static void queryData(RestClient restClient, String index) {
    Response response;
    String jsonStr;
    jsonStr = "{\"sort\":{\"height\":{“desc”:”desc\\”, “weight”:“asc\\”}},“track_total_hits”: false}”;
    StringEntity entity = new StringEntity(jsonStr, ContentType.APPLICATION_JSON);
    try {
        Request request = new Request("GET", "/" + index + "/_search");
        request.addParameter("pretty", "true");
        request.setEntity(entity);
        response = restClient.performRequest(request);
        if (response.getStatusLine().getStatusCode() == HttpStatus.SC_OK) {
            LOG.info("Query sorting index successfully.");
        } else {
            LOG.error("Failed to query sorting index.");
        }
        LOG.info("Query sorting index response entity is {}.", EntityUtils.toString(response.getEntity()));
    } catch (IOException | ParseException e) {
        LOG.error("Failed to query sorting index, exception occurred.", e);
    }
}
```

### 1.7.3.3 High Level Rest Client Sample Code

#### 1.7.3.3.1 Connecting the Client to a Cluster

## Function

You can obtain the client and connect to a specific Elasticsearch cluster by setting the IP address and port. This is necessary before you use the API provided by the Elasticsearch.

Call **RestHighLevelClient.close()** to close requested resources after the Elasticsearch service operation is complete.

```
public static void main(String[] args) {
    RestHighLevelClient highLevelClient = null;
    HwRestClient hwRestClient = new HwRestClient();
    try {
        highLevelClient = new RestHighLevelClient(hwRestClient.getRestClientBuilder());
        /...
    } finally {
        try {
            if (highLevelClient != null) {
                highLevelClient.close();
            }
        } catch (IOException e) {
            LOG.error("Failed to close RestHighLevelClient.", e);
        }
    }
}
```

#### NOTE

- By default, the HwRestClient reads the following configuration files from the **conf** directory in the code running path: **esParams.properties**, **krb5.conf**, and **user.keytab**.
- The configuration file path can be customized. For example, if the code runs in the Windows operating system, and the configuration files are stored in the root directory of drive D, you can set **HwRestClient hwRestClient** to **new HwRestClient("D:\\")**.

### 1.7.3.3.2 Querying Cluster Status Information

#### Function

**QueryClusterInfo.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/cluster** directory is used to query information about the Elasticsearch cluster.

```
/*
 * Get cluster information
 */
public static void queryClusterInfo(RestHighLevelClient highLevelClient) {

    try {
        MainResponse response = highLevelClient.info(RequestOptions.DEFAULT);
        ClusterName clusterName = response.getClusterName();
        LOG.info("ClusterName:[{}], clusterUuid:[{}], nodeName:[{}], version:[{}].", new Object[]
        { clusterName.value(),
            response.getClusterUuid(), response.getNodeName(), response.getVersion().toString() });
    } catch (Exception e) {
        LOG.error("QueryClusterInfo is failed,exception occurred.", e);
    }
}
```

### 1.7.3.3.3 Writing Index Data

Data can be written to a specified index by specifying data sources in different formats, such as a character string in the JSON format, a data source in the Map format, and a data source in the XContentBuilder format.

#### Writing Data by Using the Character String in the JSON Format

**IndexByJson.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/index** directory is used to write data into a specified index by using a data source in the JSON format.

The variable *jsonString* is data to be inserted and can be customized.

```
/*
 * Create or update index by json
 */
public static void indexByJson(RestHighLevelClient highLevelClient, String index, String type, String id) {
    try {
        IndexRequest indexRequest = new IndexRequest(index, type, id);
        String jsonString = "{" + "\"user\":\"kimchy1\"," + "\"age\":\"100\"," + "\"postDate\"
        ":"2020-01-01",
            + "\"message\":\"trying out Elasticsearch\"," + "\"reason\":\"daily update\",
            + "\"innerObject1\":\"Object1\"," + "\"innerObject2\":\"Object2\",
            + "\"innerObject3\":\"Object3\"," + "\"uid\":\"11\"}";
        indexRequest.source(jsonString, XContentType.JSON);
        IndexResponse indexResponse = highLevelClient.index(indexRequest, RequestOptions.DEFAULT);

        LOG.info("IndexByJson response is {}.", indexResponse.toString());
    } catch (Exception e) {
```

```
        LOG.error("IndexByJson is failed,exception occurred.", e);
    }
```

## Writing Data in the Map Format

**IndexByMap.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/index** directory is used to write data into a specified index by using a data source in the MAP format.

The variable *dataMap* is data to be inserted and can be customized.

```
/*
 * Create or update index by map
 */
public static void indexByMap(RestHighLevelClient highLevelClient, String index, String type, String id) {
    try {
        Map<String, Object> dataMap = new HashMap<>();
        dataMap.put("user", "kimchy2");
        dataMap.put("age", "200");
        dataMap.put("postDate", new Date());
        dataMap.put("message", "trying out Elasticsearch");
        dataMap.put("reason", "daily update");
        dataMap.put("innerObject1", "Object1");
        dataMap.put("innerObject2", "Object2");
        dataMap.put("innerObject3", "Object3");
        dataMap.put("uid", "22");
        IndexRequest indexRequest = new IndexRequest(index, type, id).source(dataMap);
        IndexResponse indexResponse = highLevelClient.index(indexRequest, RequestOptions.DEFAULT));

        LOG.info("IndexByMap response is {}.", indexResponse.toString());
    } catch (Exception e) {
        LOG.error("IndexByMap is failed,exception occurred.", e);
    }
}
```

## Writing Data in the XContentBuilder format

**IndexByXContentBuilder.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/index** directory is used to write data into a specified index by using a data source in the XContentBuilder format.

The variable *builder* is data to be inserted and can be customized.

```
/*
 * Create or update index by XContentBuilder
 */
public static void indexByXContentBuilder(RestHighLevelClient highLevelClient, String index, String type, String id) {

    try {
        XContentBuilder builder = XContentFactory.jsonBuilder();
        builder.startObject();
        {
            builder.field("user", "kimchy3");
            builder.field("age", "300");
            builder.field("postDate", "2020-01-01");
            builder.field("message", "trying out Elasticsearch");
            builder.field("reason", "daily update");
            builder.field("innerObject1", "Object1");
            builder.field("innerObject2", "Object2");
            builder.field("innerObject3", "Object3");
            builder.field("uid", "33");
        }
    }
}
```

```
builder.endObject();
IndexRequest indexRequest = new IndexRequest(index, type, id).source(builder);
IndexResponse indexResponse = highLevelClient.index(indexRequest, RequestOptions.DEFAULT);

LOG.info("IndexByXContentBuilder response is {}", indexResponse.toString());
} catch (Exception e) {
    LOG.error("IndexByXContentBuilder is failed,exception occurred.", e);
}
```

#### 1.7.3.3.4 Operations in Batches

### Function

**Bulk.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/bulk** directory is used to perform operations in batches, for example, create an index, update an index, or delete an index.

```
/*
 * Bulk request can be used to execute multiple index,update or delete
 * operations using a single request.
 */
private static void bulk(RestHighLevelClient highLevelClient, String index, String type) {

    try {
        Map<String, Object> jsonMap = new HashMap<>();
        for (int i = 1; i <= 100; i++) {
            BulkRequest request = new BulkRequest();
            for (int j = 1; j <= 1000; j++) {
                jsonMap.clear();
                jsonMap.put("user", "Linda");
                jsonMap.put("age", ThreadLocalRandom.current().nextInt(18, 100));
                jsonMap.put("postDate", "2020-01-01");
                jsonMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
                jsonMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
                request.add(new IndexRequest(index, type).source(jsonMap));
            }
            BulkResponse bulkResponse = highLevelClient.bulk(request, RequestOptions.DEFAULT);

            if (RestStatus.OK.equals((bulkResponse.status()))) {
                LOG.info("Bulk is successful");
            } else {
                LOG.info("Bulk is failed");
            }
        }
    } catch (Exception e) {
        LOG.error("Bulk is failed,exception occurred.", e);
    }
}
```

#### 1.7.3.3.5 Batch write data to specified routes

### Function

**BulkRoutingSample.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/bulk** directory is used to set routing for each request in the bulk, route documents with the same routing to the same segment, and specify routing during query to narrow the query range and improve the query speed.

```
/*
 * Number of documents to be written.
 */
```

```
private static final int NUM_OF_DOC = 100;

/**
 * Use bulk to write data and specify routing.
 */
private static void bulkWithRouting(RestHighLevelClient highLevelClient, String indexName) {
    try {
        Map<String, Object> jsonMap = new HashMap<>();
        BulkRequest request = new BulkRequest();
        int age;
        for (int i = 1; i <= NUM_OF_DOC; i++) {
            jsonMap.clear();
            jsonMap.put("user", "Linda" + i);
            age = ThreadLocalRandom.current().nextInt(18, 100);
            jsonMap.put("age", age);
            jsonMap.put("postDate", "2020-01-01");
            jsonMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
            jsonMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
            // Route documents of the same age to the same shard based on the age.
            request.add(new IndexRequest(indexName).source(jsonMap).routing(String.valueOf(age)));
        }
        BulkResponse bulkResponse = highLevelClient.bulk(request, RequestOptions.DEFAULT);
        if (RestStatus.OK.equals(bulkResponse.status())) {
            LOG.info("Bulk routing is successful.");
        } else {
            LOG.info("Bulk routing is failed.");
        }
    } catch (IOException e) {
        LOG.error("Bulk routing is failed, exception occurred.", e);
    }
}
```

### 1.7.3.3.6 Updating Index Information

## Function

**Update.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/update` directory is used to update the index.

```
/**
 * Update index
 */
public static void update(RestHighLevelClient highLevelClient, String index, String type, String id) {
    try {
        XContentBuilder builder = XContentFactory.jsonBuilder();
        builder.startObject();
        { // update information
            builder.field("postDate", new Date());
            builder.field("reason", "update again");
        }
        builder.endObject();
        UpdateRequest request = new UpdateRequest(index, type, id).doc(builder);
        UpdateResponse updateResponse = highLevelClient.update(request, RequestOptions.DEFAULT);

        LOG.info("Update response is {}.", updateResponse.toString());
    } catch (Exception e) {
        LOG.error("Update is failed,exception occurred.", e);
    }
}
```

### 1.7.3.3.7 Querying Index Information

#### Function

**GetIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/search** directory is used to query information about a document with specified **index**, **type**, and **id**.

```
/*
 * Get index information
 */
private static void getIndex(RestHighLevelClient highLevelClient, String index, String type, String id) {
    try {
        GetRequest getRequest = new GetRequest(index, type, id);
        String[] includes = new String[] { "message", "test*" };
        String[] excludes = Strings.EMPTY_ARRAY;
        FetchSourceContext fetchSourceContext = new FetchSourceContext(true, includes, excludes);
        getRequest.fetchSourceContext(fetchSourceContext);
        getRequest.storedFields("message");
        GetResponse getResponse = highLevelClient.get(getRequest, RequestOptions.DEFAULT);

        LOG.info("GetIndex response is {}", getResponse.toString());
    } catch (Exception e) {
        LOG.error("GetIndex is failed,exception occurred.", e);
    }
}
```

### 1.7.3.3.8 Searching for Document Information

#### Function

**Search.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/search** directory is used to query related document information in a specified index. You can customize specified sorting, filtering, highlighting, feedback data range, timeout interval, and the like.

```
/*
 * Search some information in index
 */
public static void search(RestHighLevelClient highLevelClient, String index) {
    try {
        SearchRequest searchRequest = new SearchRequest(index);
        SearchSourceBuilder searchSourceBuilder = new SearchSourceBuilder();
        searchSourceBuilder.query(QueryBuilders.termQuery("user", "kimchy1"));

        //Specifying Sorting
        searchSourceBuilder.sort(new FieldSortBuilder("_doc").order(SortOrder.ASC));

        // Source filter
        String[] includeFields = new String[] { "message", "user", "innerObject*" };
        String[] excludeFields = new String[] { "postDate" };
        searchSourceBuilder.fetchSource(includeFields, excludeFields);
        // Control which fields get included
        // excluded

        // Request Highlighting
        HighlightBuilder highlightBuilder = new HighlightBuilder();
        HighlightBuilder.Field highlightUser = new HighlightBuilder.Field("user");
        // Create a field highlighter for
        // the user field

        highlightBuilder.field(highlightUser);
    }
```

```
searchSourceBuilder.highlighter(highlightBuilder);
searchSourceBuilder.from(0);
searchSourceBuilder.size(2);
searchSourceBuilder.timeout(new TimeValue(60, TimeUnit.SECONDS));
searchRequest.source(searchSourceBuilder);
SearchResponse searchResponse = highLevelClient.search(searchRequest, RequestOptions.DEFAULT);

LOG.info("Search response is {}.", searchResponse.toString());
} catch (Exception e) {
    LOG.error("Search is failed,exception occurred.", e);
}
}
```

### 1.7.3.3.9 Searching for Document Information by Using a Cursor

#### Function

**SearchScroll.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/searchscroll` directory is used to query related document information in a specified index by using a cursor. The method returns a **scrollId**. You can use the **scrollId** to clear the cursor. For details about the clearing method, see [Clearing a Cursor](#).

```
/*
 * Send a search scroll request
 */
public static String searchScroll(RestHighLevelClient highLevelClient, String index) {
    String scrollId = null;
    try {
        final Scroll scroll = new Scroll(TimeValue.timeValueMinutes(1L));
        SearchRequest searchRequest = new SearchRequest(index);
        searchRequest.scroll(scroll);
        SearchSourceBuilder searchSourceBuilder = new SearchSourceBuilder();
        searchSourceBuilder.query(QueryBuilders.matchQuery("title", "Elasticsearch"));
        searchRequest.source(searchSourceBuilder);

        SearchResponse searchResponse = highLevelClient.search(searchRequest, RequestOptions.DEFAULT);
        scrollId = searchResponse.getScrollId();
        SearchHit[] searchHits = searchResponse.getHits().getHits();
        LOG.info("SearchHits is {}", searchResponse.toString());

        while (searchHits != null && searchHits.length > 0) {
            SearchScrollRequest scrollRequest = new SearchScrollRequest(scrollId);
            scrollRequest.scroll(scroll);
            searchResponse = highLevelClient.searchScroll(scrollRequest, RequestOptions.DEFAULT);
            scrollId = searchResponse.getScrollId();
            searchHits = searchResponse.getHits().getHits();
            LOG.info("SearchHits is {}", searchResponse.toString());
        }
    } catch (Exception e) {
        LOG.error("SearchScroll is failed,exception occurred.", e);
        return null;
    }
    return scrollId;
}
```

### 1.7.3.3.10 Clearing a Cursor

#### Function

**SearchScroll.java** in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/searchscroll` directory includes the method **clearScroll(highLevelClient,scrollId)**, which is used to clear a cursor specified by **scrollId**.

```
/*
 * Clear a search scroll
 */
public static void clearScroll(RestHighLevelClient highLevelClient, String scrollId) {
    ClearScrollRequest clearScrollRequest = new ClearScrollRequest();
    clearScrollRequest.addScrollId(scrollId);
    ClearScrollResponse clearScrollResponse;
    try {
        clearScrollResponse = highLevelClient.clearScroll(clearScrollRequest, RequestOptions.DEFAULT);
        if (clearScrollResponse.isSucceeded()) {
            LOG.info("ClearScroll is successful.");
        } else {
            LOG.error("ClearScroll is failed.");
        }
    } catch (IOException e) {
        LOG.error("ClearScroll is failed,exception occurred.", e);
    }
}
```

### 1.7.3.3.11 Deleting an Index

#### Function

**DeleteIndex.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/delete** directory is used to delete a specified index.

```
/*
 * Delete the index
 */
public static void deleteIndex(RestHighLevelClient highLevelClient, String index) {
    try {
        DeleteIndexRequest request = new DeleteIndexRequest(index);
        DeleteIndexResponse deleteResponse = highLevelClient.indices().deleteIndex(request,
RequestOptions.DEFAULT);

        if (deleteResponse.isAcknowledged()) {
            LOG.info("Delete index is successful");
        } else {
            LOG.info("Delete index is failed");
        }
    } catch (Exception e) {
        LOG.error("Delete index : {} is failed, exception occurred.", index, e);
    }
}
```

### 1.7.3.3.12 Multi-Thread Request

#### Function

**MultithreadRequest.java** in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/multithread** directory is used to create a thread class **sendRequestThread**, rewrite a **run** method, implement a **bulk** request, and write data in batches.

```
/*
 * The thread that send a bulk request
 */
public static class sendRequestThread implements Runnable {

    private RestHighLevelClient highLevelClientTh;
    @Override
    public void run() {
```

```
LOG.info("Thread begin.");
HwRestClient hwRestClient = new HwRestClient();
try {
    highLevelClientTh = new RestHighLevelClient(hwRestClient.getRestClientBuilder());
    LOG.info("Thread name: " + Thread.currentThread().getName());
    bulk(highLevelClientTh,"huawei1","type1");
} catch (Exception e) {
    LOG.error("SendRequestThread had exception.", e);
} finally {
    if (highLevelClientTh != null) {
        try {
            highLevelClientTh.close();
            LOG.info("Close the highLevelClient successful in thread : " +
Thread.currentThread().getName());
        } catch (IOException e) {
            LOG.error("Close the highLevelClient failed.", e);
        }
    }
}
```

In the **main** method, the **fixedThreadPool** thread pool is created. By specifying **threadPoolSize** and **jobNumber**, multiple threads are supported to send bulk requests and data can be concurrently written in batches.

```
public static void main(String[] args) throws Exception {  
    LOG.info("Start to do bulk request !");  
  
    ExecutorService fixedThreadPool;  
    int threadPoolSize = 2;  
    int jobNumber = 5;  
    if (HighLevelUtils.getConfig()) {  
        try {  
            fixedThreadPool = Executors.newFixedThreadPool(threadPoolSize);  
            for (int i = 0; i < jobNumber; i++) {  
                fixedThreadPool.execute(new sendRequestThread());  
            }  
            fixedThreadPool.shutdown();  
        } catch (Exception e) {  
            LOG.error("SendRequestThread is failed,exception occurred.", e);  
        }  
    } else {  
        LOG.error("Failed to get configuration!");  
    }  
}
```

### **1.7.3.3.13 BulkProcessor Batch Import Example**

## Description

The `BulkProcessorSample.java` file in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/bulk` directory is used to instruct users to use BulkProcessor to import data to the database in batches.

## BulkProcessor initialization:

```
private static BulkProcessor getBulkProcessor(RestHighLevelClient highLevelClient) {  
    BulkProcessor.Listener listener = new BulkProcessor.Listener() {  
        @Override  
        public void beforeBulk(long executionId, BulkRequest bulkRequest) {  
            int numberOfActions = bulkRequest.numberOfActions();  
            LOG.info("Executing bulk {} with {} requests.", executionId, numberOfActions);  
        }  
    };  
    return BulkProcessor.builder(bulkRequest::add).setListener(listener).build();  
}
```

```

    }

    @Override
    public void afterBulk(long executionId, BulkRequest bulkRequest, BulkResponse bulkResponse) {
        if (bulkResponse.hasFailures()) {
            LOG.warn("Bulk {} executed with failures.", executionId);
        } else {
            LOG.info("Bulk {} completed in {} milliseconds.", executionId,
                    bulkResponse.getTook().getMillis());
        }
    }

    @Override
    public void afterBulk(long executionId, BulkRequest bulkRequest, Throwable throwable) {
        LOG.error("Failed to execute bulk.", throwable);
    }
};

BiConsumer<BulkRequest, ActionListener<BulkResponse>> bulkConsumer =
    (request, bulkListener) -> highLevelClient.bulkAsync(request, RequestOptions.DEFAULT,
bulkListener);

BulkProcessor bulkProcessor = BulkProcessor.builder(bulkConsumer, listener)
    .setBulkActions(onceBulkMaxNum)
    .setBulkSize(new ByteSizeValue(onceBulkMaxSize, ByteSizeUnit.MB))
    .setConcurrentRequests(concurrentRequestsNum)
    .setFlushInterval(TimeValue.timeValueSeconds(flushTime))
    .setBackoffPolicy(BackoffPolicy.constantBackoff(TimeValue.timeValueSeconds(1L), maxRetry))
    .build();

LOG.info("Init bulkProcess successfully.");
return bulkProcessor;
}

```

**BulkProcessor import example:**

```

private void singleThreadBulk() {
    //single thread
    int bulkTime = 0;
    while (bulkTime++ < totalNumberForThread) {
        Map<String, Object> dataMap = new HashMap<>();
        dataMap.put("date", "2019/12/9");
        dataMap.put("text", "the test text");
        dataMap.put("title", "the title");
        bulkProcessor.add(new IndexRequest(indexName, indexType).source(dataMap));
    }
    LOG.info("This thread bulks successfully, the thread name is {}.", Thread.currentThread().getName());
}

```

#### 1.7.3.3.14 Pre-sorting Indices

### Function Description

The **IndexSorting.java** file in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/example/highlevel/index** directory is used to configure the fields to be sorted when an index is created, implement the **bulk** request, write data in batches, and query the top N documents.

During index creation, specify the fields to be sorted and specify whether each field is sorted in descending or ascending order.

```

private static void createIndexWithSorting(RestHighLevelClient highLevelClient, String index) {
    try {
        CreateIndexRequest indexRequest = new CreateIndexRequest(index);
        indexRequest.settings(

```

```

Settings.builder().put("index.number_of_shards", 3)
    .put("index.number_of_replicas", 1)
    .putList("index.sort.field", "height", "weight")
    .putList("index.sort.order", SortOrder.DESC.toString(), SortOrder.ASC.toString());
indexRequest.mapping("{\"properties\": {\"height\": {\"type\": \"float\"},\n" +
    + "\"weight\": {\"type\": \"float\"}}}", XContentType.JSON);
CreateIndexResponse response = highLevelClient.indices().create(indexRequest,
RequestOptions.DEFAULT);
if (response.isAcknowledged() || response.isShardsAcknowledged()) {
    LOG.info("Create index with sorting successfully.");
}
} catch (IOException e) {
    LOG.error("Failed to create index with sorting, exception occurred.", e);
}
}

```

Then, write data in batches.

```

public static void bulk(RestHighLevelClient highLevelClient, String index) {
    try {
        Map<String, Object> jsonMap = new HashMap<>();
        for (int i = 1; i <= 10; i++) {
            BulkRequest request = new BulkRequest();
            for (int j = 1; j <= 1000; j++) {
                jsonMap.clear();
                jsonMap.put("user", "Linda");
                jsonMap.put("age", ThreadLocalRandom.current().nextInt(18, 100));
                jsonMap.put("postDate", "2020-01-01");
                jsonMap.put("height", (float) ThreadLocalRandom.current().nextInt(140, 220));
                jsonMap.put("weight", (float) ThreadLocalRandom.current().nextInt(70, 200));
                request.add(new IndexRequest(index).source(jsonMap));
            }
            BulkResponse bulkResponse = highLevelClient.bulk(request, RequestOptions.DEFAULT);

            if (RestStatus.OK.equals((bulkResponse.status()))) {
                LOG.info("Bulk is successful");
            } else {
                LOG.info("Bulk is failed");
            }
        }
    } catch (IOException e) {
        LOG.error("Bulk is failed,exception occurred.", e);
    }
}

```

Perform the refresh operation so that the data can be queried after being written in batches.

```

private static void refresh(RestHighLevelClient highLevelClient, String index) {
    try {
        RefreshRequest refRequest = new RefreshRequest(index);
        highLevelClient.indices().refresh(refRequest, RequestOptions.DEFAULT);
        LOG.info("Refresh sorting index successfully.");
    } catch (IOException e) {
        LOG.error("Failed to refresh sorting index, exception occurred.", e);
    }
}

```

Then, you can query the sorting field. By default, the top 10 documents are obtained.

```

private static void queryData(RestHighLevelClient highLevelClient, String index) {
    try {
        SearchSourceBuilder searchSourceBuilder = new SearchSourceBuilder();
        searchSourceBuilder.sort(new FieldSortBuilder("height").order(SortOrder.DESC));
        searchSourceBuilder.sort(new FieldSortBuilder("weight").order(SortOrder.ASC));
        // Source filter
        String[] includeFields = new String[]{"weight", "height", "age"};
        String[] excludeFields = new String[]{};
    }
}

```

```
searchSourceBuilder.fetchSource(includeFields, excludeFields);
// Control which fields get included or excluded
// Request Highlighting
HighlightBuilder highlightBuilder = new HighlightBuilder();
HighlightBuilder.Field highlightUser = new HighlightBuilder.Field("height");
highlightBuilder.field(highlightUser);
searchSourceBuilder.highlighter(highlightBuilder);
searchSourceBuilder.timeout(new TimeValue(1, TimeUnit.SECONDS));
SearchRequest searchRequest = new SearchRequest(index);
searchRequest.source(searchSourceBuilder);
SearchResponse searchResponse = highLevelClient.search(searchRequest, RequestOptions.DEFAULT);
LOG.info("Search response is {}", searchResponse.toString());
} catch (IOException e) {
    LOG.error("Failed to query sorting index, exception occurred.", e);
}
}
```

### 1.7.3.4 OpenDistro JDBC Sample Code

#### 1.7.3.4.1 Connecting the Client to a Cluster

##### Function Description

This section describes how to obtain the client and set a cluster name, an IP address, and a port number, to connect to a specific Elasticsearch cluster. This is a prerequisite before using the APIs provided by Elasticsearch.

###### NOTE

- After the Elasticsearch operations are complete, you need to call **Connection.close()** to close the applied resources.
- The OpenDistro JDBC sample does not support IBM JDK.

```
public Connection sqlConnect() {
    Properties properties = initConfig();
    if (properties == null) {
        LOG.error("Get properties error");
        return null;
    }
    try {
        String url = getUrl();
        if (url == null) {
            LOG.error("Get server url error");
            return null;
        }
        return DriverManager.getConnection(url, properties);
    } catch (SQLException e) {
        LOG.error("Connect error.");
        return null;
    }
}
```

###### NOTE

By default, the client reads the following configuration files from the **conf** directory in the code running path: **esParams.properties**, **krb5.conf**, and **user.keytab**.

### 1.7.3.4.2 Querying an Index

#### Function Description

The **SqlSearch.java** file in the **elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/jdbc** directory is used to query index data.

```
private static void basicSearch(Connection connection) {
    if (connection == null) {
        LOG.error("Connection is null.");
        return;
    }
    String sql = "SELECT * FROM example-sql1 limit 10";
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.executeQuery();
        LOG.info("Search succeed.");
    } catch (SQLException e) {
        LOG.info("Search failed.");
    }
}
```

Syntax:

```
SELECT [DISTINCT] (* | EXPRESSION) [[AS] ALIAS] [, ...]
FROM INDEX_NAME
[WHERE PREDICATES]
[GROUP BY EXPRESSION [, ...]]
[HAVING PREDICATES]
[ORDER BY EXPRESSION [IS [NOT] NULL] [ASC | DESC] [, ...]]
[LIMIT [offset, ] size]
```

#### Example SQLs:

- Search for specific fields only:  
**SELECT user, age FROM example-sql1 limit 10**
- Use aliases for a field:  
**SELECT age AS user\_age FROM example-sql1 limit 10**
- Deduplicate the results:  
**SELECT DISTINCT age FROM example-sql1 limit 10**
- Example of the **Where** clause:

```
private static void whereAndLimitSearch(Connection connection) {
    if (connection == null) {
        LOG.error("Connection is null.");
        return;
    }
    String sql = "SELECT user, age FROM example-sql1 WHERE height>? limit 10";
    try (PreparedStatement statement = connection.prepareStatement(sql)) {
        statement.setInt(1, 100);
        statement.executeQuery();
        LOG.info("Search succeed.");
    } catch (SQLException e) {
        LOG.error("Search failed.");
    }
}
```

#### NOTE

You are advised to use **PreparedStatement** to perform parameterized query, which can effectively prevent SQL injection.

- GroupBy:

- ```
SELECT weight AS user_weight FROM example-sql1 GROUP BY user_weight limit 10
```
- Function use:  

```
SELECT ADD(weight,10) AS user_weight FROM example-sql1 GROUP BY ADD(weight,10) limit 10
```
  - Having clause:  

```
SELECT age, MAX(weight) FROM example-sql1 GROUP BY age HAVING MIN(weight)>20 limit 10
```
  - OrderBy:  

```
SELECT height FROM example-sql1 ORDER BY height DESC limit 10
```
  - Table association:  

```
SELECT l.height,l.weight,i.height,i.weight FROM example-sql1 l JOIN example-sql2 i ON i.age = l.age limit 10
```
  - Subquery:  

```
SELECT a.myHeight, a.myWeight FROM (SELECT height AS myHeight, weight AS myWeight FROM example-sql1 WHERE age > 25 LIMIT 5) AS a
```
  - Use a single field to search for text:  

```
SELECT user, weight, address FROM example-sql1 WHERE MATCH_QUERY(address, 'Holmes') limit 10
```
  - Split texts based on operators:  

```
SELECT user, weight, address FROM example-sql1 WHERE QUERY('address:Lane OR address:Street') limit 10
```

#### 1.7.3.4.3 Deleting Index Information

##### Function Description

The `SqlDelete.java` file in the `elasticsearch-rest-client-example/src/main/java/com/huawei/fusioninsight/elasticsearch/jdbc` directory is used to delete index data.

##### NOTICE

If the WHERE clause is not specified, all documents are deleted.

```
public static void deleteData(Connection connection) {  
    if (connection == null) {  
        LOG.error("Statement is null.");  
        return;  
    }  
    String sql = "DELETE FROM example-sql2 WHERE height=? ";  
    try (PreparedStatement statement = connection.prepareStatement(sql)) {  
        statement.setInt(1, 25);  
        statement.executeQuery();  
        LOG.info("Delete data successful.");  
    } catch (SQLException e) {  
        LOG.error("Delete data failed.");  
    }  
}
```

#### 1.7.3.4.4 Functions

The following table lists the functions supported by OpenDistro JDBC sql and their usage and examples, There are six types of functions: mathematical operation functions, trigonometric functions, time and date functions, string functions, summation functions, and advanced functions.

#### Mathematical Operation Functions

**Table 1-16** List of mathematical operation functions

Function	Description	Example
abs	abs(number T) -> T	SELECT abs(0.5) FROM my-index LIMIT 1
add	add(number T, number) -> T	SELECT add(1, 5) FROM my-index LIMIT 1
cbrt	cbrt(number T) -> T	SELECT cbrt(0.5) FROM my-index LIMIT 1
ceil	ceil(number T) -> T	SELECT ceil(0.5) FROM my-index LIMIT 1
conv	conv(string T, int a, int b) -> T	SELECT CONV('12', 10, 16), CONV('2C', 16, 10), CONV(12, 10, 2), CONV(1111, 2, 10) FROM my-index LIMIT 1
crc32	crc32(string T) -> T	SELECT crc32('MySQL') FROM my-index LIMIT 1
divide	divide(number T, number) -> T	SELECT divide(1, 0.5) FROM my-index LIMIT 1
e	e() -> double	SELECT e() FROM my-index LIMIT 1
exp	exp(number T) -> T	SELECT exp(0.5) FROM my-index LIMIT 1
expm1	expm1(number T) -> T	SELECT expm1(0.5) FROM my-index LIMIT 1
floor	floor(number T) -> T	SELECT floor(0.5) AS Rounded_Down FROM my-index LIMIT 1
ln	ln(number T) -> double	SELECT ln(10) FROM my-index LIMIT 1
log	log(number T) -> double or log(number T, number) -> double	SELECT log(10) FROM my-index LIMIT 1
log2	log2(number T) -> double	SELECT log2(10) FROM my-index LIMIT 1

Function	Description	Example
log10	log10(number T) -> double	SELECT log10(10) FROM my-index LIMIT 1
mod	mod(number T, number) -> T	SELECT modulus(2, 3) FROM my-index LIMIT 1
multiply	multiply(number T, number) -> number	SELECT multiply(2, 3) FROM my-index LIMIT 1
pi	pi() -> double	SELECT pi() FROM my-index LIMIT 1
pow	ow(number T) -> T or pow(number T, number) -> T	SELECT pow(2, 3) FROM my-index LIMIT 1
power	power(number T) -> T or power(number T, number) -> T	SELECT power(2, 3) FROM my-index LIMIT 1
rand	rand() -> number or rand(number T) -> T	SELECT rand(0.5) FROM my-index LIMIT 1
rint	rint(number T) -> T	SELECT rint(1.5) FROM my-index LIMIT 1
round	round(number T) -> T	SELECT round(1.5) FROM my-index LIMIT 1
sign	sign(number T) -> T	SELECT sign(1.5) FROM my-index LIMIT 1
signum	signum(number T) -> T	SELECT signum(0.5) FROM my-index LIMIT 1
sqrt	sqrt(number T) -> T	SELECT sqrt(0.5) FROM my-index LIMIT 1
strcmp	strcmp(string T, string T) -> T	SELECT strcmp('hello', 'hello') FROM my-index LIMIT 1
subtract	subtract(number T, number) -> T	SELECT subtract(3, 2) FROM my-index LIMIT 1
truncate	truncate(number T, number T) -> T	SELECT truncate(56.78, 1) FROM my- index LIMIT 1
/	number [op] number -> number	SELECT 1 / 100 FROM my-index LIMIT 1
%	number [op] number -> number	SELECT 1 % 100 FROM my-index LIMIT 1

## Trigonometric Functions

**Table 1-17** List of trigonometric functions

Function	Description	Example
acos	acos(number T) -> double	SELECT acos(0.5) FROM my-index LIMIT 1
asin	asin(number T) -> double	SELECT asin(0.5) FROM my-index LIMIT 1
atan	atan(number T) -> double	SELECT atan(0.5) FROM my-index LIMIT 1
atan2	atan2(number T, number) -> double	SELECT atan2(1, 0.5) FROM my-index LIMIT 1
cos	cos(number T) -> double	SELECT cos(0.5) FROM my-index LIMIT 1
cosh	cosh(number T) -> double	SELECT cosh(0.5) FROM my-index LIMIT 1
cot	cot(number T) -> double	SELECT cot(0.5) FROM my-index LIMIT 1
degrees	degrees(number T) -> double	SELECT degrees(0.5) FROM my-index LIMIT 1
radians	radians(number T) -> double	SELECT radians(0.5) FROM my-index LIMIT 1
sin	sin(number T) -> double	SELECT sin(0.5) FROM my-index LIMIT 1
sinh	sinh(number T) -> double	SELECT sinh(0.5) FROM my-index LIMIT 1
tan	tan(number T) -> double	SELECT tan(0.5) FROM my-index LIMIT 1

## Date and Time Functions

**Table 1-18** List of time and date functions

Function	Description	Example
adddate	adddate(date, INTERVAL expr unit) -> date	SELECT adddate(date('2020-08-26'), INTERVAL 1 hour) FROM my-index LIMIT 1
curdate	curdate() -> date	SELECT curdate() FROM my-index LIMIT 1

Function	Description	Example
date	date(date) -> date	SELECT date() FROM my-index LIMIT 1
date_format	date_format(date, string) -> string or date_format(date, string, string) -> string	SELECT date_format(date, 'Y') FROM my-index LIMIT 1
date_sub	date_sub(date, INTERVAL expr unit) -> date	SELECT date_sub(date('2008-01-02'), INTERVAL 31 day) FROM my-index LIMIT 1
dayofmonth	dayofmonth(date) -> integer	SELECT dayofmonth(date) FROM my-index LIMIT 1
dayname	dayname(date) -> string	SELECT dayname(date('2020-08-26')) FROM my-index LIMIT 1
dayofyear	dayofyear(date) -> integer	SELECT dayofyear(date('2020-08-26')) FROM my-index LIMIT 1
dayofweek	dayofweek(date) -> integer	SELECT dayofweek(date('2020-08-26')) FROM my-index LIMIT 1
from_days	from_days(N) -> integer	SELECT from_days(733687) FROM my-index LIMIT 1
hour	hour(time) -> integer	SELECT hour((time '01:02:03')) FROM my-index LIMIT 1
maketime	maketime(integer, integer, integer) -> date	SELECT maketime(1, 2, 3) FROM my-index LIMIT 1
microsecond	microsecond(expr) -> integer	SELECT microsecond((time '01:02:03.123456')) FROM my-index LIMIT 1
minute	minute(expr) -> integer	SELECT minute((time '01:02:03')) FROM my-index LIMIT 1
month	month(date) -> integer	SELECT month(date) FROM my-index
monthname	monthname(date) -> string	SELECT monthname(date) FROM my-index
now	now() -> date	SELECT now() FROM my-index LIMIT 1
quarter	quarter(date) -> integer	SELECT quarter(date('2020-08-26')) FROM my-index LIMIT 1
second	second(time) -> integer	SELECT second((time '01:02:03')) FROM my-index LIMIT 1

Function	Description	Example
subdate	subdate(date, INTERVAL expr unit) -> date, datetime	SELECT subdate(date('2008-01-02'), INTERVAL 31 day) FROM my-index LIMIT 1
time	time(expr) -> time	SELECT time('13:49:00') FROM my-index LIMIT 1
time_to_sec	time_to_sec(time) -> long	SELECT time_to_sec(time '22:23:00') FROM my-index LIMIT 1
timestamp	timestamp(date) -> date	SELECT timestamp(date) FROM my-index LIMIT 1
to_days	to_days(date) -> long	SELECT to_days(date '2008-10-07') FROM my-index LIMIT 1
week	week(date[mode]) -> integer	SELECT week(date('2008-02-20')) FROM my-index LIMIT 1
year	year(date) -> integer	SELECT year(date) FROM my-index LIMIT 1

## String Functions

**Table 1-19** List of string functions

Function	Description	Example
ascii	ascii(string T) -> integer	SELECT ascii(name.keyword) FROM my-index LIMIT 1
concat	concat(str1, str2) -> string	SELECT concat('hello', 'world') FROM my-index LIMIT 1
concat_ws	concat_ws(separator, string, string...) -> string	SELECT concat_ws("-", "Tutorial", "is", "fun!") FROM my-index LIMIT 1
left	left(string T, integer) -> T	SELECT left('hello', 2) FROM my-index LIMIT 1
length	length(string) -> integer	SELECT length('hello') FROM my-index LIMIT 1
locate	locate(string, string, integer) -> integer or locate(string, string) -> INTEGER	SELECT locate('o', 'hello') FROM my-index LIMIT 1, SELECT locate('l', 'hello', 3) FROM my-index LIMIT 1
replace	replace(string T, string, string) -> T	SELECT replace('hello', 'l', 'x') FROM my-index LIMIT 1

Function	Description	Example
right	right(string T, integer) -> T	SELECT right('hello', 1) FROM my-index LIMIT 1
rtrim	rtrim(string T) -> T	SELECT rtrim(name.keyword) FROM my-index LIMIT 1
substring	substring(string T, integer, integer) -> T	SELECT substring(name.keyword, 2,5) FROM my-index LIMIT 1
trim	trim(string T) -> T	SELECT trim(' hello') FROM my-index LIMIT 1
upper	upper(string T) -> T	SELECT upper('helloworld') FROM my-index LIMIT 1

## Summation Functions

**Table 1-20** List of summation functions

Function	Description	Example
avg	avg(number T) -> T	SELECT avg(2, 3) FROM my-index LIMIT 1
count	count(number T) -> T	SELECT count(date) FROM my-index LIMIT 1
min	min(number T, number) -> T	SELECT min(2, 3) FROM my-index LIMIT 1
show	show(string T) -> T	SHOW TABLES LIKE my-index

## Advanced Functions

**Table 1-21** List of advanced functions

Function	Specification	Example
if	if(boolean, es_type, es_type) -> es_type	SELECT if(false, 0, 1) FROM my-index LIMIT 1, SELECT if(true, 0, 1) FROM my-index LIMIT 1
ifnull	ifnull(es_type, es_type) -> es_type	SELECT ifnull('hello', 1) FROM my-index LIMIT 1, SELECT ifnull(null, 1) FROM my-index LIMIT 1
isnull	isnull(es_type) -> integer	SELECT isnull(null) FROM my-index LIMIT 1, SELECT isnull(1) FROM my-index LIMIT 1

## 1.7.4 Commissioning Process

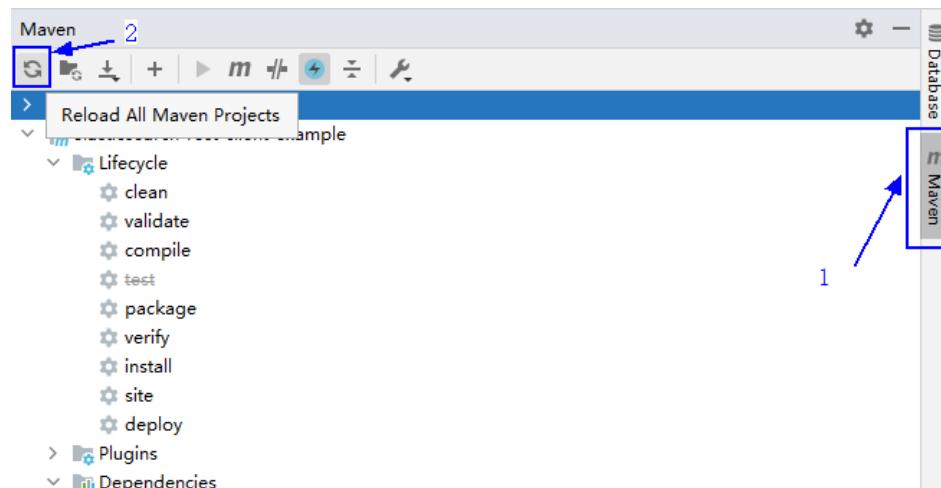

### 1.7.4.1 Commissioning Applications on Windows

#### 1.7.4.1.1 Commissioning a RestClient Application

#### Compiling and Running Applications

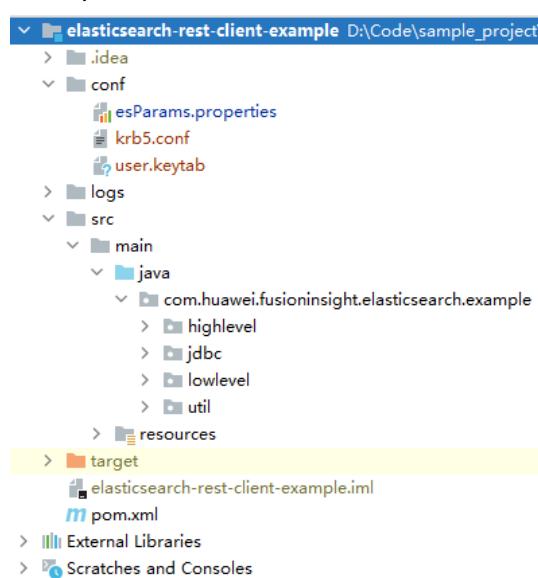

You can run an application on Windows after code development is complete. If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

1. Click **Reimport All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

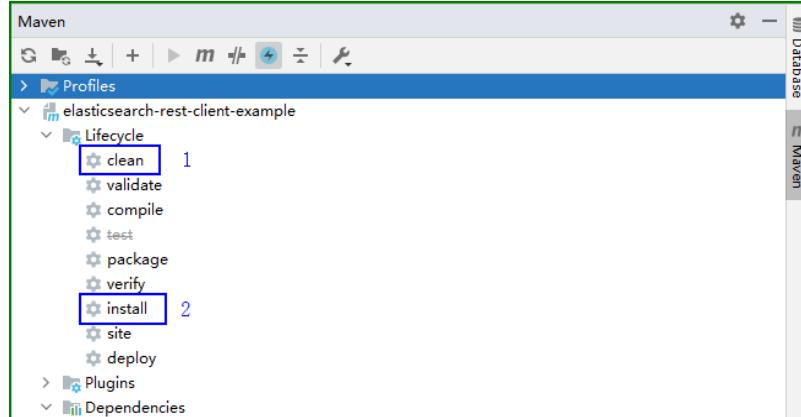

2. Compile and run an application.

- a. The following figure shows the file list after the configuration file has been placed and the code has been modified to match the login user.

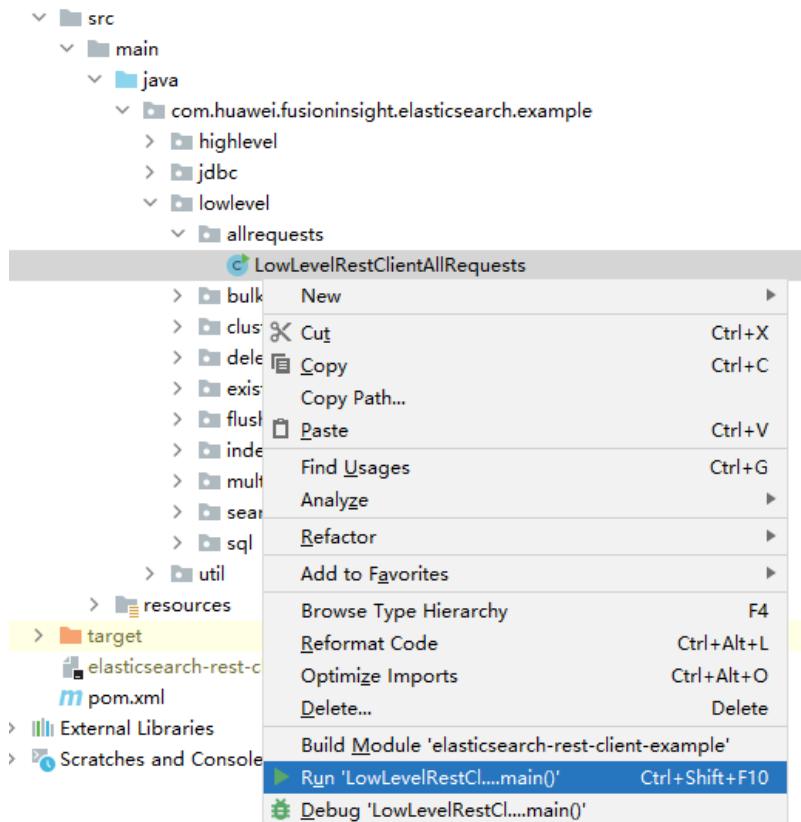

b. Compile an application.

Double-click **clean** and **install** to run the **maven clean** and **maven install** commands. After the compilation is complete, the message "Build Success" is displayed.

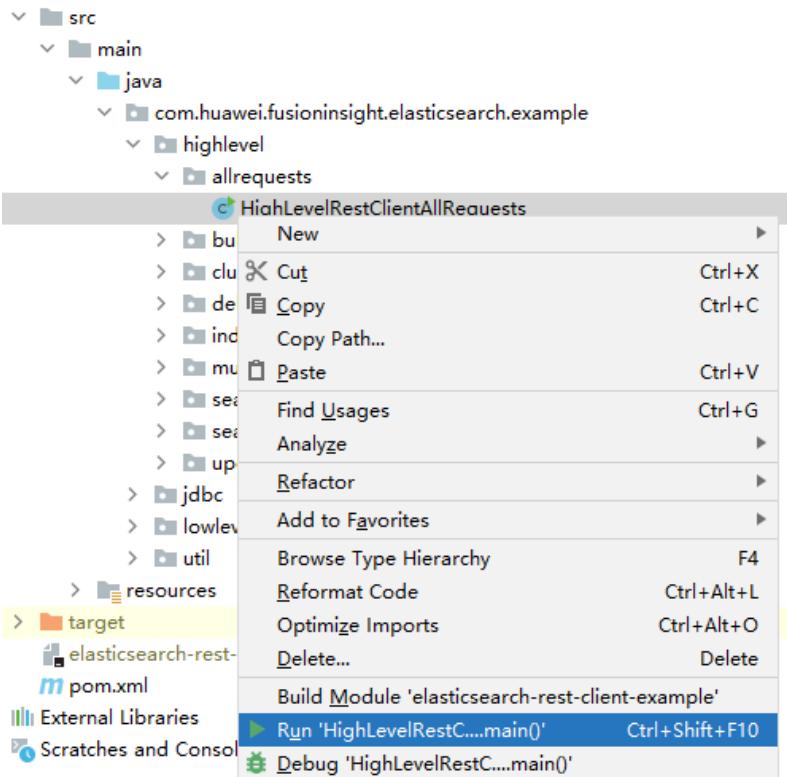

c. Run the program.

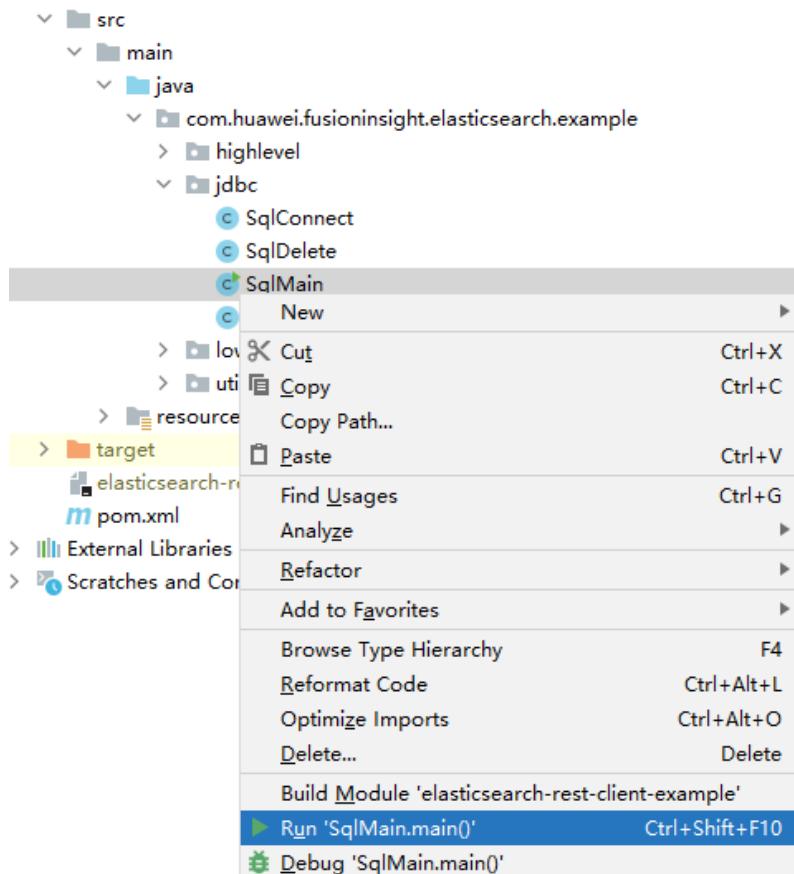

Right-click the **LowLevelRestClientAllRequests** file and choose **Run 'Low....main()'** from the shortcut menu to run all samples of the Low Level Rest Client.

Right-click the **HighLevelRestClientAllRequests** file and choose **Run 'High....main()'** from the shortcut menu to run all samples of the High Level Rest Client.

Right-click the **SqlMain** file and choose **Run 'SqlMain.main()'** from the shortcut menu to run all samples of the JDBC Rest Client.

## Viewing Commissioning Results

After you run an Elasticsearch application, you can use either of the following methods to view the running status:

- Check the running status of the application according to the running result.
- View Elasticsearch logs to learn application running status, that is, the **elasticsearch-rest-client-example/logs/es-example.log** log file in the **logs** directory.

After a complete sample of the Low Level Rest Client is run, some operation results are displayed on the console:

```

Process finished with exit code 0

## Log Description

The log level is **INFO** by default. You can view more detailed information by changing the log level (**TRACE**, **DEBUG**, **INFO**, **WARN**, and **ERROR**). You can modify the **log4j.properties** file to change log levels, for example:

```
# This sets the global logging level and specifies the appenders
log4j.rootLogger=INFO, theConsoleAppender, R

# settings for the console appender
log4j.appender.theConsoleAppender=org.apache.log4j.ConsoleAppender
log4j.appender.theConsoleAppender.Threshold=INFO
log4j.appender.theConsoleAppender.layout=org.apache.log4j.PatternLayout
log4j.appender.theConsoleAppender.layout.ConversionPattern=%d{yyyy-MM-dd HH:mm:ss,SSS} | %-5p | %t
| %m | %l%n

# R is set to be a File appender using a PatternLayout.
log4j.appender.R=org.apache.log4j.RollingFileAppender
log4j.appender.R.Append=true
log4j.appender.R.Threshold=debug
log4j.appender.R.MaxFileSize=10240KB
```

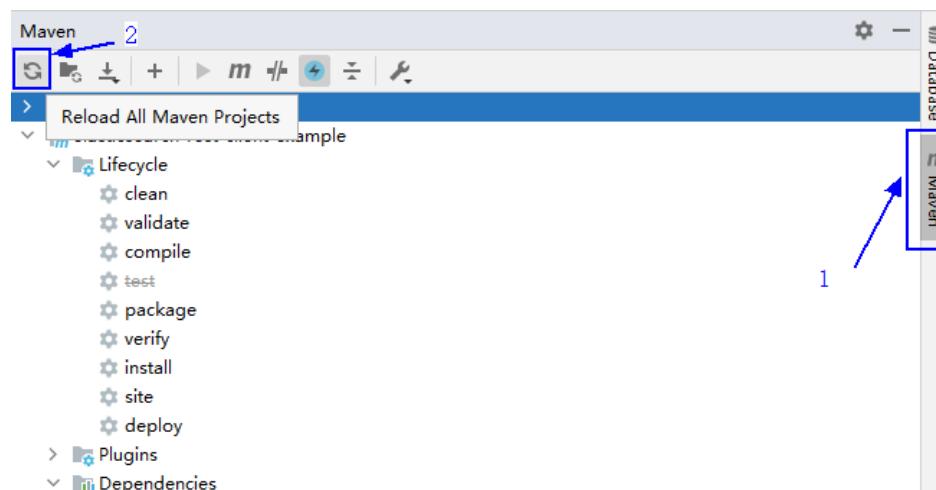

```
log4j.append.R.MaxBackupIndex=10  
log4j.append.R.File=logs/es-example.log  
log4j.append.R.layout=org.apache.log4j.PatternLayout  
log4j.append.R.layout.ConversionPattern=%d{yyyy-MM-dd HH:mm:ss,SSS} | %-5p | %t | %m | %l%n
```

### 1.7.4.1.2 Commissioning a SpringBoot Program

#### Compiling and Running Applications

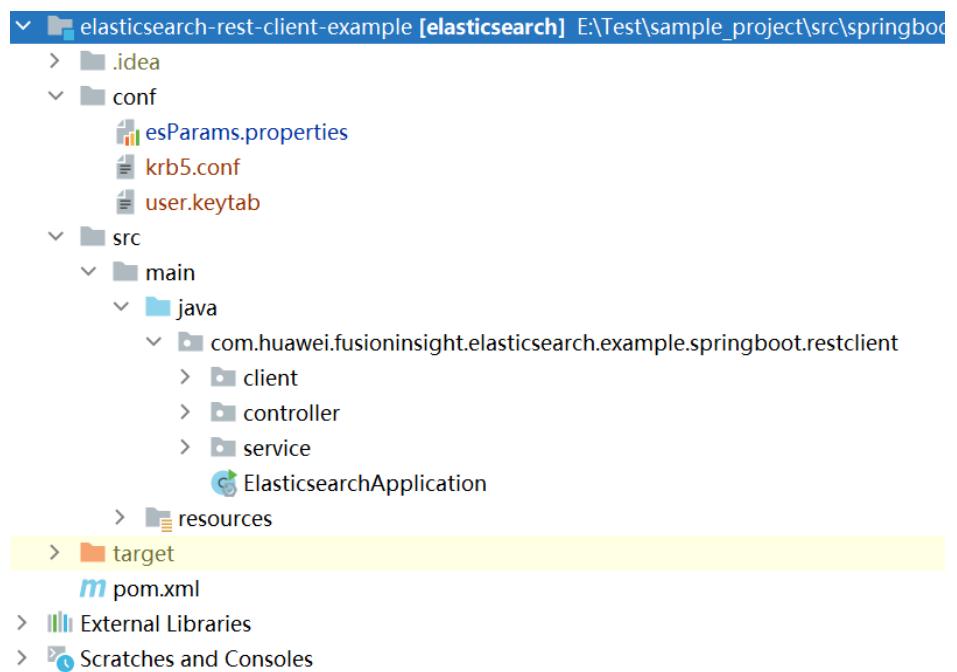

You can run applications in the Windows environment after application code development is complete. If the local and cluster service planes can communicate with each other, you can perform the commissioning on the local host.

1. Click **Reload All Maven Projects** in the Maven window on the right of IDEA to import Maven project dependency.

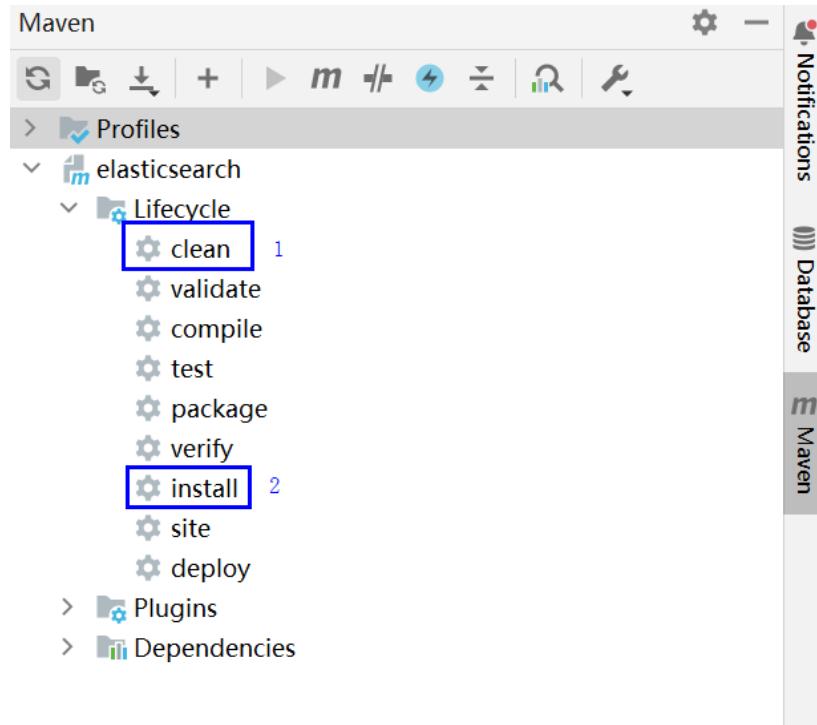

2. Compile and run an application.

- a. The following figure shows the file list after the configuration file has been placed and the code has been modified to match the login user.

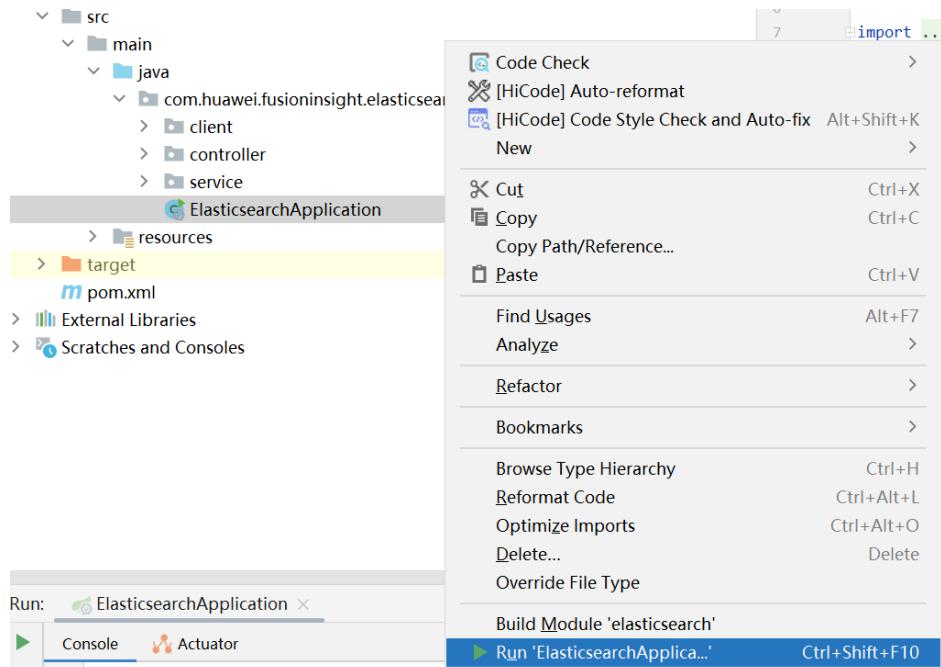

- b. Compile an application.

Double-click **clean** and **install** to run the **maven clean** and **maven install** commands. After the compilation is complete, "Build Success" is displayed.

- c. Run the program.

Right-click **ElasticsearchApplication** and choose **Run'ElasticsearchApplication...'** from the shortcut menu to start the SpringBoot service.

3. Call the SpringBoot sample API of Elasticsearch to trigger the running of the sample code.

After the SpringBoot service is started, enter the link of the specific operation to be performed in the address box of the browser. For example, to query the cluster health status, enter <http://localhost:8080/elasticsearch/cluster/health> in the address box of the browser. The following result is returned:

```
{"cluster_name":"elasticsearch_cluster","status":"green","timed_out":false,"number_of_nodes":6,"number_of_data_nodes":3,"active_primary_shards":11,"active_shards":22,"relocating_shards":0,"initializing_shards":0,"unassigned_shards":0,"delayed_unassigned_shards":0,"number_of_pending_tasks":0,"number_of_in_flight_fetch":0,"task_max_waiting_in_queue_millis":0,"active_shards_percent_as_number":100.0}
```

**Table 1-22** lists the operations that can be performed when Elasticsearch interconnects with SpringBoot.

**Table 1-22** Operations for interconnecting Elasticsearch with SpringBoot

Method	Browser Link	Description
getElasticsearch	<a href="http://localhost:8080/elasticsearch/">http://localhost:8080/elasticsearch/</a>	Obtain cluster information such as clusterName, clusterUuid, and nodeName.
clusterHealth	<a href="http://localhost:8080/elasticsearch/cluster/health">http://localhost:8080/elasticsearch/cluster/health</a>	Obtain the cluster health status.
indexByJson	<a href="http://localhost:8080/elasticsearch/indexByJson?index=/Index name">http://localhost:8080/elasticsearch/indexByJson?index=/Index name</a>	Write data in JSON format.
indexByMap	<a href="http://localhost:8080/elasticsearch/indexByMap?index=/Index name">http://localhost:8080/elasticsearch/indexByMap?index=/Index name</a>	Write data in the Map format.
indexByXContentBuilder	<a href="http://localhost:8080/elasticsearch/indexByXContentBuilder?index=/Index name">http://localhost:8080/elasticsearch/indexByXContentBuilder?index=/Index name</a>	Write data in the XContentBuilder format.
update	<a href="http://localhost:8080/elasticsearch/update?index=/Index name&amp;id=ID value">http://localhost:8080/elasticsearch/update?index=/Index name&amp;id=ID value</a>	Update index data.
bulk	<a href="http://localhost:8080/elasticsearch/bulk?index=/Index name">http://localhost:8080/elasticsearch/bulk?index=/Index name</a>	Write data in batches.
getIndex	<a href="http://localhost:8080/elasticsearch/getIndex?index=/Index name&amp;id=ID value">http://localhost:8080/elasticsearch/getIndex?index=/Index name&amp;id=ID value</a>	Query index information.
search	<a href="http://localhost:8080/elasticsearch/search?index=/Index name">http://localhost:8080/elasticsearch/search?index=/Index name</a>	Search for related document information under a specified index.

Method	Browser Link	Description
scroll	<code>http://localhost:8080/elasticsearch/scroll?index=/index name</code>	Search for document information under a specified index using a cursor. You can disable the cursor by modifying <b>scrollId</b> .
deleteIndex	<code>http://localhost:8080/elasticsearch/deleteIndex?index=/index name</code>	Delete an index.

## 1.7.4.2 Commissioning Applications in Linux

### 1.7.4.2.1 Commissioning a RestClient Application

Elasticsearch application programs can run in a Linux environment. After the code development is complete, you can upload a .jar package to the prepared Linux running environment, to run the applications.

#### Prerequisites

JDK is installed in the Linux environment. The version must be the same as that of the JDK used to export the .jar package from IntelliJ IDEA and Java environment variables have been set.

### Compiling and Running the Program

#### Step 1 Export a JAR package.

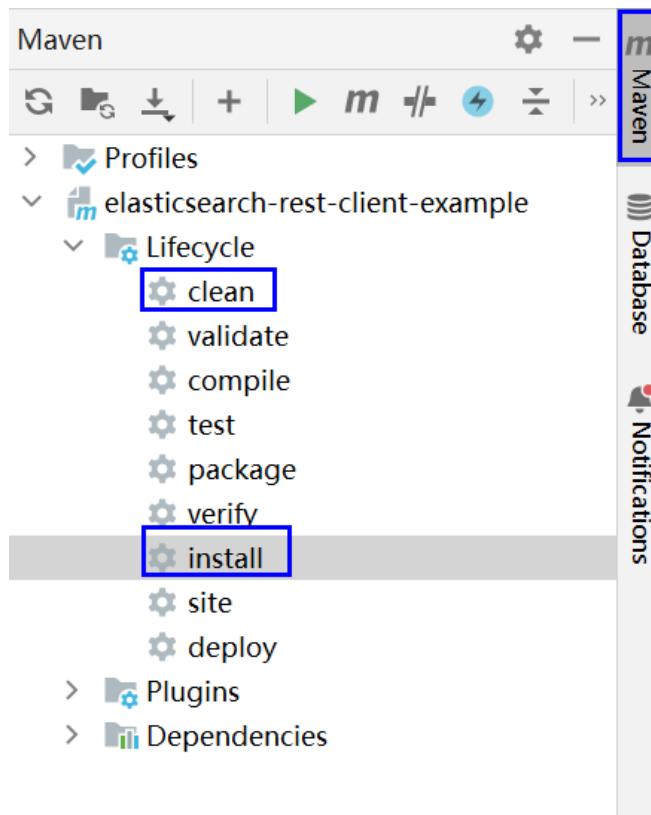

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven** > *Sample projectname* > **Lifecycle** > **clean**, double click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **install**, double click **install** to run the **install** command of Maven.

Figure 1-33 Maven tools: clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean install** command to compile the **pom.xml** file.

Figure 1-34 Enter mvn clean compile in the IDEA Terminal text box.

After the compilation is completed, the message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

### Step 2 Generate the **libs** on which the running depends.

Go to the local root directory of the project and run the following command in the Windows command prompt window to generate the **libs** on which the running depends:

**mvn dependency:copy-dependencies -DoutputDirectory=libs**

### Step 3 Run the .jar package

- Copy the directories **libs** and **conf** required for the development environment to any directory (For example, /opt/elasticsearch-rest-client-example) in the

Linux operating environment. Then, copy the **.jar** package generated in the application environment to **/opt/elasticsearch-rest-client-example/libs/**.

 **NOTE**

Modify the **esParams.properties** file in the **conf** directory based on the site requirements. For details, see [Table 1-14](#).

2. Switch to the code directory `cd /opt/elasticsearch-rest-client-example`.
3. Run the following Java command:

- Run Low Level RestClient code

```
java -cp /opt/elasticsearch-rest-client-example/conf/*:/opt/
elasticsearch-rest-client-example/libs/*
com.huawei.fusioninsight.elasticsearch.example.lowlevel.allrequests.L
owLevelRestClientAllRequests
```

- Run High Level RestClient code

```
java -cp /opt/elasticsearch-rest-client-example/conf/*:/opt/
elasticsearch-rest-client-example/libs/*
com.huawei.fusioninsight.elasticsearch.example.highlevel.allrequests.
HighLevelRestClientAllRequests
```

- Run JDBC Rest Client code

```
java -cp /opt/elasticsearch-rest-client-example/conf/*:/opt/
elasticsearch-rest-client-example/libs/*
com.huawei.fusioninsight.elasticsearch.example.jdbc.SqlMain
```

----End

## Viewing the Commissioning Result

After the Elasticsearch ends running, you can view the running status using either of the following methods:

- View the running result.
- Obtain the Elasticsearch log **/opt/elasticsearch-example/logs/es-example.log** in the **logs** directory.

After a complete sample of the Low Level RestClient is run, operation results are as follows:

```

```

## Log description

The default log level is **INFO** and more details can be viewed by changing the log level (**TRACE**, **DEBUG**, **INFO**, **WARN**, and **ERROR**). You can modify the **log4j.properties** file to change log levels, for example:

```
# This sets the global logging level and specifies the appenders
log4j.rootLogger=INFO,theConsoleAppender,R

# settings for the console appender
log4j.appender.theConsoleAppender=org.apache.log4j.ConsoleAppender
log4j.appender.theConsoleAppender.Threshold=INFO
log4j.appender.theConsoleAppender.layout=org.apache.log4j.PatternLayout
log4j.appender.theConsoleAppender.layout.ConversionPattern=%d{yyyy-MM-dd HH:mm:ss,SSS} | %-5p | %t
| %m | %l%n

# R is set to be a File appender using a PatternLayout.
log4j.appender.R=org.apache.log4j.RollingFileAppender
log4j.appender.R.Append=true
log4j.appender.R.Threshold=debug
log4j.appender.R.MaxFileSize=10240KB
log4j.appender.R.MaxBackupIndex=10
log4j.appender.R.File=logs/es-example.log
log4j.appender.R.layout=org.apache.log4j.PatternLayout
log4j.appender.R.layout.ConversionPattern=%d{yyyy-MM-dd HH:mm:ss,SSS} | %-5p | %t | %m | %l%n
```

### 1.7.4.2.2 Commissioning a SpringBoot Program

Applications that interconnect Elasticsearch with SpringBoot can run in the Linux environment. After the application code is developed, you can upload the JAR file to the prepared Linux environment.

## Prerequisites

JDK has been installed on Linux. The version must be the same as JDK version of the JAR file exported from IntelliJ IDEA. Java environment variables have been set.

## Compiling and Running Applications

**Step 1** Click Terminal in the lower left corner of the IDEA page to access the terminal. Run the **mvn clean package** command to compile the package.

```
Terminal: Local + v
Windows PowerShell
尝试新的跨平台 PowerShell https://aka.ms/powershell
PS E:\Test\sample_project\src\springboot\elasticsearch-examples\elasticsearch-rest-client-example> mvn clean package
```

If the command output contains "Build Success", the compilation is successful, as shown in the following figure. After the compilation is successful, the es-springboot.jar file is generated in the target directory of the sample project.

```
Terminal: Local + v
[INFO] -- maven-jar-plugin:3.2.2:jar (default-jar) @ elasticsearch ...
[INFO] Building jar: E:\Test\sample_project\src\springboot\elasticsearch-examples\elasticsearch-rest-client-example\target\es-springboot.jar
[INFO]
[INFO] -- spring-boot-maven-plugin:1.3.2.RELEASE:repackage (repackage) @ elasticsearch ...
[INFO]
[INFO] -- spring-boot-maven-plugin:1.3.2.RELEASE:repackage (default) @ elasticsearch ...
[INFO]
[INFO] BUILD SUCCESS
[INFO]
[INFO] Total time: 4.836 s
[INFO] Finished at: 2023-02-27T10:34:23+08:00
[INFO]
PS E:\Test\sample_project\src\springboot\elasticsearch-examples\elasticsearch-rest-client-example>
```

**Step 2** Create a directory on Linux as the running directory, for example, /opt/es-springboot, and save the es-springboot.jar and conf folders in the target directory to the directory. Modify the esParams.properties file in the conf directory and save the user credential files krb5.conf and user.keytab of Elasticsearch to the conf directory.

#### NOTE

Modify the esParams.properties configuration file in the conf directory based on the site requirements. For details, see [1.2.3.2](#).

**Step 3** Run the JAR file.

1. Switch to the code function directory.

```
cd /opt/es-springboot
```

2. Run the java command to start the SpringBoot service.

```
java -jar es-springboot.jar conf/
```

3. Start another terminal on the current node to access the Elasticsearch client.

```
cd Client installation directory
```

```
source bigdata_env
```

```
kinit esuser
```

4. Perform the curl operation of Elasticsearch. For example, if you run the curl **http://localhost:8080/elasticsearch/cluster/health** command to query the cluster health status, the following information is displayed:

```
{"cluster_name":"elasticsearch_cluster","status":"green","timed_out":false,"number_of_nodes":6,"number_of_data_nodes":3,"active_primary_shards":11,"active_shards":22,"relocating_shards":0,"initializing_shards":0,"unassigned_shards":0,"delayed_unassigned_shards":0,"number_of_pending_tasks":0,"number_of_in_flight_fetch":0,"task_max_waiting_in_queue_millis":0,"active_shards_percent_as_number":100.0}
```

For details about other operations, see [Table 1-23](#).

**Table 1-23** Curl operations for interconnecting Elasticsearch with SpringBoot

Method	Curl Commands on the Linux Client	Description
getElasticsearch	curl 'http://localhost:8080/elasticsearch/'	Obtain cluster information such as <code>clusterName</code> , <code>clusterUuid</code> , and <code>nodeName</code> .
clusterHealth	curl 'http://localhost:8080/elasticsearch/_cluster/health'	Obtain the cluster health status.
indexByJson	curl 'http://localhost:8080/elasticsearch/_indexByJson?index=/Index name'	Write data in JSON format.
indexByMap	curl 'http://localhost:8080/elasticsearch/_indexByMap?index=/Index name'	Write data in the Map format.
indexByXcontentBuilder	curl 'http://localhost:8080/elasticsearch/_indexByXContentBuilder?index=/Index name'	Write data in the XContentBuilder format.
update	curl 'http://localhost:8080/elasticsearch/_update?index=/Index name&id=/D value'	Update index data.
bulk	curl 'http://localhost:8080/elasticsearch/_bulk?index=/Index name'	Write data in batches.
getIndex	curl 'http://localhost:8080/elasticsearch/_getIndex?index=/Index name&id=/D value'	Query index information.
search	curl 'http://localhost:8080/elasticsearch/_search?index=/Index name'	Search for related document information under a specified index.
scroll	curl 'http://localhost:8080/elasticsearch/_scroll?index=/Index name'	Search for document information under a specified index using a cursor. You can disable the cursor by modifying <b>scrollId</b> .
deleteIndex	curl 'http://localhost:8080/elasticsearch/_deleteIndex?index=/Index name'	Delete an index.

**----End**

# 1.8 Flink Development Guide

## 1.8.1 Overview

### 1.8.1.1 Application Development

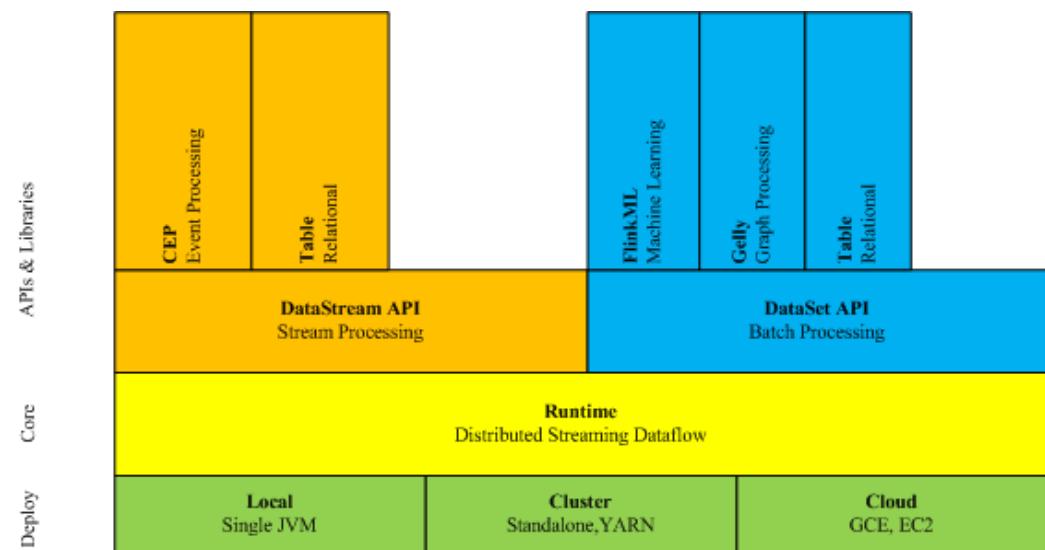

#### Overview

Flink is a unified computing framework that supports both batch processing and stream processing. It provides a stream data processing engine that supports data distribution and parallel computing. Flink features stream processing and is a top open-source stream processing engine in the industry.

Flink provides high-concurrency pipeline data processing, millisecond-level latency, and high reliability, making it suitable for low-latency data processing.

**Figure 1-35** shows the technology stack of Flink.

**Figure 1-35** Technology stack of Flink

The following lists the key features of Flink in the current version:

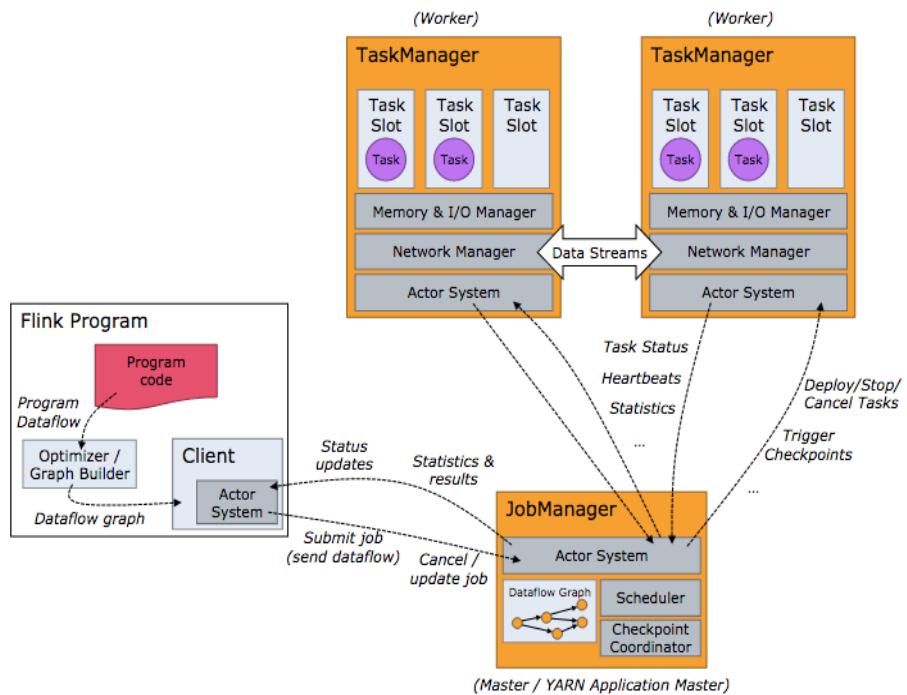

- DataStream
- Checkpoint
- Window
- Job Pipeline
- Configuration Table

For details about other Flink features, see <https://ci.apache.org/projects/flink/flink-docs-release-1.17>.

## Architecture

[Figure 1-36](#) shows the architecture of Flink.

**Figure 1-36** Flink architecture

As shown in [Figure 1-36](#), the entire Flink system consists of three parts:

- **Client**  
Flink client is used to submit jobs (streaming jobs) to Flink.
- **TaskManager**  
TaskManager (also called worker) is a service execution node of Flink. It executes specific tasks. A Flink system could have multiple TaskManagers. These TaskManagers are equivalent to each other.
- **JobManager**  
JobManager (also called master) is a management node of Flink. It manages all TaskManagers and schedules tasks submitted by users to specific TaskManagers. In high-availability (HA) mode, multiple JobManagers are deployed. Among these JobManagers, one of which is selected as the leader, and the others are standby.

Flink provides the following features:

- **Low latency**  
Millisecond-level processing capability.
- **Exactly once**  
Asynchronous snapshot mechanism, ensuring that all data is processed only once.

- High availability  
Leader/Standy JobManagers, preventing single point of failure (SPOF).
- Scale out  
Manual scale out supported by TaskManagers.

## Flink Development APIs

Flink DataStream API can be developed using Scala and Java languages, as shown in [Table 1-24](#).

**Table 1-24** Flink DataStream API

Function	Description
Scala API	API in Scala, which can be used for data processing, such as filtering, joining, windowing, and aggregation.
Java API	API in Java, which can be used for data processing, such as filtering, joining, windowing, and aggregation.

### 1.8.1.2 Basic Concepts

#### Basic Concepts

- **DataStream**  
DataStream is the minimum unit of Flink processing and is one of core concepts of Flink. DataStreams are initially imported from external systems in formats of socket, Kafka, and files. After being processed by Flink, DataStreams are exported to external systems in formats of socket, Kafka, and files.
- **Data Transformation**  
A data transformation is a data processing unit that transforms one or multiple DataStreams into a new DataStream.  
Data transformation can be classified as follows:
  - One-to-one transformation, for example, map.
  - One-to-zero, one-to-one, or one-to-multiple transformation, for example, flatMap.
  - One-to-zero or one-to-one transformation, for example, filter.
  - Multiple-to-one transformation, for example, union.
  - Transformation of multiple aggregations, for example, window and keyby.
- **Checkpoint**  
Checkpoint is the most important Flink mechanism to ensure reliable data processing. Checkpoints ensure that all application statuses can be recovered from a checkpoint in case of failure occurs and data is processed exactly once.
- **Savepoint**  
Savepoints are externally stored checkpoints that you can use to stop-and-resume or update your Flink programs. After the upgrade, you can set the

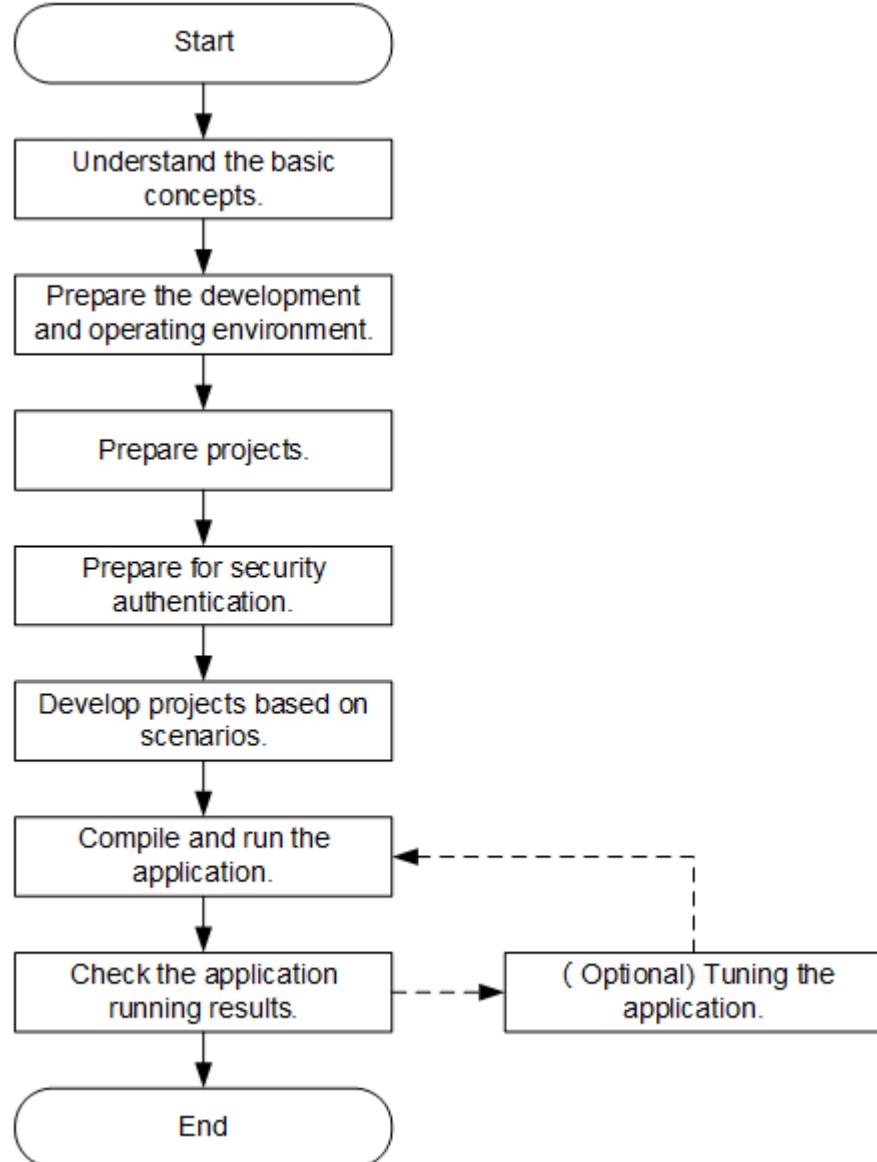

task status to the savepoint storage status and start the restoration, ensuring data continuity.

### 1.8.1.3 Development Process

#### Development Process of a Flink Application

[Figure 1-37](#) shows the Flink development process:

**Figure 1-37** Development process of a Flink application

**Table 1-25** Description of the development process

Phase	Description	Reference
Understand the basic concepts.	Before the development process, you are advised to gain a basic understanding of Flink.	<a href="#">Basic Concepts</a>
Prepare the development and operating environment.	Flink applications can be developed using Scala or Java. You are advised to use IntelliJ IDEA tool to configure the development environment as instructed, based on your development language.  The running environment of Flink is the Flink client. Install and configure the client as instructed.	<a href="#">Preparing Development and Operating Environment</a>
Prepare projects.	Flink provides sample projects for you to import and learn. Alternatively, you can create a Flink project as instructed.	<a href="#">Configuring and Importing Sample Projects</a> <a href="#">Creating a Project (Optional)</a>
Prepare for security authentication.	The security authentication is mandatory if security clusters are used.	<a href="#">Preparing for Security Authentication</a>
Develop the project.	Sample projects in Scala and Java are provided to help you quickly understand programming interfaces of Flink components.	<a href="#">Developing an Application</a>
Compile and run the application.	Guidance is provided for you to compile and run a developed application.	<a href="#">Compiling and Running the Application</a>
Check running results.	Application running results are stored in a path specified by you. You can also view application running status through Apache Flink Dashboard.	<a href="#">Viewing the Debugging Result</a>
Tune the application.	Tune the application to meet certain service requirements.  After the tuning is complete, the application needs to be compiled and run again.	"Flink Performance Tuning" in the Component Operation Guide

## 1.8.2 Environment Preparation

### 1.8.2.1 Preparing Development and Operating Environment

#### Preparing Development Environment

**Table 1-26** describes the environment required for application development.

**Table 1-26** Development environment

Item	Description
OS	<ul style="list-style-type: none"><li>Development environment: Windows OS. Windows 7 or later is supported.</li><li>Operating environment: Linux OS If the program needs to be commissioned locally, the runtime environment must be able to communicate with the cluster service plane network.</li></ul>
JDK installation	<p>Basic configuration of the development and running environment. The version requirements are as follows: The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>Oracle JDK 1.8</li><li>IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>For security purposes, the server supports only TLS V1.2 or later.</li><li>By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls</a>.</li><li>For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IDEA installation and configuration	Used for developing Flink applications. The version must be 2019.1 or other compatible version.
Scala installation	Basic configuration for the Scala development environment. The required version is 2.11.7.

Item	Description
Scala plug-in installation	Basic configuration for the Scala development environment. The required version is 1.5.4.
Maven installation	Basic configuration of the development environment for project management throughout the lifecycle of software development.
Developer account preparation	Prepare a cluster user for application development and grant permissions to the user by referring to <a href="#">Preparing a Developer Account</a> .
7-Zip	Used to decompress .zip and .rar packages, 7-Zip 16.04 is supported.
Python3	Used to run Flink Python jobs. Python 3.7 or later is required.

## Preparing an Operating Environment

During application development, prepare the code running and commissioning environment to verify that the application is running properly.

To use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.

1. Install the client in a directory, for example, `/opt/hadoopclient`, on the node. Ensure that the difference between the client time and the cluster time is less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).

### NOTE

- Verify that the configuration options in the Flink client configuration file `flink-conf.yaml` are correctly configured. For details, see [Preparing for Security Authentication](#).
  - In security mode, append the service IP address of the node where the client is installed and floating IP address of Manager to the `jobmanager.web.allow-access-address` configuration item in the `flink-conf.yaml` file. Use commas (,) to separate IP addresses.
2. Log in to the FusionInsight Manager portal. Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user `root`. Go to the decompression path of the cluster client and copy all configuration files in the `FusionInsight_Cluster_1_Services_ClientConfig\Flink\config` directory to the `conf` directory where the compiled JAR package is stored for subsequent commissioning, for example, `/opt/hadoopclient/conf`.

For example, if the client software package is `FusionInsight_Cluster_1_Services_Client.tar` and the download path is `/tmp/FusionInsight-Client` on the active management node, run the following commands:

```
cd /tmp/FusionInsight-Client
```

```
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Flink/config/* root@IP address of the client node:/opt/hadoopclient/  
conf
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. [Table 1-27](#) describes the main configuration files.

**Table 1-27** Configuration files

File	Function
core-site.xml	Configures Flink parameters.
hdfs-site.xml	Configures HDFS parameters.
yarn-site.xml	Configures Yarn parameters.
flink-conf.yaml	Configures the Flink client.
user.keytab	Provides user information for Kerberos security authentication.
krb5.conf	Provides Kerberos server configuration information.

3. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

4. (Optional) To run a Python job, perform the following additional configurations:
  - a. Log in to the node where the Flink client is installed as the **root** user and run the following command to check whether Python 3.7 or a later has been installed:  
**python3 -V**
  - b. Go to the python 3 installation path, for example, **/srv/pyflink-example**, and install the **virtualenv**:  
**cd /srv/pyflink-example**  
**virtualenv venv --python=python3.x**  
**source venv/bin/activate**
  - c. Copy the **Flink/flink/opt/python/apache-flink-\*.tar.gz** file from the client installation directory to **/srv/pyflink-example**:  
**cp /Client installation directory/Flink/flink/opt/python/apache-flink-\*.tar.gz /srv/pyflink-example**
  - d. Install the dependency package. If the following command output is displayed, the installation is successful:

```
python -m pip install apache-flink-libraries-*tar.gz
python -m pip install apache-flink- Version number.tar.gz
...
Successfully built apache-flink
Installing collected packages: apache-flink
Attempting uninstall: apache-flink
  Found existing installation: apache-flink x.xx.x
  Uninstalling apache- flink-x.xx.x.
  Successfully uninstalled apache-flink-x.xx.x
Successfully installed apache-flink-x.xx.x
```

### 1.8.2.2 Configuring and Importing Sample Projects

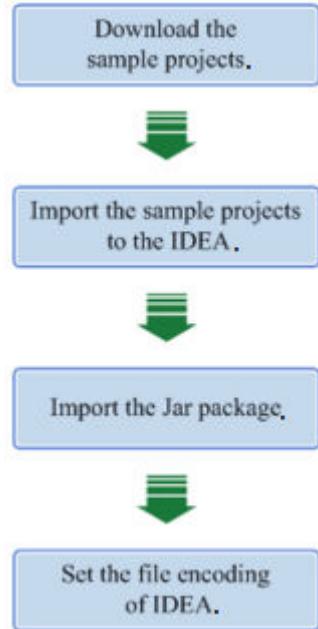

#### Scenarios

Flink provides sample projects for multiple scenarios, including Java and Scala sample projects, to help you quickly learn Flink projects.

Methods to import Java and Scala projects are the same.

The following example describes how to import Java sample code. [Figure 1-38](#) shows the operation process.

**Figure 1-38** Process of importing sample projects

#### Procedure

**Step 1** Obtain the sample project folder **flink-examples-security** in the **src\flink-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

 NOTE

- In security mode, obtain the sample project **flink-examples-security** from the **src\flink-examples** folder.
- In normal mode, obtain the sample project **flink-examples-normal** from the **src\flink-examples** folder.

**Step 2** Before importing the sample project, configure JDK for IntelliJ IDEA.

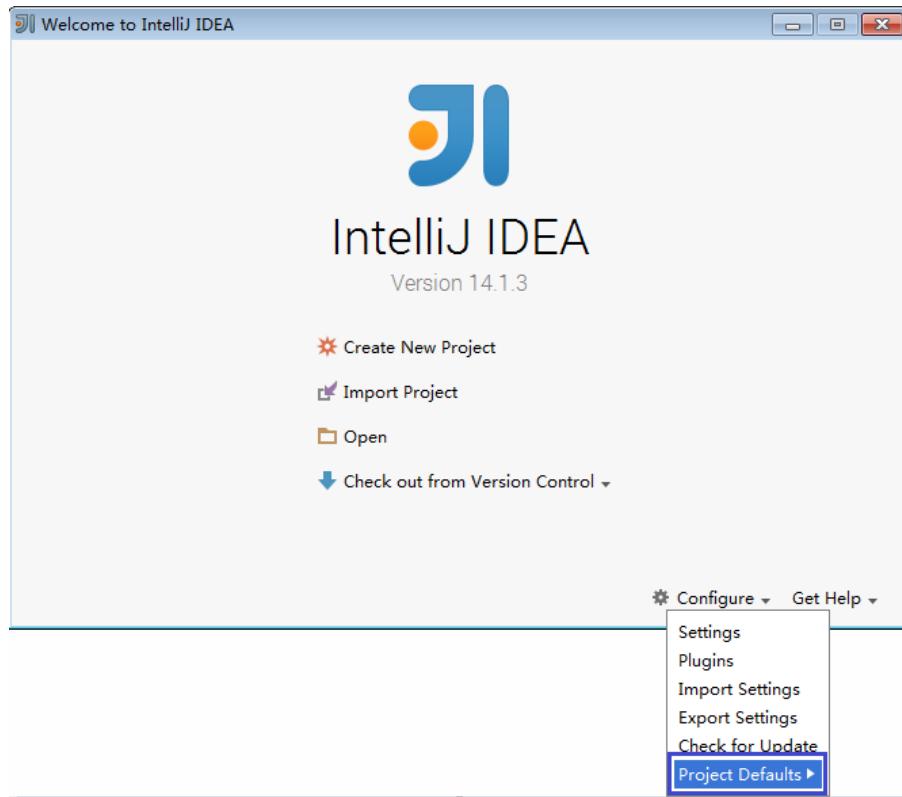

1. Start IntelliJ IDEA and click **Configure**.

**Figure 1-39** Choosing Configure

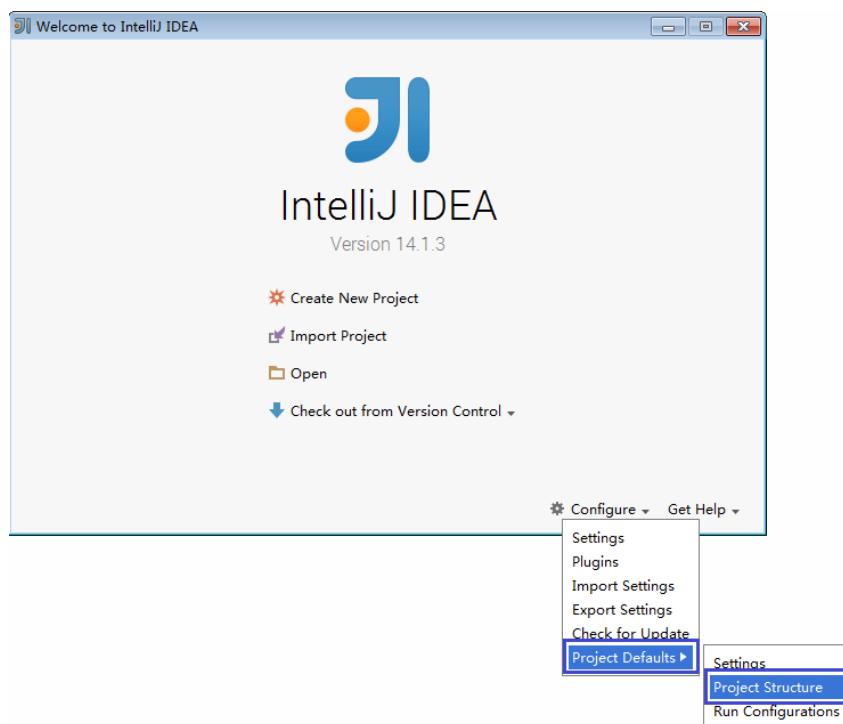

2. Choose **Project Defaults** from the **Configure** drop-down list.

Figure 1-40 Choosing Project Defaults

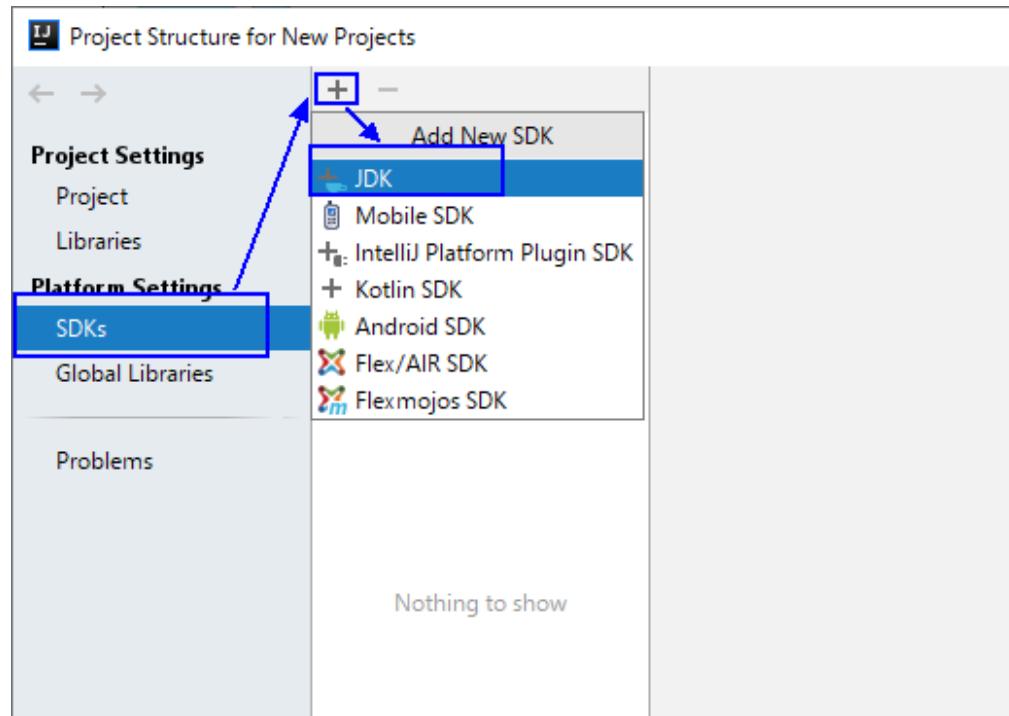

3. Choose **Project Structure** from the **Project Defaults** submenu.

Figure 1-41 Project Defaults

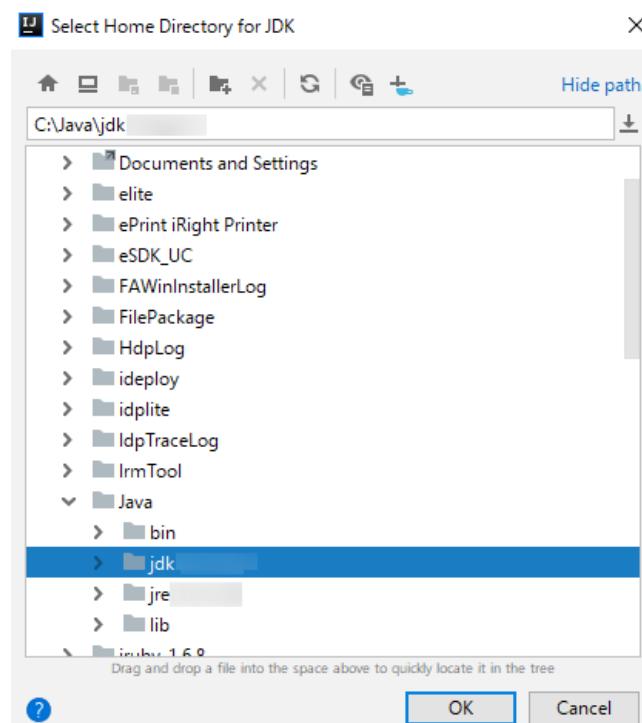

4. On the **Project Structure** page, select **SDKs** and click the plus sign to add the JDK.

Figure 1-42 Adding the JDK

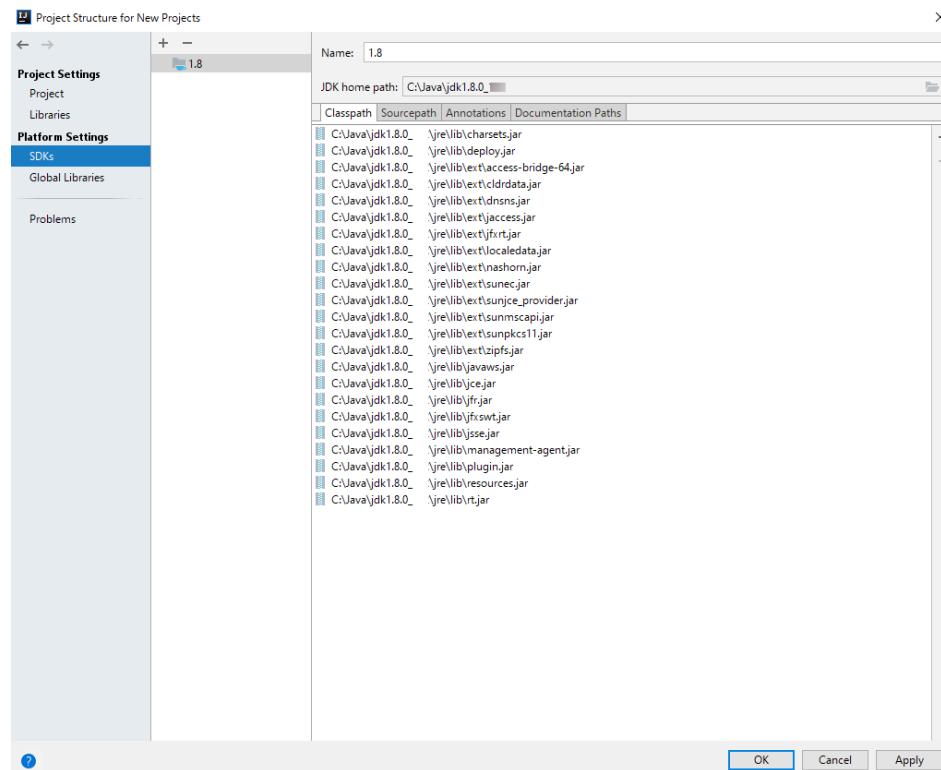

5. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.

Figure 1-43 Selecting the JDK directory

6. After the JDK is selected, click **OK** to complete the configuration.

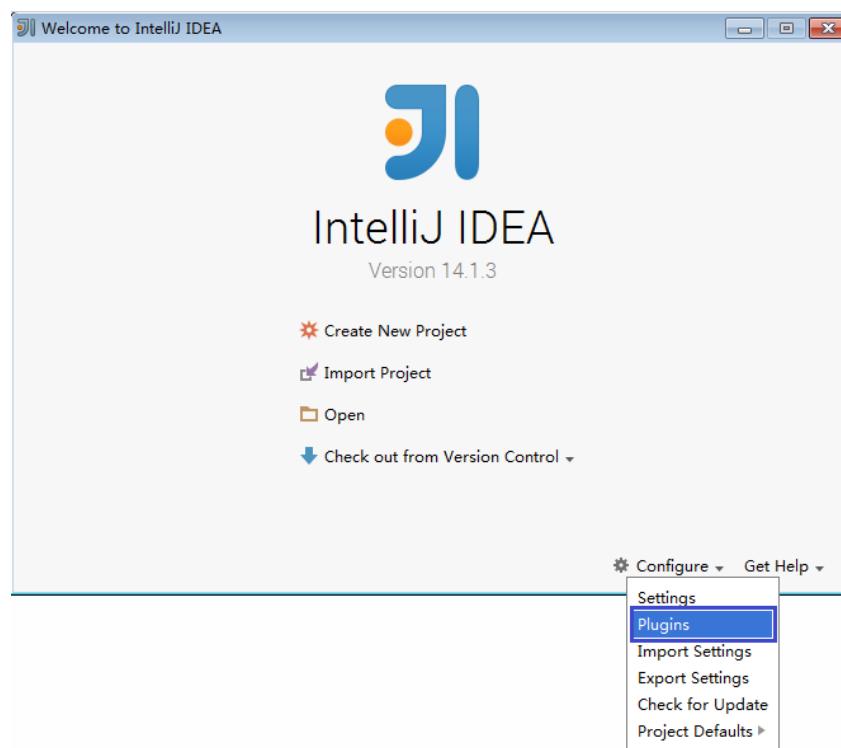

Figure 1-44 Completing the JDK configuration

**Step 3** (Optional) If a Scala sample project is imported, install Scala plug-ins in IntelliJ IDEA.

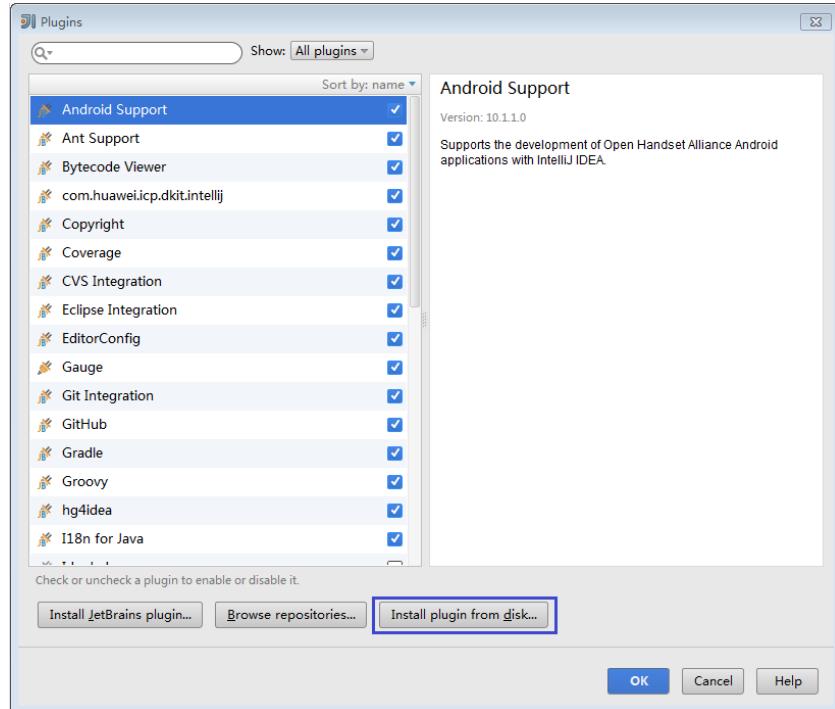

1. Choose **Plugins** from the **Configure** drop-down list.

Figure 1-45 Plugins

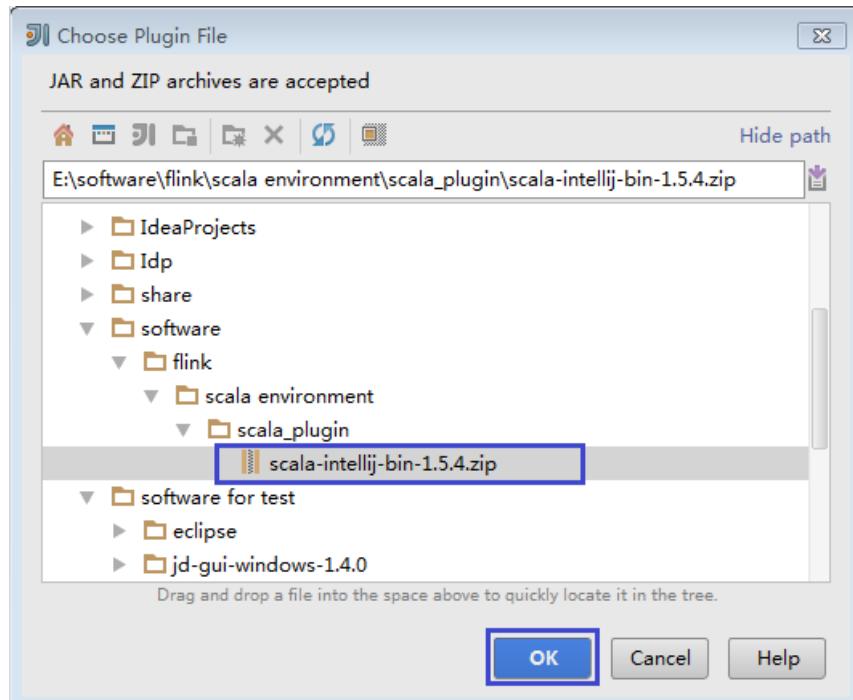

2. On the **Plugins** page, click **Install plugin from disk**.

**Figure 1-46** Install plugin from disk

3. On the **Choose Plugin File** page, select the Scala plugin file of the corresponding version and click **OK**.

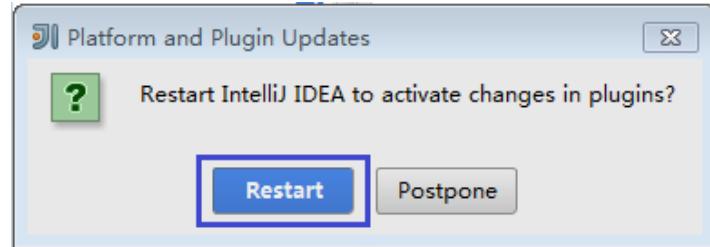

**Figure 1-47** Choose Plugin File

4. On the **Plugins** page, click **Apply** to install the Scala plugins.

5. On the **Platform and Plugin Updates** page that is displayed, click **Restart** to make the configurations take effect.

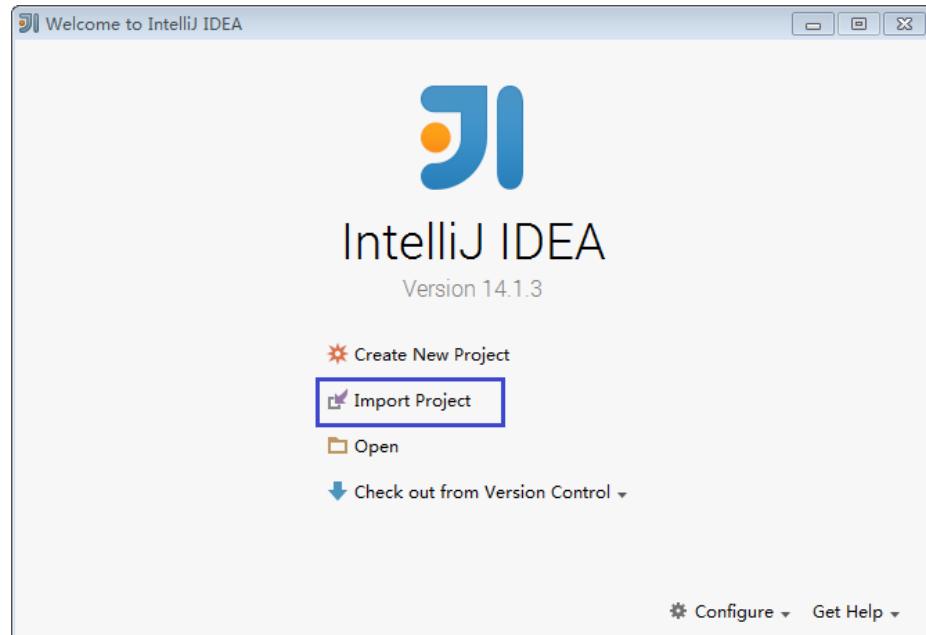

**Figure 1-48** Platform and Plugin Updates

**Step 4** Import the Java sample project to IDEA.

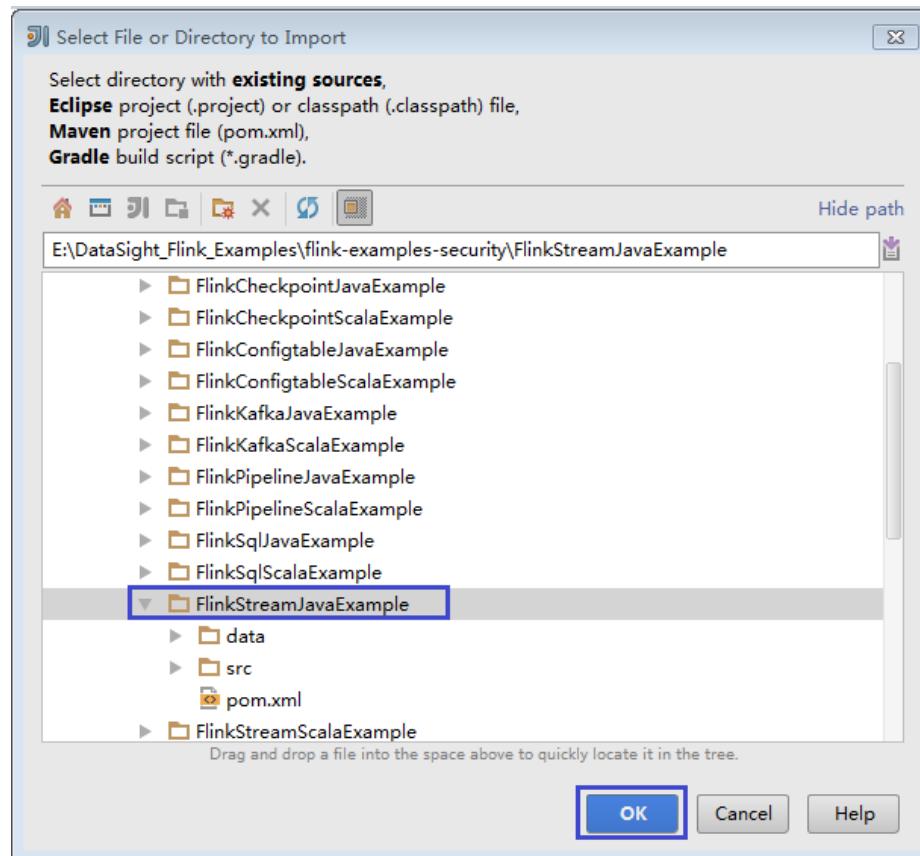

1. Start IntelliJ IDEA. On the **Quick Start** page, select **Import Project**.  
Alternatively, for the used IDEA tool, add the project directly from the IDEA home page. Choose **File > Import project...** to import a project.

**Figure 1-49** Importing a project (on the Quick Start page)

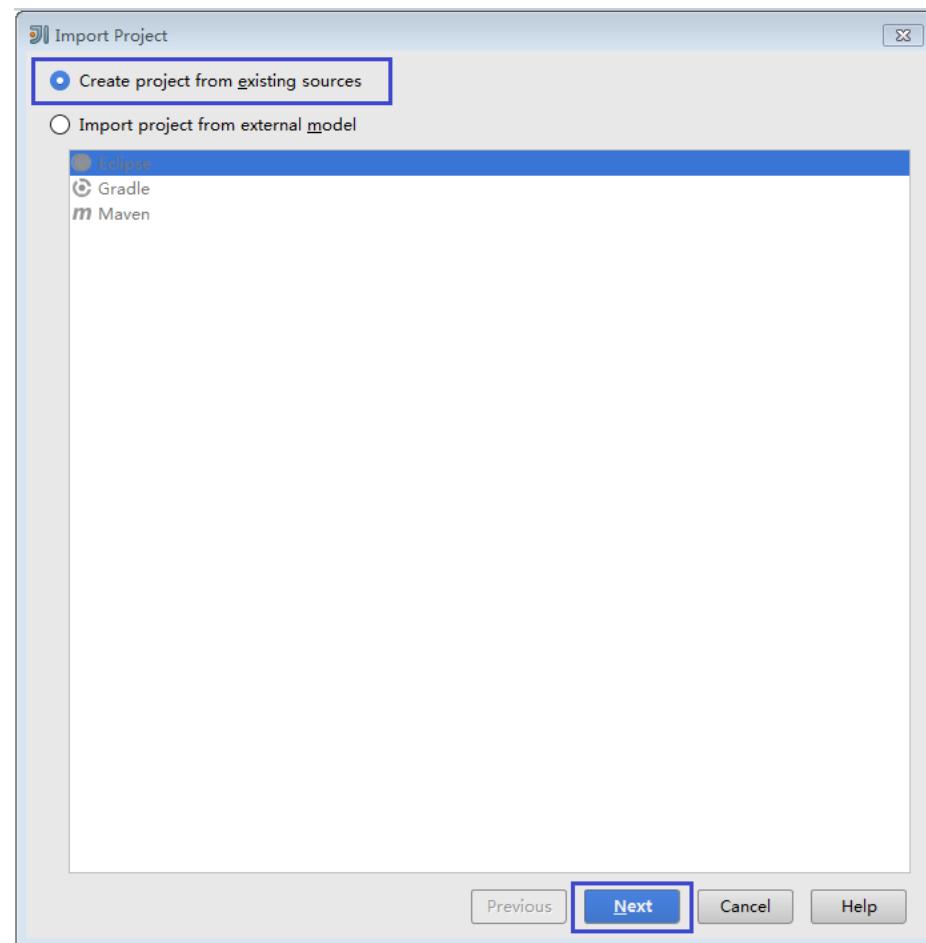

2. Select the directory for storing the imported projects and click **OK**.

Figure 1-50 Select File or Directory to Import

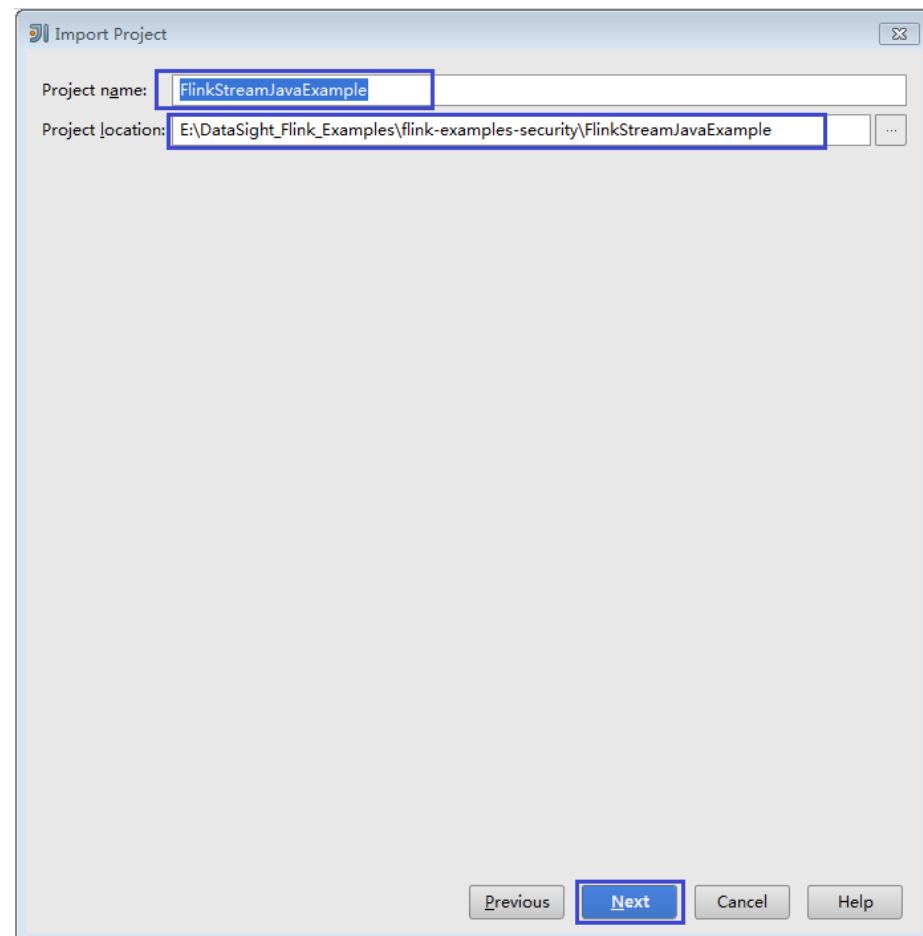

3. Select **Create project from existing sources** and click **Next**.

Figure 1-51 Create project from existing sources

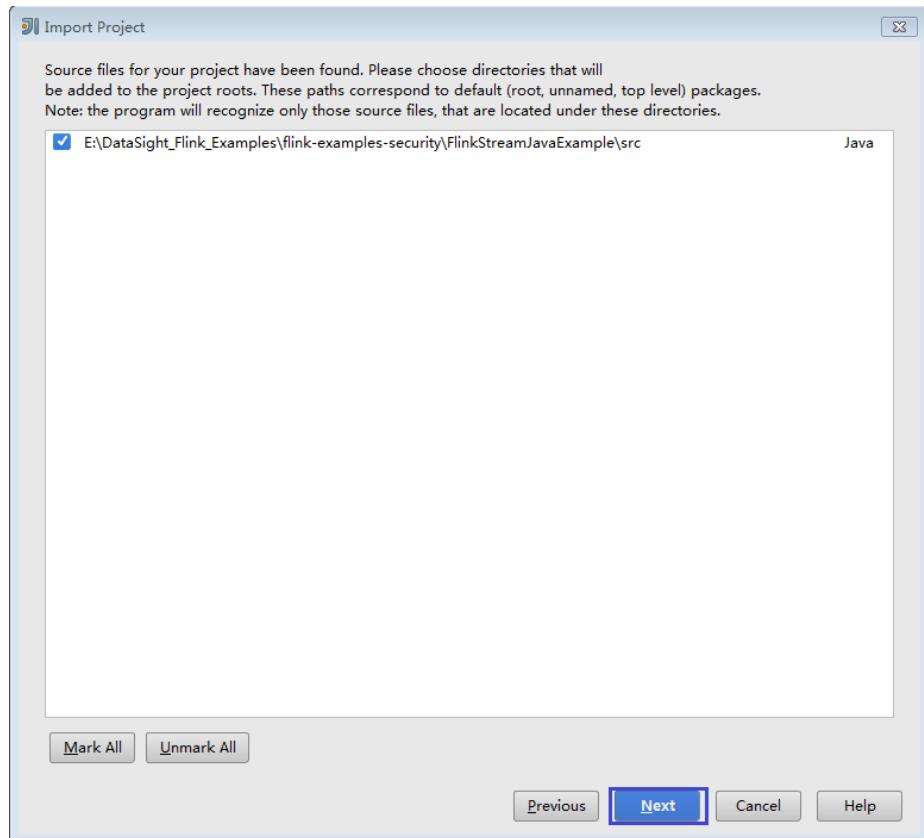

4. Confirm the project location and project name, and click **Next**.

Figure 1-52 Import Project

5. Retain the default value of the **root** directory for the project to be imported and click **Next**.

Figure 1-53 Import Project

6. Retain the default dependency library that is automatically recognized by IDEA and the suggested module structure, and click **Next**.
7. Confirm the JDK to be used by the project and click **Next**.
8. After the import is complete, click **Finish**. The imported sample project is displayed on the IDEA home page.

**Figure 1-54** Completing the import

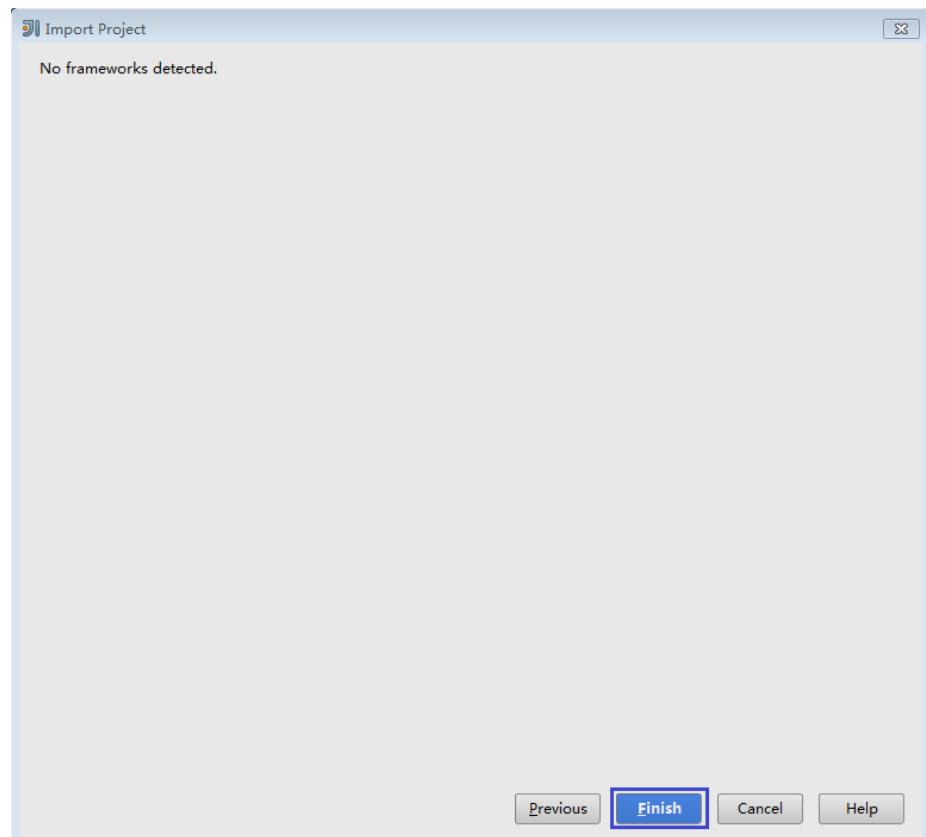

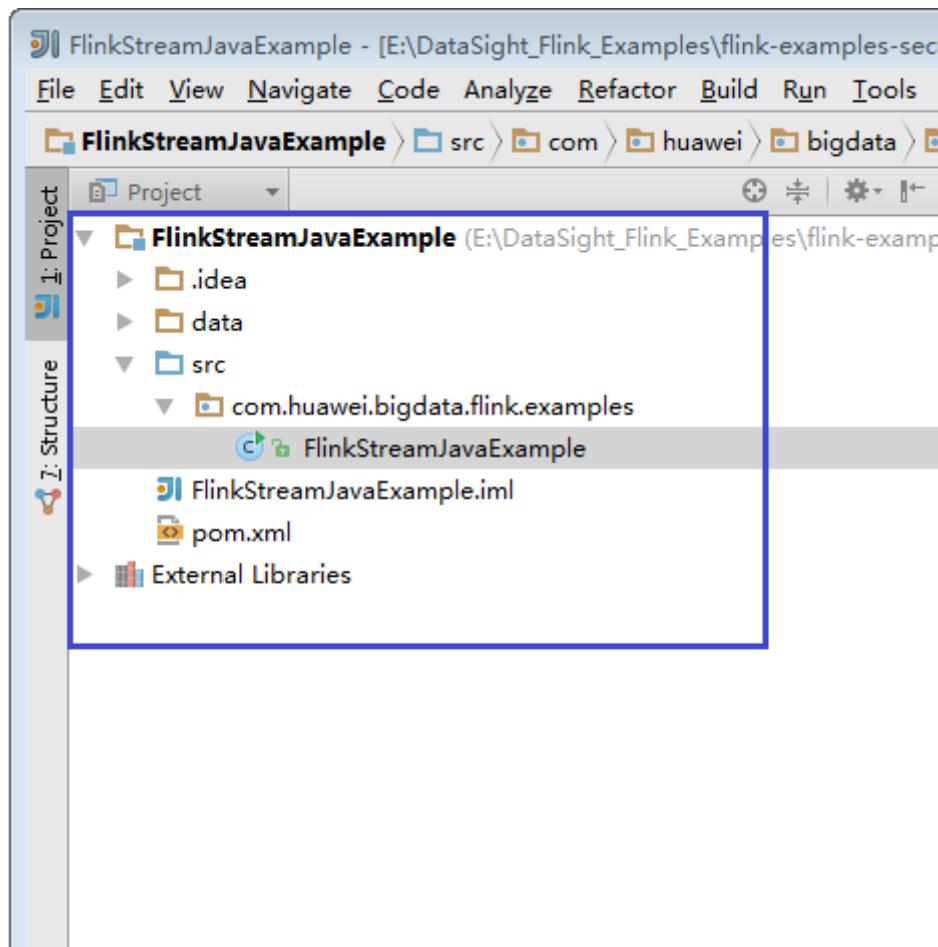

Figure 1-55 Imported project

**Step 5** Import the dependency JAR file for the sample project.

If the sample project code is obtained from an open-source image site, dependency JAR files are automatically downloaded after Maven is configured.

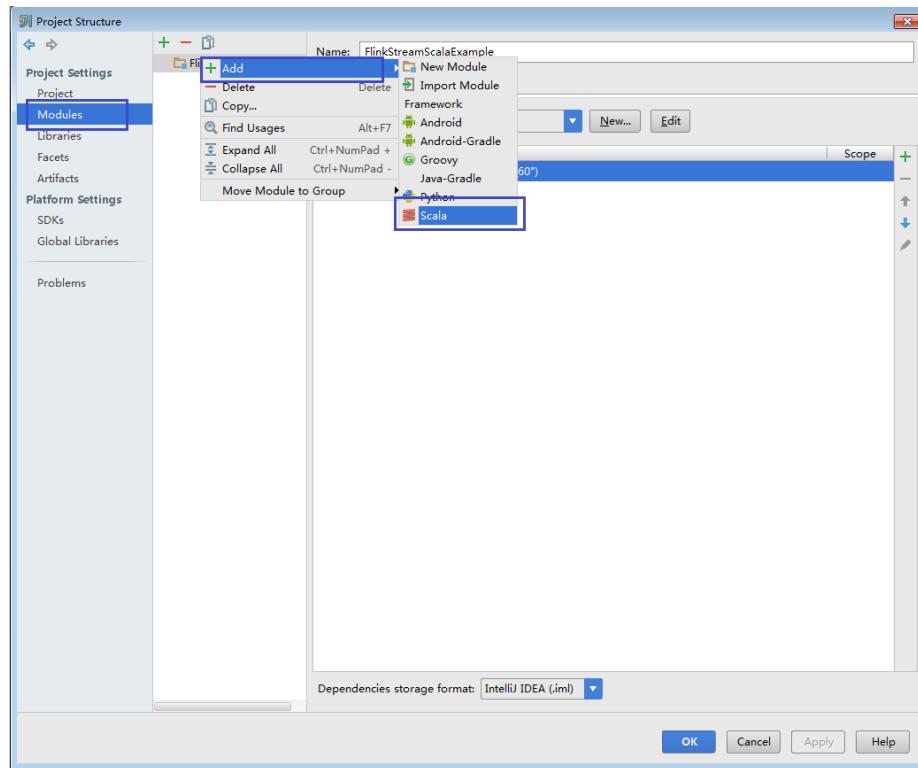

**NOTE**

If other FusionInsight components such as Kafka and Redis are used in the sample code, obtain them from the installation directory of these FusionInsight components. For details about dependency packages of sample projects, see [Reference information about the dependency package for running the sample project](#).

**Step 6** (Optional) If a Scala sample application is imported, configure a language for the project.

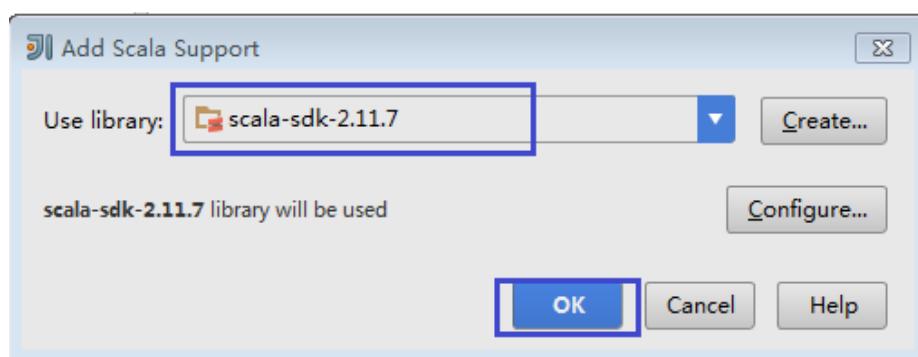

1. On the IDEA home page, choose **File > Project Structures...** to go to the **Project Structure** page.
2. Choose **Modules**, right-click a project name, and choose **Add > Scala**.

Figure 1-56 Selecting Scala

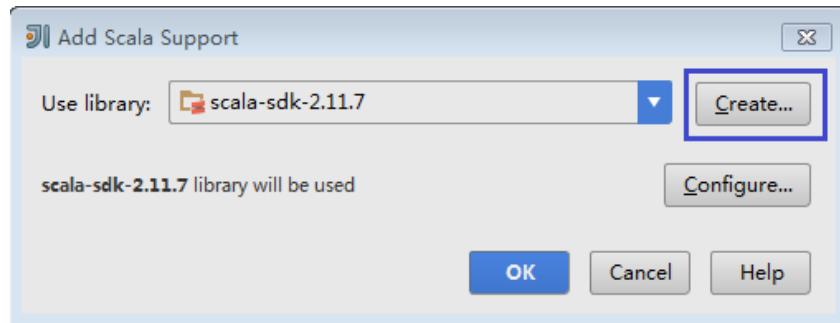

3. Wait until IDEA identifies Scala SDK, select the dependency JAR files in the **Add Scala Support** dialog box, and then click **OK**.

Figure 1-57 Add Scala Support

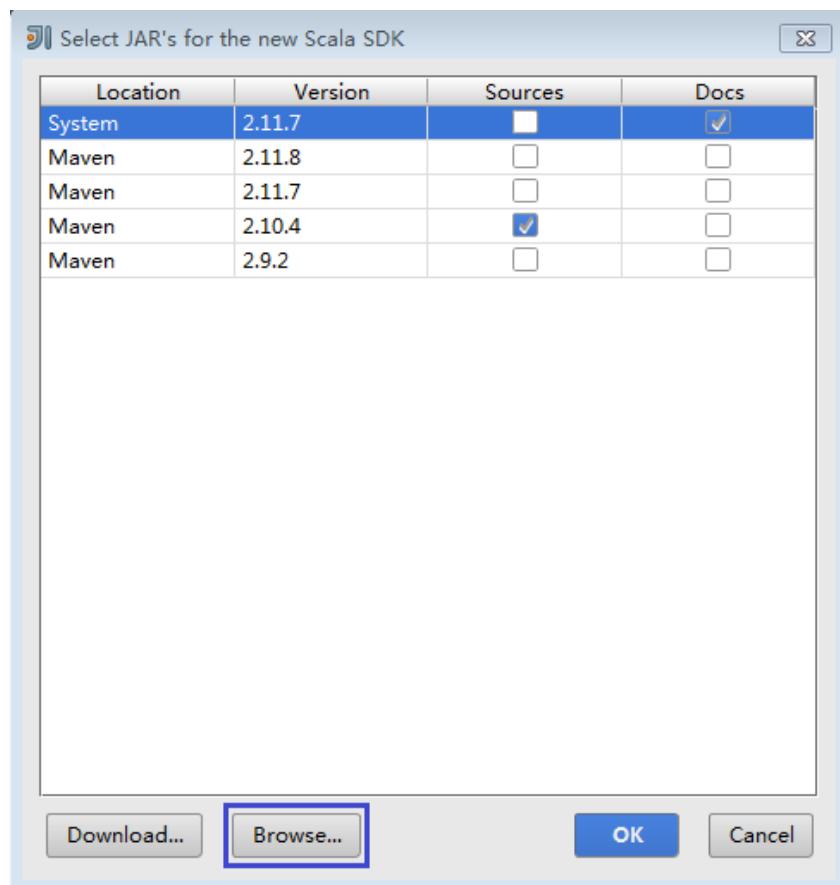

4. If IDEA fails to identify Scala SDK, create a Scala SDK.
  - a. Click **Create....**

Figure 1-58 Create...

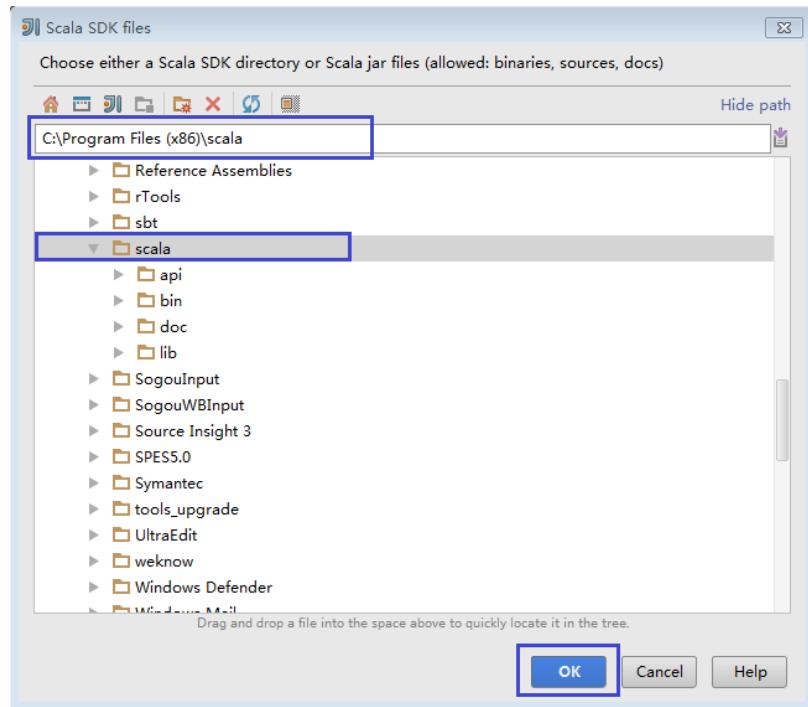

- b. On the **Select JAR's for the new Scala SDK** page, click **Browse....**

Figure 1-59 Select JAR's for the new Scala SDK

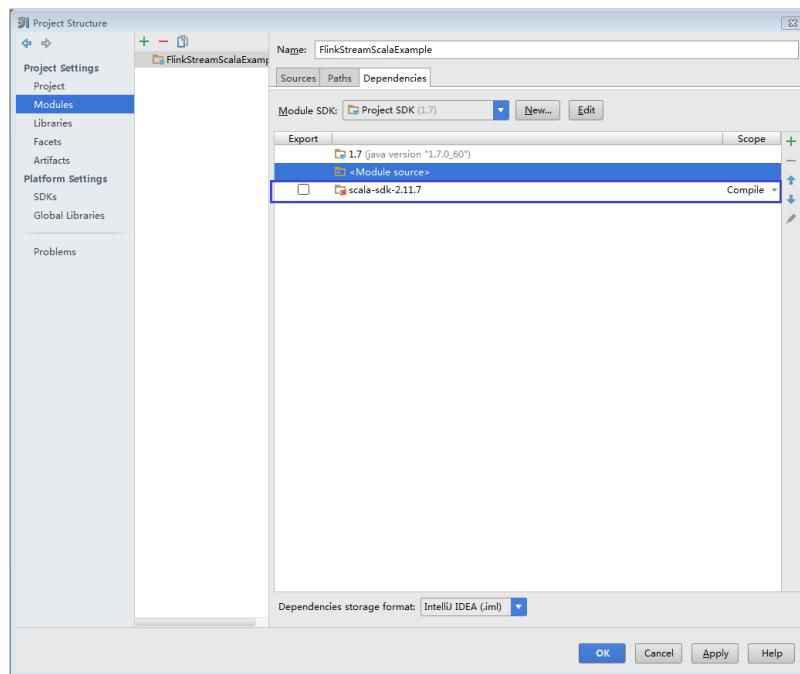

- c. On the **Scala SDK files** page, select the **scala sdk** directory and click **OK**.

Figure 1-60 Scala SDK files

5. Click OK.

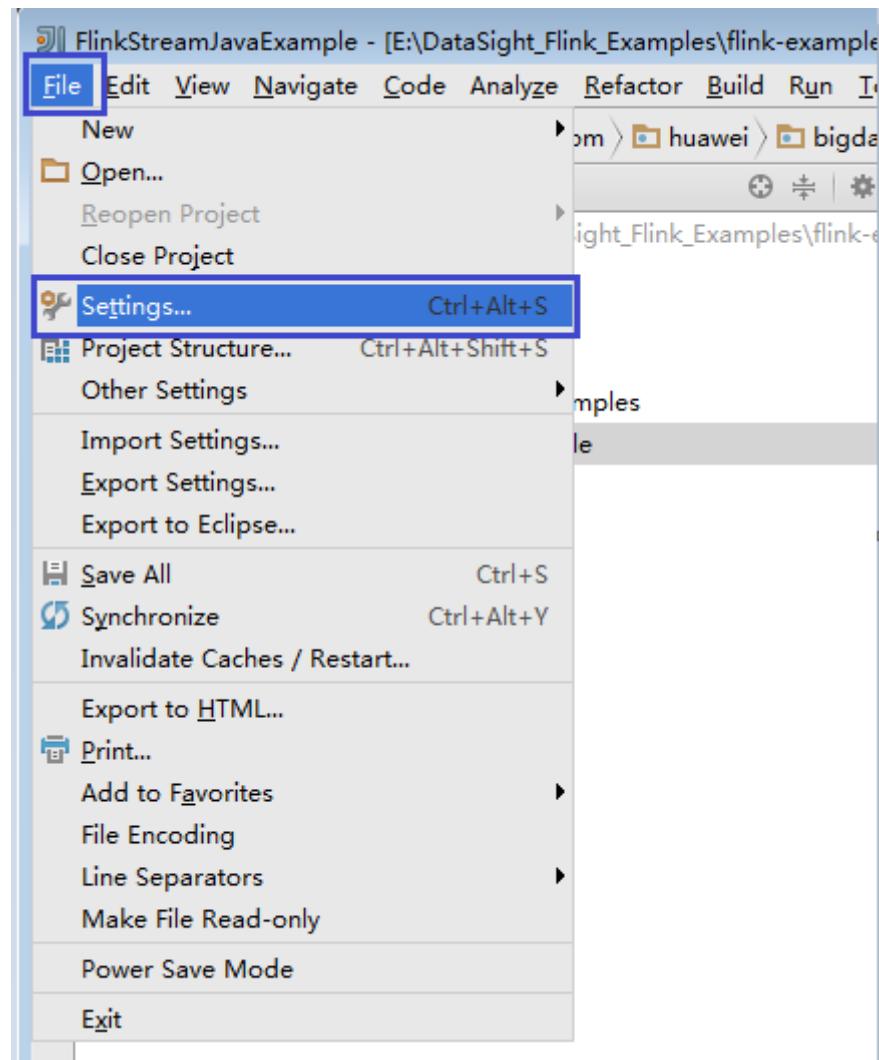

Figure 1-61 The configuration is successful.

**Step 7** Configure the text file encoding format of IDEA to prevent garbled characters.

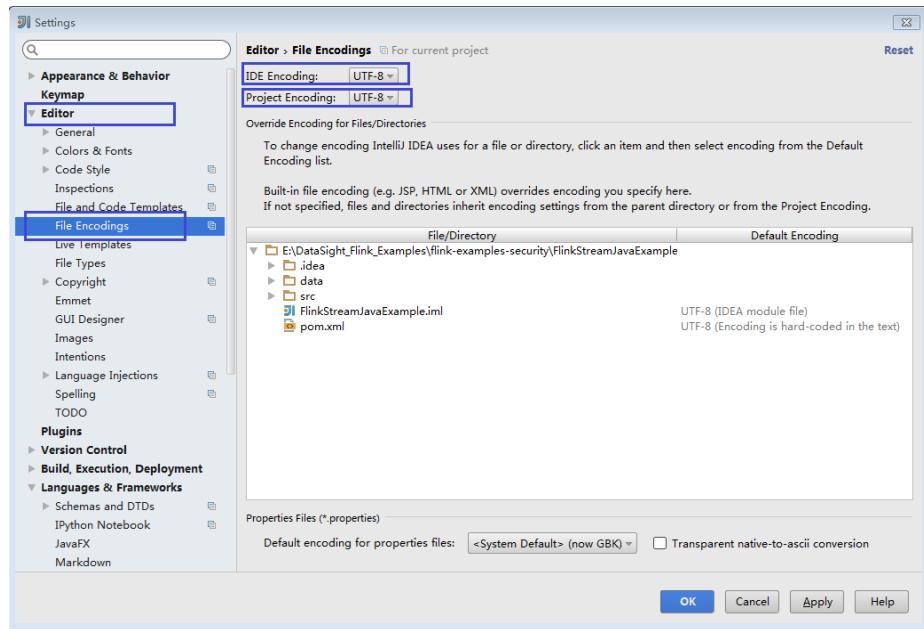

1. On the IDEA home page, choose **File > Settings....**

Figure 1-62 Choosing Settings

2. Configure encoding.
  - a. On the **Settings** page, unfold **Editor**, and choose **File Encodings**.
  - b. Select **UTF-8** from the **IDE Encoding** and **Project Encoding** drop-down lists on the right.
  - c. Click **Apply**.
  - d. Click **OK** to complete the encoding settings.

Figure 1-63 Settings

NOTE

- Obtain related dependency packages from the Flink server installation directory.
- Obtain Kafka dependency packages from the Kafka environment.
- Obtain Redis dependency packages from the Redis environment.
- For details about the dependency packages, see [Reference information about the dependency package for running the sample project](#).

----End

## Reference information about the dependency package for running the sample project

The **lib** and **opt** directories of the Flink client contain Flink JAR files. By default, the **lib** directory contains the Flink core JAR file, and the **opt** directory contains the JAR file (for example, **flink-connector-kafka\*.jar**) for connecting to external components. If it is required during application development, manually copy the related JAR files to the **lib** directory.

The dependency packages of the sample projects provided by Flink are as follows:

**Table 1-28** Dependency package for running the sample project

Sample project	Dependency package	Obtaining Dependency Packages
<ul style="list-style-type: none"><li>• Sample project of the DataStream application</li><li>• Sample project of the asynchronous checkpoint mechanism application</li></ul>	flink-dist_*.jar	Can be obtained from <b>lib</b> in the installation directory of the Flink client or server.
<ul style="list-style-type: none"><li>• Sample projects of Submitting SQL Jobs Using Flink Jar</li><li>• Sample projects of FlinkServer REST API</li></ul>	<ul style="list-style-type: none"><li>• flink-dist_*.jar</li><li>• flink-table_*.jar</li></ul>	Can be obtained from <b>lib</b> in the installation directory of the Flink client or server.

### 1.8.2.3 Creating a Project (Optional)

#### Scenarios

IntelliJ IDEA can be used to create a Flink project. A Scala project is used as an example to illustrate how to create a Flink project.

## Procedure

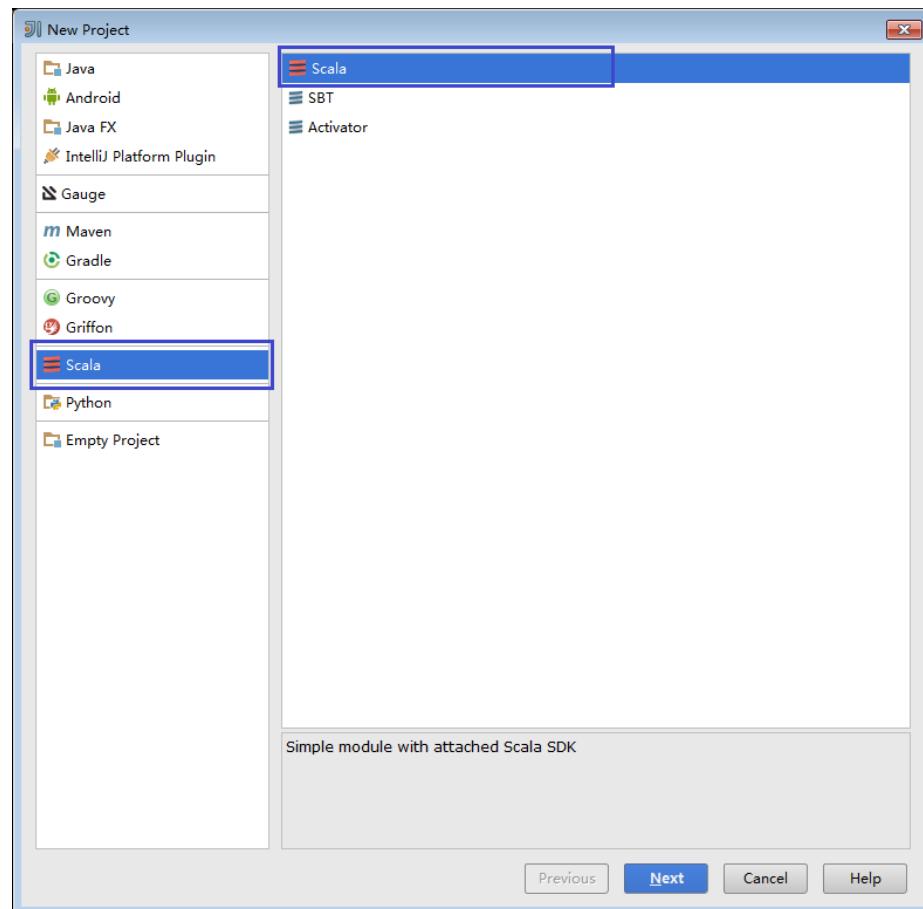

**Step 1** Start the IDEA and choose **Create New Project**.

**Figure 1-64** Creating a project

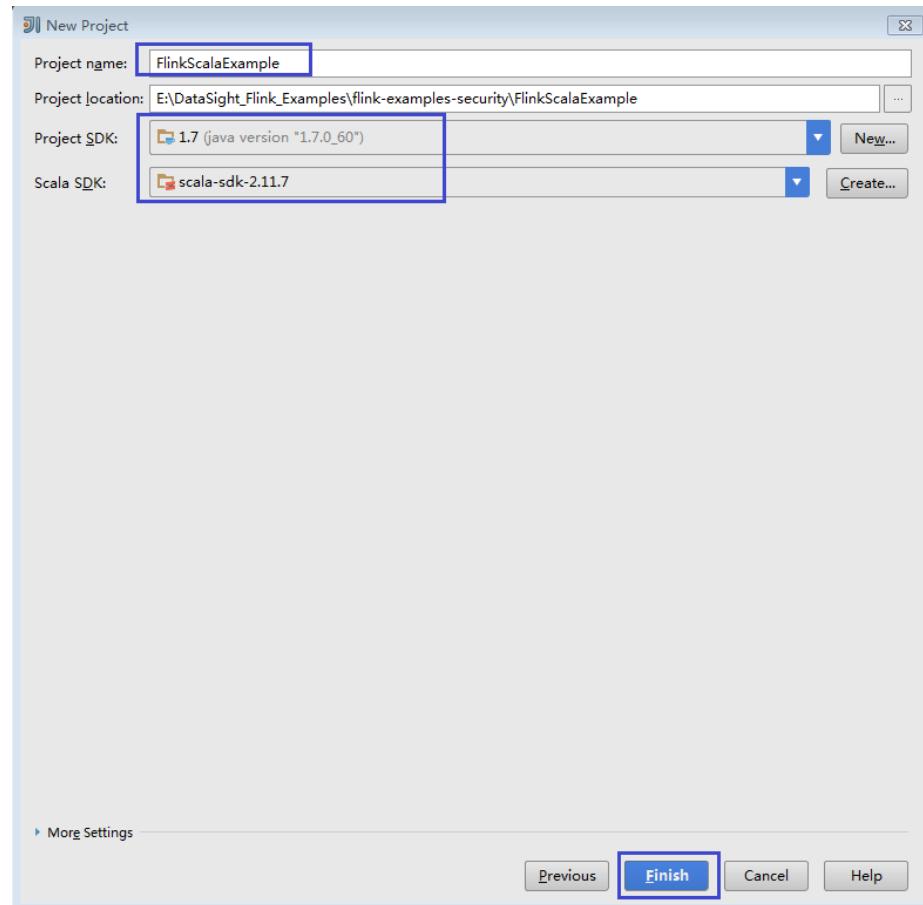

**Step 2** On the **New Project** page, choose a Scala development environment, choose **Scala Module**, and then click **Next**. If you want to create a Java project, choose corresponding parameters of Java.

Figure 1-65 Selecting a development environment

**Step 3** On the New Project page, enter the project name and project location, select the JDK version and Scala SDK, and then click **Finish**.

**Figure 1-66 Filling in project information**

----End

#### 1.8.2.4 Preparing for Security Authentication

##### Description

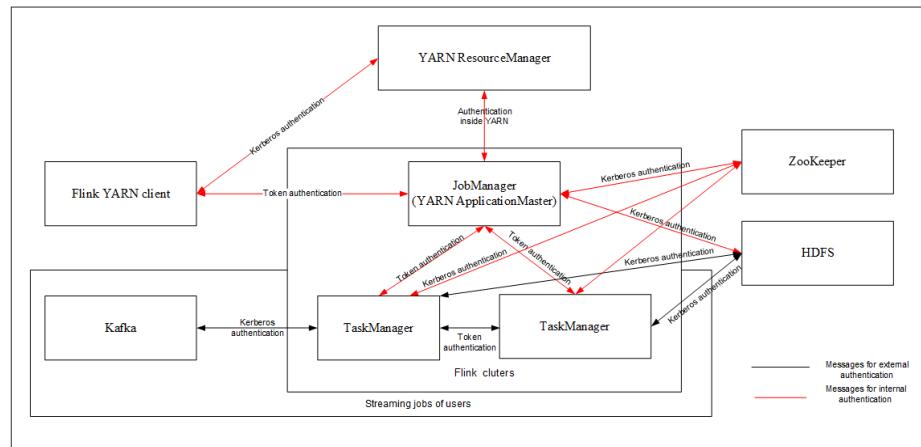

In a cluster with the security mode enabled, the components must be mutually authenticated before communicating with each other to ensure communication security.

To submit a Flink application, you need to ensure that Flink can communicate with Yarn and HDFS. Security authentication needs to be configured for the Flink application to be submitted.

Flink supports authentication and encrypted transmission. This section describes how to prepare for the authentication and encrypted transmission.

## Security Authentication

Figure 1-67 Authentication mode

Flink uses the following three authentication modes:

- Kerberos authentication is used between Flink Yarn client and Yarn ResourceManager, JobManager and ZooKeeper, JobManager and HDFS, TaskManager and HDFS, Kafka and TaskManager, and TaskManager and ZooKeeper.
- Security cookie authentication is used between Flink Yarn client and JobManager, JobManager and TaskManager, and TaskManager and TaskManager.
- Internal authentication of Yarn is used between Yarn ResourceManager and ApplicationMaster (AM).

### NOTE

- Flink JobManager and Yarn ApplicationMaster are in the same process.
- If security mode is enabled, you must use the Kerberos authentication and security cookie authentication.

**Table 1-29** Authentication methods

Authentication Mode	Configuration Method
Kerberos authentication (Currently, only keytab is supported.)	<ol style="list-style-type: none"><li>1. Download the user <b>keytab</b> file from FusionInsight Manager and save it to a directory on the node where the Flink client is deployed.</li><li>2. Configure the <b>flink-conf.yaml</b> as follows:<ol style="list-style-type: none"><li>a. Keytab path <code>security.kerberos.login.keytab: /home/flinkuser/keytab/flinkuser.keytab</code><p><b>NOTE</b> <code>/home/flinkuser/keytab/</code> indicates the directory for storing the <b>keytab</b> file.</p></li><li>b. Username for running the job <code>security.kerberos.login.principal: flinkuser</code></li><li>c. Kerberos authentication configuration required in HA mode when ZooKeeper is configured <code>zookeeper.sasl.disable: false</code> <code>security.kerberos.login.contexts: Client</code></li><li>d. Kerberos authentication (if needed) between the Kafka client and Kafka broker <code>security.kerberos.login.contexts: Client,KafkaClient</code></li></ol></li></ol>

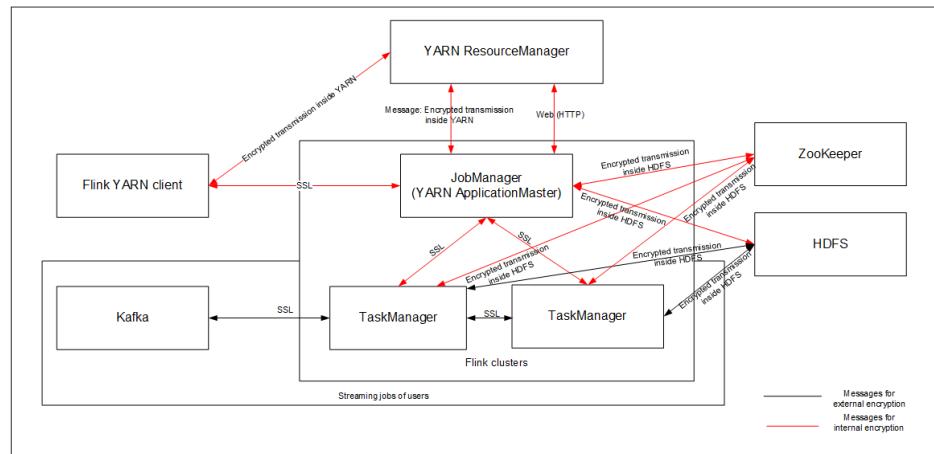

Authentication Mode	Configuration Method
Security cookie authentication	<ol style="list-style-type: none"><li>1. Obtain the SSL certificate and save it to the Flink client.</li><li>2. Set the following configuration items in the <b>flink-conf.yaml</b> file in the <b>conf</b> directory of the Flink client:<ul style="list-style-type: none"><li>• Set the <b>security.ssl.key-password</b>, <b>security.ssl.keystore-password</b>, and <b>security.ssl.truststore-password</b> to <i>&lt;password&gt;</i>.</li><li>• Set <b>security.ssl.keystore</b> to the relative path of the keystore file, for example, <b>ssl/flink.keystore</b>.</li><li>• Set <b>security.ssl.truststore</b> to the relative path of the truststore file, for example, <b>ssl/flink.truststore</b>.</li><li>• Set <b>security.cookie</b> to a random password string.</li></ul></li></ol> <p><b>NOTE</b></p> <ol style="list-style-type: none"><li>1. The generated <b>flink.keystore</b>, <b>flink.truststore</b>, and <b>security.cookie</b> items are automatically filled in the corresponding configuration items in <b>flink-conf.yaml</b>.</li><li>2. The values of <b>security.ssl.key-password</b>, <b>security.ssl.keystore-password</b>, and <b>security.ssl.truststore-password</b> must be obtained using the plaintext encryption API of Manager: <code>curl -k -i -u user name:password -X POST -HContent-type:application/json -d '{"plainText":"password"}' 'https://x.x.x.x:28443/web/api/v2/tools/encrypt'</code>. <i>user name:password</i> indicates the user name and password for logging in to the system. Password of "plainText" is the password for invoking the <b>generate_keystore.sh</b> script. <i>x.x.x.x</i> is the floating IP address of FusionInsight Manager in the cluster.</li><li>3. Set <b>security.enable</b> to true and check whether <b>security.cookie</b> is configured successfully. <code>security.cookie: ae70acc9-9795-4c48-ad35-8b5adc8071744f605d1d-2726-432e-88ae-dd39bfec40a9</code></li></ol>
Internal authentication of Yarn	You do not need to do any configuration for this authentication mode.

 **NOTE**

One Flink cluster supports only one user. One user can create multiple Flink clusters.

## Encrypted Transmission

Figure 1-68 Encrypted transmission of Flink

Flink uses following encrypted transmission modes:

- Encrypted transmission inside Yarn: It is used between the Flink Yarn client and Yarn ResourceManager, as well as Yarn ResourceManager and JobManager.
- SSL transmission is used between Flink Yarn client and JobManager, JobManager and TaskManager, and TaskManager and TaskManager.
- Internal encrypted transmission of Hadoop is used between JobManager and HDFS, TaskManager and HDFS, JobManager and ZooKeeper, and TaskManager and ZooKeeper.

### NOTE

You do not need to do any configurations for internal encryption of Yarn and Hadoop. Only SSL configuration is required.

To configure SSL encrypted transmission, perform the following steps to configure the **flink-conf.yaml** file on the client:

1. Turn on the SSL switch and set SSL encryption algorithms. **Table 1-30** describes the parameters. Set the parameters based on your need.

Table 1-30 Parameter description

Parameter	Example Value	Description
security.ssl.enabled	true	Enabling the SSL function
akka.ssl.enabled	true	Enabling Akka SSL
blob.service.ssl.enabled	true	Enabling SSL for the BLOB channel

Parameter	Example Value	Description
taskmanager.data.ssl.enabled	true	Enabling SSL for communications between TaskManagers
security.ssl.algorithms	TLS_DHE_RSA_WITH_AES_128_GCM_SHA256, TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256, TLS_DHE_RSA_WITH_AES_256_GCM_SHA384, TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	Setting SSL encryption algorithms

 NOTE

Enabling SSL for data transmission between TaskManagers may lead to a drop of system performance.

2. In the `bin` directory of the Flink client, run `sh generate_keystore.sh <password>`. The configuration items in [Table 1-31](#) are set by default, you can set these parameters as needed.

**Table 1-31 Description**

Parameter	Example Value	Description
security.ssl.keystore	<code> \${path}/flink.keystore</code>	Path for storing the <b>keystore</b> . <b>flink.keystore</b> indicates the name of the <b>keystore</b> file generated by the <b>generate_keystore.sh*</b> tool.
security.ssl.keystore-password	-	A user-defined password of <b>keystore</b> .
security.ssl.key-password	-	A user-defined password of the SSL key.
security.ssl.truststore	<code> \${path}/flink.truststore</code>	Path for storing the <b>truststore</b> . <b>flink.truststore</b> indicates the name of the <b>truststore</b> file generated by the <b>generate_keystore.sh*</b> tool.

Parameter	Example Value	Description
security.ssl.truststore-password	-	A user-defined password of <b>truststore</b> .

 NOTE

The **path** directory is a user-defined directory for storing configuration files of the SSL keystore and truststore. The commands vary according to the relative path and absolute path. For details, see [3](#) and [4](#).

3. If the **keystore** or **truststore** file path is a relative path, the Flink client directory where the command is executed needs to access this relative path directly. Either of the following method can be used to transmit the keystore and truststore file:

- Add **-t** option to the CLI **yarn-session.sh** command of Flink to transmit the keystore and truststore files to each execution node. The following is an example:  

```
cd /opt/hadoopclient/Flink/flink  
.bin/yarn-session.sh -t ssl/
```
- Add **-yt** to the **flink run** command to transfer the **keystore** and **truststore** file to execution nodes. The following is an example:  

```
.bin/flink run -yt ssl/ -ys 3 -m yarn-cluster -c  
com.huawei.SocketWindowWordCount ..lib/flink-eg-1.0.jar --  
hostname r3-d3 --port 9000
```

 NOTE

- In the example, **ssl/** is a user-defined subdirectory in the Flink client directory, which is used to store configuration files of the SSL keystore and truststore.
- The relative path of **ssl/** must be accessible from the current path where the Flink client command is run.

4. If the **keystore** or **truststore** file path is an absolute path, the **keystore** or **truststore** file must exist in the absolute path on Flink Client and all Yarn nodes.

Either of the following methods can be used to execute applications. The **-t** or **-yt** option does not need to be added to transmit the **keystore** and **truststore** files.

- Run the CLI **yarn-session.sh** command of Flink to execute applications. The following is an example:  

```
.bin/yarn-session.sh
```
- Run the **flink run** command to execute applications. The following is an example:  

```
.bin/flink run -ys 3 -m yarn-cluster -c  
com.huawei.SocketWindowWordCount ..lib/flink-eg-1.0.jar --  
hostname r3-d3 --port 9000
```

### 1.8.2.5 Configuring a Spring Boot Sample Project

#### Scenarios

Run the sample code of the Spring Boot interface in FusionInsight MRS Hive. Currently, GaussDB(DWS) and Elasticsearch SpringBoot sample projects are supported.

In the following example, an application is developed in Linux to connect GaussDB(DWS) to Flink using Spring Boot.

##### NOTE

Before running the GaussDB(DWS) sample, log in to the node where GaussDB(DWS) is deployed to create an empty table **test\_lzh1** for receiving data. The creation command is as follows:

```
create table test_lzh1 (id integer not null);
```

#### Procedure

##### Step 1 Install a client that contains only the Flink service.

The following example shows how to install the Flink client on a node in the cluster:

1. Log in to FusionInsight Manager. Choose **Cluster > Services > Flink > More > Download Client**.
2. In the dialog box that is displayed, select **Complete Client** for **Select Client Type**, select the platform type that matches the architecture of the node where the client is to install, Select **Server** from the **Select Download Location**, and click **OK**.

The generated file is stored in the **/tmp/FusionInsight-Client** directory on the active management node by default.

The name of the client software package is in the following format: **FusionInsight\_Cluster\_<Cluster ID>\_Flink\_Client.tar**. The following content uses the cluster ID **1** as an example.

3. Log in to the server where the client is to be installed as the client installation user.
4. Go to the directory where the installation package is stored and run the following commands to decompress the package:  
**cd /tmp/FusionInsight-Client**  
**tar -xvf FusionInsight\_Cluster\_1\_Flink\_Client.tar**
5. Run the following command to verify the decompressed file and check whether the command output is consistent with the information in the **sha256** file:  
**sha256sum -c FusionInsight\_Cluster\_1\_Flink\_ClientConfig.tar.sha256**
6. Decompress the obtained installation file.  
**tar -xvf FusionInsight\_Cluster\_1\_Flink\_ClientConfig.tar**
7. Go to the directory where the installation package is stored, and run the following command to install the client to a specified directory (absolute path), for example, **/opt/hadoopclient**:

```
cd /tmp/FusionInsight-Client/FusionInsight_Cluster_1_Flink_ClientConfig  
.install.sh /opt/hadoopclient
```

8. Configure security authentication and encryption. For details, see "Using Flink from Scratch" in the *Component Operation Guide*.

**Step 2** Obtain the sample project folder **flink-dws-sink-example** from **src\springboot\flink-examples** in the directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

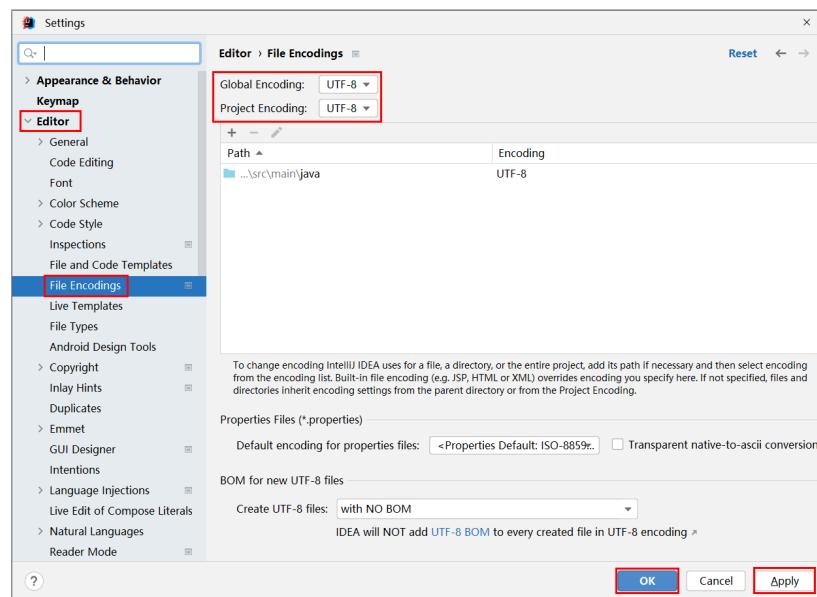

**Step 3** Import the sample project to the IntelliJ IDEA development environment.

1. On the menu bar of IntelliJ IDEA, choose **File > Open....**
2. In the **Open File or Project** dialog box that is displayed, select the **flink-dws-sink-example** folder and click **OK**.

**Step 4** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

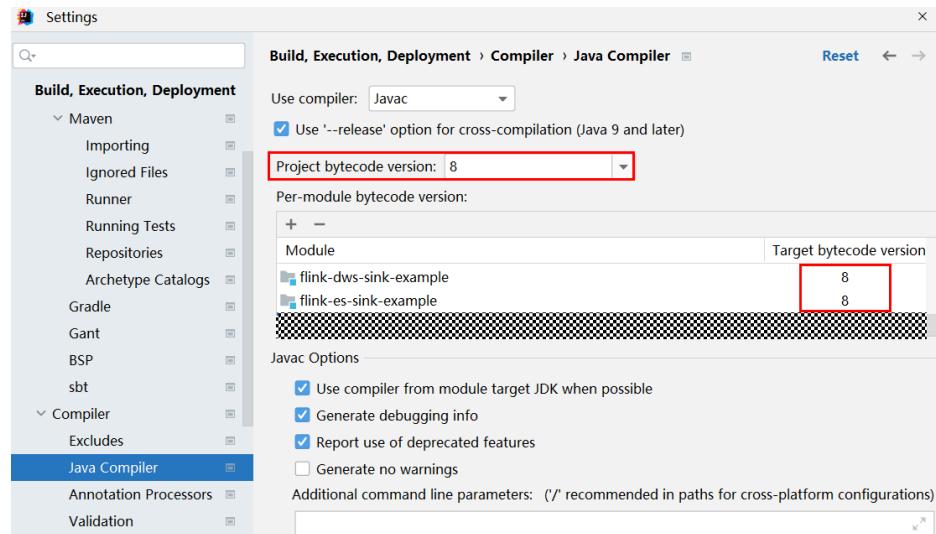

1. On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
2. In the left navigation pane, choose **Editor > File Encodings**. In the **Project Encoding** and **Global Encoding** areas, set the parameter to **UTF-8**. Click **Apply** and **OK**.

**Figure 1-69** Setting the IntelliJ IDEA coding format

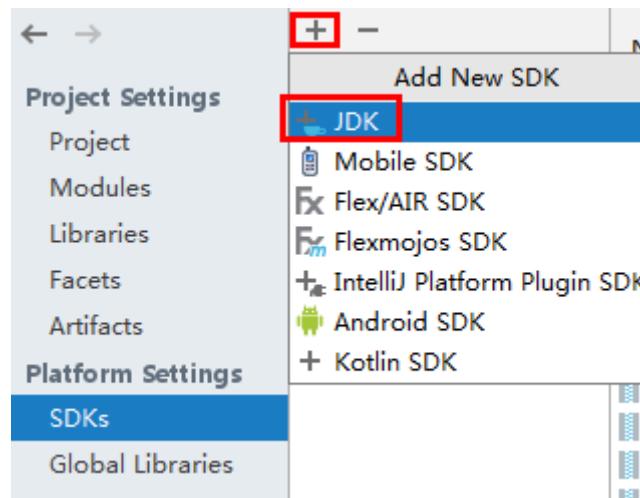

**Step 5** Set the JDK of the project.

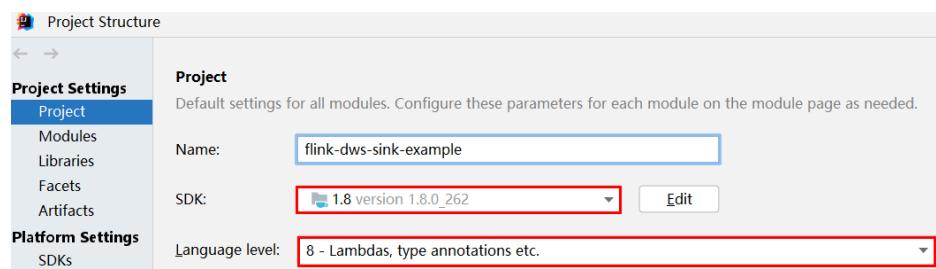

1. On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler** and select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** in **flink-dws-sink-example** to **8**.

3. Click **Apply** then **OK**.
4. On the menu bar of IntelliJ IDEA, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Choose **SDKs**, click the plus sign (+), and select **JDK**.

6. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.
7. Click **Apply**.
8. Select **Project**, select the JDK added in **SDKs** from the **SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Language level** drop-down list box.

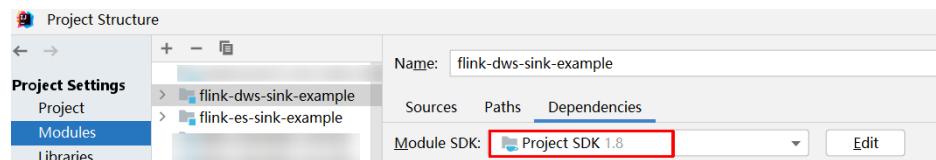

9. Click **Apply**.

- Choose **Modules**. On the **Sources** tab page, change the value of **Language level** to **8 - Lambdas, type annotations etc..**

On the **Dependencies** tab page, change the value of **Module SDK** to the JDK added in **SDKs**.

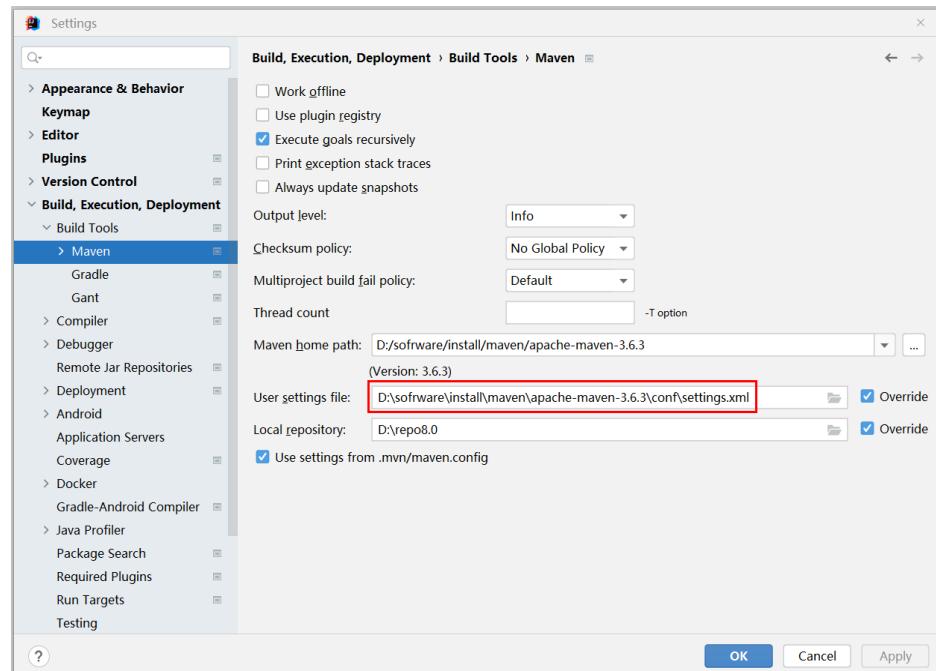

- Click **Apply** and then **OK**.

#### Step 6 Configure Maven.

- Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
- On the IntelliJ IDEA page, choose **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is **<Local Maven installation directory>\conf\settings.xml**.

**Figure 1-70** Directory for storing the **settings.xml** file

- Click the drop-down list next to **Maven home directory** and select the Maven installation directory.

- Click **Apply** and then **OK**.

**Step 7** Find the **application.properties** file in **src\main\resources** and add the following content to the file:

- Run the GaussDB(DWS) sample  
spring.datasource.dws.url=jdbc:postgresql://IP address of the GaussDB(DWS) node:8000/postgres  
spring.datasource.dws.username=dbadmin  
spring.datasource.dws.password=Password of dbadmin  
spring.datasource.dws.driver=org.postgresql.Driver
- Run the Elasticsearch sample  
spring.datasource.es.host=Service IP address of Elasticsearch EsNode  
spring.datasource.es.port=Elasticsearch EsNode Port  
spring.datasource.es.scheme=http

 **NOTE**

- log in to FusionInsight Manager and choose **Cluster > Services > Elasticsearch**. On the page that is displayed, click **Instance** and view the service IP addresses of all EsNode instances in the Elasticsearch cluster.
- Log in to FusionInsight Manager, choose **Cluster > Services > Elasticsearch > Configuration > All Configurations**, search for **SERVER\_PORT**, and view the EsNode port.

----End

## 1.8.3 Developing an Application

### 1.8.3.1 DataStream Application

#### 1.8.3.1.1 Scenarios

##### Scenarios

Develop a DataStream application of Flink to perform the following operations on logs about dwell durations of netizens for shopping online.

 **NOTE**

The DataStream application can run in both the Windows environment and the Linux environment.

- Collect statistics on female netizens who dwell on online shopping for more than 2 hours in total in a real time manner.
- The first column in the log file records names, the second column records genders, and the third column records the dwell duration in the unit of minute. Three attributes are separated by commas (,).

log1.txt: logs collected on Saturday. The log file can be obtained from the **data** directory of the sample project.

```
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,5
CaiXuyu,female,50
Liyuan,male,20
FangBo,female,50
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,50
```

```
CaiXuyu,female,50  
FangBo,female,60
```

log2.txt: logs collected on Sunday. The log file can be obtained from the **data** directory of the sample project.

```
LiuYang,female,20  
YuanJing,male,10  
CaiXuyu,female,50  
FangBo,female,50  
GuoYijun,male,5  
CaiXuyu,female,50  
Liyuan,male,20  
CaiXuyu,female,50  
FangBo,female,50  
LiuYang,female,20  
YuanJing,male,10  
FangBo,female,50  
GuoYijun,male,50  
CaiXuyu,female,50  
FangBo,female,60
```

## Data Planning

Data of DataStream sample project is stored in a **.txt** file.

Place the **log1.txt** and **log2.txt** in two directories, for example, **/opt/log1.txt** and **/opt/log2.txt**.

### NOTE

- If the data file is stored in the local file system, the data file must be stored in the specified directory on all nodes where Yarn NodeManager is deployed, and the running user access permission must be set.
- Alternatively, store the data file on HDFS and set the file read path in the program to the HDFS path, for example, **hdfs://hacluster/path/to/file**.

## Development Approach

Collect the information about female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

The process includes:

1. Read text data, generate DataStreams, and parse data to generate UserRecord information.
2. Filter the data about the time that female netizens spend online.
3. Perform keyby operation based on the name and gender, and collect the time that female netizens spend online within a time window.
4. Filter data about users whose consecutive online duration exceeds the threshold, and obtain the result.

### 1.8.3.1.2 Java Sample Code

## Function Description

Collect the information about female netizens who continuously spend more than 2 hour in online shopping and print the result.

## DataStream FlinkStreamJavaExample Sample Code

The following code segment is an example. For details, see com.huawei.bigdata.flink.examples.FlinkStreamJavaExample.

```
//Parameter description:  
//<filePath> indicates paths where text is read. Paths are separated by commas (,).  
//<windowTime> indicates the period covered by statistics window. The unit is minute.  
public class FlinkStreamJavaExample {  
    public static void main(String[] args) throws Exception {  
        //Print reference command for executing flink run.  
        System.out.println("use command as: ");  
        System.out.println("./bin/flink run --class  
com.huawei.bigdata.flink.examples.FlinkStreamJavaExample /opt/test.jar --filePath /opt/log1.txt,/opt/  
log2.txt --windowTime 2");  
        System.out.println("*****");  
        System.out.println("<filePath> is for text file to read data, use comma to separate");  
        System.out.println("<windowTime> is the width of the window, time as minutes");  
        System.out.println("*****");  
  
        //Paths where text is read. Paths are separated by commas (,)  
        final String[] filePaths = ParameterTool.fromArgs(args).get("filePath", "/opt/log1.txt,/opt/  
log2.txt").split(",");  
        assert filePaths.length > 0;  
  
        //windowTime specifies the size of the time window. By default, a window with 2 minutes as the size  
can read all data in a text file.  
        final int windowTime = ParameterTool.fromArgs(args).getInt("windowTime", 2);  
  
        //Build the execution environment and run eventTime to process window data.  
        final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();  
        env.setStreamTimeCharacteristic(TimeCharacteristic.EventTime);  
        env.setParallelism(1);  
  
        //Read DataStream of the text.  
        DataStream<String> unionStream = env.readTextFile(filePaths[0]);  
        if (filePaths.length > 1) {  
            for (int i = 1; i < filePaths.length; i++) {  
                unionStream = unionStream.union(env.readTextFile(filePaths[i]));  
            }  
        }  
  
        //Convert data, build the logic for the entire data process, calculate, and print results.  
        unionStream.map(new MapFunction<String, UserRecord>() {  
            @Override  
            public UserRecord map(String value) throws Exception {  
                return getRecord(value);  
            }  
        }).assignTimestampsAndWatermarks(  
            new Record2TimestampExtractor()  
        ).filter(new FilterFunction<UserRecord>() {  
            @Override  
            public boolean filter(UserRecord value) throws Exception {  
                return value.sex.equals("female");  
            }  
        }).keyBy(  
            new UserRecordSelector()  
        ).window(  
            TumblingEventTimeWindows.of(Time.minutes(windowTime))  
        ).reduce(new ReduceFunction<UserRecord>() {  
            @Override  
            public UserRecord reduce(UserRecord value1, UserRecord value2)  
                throws Exception {  
                value1.shoppingTime += value2.shoppingTime;  
                return value1;  
            }  
        }).filter(new FilterFunction<UserRecord>() {  
            @Override  
            public boolean filter(UserRecord value) throws Exception {  
                return value.shoppingTime > 0;  
            }  
        }).print();  
    }  
}
```

```
        return value.shoppingTime > 120;
    }
}).print();

//Call execute to trigger the execution.
env.execute("FemaleInfoCollectionPrint java");
}

//Build the keyword of keyBy as the grouping basis.
private static class UserRecordSelector implements KeySelector<UserRecord, Tuple2<String, String>> {
    @Override
    public Tuple2<String, String> getKey(UserRecord value) throws Exception {
        return Tuple2.of(value.name, value.sex);
    }
}

//Parse the row data of the text and build UserRecord data structure.
private static UserRecord getRecord(String line) {
    String[] elems = line.split(",");
    assert elems.length == 3;
    return new UserRecord(elems[0], elems[1], Integer.parseInt(elems[2]));
}

//Defines UserRecord data structure and rewrite toString printing method.
public static class UserRecord {
    private String name;
    private String sexy;
    private int shoppingTime;

    public UserRecord(String n, String s, int t) {
        name = n;
        sexy = s;
        shoppingTime = t;
    }

    public String toString() {
        return "name: " + name + " sexy: " + sexy + " shoppingTime: " + shoppingTime;
    }
}

//Build class that inherits AssignerWithPunctuatedWatermarks to configure eventTime and watermark.
private static class Record2TimestampExtractor implements
AssignerWithPunctuatedWatermarks<UserRecord> {

    //add tag in the data of datastream elements
    @Override
    public long extractTimestamp(UserRecord element, long previousTimestamp) {
        return System.currentTimeMillis();
    }

    //give the watermark to trigger the window to execute, and use the value to check if the window
    //elements are ready
    @Override
    public Watermark checkAndGetNextWatermark(UserRecord element, long extractedTimestamp) {
        return new Watermark(extractedTimestamp - 1);
    }
}
```

The following is the command output:

```
name: FangBo sexy: female shoppingTime: 320
name: CaiXuyu sexy: female shoppingTime: 300
```

[Figure 1-71](#) shows the process of execution.

**Figure 1-71 Process of execution**

### 1.8.3.1.3 Scala Sample Code

#### Function Description

Collect the information about female netizens who continuously spend more than 2 hour in online shopping and print the result.

#### DataStream FlinkStreamScalaExample Sample Code

The following code is an example. For details, see com.huawei.bigdata.flink.examples.FlinkStreamScalaExample.

```
//Parameter description
//filePath indicates paths where text is read. Paths are separated by commas (,).
//windowTime indicates the period covered by statistics window. The unit is minute.
object FlinkStreamScalaExample {
def main(args: Array[String]) {
    //Print the reference command used to execute flink run.
    System.out.println("use command as:")
    System.out.println("./bin/flink run --class"
com.huawei.bigdata.flink.examples.FlinkStreamScalaExample /opt/test.jar --filePath /opt/log1.txt,/opt/
log2.txt --windowTime 2")
    System.out.println("*****")
    System.out.println("<filePath> is for text file to read data, use comma to separate")
    System.out.println("<windowTime> is the width of the window, time as minutes")
    System.out.println("*****")

    //Paths where text is read. Paths are separated by commas (,)
    val filePaths = ParameterTool.fromArgs(args).get("filePath",
        "/opt/log1.txt,/opt/log2.txt").split(",").map(_.trim)
    assert(filePaths.length > 0)

    //windowTime specifies the size of the time window. By default, a window with 2 minutes as the size can
    //read all data in a text file.
    val windowTime = ParameterTool.fromArgs(args).getInt("windowTime", 2)

    //Build the execution environment and run eventTime to process window data.
    val env = StreamExecutionEnvironment.getExecutionEnvironment
    env.setStreamTimeCharacteristic(TimeCharacteristic.EventTime)
    env.setParallelism(1)
    //Read DataStream of the text.
    val unionStream = if (filePaths.length > 1) {
        val firstStream = env.readTextFile(filePaths.apply(0))
        firstStream.union(filePaths.drop(1).map(it => env.readTextFile(it)): _*)
    } else {
        env.readTextFile(filePaths.apply(0))
    }
}
```

```
}

//Convert data, build the logic for the entire data process, calculate, and print results.
unionStream.map(getRecord(_))
    .assignTimestampsAndWatermarks(new Record2TimestampExtractor)
    .filter(_._sexy == "female")
    .keyBy("name", "sexy")
    .window(TumblingEventTimeWindows.of(Time.minutes(windowTime)))
    .reduce((e1, e2) => UserRecord(e1.name, e1.sex, e1.shoppingTime + e2.shoppingTime))
    .filter(_._shoppingTime > 120).print()

//Call execute to trigger the execution
env.execute("FemaleInfoCollectionPrint scala")
}

//Parse the row data of the text and build UserRecord data structure.
def getRecord(line: String): UserRecord = {
    val elems = line.split(",")
    assert(elems.length == 3)
    val name = elems(0)
    val sexy = elems(1)
    val time = elems(2).toInt
    UserRecord(name, sexy, time)
}

//Defines UserRecord data structure.
case class UserRecord(name: String, sexy: String, shoppingTime: Int)

//Build class that inherits AssignerWithPunctuatedWatermarks to configure eventTime and waterMark.
private class Record2TimestampExtractor extends AssignerWithPunctuatedWatermarks[UserRecord] {

    //add tag in the data of datastream elements
    override def extractTimestamp(element: UserRecord, previousTimestamp: Long): Long = {
        System.currentTimeMillis()
    }

    //give the watermark to trigger the window to execute, and use the value to check if the window
    //elements are ready
    def checkAndGetNextWatermark(lastElement: UserRecord,
                                 extractedTimestamp: Long): Watermark = {
        new Watermark(extractedTimestamp - 1)
    }
}
```

The following is the command output:

```
UserRecord(FangBo,female,320)
UserRecord(CaiXuyu,female,300)
```

**Figure 1-72** shows the process of execution.

**Figure 1-72 Process of execution**

### 1.8.3.2 Interconnecting with Kafka

#### 1.8.3.2.1 Scenario Description

##### Scenario

Assume that a Flink service receives one message record every second.

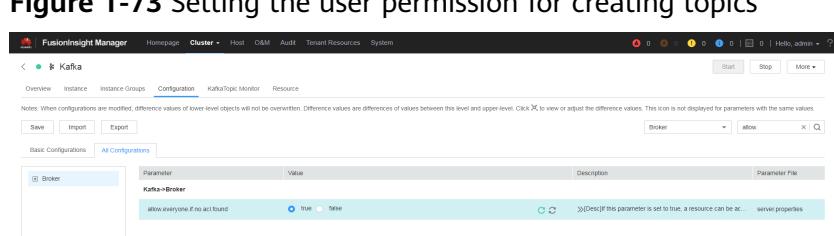

A Flink application is developed to output prefixed message content in real time based on service requirements.

##### Data Preparation

Flink's sample project data is stored in Kafka. A user with Kafka permission can send data to Kafka and receive data from it.

1. Ensure that clusters have been installed, including HDFS, Yarn, Flink, and Kafka.
2. Create a topic.
  - a. Configure the user permission for creating topics on the server. Change the value of the **allow.everyone.if.no.acl.found** parameter of Kafka Broker to **true**. See [Figure 1-73](#). After the configuration is complete, restart the Kafka service.

**Figure 1-73 Setting the user permission for creating topics**

- b. Run a Linux command line to create a topic. Before running a command, run the **kinit** command, for example, **kinit flinkuser**, to authenticate the human-machine account.

 NOTE

To create a Flink user, you need to have the permission to create Kafka topics. For details, see [Preparing a Developer Account](#).

The command for creating a Kafka topic is as follows:

```
bin/kafka-topics.sh --create --bootstrap-server <Kafka cluster IP address:21007> --command-config config/client.properties --partitions {partitionNum} --replication-factor {replicationNum} --topic {Topic}
```

**Table 1-32** Parameters

Parameter	Description
{Kafka cluster IP address}	Service IP address of the Broker node in the Kafka cluster.
{partitionNum}	Number of topic partitions
{replicationNum}	Number of data replicas of each partition in a topic
{Topic}	Topic name

For example, run the following command on the Kafka client, and the topic name is **topic1**.

```
bin/kafka-topics.sh --create --bootstrap-server  
10.96.101.32:21007,10.96.101.251:21007,10.96.101.177:21007 --partitions 5 --replication-factor 1  
--topic topic1
```

3. Perform security authentication.

You can use Kerberos authentication, SSL encryption authentication, or Kerberos + SSL authentication.

- **Kerberos authentication**

i. Configure the client.

In Flink configuration file **flink-conf.yaml**, add configurations about Kerberos authentication. For example, add **KafkaClient** in **contexts** as follows:

```
security.kerberos.login.keytab: /home/demo/flink/release/flink-x.x.x/keytab/user.keytab  
security.kerberos.login.principal: flinkuser  
security.kerberos.login.contexts: Client,KafkaClient  
security.kerberos.login.use-ticket-cache: false
```

ii. Run parameters.

Running parameters about the **SASL\_PLAINTEXT** protocol are as follows:

```
--topic topic1 --bootstrap.servers 10.96.101.32:21007 --security.protocol SASL_PLAINTEXT  
--sasl.kerberos.service.name kafka --kerberos.domain.name hadoop.System domain name.com
```

 NOTE

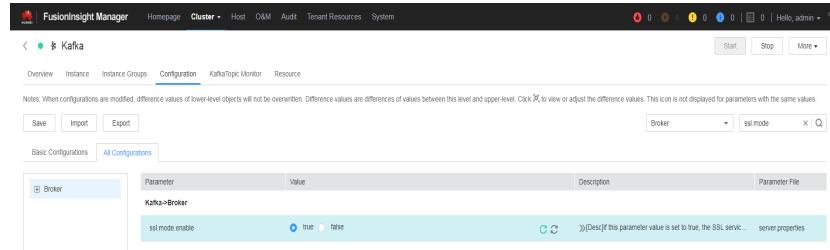

- *10.96.101.32:21007*: IP address and port number of the Kafka server.
- *System domain name*: You can log in to FusionInsight Manager, choose **System > Permission > Domain and Mutual Trust**, and check the value of **Local Domain**.

### - SSL encryption

- Configure the server.

Set `ssl.mode.enable` to `true`. See [Figure 1-74](#).

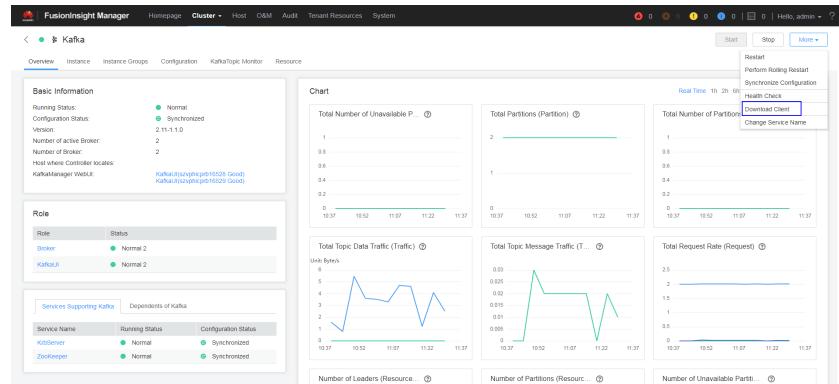

**Figure 1-74** Configuring the server

- Configure the client.

- Log in to FusionInsight Manager and choose **Cluster > Name of the desired cluster > Services > Kafka**. On the page that is displayed, choose **More > Download Client** to download the Kafka client. See [Figure 1-75](#).

**Figure 1-75** Configuring the client

- Use the `ca.crt` certificate file in the client root directory to generate the `truststore` file for the client.

Run the following command:

```
keytool -noprompt -import -alias myservercert -file ca.crt -keystore truststore.jks
```

The command output is as follows:

```
drwx----- 5 zgd users 4096 Feb 4 16:22 .
drwxr-xr-x 10 zgd users 4096 Jan 22 17:38 ..
-rwx----- 1 zgd users 135 Jan 22 17:31 application.properties
-rwx----- 1 zgd users 790 Jan 22 17:31 bigdata_env.sample
-rw----- 1 zgd users 1322 Jan 22 17:31 ca.crt
-rwx----- 1 zgd users 4508 Jan 22 17:31 conf.py
-rw----- 1 zgd users 120 Jan 22 17:31 hosts
-rwx----- 1 zgd users 745 Jan 22 17:31 install.bat
-rwx----- 1 zgd users 15082 Jan 22 17:31 install.sh
drwxr-xr-x 2 zgd users 4096 Jan 22 17:38 JDK
-rwx----- 1 zgd users 37021723 Jan 22 17:31 jython-standalone-2.7.0.jar
drwxr-xr-x 5 zgd users 4096 Jan 22 17:38 Kafka
drwxr-xr-x 3 zgd users 4096 Jan 22 17:38 KrbClient
-rwx----- 1 zgd users 473 Jan 22 17:31 log4j.properties
-rwx----- 1 zgd users 2107 Jan 22 17:31 README
-rwx----- 1 zgd users 6949 Jan 22 17:31 refreshConfig.sh
-rwx----- 1 zgd users 1736 Jan 22 17:31 switchuser.py
-rw-r--r-- 1 root root 1004 Feb 4 16:22 truststore.jks
```

3) Run parameters.

The value of **ssl.truststore.password** must be the same as the password you entered when creating **truststore**. Run the following command to run parameters:

```
--topic topic1 --bootstrap.servers 10.96.101.32:21008 --security.protocol SSL --  
ssl.truststore.location /home/zgd/software/FusionInsight_XXX_Kafka_ClientConfig/  
truststore.jks --ssl.truststore.password xxx //10.96.101.32:21008 indicates the IP:Port  
of the Kafka server. XXX indicates the FusionInsight version, xxx indicates the  
password.
```

- **Kerberos+SSL encryption**

After completing preceding configurations of the client and server of Kerberos and SSL, modify the port number and protocol type in running parameters to enable the Kerberos+SSL encryption mode.

```
--topic topic1 --bootstrap.servers 10.96.101.32:21009 --security.protocol SASL_SSL --  
sasl.kerberos.service.name kafka --ssl.truststore.location --kerberos.domain.name  
hadoop.System domain name.com /home/zgd/software/FusionInsight_XXX_Kafka_ClientConfig/  
truststore.jks --ssl.truststore.password xxx //10.96.101.32:21009 indicates the IP:Port of the  
Kafka server. XXX indicates the FusionInsight version, xxx indicates the password.
```

## Development Guideline

1. Start Flink Kafka Producer to send data to Kafka.
2. Start Flink Kafka Consumer to receive data from Kafka. Ensure that Flink Kafka Consumer and Flink Kafka Producer have the same topics.
3. Add prefixes to data content and print the results.

### 1.8.3.2.2 Java Sample Code

#### Function Description

In a Flink application, call API of the **flink-connector-kafka** module to produce and consume data.

#### Sample Code

If you want to use FusionInsight in security mode, ensure that the **kafka-clients-\*jar** is obtained from the FusionInsight client directory.

Following is the main logic code of Kafka Consumer and Kafka Producer.

For the complete code, see `com.huawei.bigdata.flink.examples.WriteIntoKafka` and `com.huawei.bigdata.flink.examples.ReadFromKafka`.

```
//producer code  
public class WriteIntoKafka {  
  
    public static void main(String[] args) throws Exception {  
        //Print the reference command of flink run.  
  
        System.out.println("use command as: ");  
  
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +  
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21005");  
  
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +  
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21007 --security.protocol
```

```
SASL_PLAINTEXT --sasl.kerberos.service.name kafka");

        System.out.println
("*****");
        System.out.println("<topic> is the kafka topic name");
        System.out.println("<bootstrap.servers> is the ip:port list of brokers");
        System.out.println
("*****");
//Build the execution environment.
StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
//Configure the parallelism.
env.setParallelism(1);
//Parse the execution parameter.
ParameterTool paraTool = ParameterTool.fromArgs(args);
//Build the StreamGraph and write data generated by customized source into Kafka.
DataStream<String> messageStream = env.addSource(new SimpleStringGenerator());

messageStream.addSink(new FlinkKafkaProducer<>(paraTool.get("topic"),
        new SimpleStringSchema(),
        paraTool.getProperties()));
//Call execute to trigger the execution.
env.execute();
}

//Customize source to continuously generate messages every one second.
public static class SimpleStringGenerator implements SourceFunction<String> {

    private static final long serialVersionUID = 2174904787118597072L;
    boolean running = true;
    long i = 0;

    @Override
    public void run(SourceContext<String> ctx) throws Exception {
        while (running) {
            ctx.collect("element-" + (i++));
            Thread.sleep(1000);
        }
    }

    @Override
    public void cancel() {
        running = false;
    }
}
```

```
}

//consumer code
public class ReadFromKafka {

    public static void main(String[] args) throws Exception {
        //Print the reference command of flink run.
        System.out.println("use command as:");

        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21005");

        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21007 --security.protocol
SASL_PLAINTEXT --sasl.kerberos.service.name kafka");

        System.out.println
("*****");
        System.out.println("<topic> is the kafka topic name");
        System.out.println("<bootstrap.servers> is the ip:port list of brokers");
        System.out.println
("*****");
        //Build the execution environment.
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        //Configure the parallelism.
        env.setParallelism(1);
        //Parse the execution parameter.
        ParameterTool paraTool = ParameterTool.fromArgs(args);
        //Build the StreamGraph, read data from Kafka and print the result in another row.
        DataStream<String> messageStream = env.addSource(new
FlinkKafkaConsumer<>(paraTool.get("topic"),
            new SimpleStringSchema(),
            paraTool.getProperties()));

        messageStream.rebalance().map(new MapFunction<String, String>() {
            @Override
            public String map(String s) throws Exception {
                return "Flink says " + s + System.getProperty("line.separator");
            }
        }).print();
        //Call execute to trigger the execution.
        env.execute();
    }
}
```

### 1.8.3.2.3 Scala Sample Code

## Function Description

In a Flink application, call API of the **flink-connector-kafka** module to produce and consume data.

## Sample Code

If you want to use FusionInsight in security mode, ensure that the **kafka-clients.jar** is obtained from the FusionInsight client directory.

Following is the main logic code of Kafka Consumer and Kafka Producer.

For the complete code, see com.huawei.bigdata.flink.examples.WriteIntoKafka and com.huawei.bigdata.flink.examples.ReadFromKafka.

```
//Code of producer
object WriteIntoKafka {

    def main(args: Array[String]) {
        //Print the reference command of flink run.
        System.out.println("use command as: ")

        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21005")

        System.out.println
        ("*****")
        System.out.println("<topic> is the kafka topic name")
        System.out.println("<bootstrap.servers> is the ip:port list of brokers")
        System.out.println
        ("*****")
        //Build the execution environment.
        val env = StreamExecutionEnvironment.getExecutionEnvironment
        //Configure the parallelism.
        env.setParallelism(1)
        //Parse the execution parameter.
        val paraTool = ParameterTool.fromArgs(args)
        //Build the StreamGraph and write data generated by customized source into Kafka
        val messageStream: DataStream[String] = env.addSource(new SimpleStringGenerator)

        messageStream.addSink(new FlinkKafkaProducer(
            paraTool.get("topic"), new SimpleStringSchema, paraTool.getProperties))
        //Call execute to trigger the execution.
        env.execute
    }
}

//Customize source to continuously generate messages every one second.
class SimpleStringGenerator extends SourceFunction[String] {

    var running = true
    var i = 0

    override def run(ctx: SourceContext[String]) {
        while (running) {
            ctx.collect("element-" + i)
            i += 1
            Thread.sleep(1000)
        }
    }
}
```

```
    }

}

override def cancel() {
    running = false
}

//consumer code
object ReadFromKafka {

    def main(args: Array[String]) {
        //Print the reference command of flink run.
        System.out.println("use command as: ")

        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21005")

        System.out.println("*****")
        System.out.println("<topic> is the kafka topic name")
        System.out.println("<bootstrap.servers> is the ip:port list of brokers")
        System.out.println("*****")

        //Build the execution environment
        val env = StreamExecutionEnvironment.getExecutionEnvironment
        //Configure the parallelism.
        env.setParallelism(1)
        //Parse the execution parameter.
        val paraTool = ParameterTool.fromArgs(args)
        //Build the StreamGraph, read data from Kafka and print the result in another row.
        val messageStream = env.addSource(new FlinkKafkaConsumer(
            paraTool.get("topic"), new SimpleStringSchema, paraTool.getProperties))

        messageStream
            .map(s => "Flink says " + s + System.getProperty("line.separator")).print()
        //Call execute to trigger the execution
        env.execute()
    }
}
```

### 1.8.3.3 Asynchronous Checkpoint Mechanism

#### 1.8.3.3.1 Scenarios

##### Scenarios

Assume that you want to collect data volume in the window covering preceding 4 seconds at the interval of one second, and achieve strict consistency of status. In

this case, when the application is recovered from failure, all operator statuses are the same.

## Data Planning

1. Customized operators generate about 10000 pieces of data per second.
2. Generated data is of four tuples (Long, String, String, Integer).
3. Statistic results are printed on the devices.
4. Printed data is of the long type.

## Development Approach

1. The source operator sends 10000 pieces of data and injects the data to the window operator every second.
2. The window operator calculates the data volume of preceding 4 seconds at the interval of one second.
3. The statistics is printed to the device at the interval of one second. Please refer to the specific[Viewing the Debugging Result](#)
4. The checkpoint is triggered at the interval of 6 seconds and the checkpoint result is stored in HDFS.

### 1.8.3.3.2 Java Sample Code

#### Function Description

Assume that you want to collect data volume in the window covering preceding 4 seconds at the interval of one second, and achieve strict consistency of status.

#### Sample Code

1. Snapshot data

The snapshot data is used to store number of data pieces recorded by operators during creation of snapshots.

```
import java.io.Serializable;

//The class is a part of the snapshot and is used to store user-defined statuses.
public class UDFState implements Serializable {
    private long count;

    //Initialize user-defined statuses.
    public UDFState() {
        count = 0L;
    }

    //Configure self-defined statuses.
    public void setState(long count) {
        this.count = count;
    }

    //Obtain user-defined statuses.
    public long getState() {
        return this.count;
    }
}
```

2. Data source with checkpoints

Code of the source operator. The code can be used to send 10000 pieces after each pause of one second. When a snapshot is created, number of sent data pieces is recorded in UDFState. When the snapshot is used for restoration, the number of sent data pieces recorded in UDFState is read and assigned to the count variable.

```
import org.apache.flink.api.java.tuple.Tuple4;
import org.apache.flink.streaming.api.checkpoint.ListCheckpointed;
import org.apache.flink.streaming.api.functions.source.RichSourceFunction;

import java.util.ArrayList;
import java.util.List;
import java.util.Random;

//The class is the source operator with checkpoint.
public class SEventSourceWithChk extends RichSourceFunction<Tuple4<Long, String, String, Integer>>
implements ListCheckpointed<UDFState> {
    private Long count = 0L;
    private boolean isRunning = true;
    private String alphabet =
"abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ0123456789abcdefghijklmnoprstuvwxyzABCDEFGHJKLMNOPQRSTUVWXYZ0123456789abcdefghijklmnoprstuvwxyzABCDEFGHIJKLMNPQRSTUVWXYZ0987654321";

    //The main logic of the operator is to inject 10000 tuples to the StreamGraph.
    public void run(SourceContext<Tuple4<Long, String, String, Integer>> ctx) throws Exception {
        Random random = new Random();
        while(isRunning) {
            for (int i = 0; i < 10000; i++) {
                ctx.collect(Tuple4.of(random.nextLong(), "hello-" + count, alphabet, 1))
                count++;
            }
            Thread.sleep(1000);
        }
    }

    //Call this when the task is canceled.
    public void cancel() {
        isRunning = false;
    }

    //Customize a snapshot.
    public List<UDFState> snapshotState(long l, long ll) throws Exception {
        UDFState udfState = new UDFState();
        List<UDFState> listState = new ArrayList<UDFState>();
        udfState.setState(count);
        listState.add(udfState);
        return listState;
    }

    //Restore data from customized snapshots.
    public void restoreState(List<UDFState> list) throws Exception {
        UDFState udfState = list.get(0);
        count = udfState.getState();
    }
}
```

### 3. Definition of window with checkpoint.

This code is about the window operator and is used to calculate number or tuples in the window.

```
import org.apache.flink.api.java.tuple.Tuple;
import org.apache.flink.api.java.tuple.Tuple4;
import org.apache.flink.streaming.api.checkpoint.ListCheckpointed;
import org.apache.flink.streaming.api.functions.windowing.WindowFunction;
import org.apache.flink.streaming.api.windowing.windows.TimeWindow;
import org.apache.flink.util.Collector;

import java.util.ArrayList;
import java.util.List;
```

```
//The class is the window operator with checkpoint.
public class WindowStatisticWithChk implements WindowFunction<Tuple4<Long, String, String, Integer>, Long, Tuple, TimeWindow>, ListCheckpointed<UDFState> {
    private Long total = 0L;

    //The implementation logic of the window operator, which is used to calculate the number of tuples in a window.
    void apply(Tuple key, TimeWindow window, Iterable<Tuple4<Long, String, String, Integer>> input,
               Collector<Long> out) throws Exception {
        long count = 0L;
        for (Tuple4<Long, String, String, Integer> event : input) {
            count++;
        }
        total += count;
        out.collect(count);
    }

    //Customize snapshot.
    public List<UDFState> snapshotState(Long l, Long ll) {
        List<UDFState> listState = new ArrayList<UDFState>();
        UDFState udfState = new UDFState();
        udfState.setState(total);
        listState.add(udfState);
        return listState;
    }

    //Restore data from customized snapshots.
    public void restoreState(List<UDFState> list) throws Exception {
        UDFState udfState = list.get(0);
        total = udfState.getState();
    }
}
```

#### 4. Application code

The code is about the definition of StreamGraph and is used to implement services. The processing time is used as the timestamp for triggering the window.

```
import org.apache.flink.runtime.state.filesystem.FsStateBackend;
import org.apache.flink.streaming.api.CheckpointingMode;
import org.apache.flink.streaming.api.environment.StreamExecutionEnvironment;
import org.apache.flink.streaming.api.windowing.assigners.SlidingProcessingTimeWindows;
import org.apache.flink.streaming.api.windowing.time.Time;

public class FlinkProcessingTimeAPIChkMain {
    public static void main(String[] args) throws Exception {

        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();

        //Set configurations and enable checkpoint.
        env.setStateBackend(new FsStateBackend("hdfs://hacluster/flink/checkpoint/"));
        env.getCheckpointConfig.setCheckpointingMode(CheckpointingMode.EXACTLY_ONCE);
        env.getCheckpointConfig.setCheckpointInterval(6000);

        //Application logic.
        env.addSource(new SEventSourceWithChk())
            .keyBy(0)
            .window(SlidingProcessingTimeWindows.of(Time.seconds(4), Time.seconds(1)))
            .apply(new WindowStatisticWithChk())
            .print()

        env.execute();
    }
}
```

### 1.8.3.3.3 Scala Sample Code

## Function Description

Assume that you want to collect data volume in the window covering preceding 4 seconds at the interval of one second, and achieve strict consistency of status.

# Sample Code

- ## 1. Formats of sent data.

```
case class SEvent(id: Long, name: String, info: String, count: Int)
```

- ## 2. Snapshot data

The snapshot data is used to store number of data pieces recorded by operators during creation of snapshots.

//User-defined statuses.

```
class UDFState extends Serializable{  
    private var count = 0L  
  
    //Configure user-defined statuses.  
    def setState(s: Long) = count = s  
  
    //Obtain user-defined statuses.  
    def getState = count  
}
```

- ### 3. Data source with checkpoints

Code of the source operator. The code can be used to send 10000 pieces after each pause of one second. When a snapshot is created, number of sent data pieces is recorded in UDFState. When the snapshot is used for restoration, the number of sent data pieces recorded in UDFState is read and assigned to the *count* variable.

```
//Create a snapshot.
override def snapshotState(l: Long, l1: Long): util.List[UDFState] = {
    val udfList: util.ArrayList[UDFState] = new util.ArrayList[UDFState]
    val udfState = new UDFState
    udfState.setState(count)
    udfList.add(udfState)
    udfList
}

//Obtain status from the snapshot.
override def restoreState(list: util.List[UDFState]): Unit = {
    val udfState = list.get(0)
    count = udfState.getState
}
}
```

#### 4. Definition of window with checkpoint.

This code is about the window operator and is used to calculate number or tuples in the window.

```
import java.util
import org.apache.flink.api.java.tuple.Tuple
import org.apache.flink.streaming.api.checkpoint.ListCheckpointed
import org.apache.flink.streaming.api.scala.function.WindowFunction
import org.apache.flink.streaming.api.windowing.windows.TimeWindow
import org.apache.flink.util.Collector

//The class is the window operator with checkpoint.
class WindowStatisticWithChk extends WindowFunction[SEvent, Long, Tuple, TimeWindow] with
ListCheckpointed[UDFState]{
    private var total = 0L

    //The implementation logic of the window operator, which is used to calculate the number of
    tuples in a window.
    override def apply(key: Tuple, window: TimeWindow, input: Iterable[SEvent], out: Collector[Long]): Unit = {
        var count = 0L
        for (event <- input) {
            count += 1L
        }
        total += count
        out.collect(count)
    }

    //Customize a snapshot.
    override def snapshotState(l: Long, l1: Long): util.List[UDFState] = {
        val udfList: util.ArrayList[UDFState] = new util.ArrayList[UDFState]
        val udfState = new UDFState
        udfState.setState(total)
        udfList.add(udfState)
        udfList
    }

    //Restore data from customized snapshots.
    override def restoreState(list: util.List[UDFState]): Unit = {
        val udfState = list.get(0)
        total = udfState.getState
    }
}
```

#### 5. Application code

The code is about the definition of StreamGraph and is used to implement services. The **event time** is used as the timestamp for triggering the window.

```
import com.huawei.rt.flink.core.{SEvent, SEventSourceWithChk, WindowStatisticWithChk}
import org.apache.flink.contrib.streaming.state.RocksDBStateBackend
import org.apache.flink.streaming.api.functions.AssignerWithPeriodicWatermarks
import org.apache.flink.streaming.api.{CheckpointingMode, TimeCharacteristic}
import org.apache.flink.streaming.api.scala.StreamExecutionEnvironment
```

```
import org.apache.flink.streaming.api.watermark.Watermark
import org.apache.flink.streaming.api.windowing.assigners.SlidingEventTimeWindows
import org.apache.flink.streaming.api.windowing.time.Time
import org.apache.flink.api.scala._
import org.apache.flink.runtime.state.filesystem.FsStateBackend
import org.apache.flink.streaming.api.environment.CHECKPOINT_CONFIG.ExternalizedCheckpointCleanup

object FlinkEventTimeAPIChkMain {
    def main(args: Array[String]): Unit ={
        val env = StreamExecutionEnvironment.getExecutionEnvironment
        env.setStreamTimeCharacteristic(TimeCharacteristic.EventTime)
        env.getConfig.setAutoWatermarkInterval(2000)
        env.getCheckpointConfig.setCheckpointingMode(CheckpointingMode.EXACTLY_ONCE)
        env.getCheckpointConfig.setCheckpointInterval(6000)

        //Application logic.
        env.addSource(new SEventSourceWithChk)
            .assignTimestampsAndWatermarks(new AssignerWithPeriodicWatermarks[SEvent] {
                //Configure watermark.
                override def getCurrentWatermark: Watermark = {
                    new Watermark(System.currentTimeMillis())
                }
                //Add timestamp for each tuple.
                override def extractTimestamp(t: SEvent, l: Long): Long = {
                    System.currentTimeMillis()
                }
            })
            .keyBy(0)
            .window(SlidingEventTimeWindows.of(Time.seconds(4), Time.seconds(1)))
            .apply(new WindowStatisticWithChk)
            .print()
        env.execute()
    }
}
```

### 1.8.3.4 Job Pipeline Program

#### 1.8.3.4.1 Scenario

##### Scenario

Assume that there are three jobs, a publisher and two subscribers. The publisher generates 10000 pieces of data each second. Data is sent by the NettySink operator from the publisher job to downstream subscribers which subscribe a same piece of data.

##### Data Planning

1. The publisher uses customized operators to generate about 10000 pieces of data per second.
2. The data contains two attributes, which are of integer and string types.
3. Configuration file
  - nettyconnector.registerserver.topic.storage: (Mandatory) Configures the path (on a third-party server) to information about IP address, port numbers, and concurrency of NettySink. For example:  
nettyconnector.registerserver.topic.storage: /flink/nettyconnector
  - nettyconnector.sinkserver.port.range: (Mandatory) Configures the range of port numbers of NettySink. For example:  
nettyconnector.sinkserver.port.range: 28444-28943

- nettyconnector.ssl.enabled: Configures whether to enable SSL encryption between NettySink and NettySource. The default value is false. For example:  
nettyconnector.ssl.enabled: true
- nettyconnector.sinkserver.subnet: Configure the network domain. For example:  
nettyconnector.sinkserver.subnet: 10.162.0.0/16

#### 4. Security authentication configuration:

- SASL authentication of ZooKeeper depends on HA-related configurations in **flink-conf.yaml**.
- SSL configurations such as keystore, truststore, keystore password, truststore password, and password inherit from **flink-conf.yaml**. For details, see [Encrypted Transmission](#).

#### 5. Description of APIs

- RegisterServer API

RegisterServerHandler stores information such as IP address, port number, and concurrency of NettySink for the connection with NettySource. Following APIs are provided for users:

```
public interface RegisterServerHandler {  
  
    /**  
     * Start the RegisterServer  
  
     * @param The configuration indicates the configuration type of Flink.  
  
     */  
    void start(Configuration configuration) throws Exception;  
    /**  
     *Create a topic node (directory) on the RegisterServer  
     *  
     * @param The topic indicates the name of the topic node  
  
     */  
    void createTopicNode(String topic) throw Exception;  
    /**  
     *Register the information to a topic node (directory)  
  
     * @param topic @param The topic indicates the directory to be registered with  
  
     * @param The registerRecord indicates the information to be registered  
  
     */  
    void register(String topic, RegisterRecord registerRecord) throws Exception;  
    /**  
     *Delete the topic node.  
     * @param The topic indicates the topic to be deleted  
     */  
    void deleteTopicNode(String topic) throws Exception;  
    /**  
     *Deregister the registration inDeregister the registration information formation  
     * @param The topic indicates the topic where the registration information locates.  
     * @param The recordId indicates the ID of the registration information to be deregistered  
  
     */  
    void unregister(String topic, int recordId) throws Exception;  
    /**  
     * Query information  
     * @param Topic where the query information locates  
     * @param The recordId indicates the ID of the query information  
  
     */  
    RegisterRecord query(String topic, int recordId) throws Exception;
```

```
/**  
 * Query whether a topic exist.  
 * @param topic  
 */  
Boolean isExist(String topic) throws Exception;  
/**  
 *Disable RegisterServerHandler.  
 */  
void shutdown() throws Exception;
```

In addition to the preceding APIs, Flink provides ZookeeperRegisterHandler.

- NettySink operator

```
Class NettySink(String name,  
String topic,  
RegisterServerHandler registerServerHandler,  
int numberOfSubscribedJobs)
```

- name: Name of a current NettySink.
- topic: The topic that generates data for the current NettySink. Different NettySinks must use different topics. Otherwise, the subscription may be disordered and data transmission may be abnormal.
- registerServerHandler: Handler of the registration server.
- numberOfSubscribedJobs: Specific number of jobs that subscribe the current NettySink. NettySink sends data only when all subscribers are connected to NettySink.

- NettySource operator

```
Class NettySource(String name,  
String topic,  
RegisterServerHandler registerServerHandler)
```

- name: name of the NettySource. The NettySource must be unique (concurrency excluded). Otherwise, connection with NettySink may be conflicted.
- topic: topic of subscribed NettySink.
- registerServerHandler: Handler of the registration server.

 NOTE

The concurrency of NettySource and the concurrency NettySink must be the same. Otherwise, the connection cannot be created.

## Development Approach

1. There are three jobs, one publisher and two subscribers.
2. The publisher transforms generated data into byte[] and sends them to the subscribers.
3. After receiving the byte[], subscribers transform data into the string type and print sampled data.

### 1.8.3.4.2 Java Sample Code

Following is the main logic code for demonstration.

For details about the complete code, see the following:

- com.huawei.bigdata.flink.examples.UserSource.
- com.huawei.bigdata.flink.examples.TestPipeline\_NettySink.
- com.huawei.bigdata.flink.examples.TestPipeline\_NettySource1.
- com.huawei.bigdata.flink.examples.TestPipeline\_NettySource2.

1. The publisher customizes source operators to generate data.

```
package com.huawei.bigdata.flink.examples;

import org.apache.flink.api.java.tuple.Tuple2;
import org.apache.flink.configuration.Configuration;
import org.apache.flink.streaming.api.functions.source.RichParallelSourceFunction;

import java.io.Serializable;

public class UserSource extends RichParallelSourceFunction<Tuple2<Integer, String>> implements Serializable {

    private boolean isRunning = true;

    public void open(Configuration configuration) throws Exception {
        super.open(configuration);

    }

    /**
     * Data generation function, which is used to generate 10000 pieces of data each second.
     */
    public void run(SourceContext<Tuple2<Integer, String>> ctx) throws Exception {

        while(isRunning) {
            for (int i = 0; i < 10000; i++) {
                ctx.collect(Tuple2.of(i, "hello-" + i));
            }
            Thread.sleep(1000);
        }
    }

    public void close() {
        isRunning = false;
    }

    public void cancel() {
        isRunning = false;
    }
}
```

2. Code for the publisher:

```
package com.huawei.bigdata.flink.examples;

import org.apache.flink.api.common.functions.MapFunction;
import org.apache.flink.api.java.tuple.Tuple2;
import org.apache.flink.streaming.api.environment.StreamExecutionEnvironment;
import org.apache.flink.streaming.connectors.netty.sink.NettySink;
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler;

public class TestPipeline_NettySink {

    public static void main(String[] args) throws Exception{

        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        //Set the concurrency of job to 2.
        env.setBufferTimeout(2);

        //Create a ZookeeperRegisterServerHandler.
        ZookeeperRegisterServerHandler zkRegisterServerHandler = new ZookeeperRegisterServerHandler();
```

```
// Add a customized source operator.  
    env.addSource(new UserSource()  
        .keyBy(0)  
        .map(new MapFunction<Tuple2<Integer, String>, byte[]>() {  
            //Transform the to-be-sent data into a byte array.  
  
        @Override  
            public byte[] map(Tuple2<Integer, String> integerStringTuple2) throws Exception {  
                return integerStringTuple2.f1.getBytes();  
            }  
        }).addSink(new NettySink("NettySink-1", "TOPIC-2", zkRegisterServerHandler, 2));//NettySink  
transmits the data.  
  
        env.execute();  
    }  
}
```

### 3. Code for the first subscriber.

```
package com.huawei.bigdata.flink.examples;  
  
import org.apache.flink.api.common.functions.MapFunction;  
import org.apache.flink.streaming.api.environment.StreamExecutionEnvironment;  
import org.apache.flink.streaming.connectors.netty.source.NettySource;  
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler;  
  
public class TestPipeline_NettySource1 {  
  
    public static void main(String[] args) throws Exception{  
  
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();  
        // Set the concurrency of job to 2.  
  
        env.setParallelism(2);  
  
        // Create a ZookeeperRegisterServerHandler.  
        ZookeeperRegisterServerHandler zkRegisterServerHandler = new ZookeeperRegisterServerHandler();  
        //Add a NettySource operator to receive messages from the publisher.  
        env.addSource(new NettySource("NettySource-1", "TOPIC-2", zkRegisterServerHandler))  
            .map(new MapFunction<byte[], String>() {  
                // Transform the received byte stream into character strings  
            @Override  
                public String map(byte[] b) {  
                    return new String(b);  
                }  
            }).print();  
  
        env.execute();  
    }  
}
```

### 4. Code for the second subscriber.

```
package com.huawei.bigdata.flink.examples;  
  
import org.apache.flink.api.common.functions.MapFunction;  
import org.apache.flink.streaming.api.environment.StreamExecutionEnvironment;  
import org.apache.flink.streaming.connectors.netty.source.NettySource;  
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler;  
  
public class TestPipeline_NettySource2 {  
  
    public static void main(String[] args) throws Exception {  
  
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();  
        // Set the concurrency of job to 2.  
        env.setParallelism(2);  
  
        //Create a ZookeeperRegisterServerHandler.  
        ZookeeperRegisterServerHandler zkRegisterServerHandler = new ZookeeperRegisterServerHandler();
```

```
//Add a NettySource operator to receive messages from the publisher.  
    env.addSource(new NettySource("NettySource-2", "TOPIC-2", zkRegisterServerHandler))  
        .map(new MapFunction<byte[], String>() {  
            //Transform the received byte array into character strings.  
            @Override  
            public String map(byte[] b) {  
                return new String(b);  
            }  
        }).print();  
  
    env.execute();  
}
```

#### 1.8.3.4.3 Scala Sample Code

Following is the main logic code for demonstration.

For details about the complete code, see the following:

- com.huawei.bigdata.flink.examples.UserSource.
- com.huawei.bigdata.flink.examples.TestPipeline\_NettySink.
- com.huawei.bigdata.flink.examples.TestPipeline\_NettySource1.
- com.huawei.bigdata.flink.examples.TestPipeline\_NettySource2.

##### 1. Code for sending messages:

```
package com.huawei.bigdata.flink.examples  
  
case class Inforamtion(index: Int, content: String) {  
  
    def this() = this(0, "")  
}
```

##### 2. The publisher customizes source operators to generate data.

```
package com.huawei.bigdata.flink.examples  
  
import org.apache.flink.configuration.Configuration  
import org.apache.flink.streaming.api.functions.source.RichParallelSourceFunction  
import org.apache.flink.streaming.api.functions.source.SourceFunction.SourceContext  
  
class UserSource extends RichParallelSourceFunction[Inforamtion] with Serializable{  
  
    var isRunning = true  
  
    override def open(parameters: Configuration): Unit = {  
        super.open(parameters)  
    }  
  
    // Generate 10000 pieces of data each second.  
    override def run(sourceContext: SourceContext[Inforamtion]) = {  
  
        while (isRunning) {  
            for (i <- 0 until 10000) {  
                sourceContext.collect(Inforamtion(i, "hello-" + i));  
            }  
            Thread.sleep(1000)  
        }  
    }  
  
    override def close(): Unit = super.close()  
  
    override def cancel() = {  
        isRunning = false  
    }  
}
```

```
}
```

### 3. Code for the publisher:

```
package com.huawei.bigdata.flink.examples

import org.apache.flink.streaming.api.scala.StreamExecutionEnvironment
import org.apache.flink.streaming.connectors.netty.sink.NettySink
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler
import org.apache.flink.streaming.api.scala._

object TestPipeline_NettySink {

    def main(args: Array[String]): Unit = {

        val env = StreamExecutionEnvironment.getExecutionEnvironment
        // Set the concurrency of job to 2.
        env.setParallelism(2)
        //Set Zookeeper as the registration server
        val zkRegisterServerHandler = new ZookeeperRegisterServerHandler
        //Add a user-defined operator to generate data.
        env.addSource(new UserSource).keyBy(0).map(x=>x.content.getBytes)//Transform the to-be-sent data
        into a byte array.
        .addSink(new NettySink("NettySink-1", "TOPIC-2", zkRegisterServerHandler, 2))//Add NettySink
        operator to send data.
        env.execute()
    }
}
```

### 4. Code for the first subscriber

```
package com.huawei.bigdata.flink.examples

import org.apache.flink.streaming.api.scala.StreamExecutionEnvironment
import org.apache.flink.streaming.connectors.netty.source.NettySource
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler
import org.apache.flink.streaming.api.scala._

import scala.util.Random

object TestPipeline_NettySource1 {

    def main(args: Array[String]): Unit = {

        val env = StreamExecutionEnvironment.getExecutionEnvironment
        // Set the concurrency of job to 2.
        env.setParallelism(2)
        //Set ZooKeeper as the registration server
        val zkRegisterServerHandler = new ZookeeperRegisterServerHandler
        //Add a NettySource operator to receive messages from the publisher.
        env.addSource(new NettySource("NettySource-1", "TOPIC-2", zkRegisterServerHandler))
        .map(x => (1, new String(x)))//Add a NettySource operator to receive messages from the publisher.
        .filter(x => {
            Random.nextInt(50000) == 10
        })
        .print

        env.execute()
    }
}
```

### 5. Code for the second subscriber.

```
package com.huawei.bigdata.flink.examples

import org.apache.flink.streaming.api.scala.StreamExecutionEnvironment
import org.apache.flink.streaming.connectors.netty.source.NettySource
import org.apache.flink.streaming.connectors.netty.utils.ZookeeperRegisterServerHandler
import org.apache.flink.streaming.api.scala._
```

```
import scala.util.Random

object TestPipeline_NettySource2 {
    def main(args: Array[String]): Unit = {
        val env = StreamExecutionEnvironment.getExecutionEnvironment
        //Set the concurrency of job to 2.
        env.setParallelism(2)
        //Set the concurrency of job to 2.
        val zkRegisterServerHandler = new ZookeeperRegisterServerHandler
        //Add NettySource operator and receive data.

        env.addSource(new NettySource("NettySource-2", "TOPIC-2", zkRegisterServerHandler))
            .map(x=>(2, new String(x)))//Transform the received byte array into character strings.

            .filter(x=>{
                Random.nextInt(50000) == 10
            })
            .print()

        env.execute()
    }
}
```

### 1.8.3.5 JOIN Operation between Configuration Tables and Streams

#### 1.8.3.5.1 Scenario Description

##### Scenario

Assume that there is a log text file about dwell durations of netizens for shopping online and a CSV table about netizen information. Develop a Flink application that achieves following functions:

- Collects statistics on female netizens who spend more than 2 hours in total for online shopping during the weekend in real time.  
The name fields in the log file and the CSV table can be used as keywords, based on which the two files are joined.
- The first column in the log file records names, the second column records gender, and the third column records the dwell duration (in minutes). Three columns are separated by commas (,).

**data.txt:** logs of netizen dwell duration on weekends

```
LA,female,20
YA,male,10
GA,male,5
CA,female,50
LAA,male,20
FA,female,50
LA,female,20
YA,male,10
GA,male,50
CA,female,50
FA,female,60
LA,female,20
YA,male,10
CA,female,50
FA,female,50
GA,male,5
```

```
CA,female,50  
LB,male,20  
CA,female,50  
FA,female,50  
LA,female,20  
YA,male,10  
FA,female,50  
GA,male,50  
CA,female,50  
FA,female,60  
NotExist,female,200
```

- **configtable.csv**: contains netizens' personal information. Fields starting from the first column to the ninth column are the name, age, company name, work place, academic degree, years of working, mobile number, domicile place, and school of graduation. These columns are separated by commas (,).

```
username,age,company,workLocation,educational,workYear,phone,nativeLocation,school  
LA,25,C1,W1,college,5,1312345678,N1,S1 university  
YA,26,C2,W2,master,6,1312345679,N2,S2 university  
GA,27,C3,W3,college,7,1312345680,N3,S3 university  
CA,28,C4,W4,master,8,1312345681,N4,S4 university  
LB,29,C5,W5,doctor,9,1312345682,N5,S5 university  
FA,30,C6,W6,doctor,10,1312345683,N6,S6 university
```

## Data Preparation

The stream data of the example project is saved in a TXT file, and the configuration table is in CSV format.

1. Ensure that clusters including HDFS, Yarn, secure Redis, and Flink are successfully installed.

### NOTE

- Redis in normal mode can be installed in clusters in security mode. To install Redis in security mode, set **REDIS\_SECURITY\_ENABLED** to **true** during installation. To install Redis in normal mode, set **REDIS\_SECURITY\_ENABLED** to **false**. When Redis is in security mode, users are authenticated using Kerberos, which affects performance. When Redis is in normal mode, users can directly access intranet clients without the need to be authenticated.
- The sample code is used to install secure Redis in a security cluster.
- For details about the sample code for installing normal Redis in a security cluster, see [JOIN Operation between Configuration Tables and Streams](#).

2. Create a Redis cluster, add the Redis user and grant permissions, and download the **user.keytab** and **krb5.conf** files.
3. Modify the **import.properties** and **read.properties** files, which are in the **config** directory specified in the sample code.

### NOTE

In the Scala sample code, the IP addresses and port numbers of all the instances in the logical cluster must be configured for the **Redis\_IP\_Port** parameter.

The formula for calculating the port number of the Redis instance is:  $22400 + Instance ID - 1$ .

To obtain the instance ID, choose **Cluster > Name of the desired cluster > Service > Redis > Redis Manager** on FusionInsight Manager and click the target Redis cluster name. For example, the port numbers of the Redis instances corresponding to the role R1 and role R2 are 22400 ( $22400 + 1 - 1 = 22400$ ) and 22401 ( $22400 + 2 - 1 = 22401$ ), respectively.

- The following is an example of configurations in the **import.properties** file:

```
#path to read csv files, it can be file or directory  
CsvPath=config/configtable.csv  
  
#csv file headers exist in file first line or not  
CsvHeaderExist=true  
#csv file headers, also the redis field names  
#Notice: if CsvHeaderExist false, you must set it, if CsvHeaderExist true, it read from csv file  
ColumnNames=username,age,company,workLocation,educational,workYear,phone,nativeLocation,school  
  
#redis security mode open or not  
Redis_Security=true  
#redis hostname/ip and port when you need to connect to redis  
Redis_IP_Port=SZV1000064084:22400,SZV1000064082:22400,SZV1000064085:22400  
#redis user principal  
Redis_Principal=test11@HADOOP.COM  
#redis keytab file path  
Redis_KeytabFile=config/user.keytab  
#redis krb5 file path  
Redis_Krb5File=config/krb5.conf  
# redis ssl on  
Redis_ssl_on=false
```

- The following is an example of configurations in the **read.properties** file:  
#the redis field names, configure which fields you need to read, Notice you need English field names  
ReadFields=username,age,company,workLocation,educational,workYear,phone,nativeLocation,school  
#redis security mode open or not  
Redis\_Security=true  
#redis hostname/ip and port when you need to connect to redis  
Redis\_IP\_Port=SZV1000064084:22400,SZV1000064082:22400,SZV1000064085:22400  
#redis user principal  
Redis\_Principal=test11@<System domain name>  
#redis keytab file path  
Redis\_KeytabFile=config/user.keytab  
#redis krb5 file path  
Redis\_Krb5File=config/krb5.conf  
# redis ssl on  
Redis\_ssl\_on=false

4. On the Flink client, create a **config** directory, and copy the **user.keytab**, **krb5.conf**, **data.txt**, **configtable.csv**, **import.properties**, and **read.properties** files to the **config** directory, for example, `/opt/hadoopclient/Flink/flink/config/configtable.csv`.

 NOTE

The **data.txt** and **configtable.csv** files are in the **data** directory specified in the sample code.

## Development Guideline

Collect the detailed information about female netizens who continuously spend more than 2 hours on online shopping on the current weekend.

To achieve the objective, the process is as follows:

- Modify the configurations in **import.properties** and **read.properties**, configure fields in the CSV file, fields read by Redis, and Redis security.
- Import the **configtable.csv** table to Redis for storage.
- Read text data, generate DataStreams, and parse data to generate OriginalRecord information.

- Call the function of asynchronous I/O, use the OriginalRecord username field as the keyword to query personal information in Redis, and transform the information into UserRecord.
- Filter the data about the time that female netizens spend online.
- Perform keyby operation based on names, and collect the time that female netizens spend online within a time window.
- Filter data about netizens whose consecutive online duration exceeds the threshold, and obtain the results.

### 1.8.3.5.2 Java Sample Code

#### Description

Collect the information from the log file about female netizens who continuously spend more than 2 hours in online shopping, collect personal information from the CSV table, and use the names of netizens as the keywords for joining the log file and the CSV table.

#### Sample Code

The following code snippet is used as an example for importing the **configtable.csv** file to Redis clusters in security mode. For the complete code, see [com.huawei.bigdata.flink.examples.RedisDataImport](#).

```
package com.huawei.bigdata.flink.examples;

import com.huawei.bigdata.security.LoginUtil;
import org.apache.flink.api.java.utils.ParameterTool;

import org.supercsv.cellprocessor.constraint.NotNull;
import org.supercsv.cellprocessor.ift.CellProcessor;
import org.supercsv.io.CsvBeanReader;
import org.supercsv.io.ICsvBeanReader;
import org.supercsv.prefs.CsvPreference;
import redis.clients.jedis.HostAndPort;
import redis.clients.jedis.JedisCluster;

import java.io.File;
import java.io.FileReader;
import java.io.IOException;
import java.util.*;

/**
 * Read data from csv file and import to redis.
 */
public class RedisDataImport {

    private static final int MAX_ATTEMPTS = 2;

    private static final int TIMEOUT = 60000;

    public static void main(String[] args) throws Exception {
        // print comment for command to use run flink
        System.out.println("use command as: \n" +
            "java -cp /opt/FI-Client/Flink/flink/lib/*:/opt/FlinkConfigtableJavaExample.jar" +
            " com.huawei.bigdata.flink.examples.RedisDataImport --configPath <config filePath>" +
            "*****\n" +
            "<config filePath> is for configure file to load\n" +
            "you may write following content into config filePath: \n" +
            "CsvPath=config/configtable.csv\n" +
            "CsvHeaderExist=true\n" +
```

```
"ColumnNames=username,age,company,workLocation,educational,workYear,phone,nativeLocation,school\n"
+
    "Redis_Security=true\n" +
    "Redis_IP_Port=SZV1000064084:22400,SZV1000064082:22400,SZV1000064085:22400\n" +
    "Redis_Principal=test11@<System domain name>\n" +

### 1.8.3.5.3 Scala Sample Code

#### Description

Collect the information from the log file about female netizens who continuously spend more than 2 hours in online shopping, collect personal information from the CSV table, and use the names of netizens as the keywords for joining the log file and the CSV table.

#### Sample Code

The following code snippet is used as an example for importing the **configurable.csv** file to Redis clusters in security mode. For the complete code, see [com.huawei.bigdata.flink.examples.RedisDataImport](#).

```
package com.huawei.bigdata.flink.examples;

import com.huawei.bigdata.security.LoginUtil;

}
```

### 1.8.3.6 Stream SQL Join Program

#### 1.8.3.6.1 Scenario

##### Scenario

Assume that a Flink service (service 1) receives a message every second. The message records the basic information about a user, including the name, gender, and age. Another Flink service (service 2) receives a message irregularly, and the message records the name and career information about the user.

To meet the requirements of some services, the Flink application is developed to achieve the following function: uses the username recorded in the message received by service 2 as the keyword to jointly query two pieces of service data.

##### Data Planning

The data of service 1 is stored in the Kafka component. Service 1 sends data (requiring Kafka user rights) to and receives data from the Kafka component. For details about how to configure Kafka, see the data planning section of [Data Preparation](#)

Service 2 receives messages using the socket. You can run the **netcat** command to input the analog data source.

- Run the **netcat -l -p <port>** command to start a simple text server.
- After starting the application to connect to the port monitored by **netcat**, enter the data information to the netcat terminal.

## Development Approach

1. Start the Flink Kafka Producer application to send data to Kafka.
2. Start the Flink Kafka Consumer application to receive data from Kafka, construct **Table1**, and ensure that the Topic is the same as that of Producer.
3. Read data from the socket and construct **Table2**.
4. Use Flink SQL to query and print **Table1** and **Table2**.

### 1.8.3.6.2 Java Sample Code

#### Function

In the Flink application, this code invokes the flink-connector-kafka module's API to generate and consume data.

#### Sample Code

If the user needs to use FusionInsight Kafka interconnected with the security mode before the development, obtain the **kafka-clients-\*jar** JAR file from the Kafka client directory.

The following lists Producer, Consumer, and the main logic code used by Flink Stream SQL Join.

For the complete code, see  
[com.huawei.bigdata.flink.examples.WriteIntoKafka](#) and  
[com.huawei.bigdata.flink.examples.SqlJoinWithSocket](#).

1. A piece of user information is generated in Kafka every second. The user information includes the name, age, and gender.

```
//Producer code
public class WriteIntoKafka {
    public static void main(String[] args) throws Exception {
        //Print the command reference for flink run.
        System.out.println("use command as: ");
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21005");
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +
            " /opt/test.jar --topic topic-test -bootstrap.servers 10.91.8.218:21007 --security.protocol
SASL_PLAINTEXT --sasl.kerberos.service.name kafka");
        System.out.println("*****");
        System.out.println("<topic> is the kafka topic name");
        System.out.println("<bootstrap.servers> is the ip:port list of brokers");
        System.out.println("*****");

        //Construct the execution environment.
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        //Set the concurrency.
        env.setParallelism(1);
        //Parse the running parameters.
        ParameterTool paraTool = ParameterTool.fromArgs(args);
        //Construct a flow diagram and write the data generated from self-defined sources to Kafka.
```

```

DataStream<String> messageStream = env.addSource(new SimpleStringGenerator());
FlinkKafkaProducer<String> producer = new FlinkKafkaProducer<>(paraTool.get("topic"),
    new SimpleStringSchema(),
    paraTool.getProperties());
producer.setWriteTimestampToKafka(true);
messageStream.addSink(producer);
//Invoke execute to trigger the execution.
env.execute();
}
//Customize the sources and generate a message every second.
public static class SimpleStringGenerator implements SourceFunction<String> {
    static final String[] NAME = {"Carry", "Alen", "Mike", "Ian", "John", "Kobe", "James"};
    static final String[] SEX = {"MALE", "FEMALE"};
    static final int COUNT = NAME.length;
    boolean running = true;
    Random rand = new Random(47);
    @Override
    //Use rand to randomly generate a combination of the name, gender, and age.
    public void run(SourceContext<String> ctx) throws Exception {
        while (running) {
            int i = rand.nextInt(COUNT);
            int age = rand.nextInt(70);
            String sexy = SEX[rand.nextInt(2)];
            ctx.collect(NAME[i] + "," + age + "," + sexy);
            thread.sleep(1000);
        }
    }
    @Override
    public void cancel() {
        running = false;
    }
}
}

```

2. Generate **Table1** and **Table2**, use Join to jointly query **Table1** and **Table2**, and print the output result.

```

public class SqJoinWithSocket {
    public static void main(String[] args) throws Exception{
        final String hostname;
        final int port;
        System.out.println("use command as: ");
        System.out.println("flink run --class com.huawei.bigdata.flink.examples.SqJoinWithSocket" +
            " /opt/test.jar --topic topic-test -bootstrap.servers xxxx.xxx.xxx:21005 --hostname
xxxx.xxxx.xxxx --port xxx");
        System.out.println("flink run --class com.huawei.bigdata.flink.examples.SqJoinWithSocket" +
            " /opt/test.jar --topic topic-test -bootstrap.servers xxxx.xxx.xxx:21007 --security.protocol
SASL_PLAINTEXT --sasl.kerberos.service.name kafka"
            + "--hostname xxx.xxx.xxxx --port xxx");
        System.out.println("*****");
        System.out.println("<topic> is the kafka topic name");
        System.out.println("<bootstrap.servers> is the ip:port list of brokers");
        System.out.println("*****");
        try {
            final ParameterTool params = ParameterTool.fromArgs(args);
            hostname = params.has("hostname") ? params.get("hostname") : "localhost";
            port = params.getInt("port");
        } catch (Exception e) {
            System.err.println("No port specified. Please run 'FlinkStreamSqlJoinExample " +
                "--hostname <hostname> --port <port>', where hostname (localhost by default) " +
                "and port is the address of the text server");
            System.err.println("To start a simple text server, run 'netcat -l -p <port>' and " +
                "type the input text into the command line");
            return;
        }
        EnvironmentSettings fsSettings =
EnvironmentSettings.newInstance().useOldPlanner().inStreamingMode().build();
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
        StreamTableEnvironment tableEnv = StreamTableEnvironment.create(env, fsSettings);
        //Perform processing based on EventTime.
    }
}

```

```
env.setStreamTimeCharacteristic(TimeCharacteristic.EventTime);
env.setParallelism(1);
ParameterTool paraTool = ParameterTool.fromArgs(args);
//Use Stream1 to read data from Kafka.
DataStream<Tuple3<String, String, String>> kafkaStream = env.addSource(new
FlinkKafkaConsumer<>(paraTool.get("topic"),
    new SimpleStringSchema(),
    paraTool.getProperties()).map(new MapFunction<String, Tuple3<String, String, String>>()
{
    @Override
    public Tuple3<String, String, String> map(String s) throws Exception {
        String[] word = s.split(",");
        return new Tuple3<>(word[0], word[1], word[2]);
    }
});
//Register Stream1 as Table1.
tableEnv.registerDataStream("Table1", kafkaStream, "name, age, sexy, proctime.proctime");
//Use Stream2 to read data from the socket.
DataStream<Tuple2<String, String>> socketStream = env.socketTextStream(hostname, port,
"\n").
map(new MapFunction<String, Tuple2<String, String>>() {
    @Override
    public Tuple2<String, String> map(String s) throws Exception {
        String[] words = s.split("\s");
        if (words.length < 2) {
            return new Tuple2<>();
        }
        return new Tuple2<>(words[0], words[1]);
    }
});
//Register Stream2 as Table2.
tableEnv.registerDataStream("Table2", socketStream, "name, job, proctime.proctime");
//Run SQL Join to perform a combined query.
Table result = tableEnv.sqlQuery("SELECT t1.name, t1.age, t1.sex, t2.job, t2.proctime as shiptime
\n" +
    "FROM Table1 AS t1\n" +
    "JOIN Table2 AS t2\n" +
    "ON t1.name = t2.name\n" +
    "AND t1.proctime BETWEEN t2.proctime - INTERVAL '1' SECOND AND t2.proctime +
INTERVAL '1' SECOND");
//Convert the query result into the stream and print the output.
tableEnv.toAppendStream(result, Row.class).print();
env.execute();
}
})
```

### 1.8.3.6.3 Scala Sample Code

#### Function

In a Flink application, call the API of the flink-connector-kafka module to produce and consume data.

#### Sample Code

If you need to interconnect with Kafka in security mode before application development, **kafka-clients-\*jar** of FusionInsight is required. You can obtain the JAR file from the Kafka client directory.

The following example provides the main code logic of Producer, Consumer, and Flink Stream SQL Join.

Complete code is provided in  
**com.huawei.bigdata.flink.examples.WriteIntoKafka** and  
**com.huawei.bigdata.flink.examples.SqJoinWithSocket**.

1. Produce a piece of user information in Kafka every second. The user information includes the name, age, and gender.

```
//Producer

object WriteIntoKafka {
    def main(args: Array[String]): Unit = {
        System.out.println("use command as: ")
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka" +
        " /opt/test.jar --topic topic-test -bootstrap.servers xxx.xxx.xxx.xxx:21005")
        System.out.println("./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka /opt/
test.jar --topic" + " topic-test -bootstrap.servers xxx.xxx.xxx.xxx:21007 --security.protocol
SASL_PLAINTEXT" + " --sasl.kerberos.service.name kafka")

        System.out.println("*****")
        System.out.println("<topic> is the kafka topic name")
        System.out.println("<bootstrap.servers> is the ip:port list of brokers")
        System.out.println("*****")
        val env = StreamExecutionEnvironment.getExecutionEnvironment
        env.setParallelism(1)

        val paraTool = ParameterTool.fromArgs(args)

        val messageStream = env.addSource(new WriteIntoKafka.SimpleStringGenerator)
        val producer = new FlinkKafkaProducer[String](paraTool.get("topic"), new SimpleStringSchema,
        paraTool.getProperties)

        producer.setWriteTimestampToKafka(true)

        messageStream.addSink(producer)
        env.execute
    }

    /**
     * String source class
     *
     */
    object SimpleStringGenerator {
        private[examples] val NAME = Array("Carry", "Alen", "Mike", "Ian", "John", "Kobe", "James")
        private[examples] val SEX = Array("MALE", "FEMALE")
        private[examples] val COUNT = NAME.length
    }

    class SimpleStringGenerator extends SourceFunction[String] {
        private[examples] var running = true
        private[examples] val rand = new Random(47)

        @throws[Exception]
        override def run(ctx: SourceFunction.SourceContext[String]): Unit = {
            while (running) {
                val i = rand.nextInt(SimpleStringGenerator.COUNT)
                val age = rand.nextInt(70)
                val sexy = SimpleStringGenerator(SEX(rand.nextInt(2)))
                ctx.collect(SimpleStringGenerator.NAME(i) + "," + age + "," + sexy)
                Thread.sleep(1000)
            }
        }

        override def cancel(): Unit = {
            running = false
        }
    }
}
```

2. Generate Table1 and Table2, use **Join** to query both Table1 and Table2, and print the output.

```

object SqJoinWithSocket {
    def main(args: Array[String]): Unit = {
        var hostname: String = null
        var port = 0
        System.out.println("use command as: ")
        System.out.println("flink run --class com.huawei.bigdata.flink.examples.SqJoinWithSocket /opt/
test.jar --topic" + " topic-test -bootstrap.servers xxxx.xxx.xxx.xxx:21005 --hostname xxxx.xxx.xxx.xxx --
port xxx")
        System.out.println("flink run --class com.huawei.bigdata.flink.examples.SqJoinWithSocket /opt/
test.jar --topic" + " topic-test -bootstrap.servers xxxx.xxx.xxx.xxx:21007 --security.protocol
SASL_PLAINTEXT" + " --sasl.kerberos.service.name kafka--hostname xxxx.xxx.xxx.xxx --port xxx")

        System.out.println("*****")
        System.out.println("<topic> is the kafka topic name")
        System.out.println("<bootstrap.servers> is the ip:port list of brokers")
        System.out.println("*****")
        try {
            val params = ParameterTool.fromArgs(args)
            hostname = if (params.has("hostname")) params.get("hostname")
            else "localhost"
            port = params.getInt("port")
        } catch {
            case e: Exception =>
                System.err.println("No port specified. Please run 'FlinkStreamSqlJoinExample " + "--hostname
<hostname> --port <port>', where hostname (localhost by default) " + "and port is the address of the
text server")
                System.err.println("To start a simple text server, run 'netcat -l -p <port>' and " + "type the input
text into the command line")
                return
        }

        val fsSettings = EnvironmentSettings.newInstance.inStreamingMode.build
        val env = StreamExecutionEnvironment.getExecutionEnvironment
        val tableEnv = StreamTableEnvironment.create(env, fsSettings)

        env.getConfig.setAutoWatermarkInterval(200)
        env.setParallelism(1)
        val paraTool = ParameterTool.fromArgs(args)

        val kafkaStream = env.addSource(new FlinkKafkaConsumer[String](paraTool.get("topic"), new
SimpleStringSchema, paraTool.getProperties)).map(new MapFunction[String, Tuple3[String, String,
String]]()) {
            @throws[Exception]
            override def map(str: String): Tuple3[String, String, String] = {
                val word = str.split(",")
                new Tuple3[String, String, String](word(0), word(1), word(2))
            }
        })

        tableEnv.createTemporaryView("Table1", kafkaStream, $("name"), $("age"), $("sexy"), $(
"proctime").proctime)

        val socketStream = env.socketTextStream(hostname, port, "\n").map(new MapFunction[String,
Tuple2[String, String]]()) {
            @throws[Exception]
            override def map(str: String): Tuple2[String, String] = {
                val words = str.split("\\s")
                if (words.length < 2) return new Tuple2[String, String]
                new Tuple2[String, String](words(0), words(1))
            }
        })

        tableEnv.createTemporaryView("Table2", socketStream, $("name"), $("job"), $(
"proctime").proctime)

        val result = tableEnv.sqlQuery("SELECT t1.name, t1.age, t1.sex, t2.job, t2.proctime as shiptime\n"
+ "FROM Table1 AS t1\n" + "JOIN Table2 AS t2\n" + "ON t1.name = t2.name\n" + "AND t1.proctime

```

```
BETWEEN t2.proctime - INTERVAL '1' SECOND AND t2.proctime + INTERVAL" + " '1' SECOND")  
  
    tableEnv.toAppendStream(result, classOf[Row]).print  
    env.execute  
}  
  
}
```

### 1.8.3.7 Submitting a SQL Job Using Flink Jar

#### 1.8.3.7.1 Scenario Description

##### Description

If SQL statements of a job are frequently modified, submit Flink SQL statements in Flink Jar mode to reduce your workload.

##### Development Guideline

Use the current sample to submit and execute specified SQL statements. Use semicolons (;) to separate multiple statements.

#### 1.8.3.7.2 Java Sample Code

The core logic for submitting SQL statements is as follows. Currently, only **CREATE** and **INSERT** statements can be submitted. For details about the complete code, see com.huawei.bigdata.flink.examples.FlinkSQLExecutor.

```
public class FlinkSQLExecutor {  
    public static void main(String[] args) throws IOException {  
        System.out.println("----- begin init -----");  
        final String sqlPath = ParameterTool.fromArgs(args).get("sql", "config/redisSink.sql");  
        final StreamExecutionEnvironment streamEnv =  
        StreamExecutionEnvironment.getExecutionEnvironment();  
        EnvironmentSettings bsSettings = EnvironmentSettings.newInstance().inStreamingMode().build();  
        StreamTableEnvironment tableEnv = StreamTableEnvironment.create(streamEnv, bsSettings);  
        StatementSet statementSet = tableEnv.createStatementSet();  
        String sqlStr = FileUtils.readFileToString(FileUtils.getFile(sqlPath), "utf-8");  
        String[] sqlArr = sqlStr.split(";");  
        for (String sql : sqlArr) {  
            sql = sql.trim();  
            if (sql.toLowerCase(Locale.ROOT).startsWith("create")) {  
                System.out.println("-----\nexecuteSql=\n" + sql);  
                tableEnv.executeSql(sql);  
            } else if (sql.toLowerCase(Locale.ROOT).startsWith("insert")) {  
                System.out.println("-----\ninser=\n" + sql);  
                statementSet.addInsertSql(sql);  
            }  
        }  
        System.out.println("----- begin exec sql -----");  
        statementSet.execute();  
    }  
}
```

##### NOTE

Copy the dependency package required by the current sample, that is, the JAR package in the **lib** file after compilation, to the **lib** folder on the client.

The following uses Kafka in a normal cluster as an example to describe how to submit SQL statements:

```
create table kafka_sink
(
    uuid varchar(20),
    name varchar(10),
    age int,
    ts timestamp(3),
    p varchar(20)
) with (
    'connector' = 'kafka',
    'topic' = '/input2',
    'properties.bootstrap.servers' = 'IP address of the Kafka broker instance',
    'properties.group.id' = 'testGroup2',
    'scan.startup.mode' = 'latest-offset',
    'format' = 'json'
);
create TABLE datagen_source
(
    uuid varchar(20),
    name varchar(10),
    age int,
    ts timestamp(3),
    p varchar(20)
) WITH (
    'connector' = 'datagen',
    'rows-per-second' = '1'
);
INSERT INTO kafka_sink
SELECT *
FROM datagen_source;
```

### 1.8.3.8 FlinkServer REST API JavaExample

#### 1.8.3.8.1 Scenario Description

##### Scenario

Call the FlinkServer RESTful API to create tenants.

##### Data Preparation

- Prepare the files required for user authentication. Specifically, log in to FusionInsight Manager and download the **user.keytab** and **krb5.conf** files.
- Prepare information required for creating a tenant, for example, **tenantId** is **92**, **tenantName** is **test92**, and **remark** is **test tenant remark1**.
- If you run this sample program in Windows, add the host names and IP addresses of all nodes where FlinkServer resides to the **C:\Windows\System32\drivers\etc\hosts** file.

##### Development Guideline

1. Configure user authentication information.
2. Log in as a user.
3. Send requests.

#### 1.8.3.8.2 Java Sample Code

##### Description

Call the FlinkServer RESTful API to create tenants.

## Sample Code

```
public class TestCreateTenants {
    public static void main(String[] args) {
        ParameterTool paraTool = ParameterTool.fromArgs(args);
        final String hostName = paraTool.get("hostName"); // Replace hostName in the hosts file with the
actual host name.
        final String keytab = paraTool.get("keytab file path"); // user.keytab file path
        final String krb5 = paraTool.get("krb5 file path"); // krb5.conf file path
        final String principal = paraTool.get("Authentication username"); // Authentication user

        System.setProperty("java.security.krb5.conf", krb5);
        String url = "https://" + hostName + ":28943/flink/v1/tenants";
        String jsonstr = "{" +
            "\n\t\"tenantId\":\"92\"," +
            "\n\t\"tenantName\":\"test92\"," +
            "\n\t\"remark\":\"test tenant remark\"," +
            "\n\t\"updateUser\":\"test_updateUser\"," +
            "\n\t\"createUser\":\"test_createUser\\"" +
            "\n}";

        try {
            LoginClient.getInstance().setConfigure(url, principal, keytab, "");
            LoginClient.getInstance().login();
            System.out.println(HttpClientUtil.doPost(url, jsonstr, "utf-8", true));
        } catch (Exception e) {
            System.out.println(e);
        }
    }
}
```

### 1.8.3.8.3 Accessing Flinkserver RESTful API as a Proxy User

## Function

Call the FlinkServer RESTful API as a proxy user. Use a proxy to access the API as a FlinkServer administrator to obtain common user permissions.

## Sample Code

Assume that the tenant user is **test92**, the tenant ID is **92**, and the user name is **flinkserveradmin** with FlinkServer administrator permissions. The following code is a complete example.

```
public class TestCreateTenants {
    public static void main(String[] args) {
        ParameterTool paraTool = ParameterTool.fromArgs(args);
        final String hostName = paraTool.get("hostName"); // Replace hostName in the hosts file with the
actual host name.
        final String keytab = paraTool.get("keytab"); // Path for storing user.keytab
        final String krb5 = paraTool.get("krb5"); // Path for storing krb5.conf
        final String principal = paraTool.get("principal"); // Authentication user

        System.setProperty("java.security.krb5.conf", krb5);
        String url = "https://" + hostName + ":28943/flink/v1/tenants";
        String jsonstr = "{" +
            "\n\t\"tenantId\":\"92\"," +
            "\n\t\"tenantName\":\"test92\"," +
            "\n\t\"remark\":\"test tenant remark\"," +
            "\n\t\"updateUser\":\"test_updateUser\"," +
            "\n\t\"createUser\":\"test_createUser\\"" +
            "\n}";

        try {
            LoginClient.getInstance().setConfigure(url, principal, keytab, "");
            LoginClient.getInstance().login(); // Log in as the FlinkServer administrator.
        }
```

```
String proxyUrl = "https://" + hostName + ":28943/flink/v1/proxyUserLogin"; // Call the proxy user API  
to obtain the common user token.  
String result = HttpClientUtil.doPost(proxyUrl, "{\n" +  
"\t\"realUser\": \"flinkserveradmin\"\n" +  
"}", "utf-8", true);  
Gson gson = new Gson();  
JsonObject jsonObject = gson.fromJson(result, JsonObject.class);  
String token = jsonObject.get("result").toString();  
token = "hadoop_auth=" + token;  
  
System.out.println(HttpClientUtil.doPost(url, jsonstr, "utf-8", true , token));  
} catch (Exception e) {  
    System.out.println(e);  
}  
}  
}
```

### 1.8.3.9 Flink Reading Data from and Writing Data to HBase

#### 1.8.3.9.1 Scenario Description

##### Typical Scenario Description

Use Flink API jobs to read data from and write data to HBase.

##### Data Preparation

Prepare the HBase configuration file and download the cluster configuration on FusionInsight Manager to obtain the **hbase-site.xml** file.

##### Development Guideline

1. Writes data to HBase:
  - a. Specify the parent directory of the **hbase-site.xml** file. Flink Sink can obtain the HBase connection.
  - b. Use the connection to determine whether a table exists. If it does not, create one.
  - c. Convert received data into Put objects and writes the Put objects to HBase.
2. Reads data from HBase:
  - a. Specify the parent directory of the **hbase-site.xml** file. Flink Source can obtain the HBase connection.
  - b. Use the connection to determine whether a table exists. If it does not, the job fails. In this case, you need to create a table in HBase shell or an upstream job.
  - c. Read data from HBase, converts result data into Row objects, and sends the Row objects to downstream operators.

#### 1.8.3.9.2 Java Sample Code

##### Description

Call Flink APIs to read data from and write data to HBase.

## Sample Code

The following example shows the main logic code of WriteHBase and ReadHBase.

For details about the complete code, see  
[com.huawei.bigdata.flink.examples.WriteHBase](#) and  
[com.huawei.bigdata.flink.examples.ReadHBase](#).

- Main logic code of WriteHBase

```
public static void main(String[] args) throws Exception {
    System.out.println("use command as: ");
    System.out.println(
        ".bin/flink run --class com.huawei.bigdata.flink.examples.WriteHBase"
        + " /opt/test.jar --tableName t1 --confDir /tmp/hbaseConf");
    System.out.println(
        "*****");
    System.out.println("<tableName> hbase tableName");
    System.out.println("<confDir> hbase conf dir");
    System.out.println(
        "*****");
    StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
    env.setParallelism(1);
    ParameterTool paraTool = ParameterTool.fromArgs(args);
    DataStream<Row> messageStream = env.addSource(new SimpleStringGenerator());
    messageStream.addSink(
        new HBaseWriteSink(paraTool.get("tableName"), createConf(paraTool.get("confDir"))));
    env.execute("WriteHBase");
}

private static org.apache.hadoop.conf.Configuration createConf(String confDir) {
    LOG.info("Create HBase configuration.");

### 1.8.3.10 Flink Reading Data from and Writing Data to Hudi

#### 1.8.3.10.1 Scenario Description

#### Typical Scenario Description

In this example, the job generates one data record per second, writes the data to the Hudi table, and reads and prints the data in the Hudi table.

## Development Guideline

1. Write data to Hudi:
  - a. Generate data through a random data generation class.
  - b. Convert the generated data into **DataStream<RowData>**.
  - c. Write data to the Hudi table.
2. Read data from Hudi:
  - a. Read data from the Hudi table.
  - b. Combine the read data into the JSON format and print the data.

### 1.8.3.10.2 Java Sample Code

#### Description

Call Flink APIs to read data from and write data to Hudi.

#### Sample Code

The following example shows the main logic code of **WriteIntoHudi** and **ReadFromHudi**.

For details about the complete code, see  
**com.huawei.bigdata.flink.examples.WriteIntoHudi** and  
**com.huawei.bigdata.flink.examples.ReadFromHudi**.

- Main logic code of **WriteIntoHudi**

```
public class WriteIntoHudi {  
    public static void main(String[] args) throws Exception {  
        System.out.println("use command as: ");  
        System.out.println(  
            "./bin/flink run -m yarn-cluster --class com.huawei.bigdata.flink.examples.WriteIntoHudi"  
            + " /opt/test.jar --hudiTableName hudiSinkTable --hudiPath hdfs://hacluster/tmp/  
            flinkHudi/hudiTable");  
        System.out.println(  
            "*****");  
        System.out.println("<hudiTableName> is the hudi table name. (Default value is hudiSinkTable)");  
        System.out.println("<hudiPath> Base path for the target hoodie table. (Default value is hdfs://  
            hacluster/tmp/flinkHudi/hudiTable)");  
        System.out.println(  
            "*****");  
  
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();  
        env.setParallelism(1);  
        env.getCheckpointConfig().setCheckpointInterval(10000);  
        ParameterTool paraTool = ParameterTool.fromArgs(args);  
        DataStream<RowData> stringDataStreamSource = env.addSource(new SimpleStringGenerator()  
            .map(new MapFunction<Tuple5<String, String, Integer, String, String>, RowData>() {  
                @Override  
                public RowData map(Tuple5<String, String, Integer, String, String> tuple5) throws

### 1.8.3.11 Python Development Examples

#### 1.8.3.11.1 Submitting a Regular Job Using Python

##### Description

Assume that you need to submit a Flink task to an MRS cluster. The main language used by the service platform is Python. The following content uses an example Python program to read and write Kafka jobs.

##### Python Sample Code

##### Function

Submit Flink Kafka read and write jobs to Yarn through Python APIs.

##### Sample Code

The main logic code in **pyflink-kafka.py** is provided. Before submitting the code, ensure that **file\_path** is the path where the SQL statement to be executed. You are advised to use a full path.

For details about the complete code, see **pyflink-kafka.py** in **flink-examples/pyflink-example/pyflink-kafka**.

```
import os
import logging
import sys
from pyflink.common import JsonRowDeserializationSchema, JsonRowSerializationSchema
from pyflink.common.typeinfo import Types
from pyflink.datastream.connectors import FlinkKafkaProducer, FlinkKafkaConsumer
from pyflink.datastream import StreamExecutionEnvironment
from pyflink.table import TableEnvironment, EnvironmentSettings
def read_sql(file_path):
    if not os.path.isfile(file_path):
        raise TypeError(file_path + " does not exist")
    all_the_text = open(file_path).read()
    return all_the_text
def exec_sql():
    # Change the SQL path before job submission.
    # file_path = "/opt/client/Flink/flink/insertData2kafka.sql"
    # file_path = os.getcwd() + "/../../../../../yarnship/insertData2kafka.sql"
    # file_path = "/opt/client/Flink/flink/conf/ssl/insertData2kafka.sql"
    file_path = "insertData2kafka.sql"
    sql = read_sql(file_path)
    t_env = TableEnvironment.create(EnvironmentSettings.in_streaming_mode())
    statement_set = t_env.create_statement_set()
    sqlArr = sql.split(";")
    for sqlStr in sqlArr:
        sqlStr = sqlStr.strip()
        if sqlStr.lower().startswith("create"):
            print("-----create-----")
            print(sqlStr)
            t_env.execute_sql(sqlStr)
        if sqlStr.lower().startswith("insert"):
            print("-----insert-----")
            print(sqlStr)
            statement_set.add_insert_sql(sqlStr)
    statement_set.execute()
def read_write_kafka():
    # find kafka connector jars
    env = StreamExecutionEnvironment.get_execution_environment()

    # specific_jars = "file://" + os.getcwd() + "/../../../../../yarnship/flink-connector-kafka-xxx.jar"
    # specific_jars = "file:///opt/client/Flink/flink/conf/ssl/flink-connector-kafka-xxx.jar"
    # the sql connector for kafka is used here as it's a fat jar and could avoid dependency issues
    env.add_jars(specific_jars)
    kafka_properties = {'bootstrap.servers': '192.168.20.162:21005', 'group.id': 'test_group'}
    deserialization_schema = JsonRowDeserializationSchema.builder() \
        .type_info(type_info=Types.ROW([Types.INT(), Types.STRING()])).build()
    kafka_consumer = FlinkKafkaConsumer(
        topics='test_source_topic',
        deserialization_schema=deserialization_schema,
        properties=kafka_properties)
    print("-----read -----")
    ds = env.add_source(kafka_consumer)
    serialization_schema = JsonRowSerializationSchema.builder().with_type_info(
        type_info=Types.ROW([Types.INT(), Types.STRING()])).build()
    kafka_producer = FlinkKafkaProducer(
        topic='test_sink_topic',
        serialization_schema=serialization_schema,
        producer_config=kafka_properties)
    print("-----write-----")
    ds.add_sink(kafka_producer)
    env.execute("pyflink kafka test")
if __name__ == '__main__':
    logging.basicConfig(stream=sys.stdout, level=logging.INFO, format"%(message)s")
    print("-----insert data to kafka-----")
    exec_sql()
    print("-----read_write_kafka-----")
    read_write_kafka()
```

**Table 1-33** Parameters for submitting a regular job using Python

Parameter	Description	Example
bootstrap.servers	Service IP address and port number of the Broker instance of Kafka	192.168.12.25:21005
specific_jars	<p>Package path: <i>Client installation directory/Flink/flink/lib/flink-connector-kafka-*.jar</i>. You are advised to use a full path.</p> <p><b>NOTE</b> If a job needs to be submitted as yarn-application, replace the following path. Replace the JAR package version with the actual one.</p> <pre>specific_jars="file://" + os.getcwd() + "/../../../../../yarnship/flink-connector-kafka-xxx-h0.cbu.mrs.xxx.jar"</pre>	specific_jars = file:///Client installation directory/Flink/flink/lib/flink-connector-kafka-xxx-h0.cbu.mrs.xxx.jar
file_path	<p>Path of the <b>insertData2kafka.sql</b> file. You are advised to use a full path. Obtain the package from the secondary development sample code and upload it to the specified directory on the client.</p> <p><b>NOTE</b> If a job needs to be submitted as yarn-application, replace the following path:</p> <pre>file_path = os.getcwd() + "/../../../../../yarnship/insertData2kafka.sql"</pre>	file_path = /Client installation directory/Flink/flink/insertData2kafka.sql

The following is an example SQL statement:

```
create table kafka_sink_table (
    age int,
    name varchar(10)
) with (
    'connector' = 'kafka',
    'topic' = 'test_source_topic', --Name of the topic written to Kafka. Ensure that the topic name is the same as that in the Python file.
    'properties.bootstrap.servers' = 'IP address of the Kafka broker instance.Kafka port number',
    'properties.group.id' = 'test_group',
    'format' = 'json'
);
create TABLE datagen_source_table (
    age int,
    name varchar(10)
) WITH (
    'connector' = 'datagen',
    'rows-per-second' = '1'
);
INSERT INTO
    kafka_sink_table
SELECT
    *
FROM
    datagen_source_table;
```

# Running the Program

- Step 1** Obtain `pyflink-kafka.py` and `insertData2kafka.sql` from the sample project `flink-examples/pyflink-example/pyflink-kafka`.

**Step 2** Package the prepared Python virtual environment by referring to [Preparing Development and Operating Environment](#) and obtain the `venv.zip` file.

```
zip -q -r venv.zip venv/
```

- Step 3** Log in to the active management node as the **root** user and upload **venv.zip**, **pyflink-kafka.py**, and **insertData2kafka.sql** files obtained in **Step 1** and **Step 2** to the client environment.

  - Per-job: Upload the preceding files to *Client installation directory/Flink/flink*.
  - yarn-application: Upload the preceding files and the **flink-connector-kafka-Actual version number.jar** package to *Client installation directory/Flink/flink/yarnship*.

- Step 4** Change the `specific_jars` path in `pyflink-kafka.py`.

- per-job: Change the path to the actual path of the SQL file, for example,  
`file:///Client installation directory/Flink/flink/lib/flink-connector-kafka-Actual version number.jar`.
  - yarn-application: Change to `file://" + os.getcwd() + "/../../../../yarnship/flink-connector-kafka-Actual version number.jar`.

- ## **Step 5 Change file\_path in pyflink-kafka.py.**

- per-job: Change the path to the actual path of the SQL file. For example:  
*Client installation directory/Flink/flink/insertData2kafka.sql*
  - yarn-application: Change the path to **os.getcwd () + "../../../../../yarnship/insertData2kafka.sql"**

- Step 6** Run the following command to specify the running environment:

```
export PYFLINK_CLIENT_EXECUTABLE=venv.zip/venv/bin/python3
```

- Step 7** Run the following command to run the program:

- Per-job:  
./bin/flink run --detached -t yarn-per-job -Dyarn.application.name=py\_kafka -pyarch venv.zip -pyexec venv.zip/venv/bin/python3 -py pyflink-kafka.py

## Execution result:

```
[root@ip-10-10-10-10 ~]# ./checkfile.sh /etc/apollo/apollo.yaml & ./apollo start v=v1 --skip-ssl-validation >/dev/null
```

Class name contains multiple static handles.

```
[root@ip-10-10-10-10 ~]# ./checkfile.sh /etc/apollo/apollo.yaml & ./apollo start v=v1 --skip-ssl-validation >/dev/null
```

Actual class found in file /etc/apollo/apollo.yaml

```
[root@ip-10-10-10-10 ~]# ./checkfile.sh /etc/apollo/apollo.yaml & ./apollo start v=v1 --skip-ssl-validation >/dev/null
```

Actual binding found in file /etc/apollo/apollo.yaml

### 1.8.3.11.2 Submitting a SQL Job Using Python

## Description

Assume that you need to submit Flink tasks to the MRS cluster, the main language used by the service platform is Python, and core service processing requires SQL. The following content provides an example to describe how to submit a SQL job using Python.

# Python Sample Code

## Function

Submit a Flink SQL job to Yarn through Python APIs.

## Sample Code

The main logic code in **pyflink-sql.py** is provided. Before submitting the code, ensure that **file\_path** is the path where the SQL statement to be executed. You are advised to use a full path.

For details about the complete code, see `pyflink-sql.py` in `flink-examples/pyflink-example/pyflink-sql`.

```
import logging
import sys
import os
from pyflink.table import (EnvironmentSettings, TableEnvironment)
def read_sql(file_path):
    if not os.path.isfile(file_path):
        raise TypeError(file_path + " does not exist")
    all_the_text = open(file_path).read()
    return all_the_text
def exec_sql():
    # Change the SQL path before job submission.
    file_path = "datagen2kafka.sql"
    sql = read_sql(file_path)
    t_env = TableEnvironment.create(EnvironmentSettings.in_streaming_mode())
    statement_set = t_env.create_statement_set()
    sqlArr = sql.split(";")
    for sqlStr in sqlArr:
        sqlStr = sqlStr.strip()
        if sqlStr.lower().startswith("create"):
            print("-----create-----")
            print(sqlStr)
            t_env.execute_sql(sqlStr)
        if sqlStr.lower().startswith("insert"):
            print("-----insert-----")
            print(sqlStr)
            statement_set.add_insert_sql(sqlStr)
    statement_set.execute()
```

```
if __name__ == '__main__':
    logging.basicConfig(stream=sys.stdout, level=logging.INFO, format"%(message)s")
    exec_sql()
```

**Table 1-34** Parameters for submitting a SQL job using Python

Parameter	Description	Example
file_path	<p>Path of the <b>datagen2kafka.sql</b> file. You are advised to use a full path. Obtain the package from the secondary development sample code and upload it to the specified directory on the client.</p> <p><b>NOTE</b> If a job needs to be submitted as yarn-application, replace the following path: <code>file_path = os.getcwd() + "/../../../../../yarnship/datagen2kafka.sql"</code></p>	<code>file_path = /Client installation directory/ Flink/flink/ datagen2kafka.sql</code>

The following is an example SQL statement:

```
create table kafka_sink (
    uuid varchar(20),
    name varchar(10),
    age int,
    ts timestamp(3),
    p varchar(20)
) with (
    'connector' = 'kafka',
    'topic' = 'input2',
    'properties.bootstrap.servers' = 'IP address of the Kafka broker instance.Kafka port number',
    'properties.group.id' = 'testGroup2',
    'scan.startup.mode' = 'latest-offset',
    'format' = 'json'
);
create TABLE datagen_source (
    uuid varchar(20),
    name varchar(10),
    age int,
    ts timestamp(3),
    p varchar(20)
) WITH (
    'connector' = 'datagen',
    'rows-per-second' = '1'
);
INSERT INTO
    kafka_sink
SELECT
    *
FROM
    datagen_source;
```

## Running the Program

**Step 1** Obtain **pyflink-sql.py** and **datagen2kafka.sql** from the sample project **flink-examples/pyflink-example/pyflink-sql**.

**Step 2** Package the prepared Python virtual environment by referring to [Preparing Development and Operating Environment](#) and obtain the **venv.zip** file.

```
zip -q -r venv.zip venv/
```

**Step 3** Log in to the active management node as the **root** user and upload **venv.zip**, **pyflink-sql.py**, and **datagen2kafka.sql** files obtained in **Step 1** and **Step 2** to the client environment.

- Per-job: Upload the preceding files to *Client installation directory/Flink/flink*.
- yarn-application: Upload the preceding files to *Client installation directory/Flink/flink/yarnship*.
- yarn-session: Upload the preceding files to *Client installation directory/Flink/flink/conf/ssl*.

**Step 4** Change **file\_path** in **pyflink-sql.py**.

- per-job: Change the path to the actual path of the SQL file. For example: *Client installation directory/Flink/flink/datagen2kafka.sql*
- yarn-application: Change the path to **os.getcwd() + "/../../..../yarnship/datagen2kafka.sql"**
- yarn-session: Change the path to the actual path of the SQL file. For example: *Client installation directory/Flink/flink/conf/ssl//datagen2kafka.sql*

**Step 5** Run the following command to specify the running environment:

```
export PYFLINK_CLIENT_EXECUTABLE=venv.zip/venv/bin/python3
```

**Step 6** Run the following command to run the program:

- Per-job:

```
./bin/flink run --detached -t yarn-per-job -Dyarn.application.name=py_sql -pyarch venv.zip -pyexec venv.zip/venv/bin/python3 -py pyflink-sql.py
```

Execution result:

```
[2023-07-19 19:41:52.665 [INFO] [main] Login succeeded for user centos using keytab file user.keytab. Keytab file removed in 0.0001 [org.apache.hadoop.security.UserGroupInformation.loginFromKeytabForDelegationToken, java:1120]

[2023-07-20 20:51:33.049 [INFO] [main] [Thread-1] Job has been submitted with jobID 220ef088bc09decc870dc7a014]
```

- yarn-session

Before starting the Yarn session, prepare the running environment by referring to **Preparing Development and Operating Environment**. Run the following command to start **yarn-session**:

```
bin/yarn-session.sh -jm 1024 -tm 4096 -t conf/ssl/ -d
```

Run the following command to submit the job:

```
./bin/flink run --detached -t yarn-session -Dyarn.application.name=py_sql -  
Dyarn.application.id=application_1685505909197_0285 -pyarch conf/ssl/venv.zip -pyexec conf/ssl/  
venv.zip/venv/bin/python3 -py conf/ssl/pyflink-sql.py
```

#### Execution result:

```

## 1.8.4 Debugging the Application

### 1.8.4.1 Compiling and Running the Application

#### Scenarios

After developing the application code, you can compile the code into a JAR package and upload it to the Linux client for running. The procedures for running applications developed using Scala or Java are the same on the Flink client.

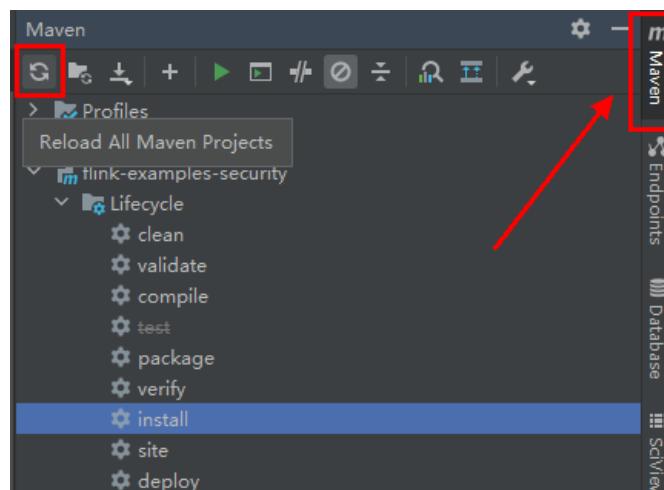

Flink applications of a Yarn cluster can run only on Linux, but not on Windows.

#### Procedure

- Step 1** In IntelliJ IDEA, click **Reload All Maven Projects** in the Maven window on the right of IDEA to import Maven project dependencies.

Figure 1-76 Reload projects

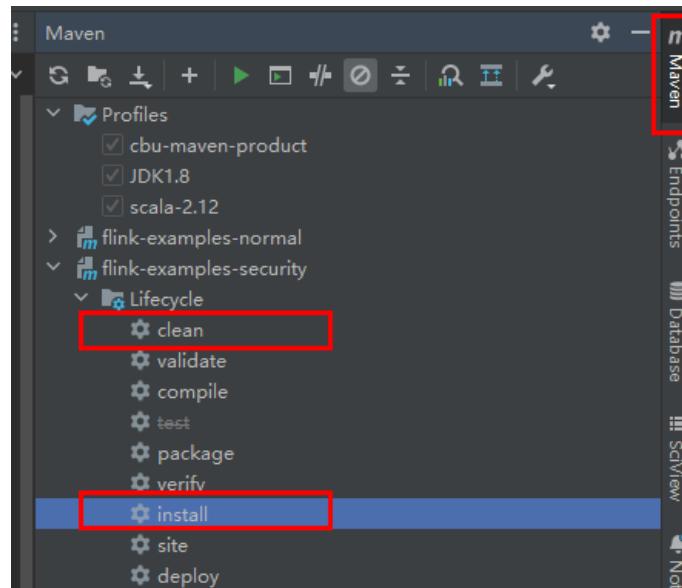

**Step 2** Compile and run the application.

Use either of the following two methods:

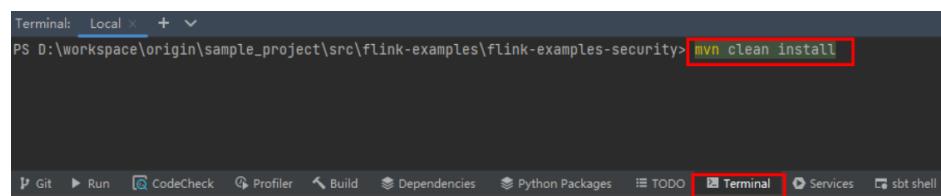

- Method 1:
  - a. Choose **Maven**, locate the target project name, and double-click **clean** under **Lifecycle** to run the **clean** command of Maven.
  - b. Choose **Maven**, locate the target project name, and double-click **install** under **Lifecycle** to run the **install** command of Maven.

**Figure 1-77** Maven clean and install

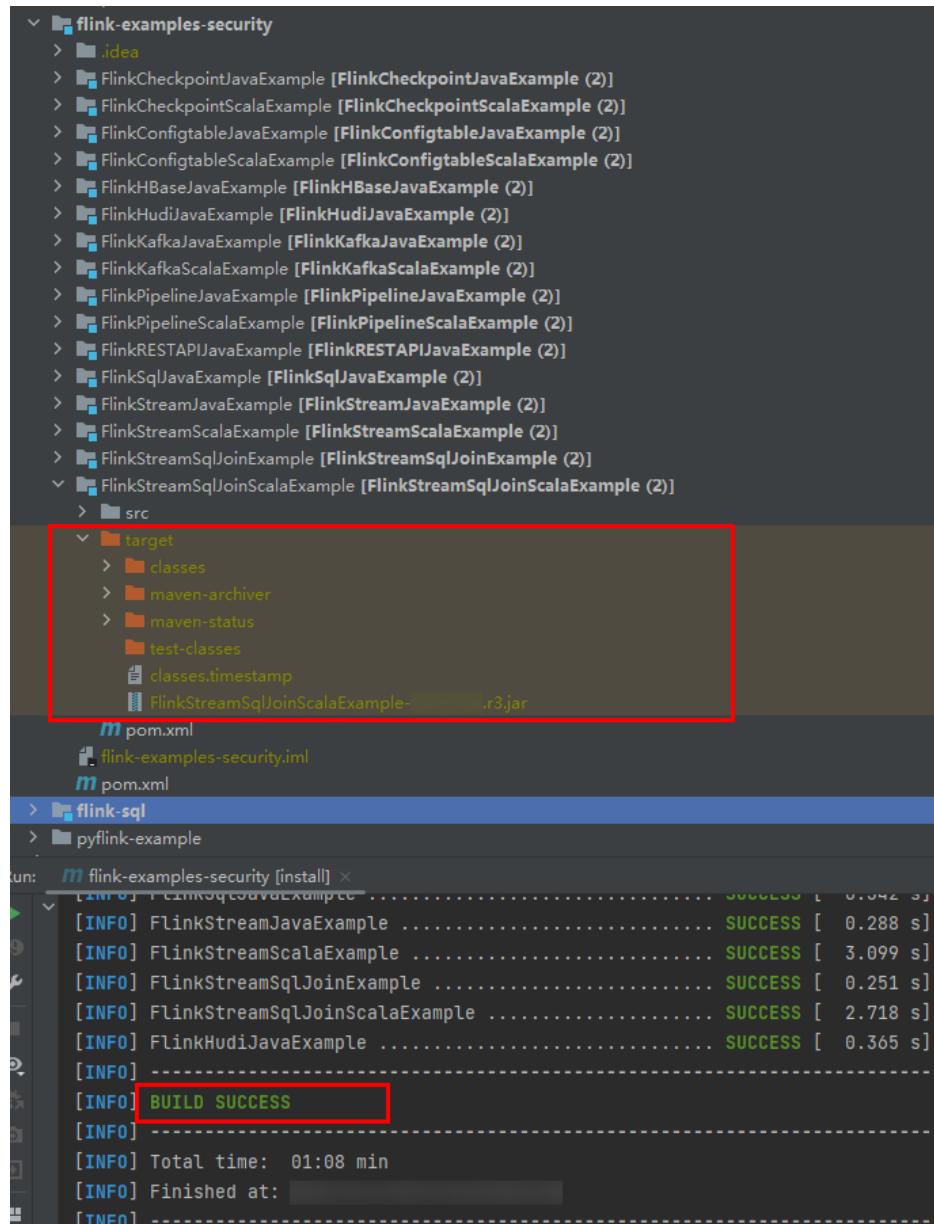

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window of IDEA, and run the **mvn clean install** command to build the file.

**Figure 1-78** Entering **mvn clean install** in the IDEA Terminal text box

**Step 3** After the compilation is complete, the message "BUILD SUCCESS" is printed and the **target** directory is generated. Obtain the JAR package in the directory.

Figure 1-79 Compilation completed

**Step 4** Copy the JAR package (for example, **FlinkStreamJavaExample.jar**) generated in **Step 3** to the related directory of the Flink client node, for example, **/opt/hadoopclient**. Create the **conf** directory in the directory and copy the required configuration file to the **conf** directory. For details, see [Preparing an Operating Environment](#). Run the Flink application.

Start the Flink cluster before running the Flink applications on Linux. On the Flink client, run the **yarn session** command to start the Flink cluster.

The following is an example:

```
cd /opt/hadoopclient/Flink/flink
bin/yarn-session.sh -jm 1024 -tm 4096 -t conf/ssl/
```

 NOTE

- Before running the **yarn-session.sh** command, copy the dependency package of the Flink application to the client directory `#{Client installation directory}/Flink/flink/lib`. For details about the dependency packages of the application, see [Reference information about the dependency package for running the sample project](#).
  - Do not restart the HDFS service or all DataNode instances during Flink job running. Otherwise, the job may fail and some temporary application data cannot be cleared.
  - In the example, **ssl/** is a user-defined subdirectory in the Flink client directory, which is used to store configuration files of the SSL keystore and truststore.
  - The memory size of TaskManagers specified by using the **-tm** command must be at least 4,096 MB.
- Running the DataStream sample application (in Scala or Java)
- Open another window on the terminal. Go to the Flink client directory and call the **bin/flink run** script to run code.
- Java  
**bin/flink run --class com.huawei.bigdata.flink.examples.FlinkStreamJavaExample /opt/hadoopclient/FlinkStreamJavaExample.jar --filePath /opt/log1.txt,/opt/log2.txt --windowTime 2**
  - Scala  
**bin/flink run --class com.huawei.bigdata.flink.examples.FlinkStreamScalaExample /opt/hadoopclient/FlinkStreamScalaExample.jar --filePath /opt/log1.txt,/opt/log2.txt --windowTime 2**

 NOTE

If **log1.txt** and **log2.txt** need to be stored locally, they must be stored on each node where the Yarn NodeManager instance is deployed. The permission is 755.

**Table 1-35** Parameters

Parameter	Description
<code>&lt;filePath&gt;</code>	File path in the local file system. The <code>/opt/log1.txt</code> and <code>/opt/log2.txt</code> files must be stored on every node. The default value can be retained or changed.
<code>&lt;windowTime&gt;</code>	Duration of a time window. The unit is minute. The default value can be retained or changed.

- Running the sample application for producing and consuming data in Kafka (in Java or Scala)

Command for starting the application to produce data

```
bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka /opt/hadoopclient/  
FlinkKafkaJavaExample.jar <topic> <bootstrap.servers> [security.protocol] [sasl.kerberos.service.name]  
[ssl.truststore.location] [ssl.truststore.password] [kerberos.domain.name]
```

Command for starting the application to consume data

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/  
FlinkKafkaJavaExample.jar <topic> <bootstrap.servers> [security.protocol] [sasl.kerberos.service.name]  
[ssl.truststore.location] [ssl.truststore.password]
```

**Table 1-36** Parameters

Parameter	Description	Mandatory or Not
topic	Kafka topic name	Yes
bootstrap.server	List of IP addresses or ports of broker clusters	Yes

Parameter	Description	Mandatory or Not
security.protocol	<p>The parameter can be set to protocols PLAINTEXT (optional), SASL_PLAINTEXT, SSL, and SASL_SSL, corresponding to ports 21005, 21007, 21008, and 21009 of the FusionInsight Kafka cluster, respectively.</p> <ul style="list-style-type: none"> <li>- If the SASL is configured, the value of <b>sasl.kerberos.service.name</b> must be set to <b>kafka</b> and that of <b>kerberos.domain.name</b> must be set to <b>hadoop.SystemDomain name</b>, and the configuration items related to <b>security.kerberos.login</b> in <b>conf/flink-conf.yaml</b> must be set.</li> </ul> <p><b>NOTE</b>  Log in to FusionInsight Manager and choose <b>System &gt; Permission &gt; Domain and Mutual Trust</b>. On the displayed page, the value of <b>Local Domain</b> is the system domain name. (All letters in the system domain name must be converted into lowercase letters.)</p> <ul style="list-style-type: none"> <li>- If the SSL is configured, <b>ssl.truststore.location</b> (path of <b>truststore</b>) and <b>ssl.truststore.password</b> (password of <b>truststore</b>) must be set.</li> </ul>	<p>No</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"> <li>- If this parameter is not configured, Kafka is in non-security mode.</li> <li>- If SSL needs to be configured, find more information about how to generate the <b>truststore.jks</b> file in <b>More Information &gt; External Interfaces &gt; SSL Encryption Function Used by a Client of Kafka Development Guide</b>.</li> </ul>

 NOTE

- To execute the sample application, set **allow.everyone.if.no.acl.found** to **true**.
- The following **.jar** packages need to be added to Kafka applications:
  - **flink-dist\_\*.jar** in the **lib** directory under the installation directory of Flink server.
  - **flink-connector-kafka\_\*.jar** in the **opt** directory under the installation directory of Flink server.
  - **kafka-clients-\*.jar** in the **lib** directory under the installation directory of Kafka client or server.
  - If **truststore.jks** is set to an absolute path, place the **truststore.jks** file in the specified directory of each Yarn nodemanager. If this parameter is set to a relative path, add the upload directory when executing the **yarn-session.sh** script. For example, before executing **Command 4**, run the **yarn-session.sh -t config/ \*\*\*** command.

The following commands use ReadFromKafka as an example and the cluster domain name is **HADOOP.COM**:

- Command 1:  

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/
FlinkKafkaJavaExample.jar --topic topic1 --bootstrap.servers 10.96.101.32:21005
```
- Command 2:  

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/
FlinkKafkaJavaExample.jar --topic topic1 --bootstrap.servers 10.96.101.32:21007 --
security.protocol SASL_PLAINTEXT --sasl.kerberos.service.name kafka --kerberos.domain.name
hadoop.hadoop.com
```
- Command 3:  

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/conf/
FlinkKafkaJavaExample.jar --topic topic1 --bootstrap.servers 10.96.101.32:21008 --
security.protocol SSL --ssl.truststore.location /home/truststore.jks --ssl.truststore.password xxx
```
- Command 4:  

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromKafka /opt/hadoopclient/
FlinkKafkaJavaExample.jar --topic topic1 --bootstrap.servers 10.96.101.32:21009 --
security.protocol SASL_SSL --sasl.kerberos.service.name kafka --ssl.truststore.location config/
truststore.jks --ssl.truststore.password xxx --kerberos.domain.name hadoop.hadoop.com
```
- Running the sample application of the asynchronous checkpoint mechanism (in Scala or Java)

To diversify sample code, the processing time is used as a timestamp for data stream in Java, and the event time is used as a timestamp for data stream in Scala. The command reference is as follows:

- Saving checkpoint snapshot information to HDFS
  - Java  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkProcessingTimeAPIMain /opt/
hadoopclient/FlinkCheckpointJavaExample.jar --chkPath hdfs://hacluster/flink/checkpoint/
```
  - Scala  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkEventTimeAPIChkMain /opt/
hadoopclient/conf/FlinkCheckpointScalaExample.jar --chkPath hdfs://hacluster/flink/
checkpoint/
```
- Saving checkpoint snapshot information to a local file
  - Java  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkProcessingTimeAPIMain /opt/
hadoopclient/FlinkCheckpointJavaExample.jar --chkPath file:///home/zzz/flink-checkpoint/
```

■ Scala

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkEventTimeAPIChkMain  
/opt/hadoopclient/FlinkCheckpointScalaExample.jar --ckkPath file:///home/zzz/flink-  
checkpoint/
```

 NOTE

- Checkpoint source file path: **flink/checkpoint/fd5f5b3d08628d83038a30302b611/chk-X/4f854bf4-ea54-4595-a9d9-9b9080779ffe**

**flink/checkpoint:** indicates the specified root directory.

**fd5f5b3d08628d83038a30302b611:** indicates the level-2 directory named after jobID.

**chk-X:** "X" indicates the checkpoint number, which is the level-3 directory.

**4f854bf4-ea54-4595-a9d9-9b9080779ffe:** indicates a checkpoint source file.

- If Flink is in cluster mode, the checkpoint stores the file in HDFS. A local path can only be used when Flink is in local mode, facilitating commissioning.

● Running the Pipeline sample application

- Java

- i. Start the publisher job.

```
bin/flink run -p 2 --class com.huawei.bigdata.flink.examples.TestPipeline_NettySink /opt/  
hadoopclient/FlinkPipelineJavaExample.jar
```

- ii. Start the subscriber Job1.

```
bin/flink run --class com.huawei.bigdata.flink.examples.TestPipeline_NettySource1 /opt/  
hadoopclient/FlinkPipelineJavaExample.jar
```

- iii. Start the subscriber Job2.

```
bin/flink run --class com.huawei.bigdata.flink.examples.TestPipeline_NettySource2 /opt/  
hadoopclient/FlinkPipelineJavaExample.jar
```

- Scala

- i. Start the publisher job.

```
bin/flink run -p 2 --class com.huawei.bigdata.flink.examples.TestPipeline_NettySink /opt/  
hadoopclient/FlinkPipelineScalaExample.jar
```

- ii. Start the subscriber Job1.

```
bin/flink run --class com.huawei.bigdata.flink.examples.TestPipeline_NettySource1 /opt/  
hadoopclient/FlinkPipelineScalaExample.jar
```

- iii. Start the subscriber Job2.

```
bin/flink run --class com.huawei.bigdata.flink.examples.TestPipeline_NettySource2 /opt/  
hadoopclient/FlinkPipelineScalaExample.jar
```

● Sample application of the JOIN between configuration tables and streams.  
FlinkConfigtableJavaExample and FlinkConfigtableScalaExample are used as examples.

The execution modes of Java are as follows:

- yarn-session mode

- i. Import **configtable.csv** to the Redis cluster.

```
java -cp /opt/hadoopclient/Flink/flink/lib/*:/opt/hadoopclient/  
FlinkConfigtableJavaExample.jar com.huawei.bigdata.flink.examples.RedisDataImport --  
configPath config/import.properties
```

- ii. Start the Flink cluster.

```
bin/yarn-session.sh -t config -jm 1024 -tm 1024
```

- iii. Stream data reads personal information from Redis using netizen names as keywords, joins the information, and generates the output.

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkConfigtableJavaExample /opt/  
hadoopclient/FlinkConfigtableJavaExample.jar --dataPath config/data.txt
```

- yarn-cluster mode
  - i. Import **configtable.csv** to the Redis cluster.  

```
java -cp /opt/hadoopclient/Flink/flink/lib/*:/opt/hadoopclient/  
FlinkConfigtableJavaExample.jar com.huawei.bigdata.flink.examples.RedisDataImport --  
configPath config/import.properties
```
  - ii. Start the Flink cluster. Stream data reads personal information from  
Redis using netizen names as keywords, joins the information, and  
generates the output.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkConfigtableJavaExample -m  
yarn-cluster -yt config -yjm 1024 -ytm 4096 /opt//opt/hadoopclient/  
FlinkConfigtableJavaExample.jar --dataPath config/data.txt
```

The execution modes of Scala are as follows:

- yarn-session mode
  - i. Import **configtable.csv** to the Redis cluster.  

```
java -cp /opt/hadoopclient/Flink/flink/lib/*:/opt/hadoopclient/  
FlinkConfigtableScalaExample.jar com.huawei.bigdata.flink.examples.RedisDataImport --  
configPath config/import.properties
```
  - ii. Start the Flink cluster.  

```
bin/yarn-session.sh -t config -jm 1024 -tm 4096
```
  - iii. Stream data reads personal information from Redis using netizen  
names as keywords, joins the information, and generates the output.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkConfigtableScalaExample /opt/  
hadoopclient/FlinkConfigtableScalaExample.jar --dataPath config/data.txt
```
- yarn-cluster mode
  - i. Import **configtable.csv** to the Redis cluster.  

```
java -cp /opt/hadoopclient/Flink/flink/lib/*:/opt/hadoopclient/  
FlinkConfigtableScalaExample.jar com.huawei.bigdata.flink.examples.RedisDataImport --  
configPath config/import.properties
```
  - ii. Start the Flink cluster. Stream data reads personal information from  
Redis using netizen names as keywords, joins the information, and  
generates the output.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.FlinkConfigtableScalaExample -m  
yarn-cluster -yt config -yjm 1024 -ytm 4096 /opt/hadoopclient/  
FlinkConfigtableScalaExample.jar --dataPath config/data.txt
```

- Running the Stream SQL Join sample application

- Java
  - i. Start the application to produce data in Kafka. For details about how  
to configure Kafka, see [Running the sample application for  
producing and consuming data in Kafka \(in Java or Scala\)](#).  

```
bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka /opt/hadoopclient/  
FlinkStreamSqlJoinExample.jar --topic topic-test --bootstrap.servers xxx.xxx.xxx.21005
```
  - ii. Run the **netcat** command on any node in the cluster to wait for an  
application connection.  

```
netcat -l -p 9000
```
  - iii. Start the application to receive socket data and perform a joint  
query.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.SqlJoinWithSocket /opt/  
hadoopclient/FlinkStreamSqlJoinExample.jar --topic topic-test --bootstrap.servers  
xxx.xxx.xxx.21005 --hostname xxx.xxx.xxx.21005 --port 9000
```
- Scala
  - i. Start the application to produce data in Kafka. For details about how  
to configure Kafka, see [Running the sample application for  
producing and consuming data in Kafka \(in Java or Scala\)](#).

- ```
bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoKafka /opt/hadoopclient/
FlinkStreamSqlJoinScalaExample.jar --topic topic-test --bootstrap.servers
xxx.xxx.xxx.21005
```
  - ii. Run the **netcat** command on any node in the cluster to wait for an application connection.  

```
netcat -l -p 9000
```
  - iii. Start the application to receive socket data and perform a joint query.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.SqlJoinWithSocket /opt/
hadoopclient/FlinkStreamSqlJoinScalaExample.jar --topic topic-test --bootstrap.servers
xxx.xxx.xxx.21005 --hostname xxx.xxx.xxx.9000 --port 9000
```
- Running the Flink HBase sample application .
    - yarn-session mode
      - i. Start the Flink cluster.  

```
./bin/yarn-session.sh -t config -jm 1024 -tm 4096
```
      - ii. Run the Flink application and enter parameters.  

```
bin/flink run --class com.huawei.bigdata.flink.examples.WriteHBase /opt/client1/Flink/flink/
FlinkHBaseJavaExample-xxx.jar --tableName xxx --confDir xxx
```

```
bin/flink run --class com.huawei.bigdata.flink.examples.ReadHBase /opt/client1/Flink/flink/
FlinkHBaseJavaExample-xxx.jar --tableName xxx --confDir xxx
```
    - yarn-cluster mode
      - ```
bin/flink run -m yarn-cluster --class com.huawei.bigdata.flink.examples.WriteHBase /opt/client1/
Flink/flink/FlinkHBaseJavaExample-xxx.jar --tableName xxx --confDir xxx
```
      - ```
bin/flink run -m yarn-cluster --class com.huawei.bigdata.flink.examples.ReadHBase /opt/client1/
Flink/flink/FlinkHBaseJavaExample-xxx.jar --tableName xxx --confDir xxx
```
  - Running the Flink Hudi sample application .
    - yarn-session mode
      - i. Start the Flink cluster.  

```
./bin/yarn-session.sh -t config -jm 1024 -tm 4096
```
      - ii. Run the Flink application and enter parameters.  

```
./bin/flink run --class com.huawei.bigdata.flink.examples.WriteIntoHudi /opt/test.jar --
hudiTableName hudiSinkTable --hudiPath hdfs://hacluster/tmp/flinkHudi/hudiTable
```

```
./bin/flink run --class com.huawei.bigdata.flink.examples.ReadFromHudi /opt/test.jar --
hudiTableName hudiSourceTable --hudiPath hdfs://hacluster/tmp/flinkHudi/hudiTable --
read.start-commit xxx
```
    - yarn-cluster mode
      - ```
./bin/flink run -m yarn-cluster -yt config --class
com.huawei.bigdata.flink.examples.WriteIntoHudi /opt/test.jar --hudiTableName hudiSinkTable --
hudiPath hdfs://hacluster/tmp/flinkHudi/hudiTable
```
      - ```
./bin/flink run -m yarn-cluster -yt config --class
com.huawei.bigdata.flink.examples.ReadFromHudi /opt/test.jar --hudiTableName
hudiSourceTable --hudiPath hdfs://hacluster/tmp/flinkHudi/hudiTable --read.start-commit xxx
```
  - Running the REST APIs for tenant sample program creation (The TestCreateTenants program is used as an example.)
    - yarn-session mode
      - i. Start the Flink cluster.  

```
./bin/yarn-session.sh -t config -jm 1024 -tm 4096
```
      - ii. Run the Flink program and enter parameters.  

```
./bin/flink run --class com.huawei.bigdata.flink.examples.TestCreateTenants /opt/
hadoopclient/FlinkRESTAPIJavaExample-xxx.jar --hostName xx-xx-xx-xx --keytab xx/xx/
user.keytab --krb5 xx/xx/krb5.conf --principal username
```
    - yarn-cluster mode

```
./bin/flink run -m yarn-cluster -yt config -yjm 1024 -ytm 4096 --class com.huawei.bigdata.flink.examples.TestCreateTenants /opt//opt/hadoopclient/FlinkRESTAPIJavaExample-xxx.jar --hostName xx-xx-xx-xx --keytab xx/xx/user.keytab --krb5 xx/xx/krb5.conf --principal username
```

- Run a SQL task to submit Flink JAR jobs.
  - yarn-session mode
    - i. Start the Flink cluster.  
./bin/yarn-session.sh -t config -jm 1024 -tm 4096
    - ii. Run the Flink application and enter parameters.  
bin/flink run -d --class com.huawei.mrs.FlinkSQLExecutor /opt/flink-sql-xxx.jar --sql ./sql/datanen2kafka.sql
  - yarn-cluster mode  
bin/flink run -m yarn-cluster -yt config -yjm 1024 -ytm 4096 -d --class com.huawei.mrs.FlinkSQLExecutor /opt/flink-sql-xxx.jar --sql ./sql/datanen2kafka.sql

----End

#### NOTE

For details about sample projects of dependency packages provided by Flink, see [Reference information about the dependency package for running the sample project](#).

If HA is enabled for Flink, the value of **--hostName** in the REST API example for creating a tenant is the floating IP address of FlinkServer.

### 1.8.4.2 Viewing the Debugging Result

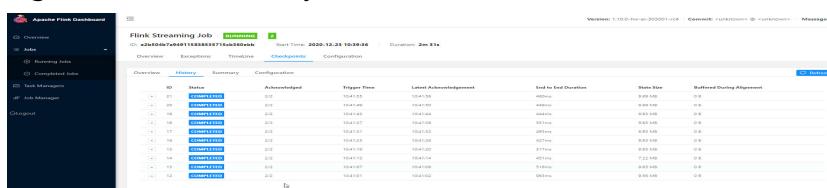

#### Scenarios

After a Flink application completes running, you can view the running result, or use Apache Flink Dashboard to view application running status.

#### Procedure

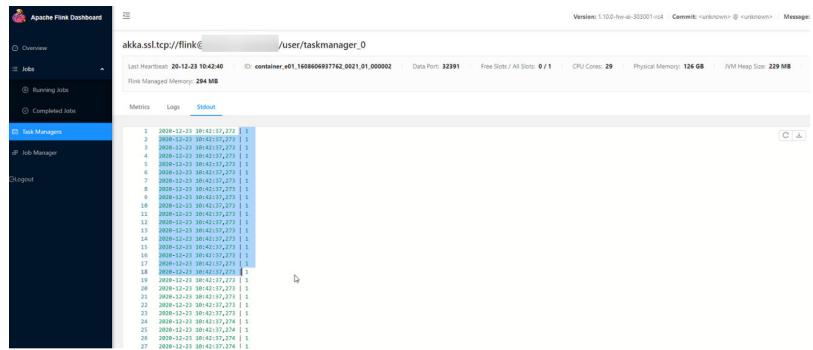

- **View the running result of the Flink application.**
  - If you want to check the execution result, view the Stdout log of Task Manager on the Apache Flink Dashboard.
  - If the execution result is exported to a file or a location specified by Flink, view the result from the exported file or the location. The checkpoint, pipeline, and join between configuration tables and streams are used as examples.
  - **View checkpoint results and files**
    - The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Checkpoints** to view the submitted jobs as shown in [Figure 1-80](#). Choose **Task Managers > Stdout** to view the running result, as shown in [Figure 1-81](#).

Figure 1-80 submitted jobs

| 13 | 13   | 2020-12-29 10:42:00 | 2020-12-29 10:42:00 | 2020-12-29 10:42:00    | 0ms                 | 0.0B       | 0.0                            |

Figure 1-81 execution result

- Either the following methods can be used to view the checkpoint file:
  - If the checkpoint snapshot information is saved in the HDFS, run the **hdfs dfs -ls hdfs://hacluster/flink/checkpoint/** command to view checkpoint files.
  - If the checkpoint snapshot information is saved to a local file, log in to each node to view checkpoint files.

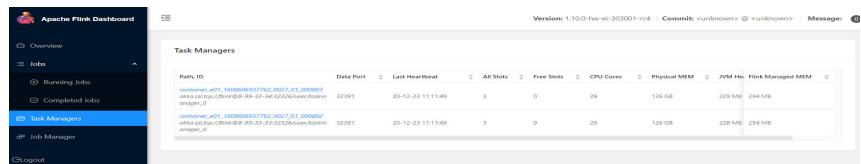

#### - View pipeline results

- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Running Jobs** to view the running jobs as shown in [Figure 1-82](#). Choose **Task Managers**. You can see two tasks, as shown in [Figure 1-83](#). Click any task, choose **Stdout** to view the output of the task, as shown in [Figure 1-84](#) and [Figure 1-85](#).

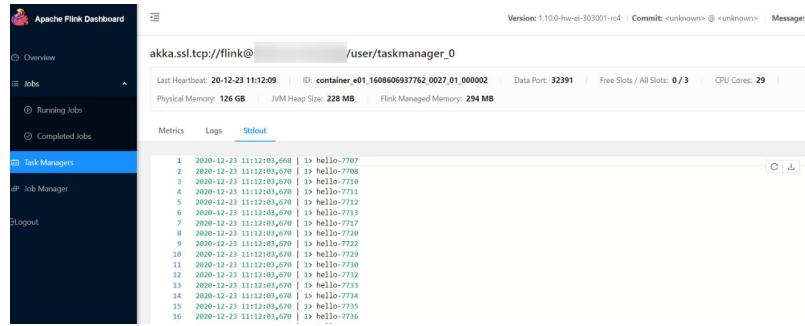

Figure 1-82 running jobs

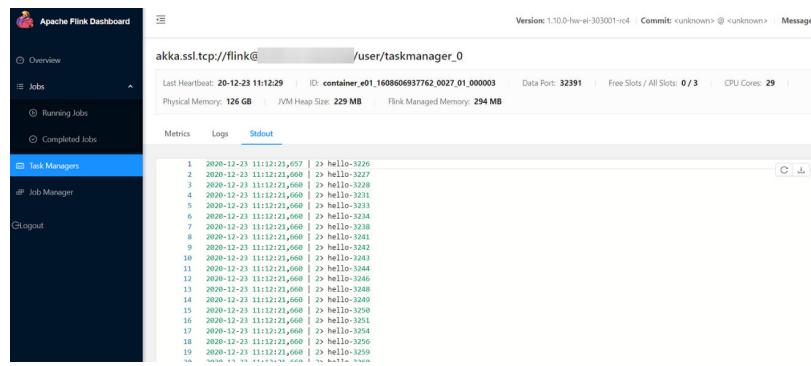

Figure 1-83 submitted Tasks

**Figure 1-84** output of task1

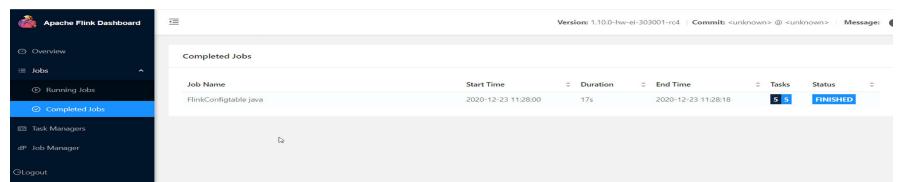

**Figure 1-85** output of task2

- View the JOIN result of configuration table and streams

- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Completed Jobs** to view the completed job as shown in **Figure 1-86**. Choose **Task Managers**, you can see submitted task, as shown in **Figure 1-87**. Choose **Stdout** to view the running result, as shown in **Figure 1-88**.

## **Figure 1-86 completed job**

**Figure 1-87** submitted task

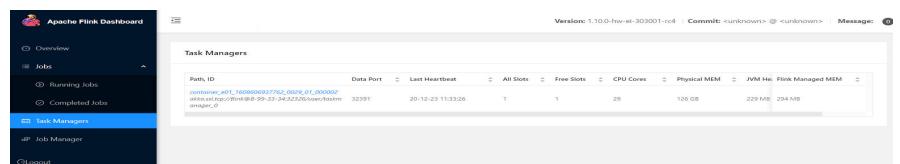

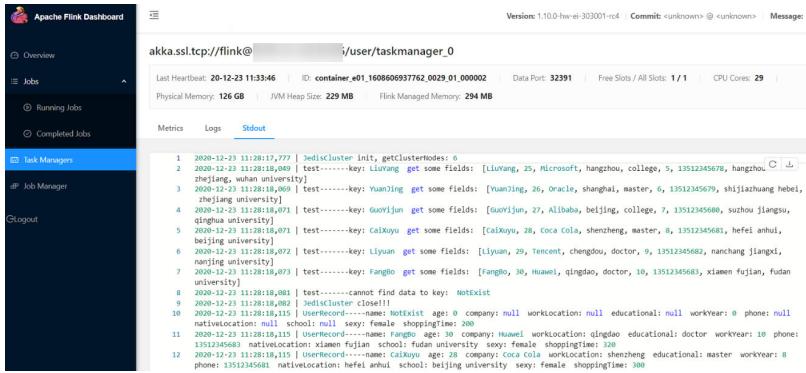

Figure 1-88 execution result

### - View the result of DataStream

- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Completed Jobs** to view the completed job as shown in **Figure 1-89**. Choose **Task Managers**, you can see submitted task, as shown in **Figure 1-90**. Choose **Stdout** to view the running result, as shown in **Figure 1-91**.

Figure 1-89 completed job

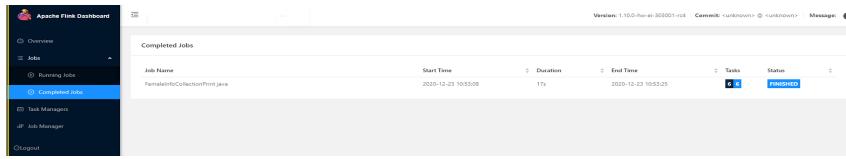

Figure 1-90 submitted task

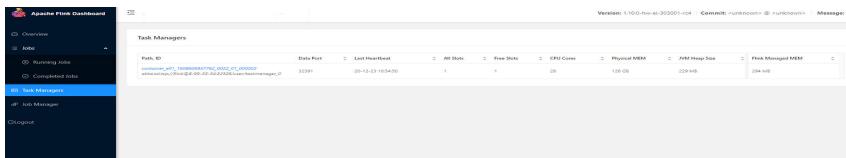

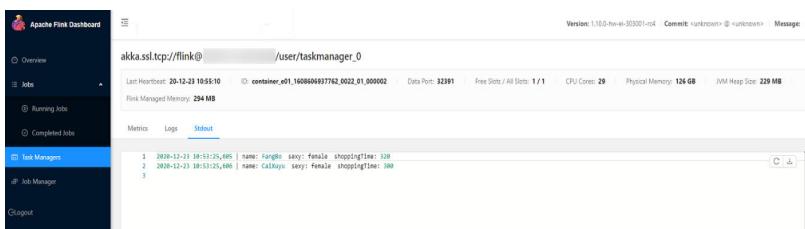

Figure 1-91 execution result

### - View the result of stream sql join

- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Running Jobs** to view the running jobs as shown in **Figure 1-92**. Choose **Task Managers**, you can see submitted task, as shown in **Figure 1-93**. Choose **Stdout** to view the running result, as shown in **Figure 1-94**.

Figure 1-92 running jobs

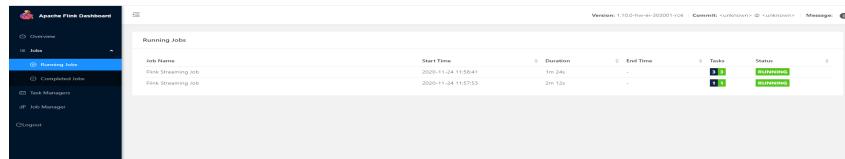

Figure 1-93 submitted task

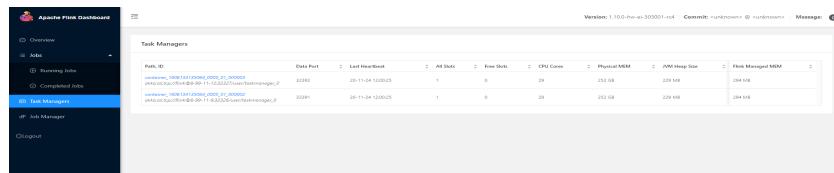

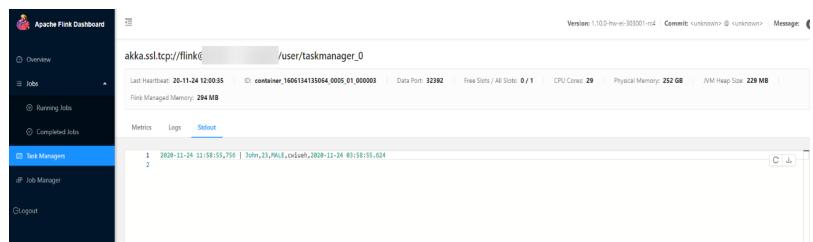

Figure 1-94 execution result

- View the result of produce and consume data in Kafka
- The results are stored in the **taskmanager.out** file of Flink. User can log in to the WEB UI of the Yarn. Choose **Jobs > Running Jobs** to view the running jobs as shown in [Figure 1-95](#). Choose **Task Managers**, you can see submitted task, as shown in [Figure 1-96](#). Choose **Stdout** to view the running result, as shown in [Figure 1-97](#).

Figure 1-95 running jobs

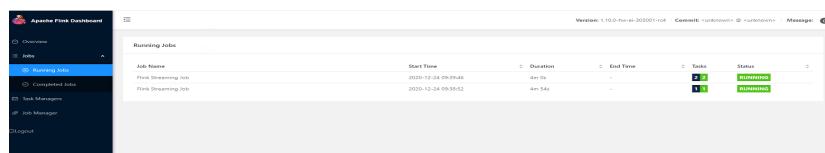

Figure 1-96 submitted task

Figure 1-97 execution result

- Use Apache Flink Dashboard to view the running status of the Flink application.

The Apache Flink Dashboard mainly includes Overview, Running Jobs, Completed Jobs, Task Managers, Job Manager and Logout and so on.

On In the YARN web UI, find the desired Flink application. Click the **ApplicationMaster** at the last column of the application to switch to the Apache Flink Dashboard.

View the print results of the program execution: find the corresponding **Task Manager** to see the corresponding **Stdout** tag log information.

- **View Flink logs.**

Three methods can be used to obtain Flink logs:

- Log in to the Apache Flink Dashboard and view logs of TaskManagers and JobManager.
  - Log in to the YARN web UI to view logs about JobManager and GC.

On the YARN web UI wind, find the desired Flink application. Click the **ID** of the application. On the switched page, click **Logs** in the Logs column.

- On the Yarn client, obtain or view logs of Task Managers and Job Manager.

i. Download and install the Yarn client, for example, in the /opt/hadoopclient directory.

ii. Log in to the node where the client is installed as the client installation user.

iii. Run the following command to switch to the client installation directory:

**cd /opt/hadoopclient**

iv. Run the following command to configure environment variables:

**source bigdata\_env**

v. If the cluster employs the security mode, run the following command to authenticate the user. If the normal mode is used, skip this step.

**kinit component service user**

vi. Run the following commands to obtain container information of the Flink cluster:

**yarn logs -applicationId application\_\* -show\_application\_log\_info**

```
[redacted]:/opt/flinkclient/Flink/flink # yarn logs -applicationId application_1547547065745_0001 -show_application_log_info
WARNING: YARN_CONF_DIR has been replaced by HADOOP_CONF_DIR. Using value of YARN_CONF_DIR.
Application State: Running.
Container: container_1547547065745_0001_01_000001 on [redacted]:26009
Container: container_1547547065745_0001_01_000002 on [redacted]:26009
Container: container_1547547065745_0001_01_000003 on [redacted]:26009
Container: container_1547547065745_0001_01_000004 on [redacted]:26009
```

vii. Run the following command to obtain run logs of the specified container. Generally, container\_\*\_000001 is the container where the Job Manager is running.

**yarn logs -applicationId application\_\* --containerId container\_1547547065745\_0001\_01\_000004 -out logdir/**

```
[redacted]:/opt/flinkclient/Flink/flink/logdir/[redacted]_0001_01_000004_26009 # 11
total 172
-rw-r--r-- 1 root root 170605 Jan 17 10:24 container_1547547065745_0001_01_000004
[redacted]:/opt/flinkclient/Flink/flink/logdir/[redacted]_0001_01_000004_26009 #
```

After the command is executed, container run logs, including run logs of the Task Manager and Job Manager and GC logs, are downloaded to the local host.

- viii. You can also run a command to obtain the log with the specified name:

The following command is used to obtain the container log list.

```
yarn logs -applicationId application_* -show_container_log_info --containerId container_1547547065745_0001_01_000004
```

| LogFile                    | LogLength | LastModificationTime           | LogAggregationType |
|----------------------------|-----------|--------------------------------|--------------------|
| container-localizer-syslog | 184       | Wed Jan 16 17:49:27 +0800 2019 | LOCAL              |
| taskmanager.log            | 131430    | Wed Jan 16 17:49:35 +0800 2019 | LOCAL              |
| tasklog.0.com              | 17950     | Wed Jan 16 17:49:35 +0800 2019 | LOCAL              |
| taskmanager.out            | 0         | Wed Jan 16 17:49:31 +0800 2019 | LOCAL              |
| launch_container.sh        | 12232     | Wed Jan 16 17:49:31 +0800 2019 | LOCAL              |
| directory.info             | 3661      | Wed Jan 16 17:49:31 +0800 2019 | LOCAL              |
| taskmanager.out            | 1060      | Wed Jan 16 17:49:31 +0800 2019 | LOCAL              |
| prelauch.out               | 160       | Wed Jan 16 17:49:31 +0800 2019 | LOCAL              |
| prelauch.err               | 0         | Wed Jan 16 17:49:31 +0800 2019 | LOCAL              |

Download **taskmanager.log** to the local host.

```
yarn logs -applicationId application_* --containerId
container_1547547065745_0001_01_000004 -log_files
taskmanager.log -out localpath
```

### 1.8.4.3 Running a Spring Boot Sample Project and Viewing Results

#### Running the Spring Boot Sample in CLI

**Step 1** Use Maven to run **install** on the IDEA.

If "BUILD SUCCESS" is displayed, the compilation is successful. A JAR file containing the **flink-dws-sink-example-1.0.0-SNAPSHOT** field is generated in the **target** directory of the sample project.

```
[INFO] Dependency-reduced POM written at: D:\code\springsample_project\src\main\flink-examples\flink-dws-sink-example\dependency-reduced-pom.xml
[INFO]
[INFO] --- maven-install-plugin:2.5.2:install (default-install) @ flink-dws-sink-example ---
[INFO] Installing D:\code\springsample_project\src\main\flink-examples\flink-dws-sink-example\target\flink-dws-sink-example.jar to D:\soft\maven\local\org\springframework\boot\flink-dws-sink-example\flink-dws-sink-example-1.0.0-SNAPSHOT.jar
[INFO] Installing D:\code\springsample_project\src\main\flink-examples\flink-dws-sink-example\dependency-reduced-pom.xml to D:\soft\maven\local\org\springframework\boot\flink-dws-sink-example\flink-dws-sink-example-1.0.0-SNAPSHOT.pom
[INFO] -----
[INFO] BUILD SUCCESS
[INFO] -----
[INFO] Total time: 15.581 s
[INFO] Finished at: 2023-08-18T11:39:01+08:00
[INFO] -----
```

Process finished with exit code 0

**Step 2** On Linux, go to the client installation directory, for example, **/opt/client/Flink/flink/conf**, and save the JAR packages whose names contain **flink-dws-sink-example-1.0.0-SNAPSHOT** in the **target** directory generated in to this directory.

The Flink client running the Spring Boot sample must contain only the Flink service.

**Step 3** Run the following command to create a Yarn session:

```
yarn-session.sh -t ssl/ -nm "session-spring11" -d
```

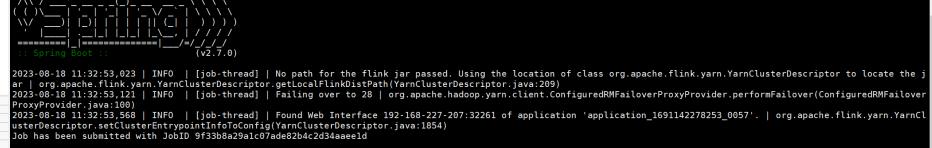

```
[root@host1 conf]#
[root@host1 conf]#
[root@host1 conf]# yarn-session.sh -t ssl/ -nm "session-spring11" -d
SLF4J: Class path contains multiple SLF4J bindings.

```

**Step 4** Run the following command to start the SpringBoot service:

- Run the GaussDB(DWS) sample

**flink run flink-dws-sink-example.jar**

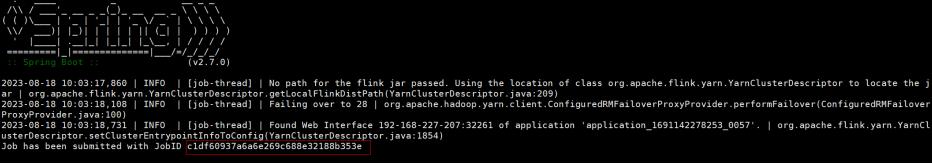

```
Password for test@host001:root:
[root@host01 conf]# flink run flink-dws-sink-example.jar

## 1.8.5 More Information

### 1.8.5.1 Introduction to Common APIs

#### 1.8.5.1.1 Java

To avoid API compatibility or reliability issues after updates to the open-source Flink, recommended that APIs of the matching version are recommended.

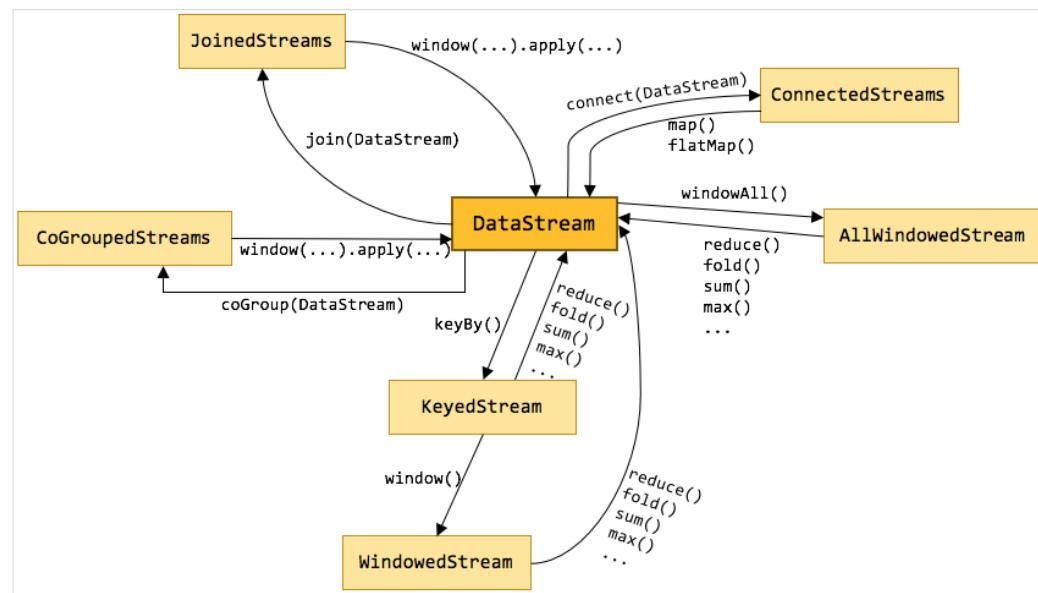

### Common APIs of Flink

Flink mainly uses the following APIs:

- StreamExecutionEnvironment: provides the execution environment, which is the basis of Flink stream processing.
- DataStream: represents streaming data. DataStream can be regarded as unmodifiable collection that contains duplicate data. The number of elements in DataStream are unlimited.
- KeyedStream: generates the stream by performing keyBy grouping operations on DataStream. Data is grouped based on the specified key value.
- WindowedStream: generates the stream by performing the window function on KeyedStream, sets the window type, and defines window triggering conditions.

- AllWindowedStream: generates streams by performing the window function on DataStream, sets the window type, defines window triggering conditions, and performs operations on the window data.
- ConnectedStreams: generates streams by connecting the two DataStreams and retaining the original data type, and performs the map or flatMap operation.
- JoinedStreams: performs equijoin (which is performed when two values are equal, for example, a.id = b.id) operation to data in the window. The join operation is a special scenario of coGroup operation.
- CoGroupedStreams: performs the coGroup operation on data in the window. CoGroupedStreams can perform various types of join operations.

**Figure 1-98** Conversion of Flink stream types

## Data Stream Source

**Table 1-37** APIs about data stream source

| API                                                                                                              | Description                                                                                                                                                                                                                                     |

## Data Output

**Table 1-38** APIs about data output

| API                                                                                                                                          | Description                                                                                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| public DataStreamSink<T> print()                                                                                                             | Print data as the standard output stream.                                                                                      |
| public DataStreamSink<T> printToErr()                                                                                                        | Print data as the standard error output stream.                                                                                |
| public DataStreamSink<T><br>writeAsText(String path)                                                                                         | Write data to a specific text file.<br>• <b>path</b> indicates the path of the text file.                                      |
| public DataStreamSink<T><br>writeAsText(String path, WriteMode<br>writeMode)                                                                 | • <b>writeMode</b> indicates the writing mode, which can be <b>OVERWRITE</b> or <b>NO_OVERWRITE</b> .                          |
| public DataStreamSink<T><br>writeAsCsv(String path)                                                                                          | Writhe data to a specific .csv file.<br>• <b>path</b> indicates the path of the text file.                                     |
| public DataStreamSink<T><br>writeAsCsv(String path, WriteMode<br>writeMode)                                                                  | • <b>writeMode</b> indicates the writing mode, which can be <b>OVERWRITE</b> or <b>NO_OVERWRITE</b> .                          |
| public <X extends Tuple><br>DataStreamSink<T> writeAsCsv(String<br>path, WriteMode writeMode, String<br>rowDelimiter, String fieldDelimiter) | • <b>rowDelimiter</b> indicates the row separator.<br>• <b>fieldDelimiter</b> indicates the column separator.                  |
| public DataStreamSink<T><br>writeToSocket(String hostName, int<br>port, SerializationSchema<T> schema)                                       | Write data to the socket connection.<br>• <b>hostName</b> indicates the host name.<br>• <b>port</b> indicates the port number. |
| public DataStreamSink<T><br>writeUsingOutputfor-<br>mat(Outputformat<T> format)                                                              | Write data to a file, for example, a binary file.                                                                              |

| API                                                                  | Description                                                                                                                                                                              |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public DataStreamSink<T><br>addSink(SinkFunction<T><br>sinkFunction) | Export data in a user-defined manner. The flink-connectors allows the addSink method to support exporting data to Kafka. The implementation method is the invoke method of SinkFunction. |

## Filtering and Mapping

**Table 1-39** APIs about filtering and mapping

| API                                                                                      | Description                                                                          |
|------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|
| public <R> SingleOutputStreamOperator<R> map(MapFunction<T, R><br>mapper)                | Transform an element into another element of the same type.                          |
| public <R> SingleOutputStreamOperator<R> flatMap(FlatMapFunction<T, R><br>flatMapMapper) | Transform an element into zero, one, or multiple elements.                           |
| public SingleOutputStreamOperator<T> filter(FilterFunction<T> filter)                    | Run a Boolean function on each element and retain elements that return <b>true</b> . |

## Aggregation

**Table 1-40** APIs about aggregation

| API                                                          | Description                                                                                                                                                                                               |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public KeyedStream<T, Tuple><br>keyBy(int... fields)         | Logically divide a stream into multiple partitions, each containing elements with the same key. The partitioning is internally implemented using hash partition. A KeyedStream is returned.               |
| public KeyedStream<T, Tuple><br>keyBy(String... fields)      | Return the KeyedStream after the KeyBy operation, and call the KeyedStream function, such as reduce, fold, min, minby, max, maxby, sum, and sumby.                                                        |
| public <K> KeyedStream<T, K><br>keyBy(KeySelector<T, K> key) | <ul style="list-style-type: none"> <li>• <b>fields</b> indicates the numbers of columns or names of member variables.</li> <li>• <b>key</b> indicates the user-defined basis for partitioning.</li> </ul> |

| API                                                                                      | Description                                                                                                                                                                                                                  |
|------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public SingleOutputStreamOperator<T> reduce(ReduceFunction<T> reducer)                   | Perform reduce on KeyedStream in a rolling manner. Aggregate the current element and the last reduced value into a new value. The types of the three values are the same.                                                    |
| public <R> SingleOutputStreamOperator<R> fold(R initialValue, FoldFunction<T, R> folder) | Perform fold operation on KeyedStream based on an initial value in a rolling manner. Aggregate the current element and the last folded value into a new value. The input and returned values of Fold can be different.       |
| public SingleOutputStreamOperator<T> sum(int positionToSum)                              | Calculate the sum in a KeyedStream in a rolling manner.                                                                                                                                                                      |
| public SingleOutputStreamOperator<T> sum(String field)                                   | <b>positionToSum</b> and <b>field</b> indicate calculating the sum of a specific column.                                                                                                                                     |
| public SingleOutputStreamOperator<T> min(int positionToMin)                              | Calculate the minimum value in a KeyedStream in a rolling manner. <b>min</b> returns the minimum value, without guarantee of the correctness of columns of non-minimum values.                                               |
| public SingleOutputStreamOperator<T> min(String field)                                   | <b>positionToMin</b> and <b>field</b> indicate calculating the minimum value of a specific column.                                                                                                                           |
| public SingleOutputStreamOperator<T> max(int positionToMax)                              | Calculate the maximum value in KeyedStream in a rolling manner. <b>max</b> returns the maximum value, without guarantee of the correctness of columns of non-maximum values.                                                 |
| public SingleOutputStreamOperator<T> max(String field)                                   | <b>positionToMax</b> and <b>field</b> indicate calculating the maximum value of a specific column.                                                                                                                           |
| public SingleOutputStreamOperator<T> minBy(int positionToMinBy)                          | Obtain the row where the minimum value of a column locates in a KeyedStream. <b>minBy</b> returns all elements of that row.                                                                                                  |
| public SingleOutputStreamOperator<T> minBy(String positionToMinBy)                       |                                                                                                                                                                                                                              |
| public SingleOutputStreamOperator<T> minBy(int positionToMinBy, boolean first)           | <ul style="list-style-type: none"><li>• <b>positionToMinBy</b> indicates the column on which the minBy operation is performed.</li><li>• <b>first</b> indicates whether to return the first or last minimum value.</li></ul> |
| public SingleOutputStreamOperator<T> minBy(String field, boolean first)                  |                                                                                                                                                                                                                              |

| API                                                                            | Description                                                                                                                                                                                                                  |
|--------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public SingleOutputStreamOperator<T> maxBy(int positionToMaxBy)                | Obtain the row where the maximum value of a column locates in a KeyedStream. maxBy returns all elements of that row.                                                                                                         |
| public SingleOutputStreamOperator<T> maxBy(String positionToMaxBy)             |                                                                                                                                                                                                                              |
| public SingleOutputStreamOperator<T> maxBy(int positionToMaxBy, boolean first) |                                                                                                                                                                                                                              |
| public SingleOutputStreamOperator<T> maxBy(String field, boolean first)        | <ul style="list-style-type: none"><li>• <b>positionToMaxBy</b> indicates the column on which the maxBy operation is performed.</li><li>• <b>first</b> indicates whether to return the first or last maximum value.</li></ul> |

## DataStream Distribution

**Table 1-41** APIs about DataStream distribution

| API                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public <K><br>DataStream<T><br>partitionCustom(Partitioner<K> partitioner,<br>int field)                        | Use a user-defined partitioner to select target task for each element. <ul style="list-style-type: none"><li>• <b>partitioner</b> indicates the user-defined method for repartitioning.</li><li>• <b>field</b> indicates the input parameters of partitioner.</li><li>• <b>keySelector</b> indicates the user-defined input parameters of partitioner.</li></ul> |
| public <K><br>DataStream<T><br>partitionCustom(Partitioner<K> partitioner,<br>String field)                     |                                                                                                                                                                                                                                                                                                                                                                  |
| public <K><br>DataStream<T><br>partitionCustom(Partitioner<K> partitioner,<br>KeySelector<T, K><br>keySelector) |                                                                                                                                                                                                                                                                                                                                                                  |

|----------------------------------------|-------------------------------------------|
| public<br>DataStream<T><br>broadcast() | Broadcast each element to all partitions. |

## Project Capabilities

**Table 1-42** APIs about projecting

| API                                                                                          | Description                                                                                                                                                                    |
|----------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public <R extends Tuple><br>SingleOutputStreamOperator<R><br>project(int...<br>fieldIndexes) | Select some field subset from the tuple.<br><b>fieldIndexes</b> indicates some sequences of the tuple.<br><b>NOTE</b><br>Only tuple data type is supported by the project API. |

## Configuring the eventtime Attribute

**Table 1-43** APIs about configuring the eventtime attribute

| API                                                                                                                                            | Description                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| public<br>SingleOutputStreamOperator<T><br>assignTimestampsAndWatermarks(AssignerWithPeriodicWatermarks<T><br>timestampAndWatermarkAssigner)   | Extract timestamp from records, enabling event time window to trigger computing. |
| public<br>SingleOutputStreamOperator<T><br>assignTimestampsAndWatermarks(AssignerWithPunctuatedWatermarks<T><br>timestampAndWatermarkAssigner) |                                                                                  |

**Table 1-44** lists differences of AssignerWithPeriodicWatermarks and AssignerWithPunctuatedWatermarks APIs.

**Table 1-44** Difference of AssignerWithPeriodicWatermarks and AssignerWithPunctuatedWatermarks APIs

| Parameter                        | Description                                                                                                               |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| AssignerWithPeriodicWatermarks   | Generate Watermark based on the getConfig().setAutoWatermarkInterval(200L) timestamp of StreamExecutionEnvironment class. |
| AssignerWithPunctuatedWatermarks | Generate a Watermark each time an element is received. Watermarks can be different based on received elements.            |

## Iteration

**Table 1-45** APIs about iteration

| API                                                       | Description                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public IterativeStream<T> iterate()                       | In the flow, create in a feedback loop to redirect the output of an operator to a preceding operator.<br><b>NOTE</b> <ul style="list-style-type: none"><li>This API is helpful to algorithms that require constant update of models.</li><li>long maxWaitTimeMillis: The timeout period of each round of iteration.</li></ul> |
| public IterativeStream<T> iterate(long maxWaitTimeMillis) |                                                                                                                                                                                                                                                                                                                               |

## Stream Splitting

**Table 1-46** APIs about stream splitting

| API                                                           | Description                                                                                                                                                                                                                               |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public SplitStream<T> split(OutputSelector<T> outputSelector) | Use OutputSelector to rewrite select method, specify stream splitting basis (by tagging), and construct SplitStream streams. That is, a string is tagged for each element, so that a stream of a specific tag can be selected or created. |
| public DataStream<OUT> select(String... outputNames)          | Select one or multiple streams from a SplitStream. outputNames indicates the sequence of string tags created for each element using the split method.                                                                                     |

## Window

Windows can be classified as tumbling windows and sliding windows.

- APIs such as Window, TimeWindow, CountWindow, WindowAll, TimeWindowAll, and CountWindowAll can be used to generate windows.
- APIs such as Window Apply, Window Reduce, Window Fold, and Aggregations on windows can be used to operate windows.
- Multiple Window Assigners are supported, including TumblingEventTimeWindows, TumblingProcessingTimeWindows, SlidingEventTimeWindows, SlidingProcessingTimeWindows, EventTimeSessionWindows, ProcessingTimeSessionWindows, and GlobalWindows.
- ProcessingTime, EventTime, and IngestionTime are supported.
- Timestamp modes EventTime: AssignerWithPeriodicWatermarks and AssignerWithPunctuatedWatermarks are supported.

**Table 1-47** lists APIs for generating windows.

**Table 1-47** APIs for generating windows

| API                                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| public <W extends Window><br>WindowedStream<T,<br>KEY, W><br>window(WindowAssigner<? super T, W><br>assigner)  | Define windows in partitioned KeyedStreams. A window groups each key according to some characteristics (for example, data received within the latest 5 seconds).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| public <W extends Window><br>AllWindowedStream<T,<br>W><br>windowAll(WindowAssigner<? super T, W><br>assigner) | Define windows in DataStreams.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| public<br>WindowedStream<T,<br>KEY, TimeWindow><br>timeWindow(Time size)                                       | Define time windows in partitioned KeyedStreams, select ProcessingTime or EventTime based on the environment.getStreamTimeCharacteristic() parameter, and determine whether the window is TumblingWindow or SlidingWindow depends on the number of parameters. <ul style="list-style-type: none"><li>• <b>size</b> indicates the duration of the window.</li><li>• <b>slide</b> indicates the sliding time of window.</li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• WindowedStream and AllWindowedStream indicates two types of streams.</li><li>• If the API contains only one parameter, the window is TumblingWindow. If the API contains two or more parameters, the window is SlidingWindow.</li></ul> |

|        | public SingleOutputStreamOperator<T> max(String field)                               | <b>positionToMax</b> and <b>field</b> indicate calculating the maximum value of a specific column.                                                                                 |
|        | The default public SingleOutputStreamOperator<T> maxBy(int positionToMaxBy)//true    | Obtain the row where the maximum value of a column locates in the window data. <b>maxBy</b> returns all elements of that row.                                                      |
|        | The default public SingleOutputStreamOperator<T> maxBy(String positionToMaxBy)//true | <ul style="list-style-type: none"><li>• <b>positionToMaxBy</b> indicates the column on which the <b>maxBy</b> operation is performed.</li></ul>                                    |
|        | public SingleOutputStreamOperator<T> maxBy(int positionToMaxBy, boolean first)       | <ul style="list-style-type: none"><li>• <b>first</b> indicates whether to return the first or last maximum value.</li></ul>                                                        |
|        | public SingleOutputStreamOperator<T> maxBy(String field, boolean first)              |                                                                                                                                                                                    |

## Combining Multiple DataStreams

**Table 1-49** APIs about combining multiple DataStreams

| API                                                                                                                                         | Description                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>public final<br/>DataStream&lt;T&gt;<br/>union(DataStream&lt;T&gt;..<br/>. streams)</pre>                                              | <p>Perform union operation on multiple DataStreams to generate a new data stream containing all data from original DataStreams.</p> <p><b>NOTE</b><br/>If you perform union operation on a piece of data with itself, there are two copies of the same data.</p> |
| <pre>public &lt;R&gt;<br/>ConnectedStreams&lt;T,<br/>R&gt;<br/>connect(DataStream&lt;R<br/>&gt; dataStream)</pre>                           | Connect two DataStreams and retain the original type. The connect API method allows two DataStreams to share statuses. After ConnectedStreams is generated, map or flatMap operation can be called.                                                              |
| <pre>public &lt;R&gt;<br/>SingleOutputStreamOperator&lt;R&gt;<br/>map(CoMapFunction&lt;I<br/>N1, IN2, R&gt; coMapper)</pre>                 | Perform mapping operation, which is similar to map and flatMap operation in a ConnectedStreams, on elements. After the operation, the type of the new DataStreams is string.                                                                                     |
| <pre>public &lt;R&gt;<br/>SingleOutputStreamOperator&lt;R&gt;<br/>flatMap(CoFlatMapFun<br/>ction&lt;IN1, IN2, R&gt;<br/>coFlatMapper)</pre> | Perform mapping operation, which is similar to flatMap operation in DataStream, on elements.                                                                                                                                                                     |

## Join Operation

**Table 1-50** APIs about join operation

| API                                                                                                                   | Description                                                       |
|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| <pre>public &lt;T2&gt;<br/>JoinedStreams&lt;T, T2&gt;<br/>join(DataStream&lt;T2&gt;<br/>otherStream)</pre>            | Join two DataStreams using a given key in a specified window.     |
| <pre>public &lt;T2&gt;<br/>CoGroupedStreams&lt;T,<br/>T2&gt;<br/>coGroup(DataStream&lt;<br/>T2&gt; otherStream)</pre> | Co-group two DataStreams using a given key in a specified window. |

### 1.8.5.1.2 Scala

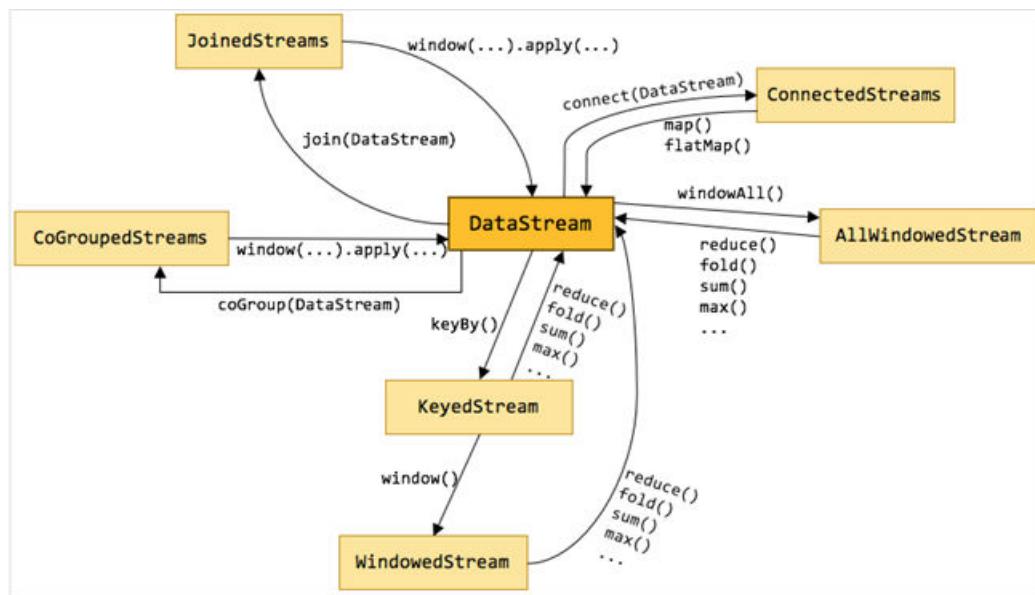

To avoid API compatibility or reliability issues after updates to the open-source Flink, recommended that APIs of the matching version are recommended.

## Common APIs of Flink

Flink mainly uses the following APIs:

- StreamExecutionEnvironment: provides the execution environment, which is the basis of Flink stream processing.
- DataStream: represents streaming data. DataStream can be regarded as unmodifiable collection that contains duplicate data. The number of elements in DataStream are unlimited.
- KeyedStream: generates the stream by performing keyBy grouping operations on DataStream. Data is grouped based on the specified key value.
- WindowedStream: generates the stream by performing the window function on KeyedStream, sets the window type, and defines window triggering conditions.
- AllWindowedStream: generates streams by performing the window function on DataStream, sets the window type, defines window triggering conditions, and performs operations on the window data.
- ConnectedStreams: generates streams by connecting the two DataStreams and retaining the original data type, and performs the map or flatMap operation.
- JoinedStreams: performs equijoin operation to data in the window. The join operation is a special scenario of coGroup operation.
- CoGroupedStreams: performs the coGroup operation on data in the window. CoGroupedStreams can perform various types of join operations.

Figure 1-99 Conversion of Flink stream types

## Data Stream Source

**Table 1-51** APIs about data stream source

| API                                                                                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                     |

## Aggregation

**Table 1-54** APIs about aggregation

| API                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| def keyBy(fields: Int*): KeyedStream[T, JavaTuple]                                       | Logically divide a stream into multiple partitions, each containing elements with the same key. The partitioning is internally implemented using hash partition. A KeyedStream is returned.                                                                                                                                                                                                                       |
| def keyBy(firstField: String, otherFields: String*): KeyedStream[T, JavaTuple]           |                                                                                                                                                                                                                                                                                                                                                                                                                   |
| def keyBy[K: TypeInformation](fun: T => K): KeyedStream[T, K]                            | Return the KeyedStream after the KeyBy operation, and call the KeyedStream function, such as reduce, fold, min, minby, max, maxby, sum, and sumby. <ul style="list-style-type: none"><li>• <b>fields</b> indicates the IDs of certain columns</li><li>• <b>firstField</b> and <b>otherFields</b> are names of member variables.</li><li>• <b>key</b> indicates the user-defined basis for partitioning.</li></ul> |
| def reduce(fun: (T, T) => T): DataStream[T]                                              | Perform reduce on KeyedStream in a rolling manner. Aggregate the current element and the last reduced value into a new value. The types of the three values are the same.                                                                                                                                                                                                                                         |
| def reduce(reducer: ReduceFunction[T]): DataStream[T]                                    |                                                                                                                                                                                                                                                                                                                                                                                                                   |
| def fold[R: TypeInformation] (initialValue: R)(fun: (R,T) => R): DataStream[R]           | Perform fold operation on KeyedStream based on an initial value in a rolling manner. Aggregate the current element and the last folded value into a new value. The input and returned values of Fold can be different.                                                                                                                                                                                            |
| def fold[R: TypeInformation] (initialValue: R, folder: FoldFunction[T,R]): DataStream[R] |                                                                                                                                                                                                                                                                                                                                                                                                                   |
| def sum(position: Int): DataStream[T]                                                    | Calculate the sum in a KeyedStream in a rolling manner.                                                                                                                                                                                                                                                                                                                                                           |

| <code>def partitionCustom[K: TypeInformation](partitioner: Partitioner[K], fun: T =&gt; K): DataStream[T]</code> |                                                                                                                                                                                                                                                                                                                                                                  |
| <code>def shuffle: DataStream[T]</code>                                                                          | Randomly and evenly partition elements.                                                                                                                                                                                                                                                                                                                          |
| <code>def rebalance: DataStream[T]</code>                                                                        | Partition elements in round-robin manner, ensuring load balance of each partition. This partitioning is helpful to data with skewness.                                                                                                                                                                                                                           |
| <code>def rescale: DataStream[T]</code>                                                                          | Distribute elements into downstream subset in round-robin manner.<br><b>NOTE</b><br>The method for checking the code is similar to the rebalance method.                                                                                                                                                                                                         |
| <code>def broadcast: DataStream[T]</code>                                                                        | Broadcast each element to all partitions.                                                                                                                                                                                                                                                                                                                        |

## Configuring the eventtime Attribute

**Table 1-56** APIs about configuring the eventtime attribute

| API                                                                                                        | Description                                                                      |
|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <code>def assignTimestampsAndWatermarks(assigner: AssignerWithPeriodicWatermarks[T]): DataStream[T]</code> | Extract timestamp from records, enabling event time window to trigger computing. |

| API                                                                                                          | Description |
|--------------------------------------------------------------------------------------------------------------|-------------|
| <code>def assignTimestampsAndWatermarks(assigner: AssignerWithPunctuatedWatermarks[T]): DataStream[T]</code> |             |

## Iteration

**Table 1-57** APIs about iteration

| API                                                                                                                                                                           | Description                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>def iterate[R](stepFunction: DataStream[T] =&gt; (DataStream[T], DataStream[R]), maxWaitTimeMillis: Long = 0, keepPartitioning: Boolean = false) : DataStream[R]</code> | <p>In the flow, create in a feedback loop to redirect the output of an operator to a preceding operator.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"> <li>• This API is helpful to algorithms that require constant update of models.</li> <li>• long maxWaitTimeMillis: The timeout period of each round of iteration.</li> </ul> |
| <code>def iterate[R, F: TypeInformation](stepFunction: ConnectedStreams[T, F] =&gt; (DataStream[F], DataStream[R]), maxWaitTimeMillis: Long): DataStream[R]</code>            |                                                                                                                                                                                                                                                                                                                                                 |

## Stream Splitting

**Table 1-58** APIs about stream splitting

| API                                                                 | Description                                                                                                                                                                                                                               |
|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>def split(selector: OutputSelector[T]): SplitStream[T]</code> | Use OutputSelector to rewrite select method, specify stream splitting basis (by tagging), and construct SplitStream streams. That is, a string is tagged for each element, so that a stream of a specific tag can be selected or created. |
| <code>def select(outputNames: String*): DataStream[T]</code>        | Select one or multiple streams from a SplitStream. outputNames indicates the sequence of string tags created for each element using the split method.                                                                                     |

## Window

Windows can be classified as tumbling windows and sliding windows.

- APIs such as Window, TimeWindow, CountWindow, WindowAll, TimeWindowAll, and CountWindowAll can be used to generate windows.
- APIs such as Window Apply, Window Reduce, Window Fold, and Aggregations on windows can be used to operate windows.
- Multiple Window Assigners are supported, including TumblingEventTimeWindows, TumblingProcessingTimeWindows, SlidingEventTimeWindows, SlidingProcessingTimeWindows, EventTimeSessionWindows, ProcessingTimeSessionWindows, and GlobalWindows.
- ProcessingTime, EventTime, and IngestionTime are supported.
- Timestamp modes EventTime: AssignerWithPeriodicWatermarks and AssignerWithPunctuatedWatermarks are supported.

[Table9 APIs for generating windows](#) lists APIs for generating windows.

**Table 1-59** APIs for generating windows

| API                                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>def window[W &lt;: Window](assigner: WindowAssigner[_ &gt;: T, W]): WindowedStream[T, K, W]</code>    | Define windows in partitioned KeyedStreams. A window groups each key according to some characteristics (for example, data received within the latest 5 seconds).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>def windowAll[W &lt;: Window](assigner: WindowAssigner[_ &gt;: T, W]): AllWindowedStream[T, W]</code> | Define windows in DataStreams.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>def timeWindow(size: time<br/>WindowedStream[T, K, TimeWindow]</code>                                 | Define time windows in partitioned KeyedStreams, select ProcessingTime or EventTime based on the environment.getStreamTimeCharacteristic() parameter, and determine whether the window is TumblingWindow or SlidingWindow depends on the number of parameters. <ul style="list-style-type: none"><li>• <b>size</b> indicates the duration of the window.</li><li>• <b>slide</b> indicates the sliding time of window.</li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• WindowedStream and AllWindowedStream indicates two types of streams.</li><li>• If the API contains only one parameter, the window is TumblingWindow. |                                | def minBy(position: Int):<br>DataStream[T] | Obtain the row where the minimum value of a column locates in the window data. <b>minBy</b> returns all elements of that row.                                                      |
|                                | def minBy(field: String):<br>DataStream[T] | <b>position</b> and <b>field</b> indicate the column on which the <b>minBy</b> operation is performed.                                                                             |
|                                | def maxBy(position: Int):<br>DataStream[T] | Obtain the row where the maximum value of a column locates in the window data. <b>maxBy</b> returns all elements of that row.                                                      |
|                                | def maxBy(field: String):<br>DataStream[T] | <b>position</b> and <b>field</b> indicate the column on which the <b>maxBy</b> operation is performed.                                                                             |

## Combining Multiple DataStreams

**Table 1-61** APIs about combining multiple DataStreams

| API                                                                                                                                     | Description                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>def union(dataStreams: DataStream[T]*): DataStream[T]</code>                                                                      | Perform union operation on multiple DataStreams to generate a new data stream containing all data from original DataStreams.<br><b>NOTE</b><br>If you perform union operation on a piece of data with itself, there are two copies of the same data. |
| <code>def connect[T2] (dataStream: DataStream[T2]): ConnectedStreams[T, T2]</code>                                                      | Connect two DataStreams and retain the original type. The connect API method allows two DataStreams to share statuses. After ConnectedStreams is generated, map or flatMap operation can be called.                                                  |
| <code>def map[R: TypeInformation] (coMapper: CoMapFunction[IN1, IN2, R]): DataStream[R]</code>                                          | Perform mapping operation, which is similar to map and flatMap operation in a ConnectedStreams, on elements. After the operation, the type of the new DataStreams is string.                                                                         |
| <code>def map[R: TypeInformation](fun1: IN1 =&gt; R, fun2: IN2 =&gt; R): DataStream[R]</code>                                           |                                                                                                                                                                                                                                                      |
| <code>def flatMap[R: TypeInformation] (coFlatMapper: CoFlatMapFunction[IN1, IN2, R]): DataStream[R]</code>                              | Perform union operation on multiple DataStreams to generate a new data stream containing all data from original DataStreams.<br><b>NOTE</b><br>If you perform union operation on a piece of data with itself, there are two copies of the same data. |
| <code>def flatMap[R: TypeInformation](fun1: (IN1, Collector[R]) =&gt; Unit, fun2: (IN2, Collector[R]) =&gt; Unit): DataStream[R]</code> |                                                                                                                                                                                                                                                      |
| <code>def flatMap[R: TypeInformation] (fun1: IN1 =&gt; TraversableOnce[R], fun2: IN2 =&gt; TraversableOnce[R]): DataStream[R]</code>    |                                                                                                                                                                                                                                                      |

## Join Operation

**Table 1-62** APIs about join operation

| API                                                                                                 | Description                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>def join[T2]<br/>(otherStream:<br/>DataStream[T2]):<br/>JoinedStreams[T, T2]</code>           | Join two DataStreams using a given key in a specified window.<br>The key value of the join operation is specified by the <b>where</b> and <b>equalTo</b> method, indicating filtering data with equivalent conditions from two DataStreams. |
| <code>def coGroup[T2]<br/>(otherStream:<br/>DataStream[T2]):<br/>CoGroupedStreams[T,<br/>T2]</code> | Co-group two DataStreams using a given key in a specified window.<br>The key value of the coGroup operation is specified by the where and equalTo method, indicating partitioning two DataStreams using equivalent conditions.              |

### 1.8.5.2 Overview of RESTful APIs

Flink has a monitoring API that can be used to query status and statistics of running jobs, as well as recent completed jobs. This monitoring API is used by Apache Flink Dashboard.

The monitoring API is a RESTful API that accepts HTTP GET requests and responds with JSON data. RESTful API is a set of APIs used to log in to the web server. In Flink, web server is a module of JobManager and shares the same process with JobManager. By default, the listening port of web server is 8081. If you want to change the listening port, modify **jobmanager.web.port** in the **flink-conf.yaml** file.

The *Netty* and the *Netty Router* library are used to handle REST requests and analysis URLs.

RESTful APIs are executed through HTTP requests.

The format of the HTTP requests is `http://<JobManager_IP>:<JobManager_Port><Path>`

The *JobManager\_IP* indicates the IP address of JobManager, *JobManager\_Port* indicates the listening port of JobManager, and *Path* indicates the path. For details, see [Table 1-63](#). For example, `http://10.162.181.57:32261/config`.

#### NOTE

If you want to modify the configuration file **flink-conf.yaml** of the Flink Client, add to-be-visited IP addresses (separated with commas) in **jobmanager.web.allow-access-address** and **jobmanager.web.access-control-allow-origin** parameters.

[Table 1-63](#) lists all RESTful API paths supported by Flink.

**Table 1-63** Paths supported by Flink

| Path                              | Description                                                                                                                                                                                           |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /config                           | Some information about the monitoring API and the server setup.                                                                                                                                       |
| /logout                           | Some information about the logout.                                                                                                                                                                    |
| /overview                         | Simple summary of the Flink cluster status.                                                                                                                                                           |
| /jobs                             | IDs of the jobs, grouped by status <i>running</i> , <i>finished</i> , <i>failed</i> , <i>canceled</i> .                                                                                               |
| /jobmanager/config                | the configuration of the jobmanager.                                                                                                                                                                  |
| /joboverview                      | Jobs, grouped by status, each with a small summary of its status.                                                                                                                                     |
| /joboverview/running              | Jobs, grouped by status, each with a small summary of its status. The same as <a href="#">/joboverview</a> , but containing only currently running jobs.                                              |
| /joboverview/completed            | Jobs, grouped by status, each with a small summary of its status. The same as <a href="#">/joboverview</a> , but containing only completed (finished, canceled, or failed) jobs.                      |
| /jobs/<jobid>                     | Summary of one job, listing dataflow plan, status, timestamps of state transitions, aggregate information for each vertex (operator).                                                                 |
| /jobs/<jobid>/vertices            | Currently the same as <a href="#">/jobs/&lt;jobid&gt;</a> .                                                                                                                                           |
| /jobs/<jobid>/config              | The user-defined execution config used by the job.                                                                                                                                                    |
| /jobs/<jobid>/exceptions          | The non-recoverable exceptions that have been observed by the job. The truncated flag defines whether more exceptions occurred, but are not listed, because the response would otherwise get too big. |
| /jobs/<jobid>/accumulators        | The aggregated user accumulators plus job accumulators.                                                                                                                                               |
| /jobs/<jobid>/checkpoints         | checkpoint stats for a job.                                                                                                                                                                           |
| /jobs/<jobid>/metrics             | a job a list of all available metrics.                                                                                                                                                                |
| /jobs/<jobid>/vertices/<vertexid> | Information about one specific vertex, with a summary for each of its subtasks.                                                                                                                       |

| Path                                                                                    | Description                                                                                                                                                                                                      |
|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /jobs/<jobid>/vertices/<vertexid>/subtasktimes                                          | This request returns the timestamps for the state transitions of all subtasks of a given vertex. These can be used, for example, to create time-line comparisons between subtasks.                               |
| /jobs/<jobid>/vertices/<vertexid>/taskmanagers                                          | TaskManager statistics for one specific vertex. This is an aggregation of subtask statistics returned by /jobs/<jobid>/vertices/<vertexid>.                                                                      |
| /jobs/<jobid>/vertices/<vertexid>/accumulators                                          | The aggregated user-defined accumulators, for a specific vertex.                                                                                                                                                 |
| /jobs/<jobid>/vertices/<vertexid>/checkpoints                                           | checkpoint stats for a single job vertex.                                                                                                                                                                        |
| /jobs/<jobid>/vertices/<vertexid>/backpressure                                          | back pressure stats for a single job vertex and all its sub tasks.                                                                                                                                               |
| /jobs/<jobid>/vertices/<vertexid>/metrics                                               | a given task of the values for a set of metrics.                                                                                                                                                                 |
| /jobs/<jobid>/vertices/<vertexid>/subtasks/accumulators                                 | Gets all user-defined accumulators for all subtasks of a given vertex. These are the individual accumulators that are returned in aggregated form by the request /jobs/<jobid>/vertices/<vertexid>/accumulators. |
| /jobs/<jobid>/vertices/<vertexid>/subtasks/<subtasknum>                                 | Summary of the current or latest execution attempt of a specific subtask. See below for a sample.                                                                                                                |
| /jobs/<jobid>/vertices/<vertexid>/subtasks/<subtasknum>/attempts/<attempt>              | Summary of a specific execution attempt of a specific subtask. Multiple execution attempts happen in case of failure/recovery.                                                                                   |
| /jobs/<jobid>/vertices/<vertexid>/subtasks/<subtasknum>/attempts/<attempt>/accumulators | The accumulators collected for one specific subtask during one specific execution attempt (multiple attempts happen in case of failure/recovery).                                                                |
| /jobs/<jobid>/plan                                                                      | The dataflow plan of a job. The plan is also included in the job summary (/jobs/<jobid>).                                                                                                                        |
| /taskmanagers                                                                           | Some information of the TaskManagers.                                                                                                                                                                            |
| /taskmanagers/<taskmanagerid>/metrics                                                   | the metrics information of a TaskManager.                                                                                                                                                                        |

| Path                                 | Description                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------------|
| /taskmanagers/<taskmanagerid>/log    | the log information of a TaskManager.                                             |
| /taskmanagers/<taskmanagerid>/stdout | the stdout of a TaskManager.                                                      |
| /jobmanager/log                      | the log of Jobmanager.                                                            |
| /jobmanager/stdout                   | the stdout of Jobmanager.                                                         |
| /jobmanager/metrics                  | the metrics of Jobmanager.                                                        |
| /*                                   | services requests to web frontend's static files, such as HTML, CSS, or JS files. |

**Table 1-64** describes variables listed in **Table 1-63**.

**Table 1-64** Description of variables

| Variable      | Description                      |
|---------------|----------------------------------|
| jobid         | ID of jobs                       |
| vertexid      | Vertices ID of the flow diagram. |
| subtasknum    | Sum of subtasks.                 |
| attempt       | Times of attempts                |
| taskmanagerid | ID of TaskManager                |

### 1.8.5.3 Overview of Savepoints CLI

#### Overview

Savepoints are externally stored checkpoints that you can use to stop-and-resume or update your Flink programs. They use Flink's checkpoint mechanism to create a snapshot of the state of your streaming program and write the checkpoint meta data out to an external file system.

It is highly recommended that you adjust your programs as described in this section in order to be able to upgrade your programs in the future. The main required change is to manually specify operator IDs via the **uid(String)** method. These IDs are used to scope the state of each operator.

```
DataStream<String> stream = env
//Statefulesource(e.g.Kafka)withID
.addSource(new StatefulSource())
.uid("source-id") //IDforthesourceoperator
.shuffle()
//StatefulemapperwithID
.map(new StatefulMapper())
```

```
.uid("mapper-id") //IDforthemapper  
//Statelessprintingsink  
.print(); //Auto-generatedID
```

## Savepoint Recovery

If you do not specify the IDs manually, they will be generated automatically. You can automatically restore from the savepoint if these IDs do not change. The generated IDs depend on the structure of your program and are sensitive to program changes. Therefore, it is highly recommended to assign these IDs manually. When a savepoint is triggered, a single savepoint file will be created containing the checkpoint metadata. The actual checkpoint state will be kept around in the configured checkpoint directory, for example, with a FsStateBackend or RocksDBStateBackend:

1. Trigger a savepoint.

```
$ bin/flink savepoint jobId [targetDirectory]
```

This command will trigger a savepoint for the job with ID:*jobid*. Furthermore, you can specify a target file system directory to store the savepoint. The directory must be accessible by JobManager. The targetDirectory is optional. If targetDirectory is not configured, the directory specified by **state.savepoints.dir** in the configuration file is used to store savepoint.

You can configure a default savepoint target directory via the **state.savepoints.dir** key in the **flink-conf.yaml** file.

```
# Default savepoint target directory
```

### NOTE

You are advised to configure targetDirectory to an HDFS path.

For example:

```
bin/flink savepoint 405af8c02cf6dc069a0f9b7a1f7be088 hdfs://savepoint.
```

2. Cancel a job with a savepoint.

```
$ bin/flink cancel -s [targetDirectory] jobId
```

This will atomically trigger a savepoint for the job with ID:*jobid* and cancel the job. Furthermore, you can specify a target file system directory to store the savepoint. The directory must be accessible by JobManager.

3. Resume jobs.

- Resume from a savepoint.

```
$ bin/flink run -s savepointPath [runArgs]
```

This command submits a job and specifies the savepoint path. The execution will resume from the respective savepoint state.

### NOTE

**runArgs** is a user-defined parameter with parameter format and name varying depending on users.

- Allow non-restored state.

```
$ bin/flink run -s savepointPath -n [runArgs]
```

By default the resume operation will try to map all state of the savepoint back to the program you are restoring with. If you dropped an operator, you can skip the state that cannot be mapped to the new program via -allowNonRestoredState (short: -n).

4. Dispose savepoints.

```
$ bin/flink savepoint -d savepointPath
```

This command disposes the savepoint stored in: *savepointPath*.

## Precautions

- Chained operators are identified by the ID of the first task. It is not possible to manually assign an ID to an intermediate chained task, for example, in the chain [ a -> b -> c ] only **a** can have its ID assigned manually, but not **b** or **c**. To work around this, you can manually define the task chains. To manually define chains, use the **disableChaining()** interface. See the following example:

```
env.addSource(new GetDataSource())
.keyBy(0)
.timeWindow(Time.seconds(2)).uid("window-id")
.reduce(_+_).uid("reduce-id")
.map(f->(f1)).disableChaining().uid("map-id")
.print().disableChaining().uid("print-id")
```
- During job upgrade, the data type of operators cannot be changed.

### 1.8.5.4 Introduction to Flink Client CLI

#### Common CLIs

Common Flink CLIs are as follows:

- yarn-session.sh**
  - You can run **yarn-session.sh** to start a standing Flink cluster to receive tasks submitted by clients. Run the following command to start a Flink cluster with three TaskManager instances:

```
bin/yarn-session.sh
```
  - Run the following command to obtain other parameters of **yarn-session.sh**:

```
bin/yarn-session.sh -help
```
- flink**
  - You can run Flink commands to submit a Flink job to a standing Flink cluster or to execute the job in single-server mode.
    - Run the following command to submit a Flink job to a standing Flink cluster:

```
bin/flink run ..//examples/streaming/WindowJoin.jar
```

#### NOTE

Before using the command to submit a task, you need to run **yarn-session.sh** to start the Flink cluster.

- Run the following command to execute a per-job YARN Cluster mode:

```
bin/flink run -m yarn-cluster ..//examples/streaming/WindowJoin.jar
```

#### NOTE

The **-m** **yarn-cluster** parameter is used to specify a job to independently start a Flink cluster.

- List scheduled and running jobs (including their JobIDs):

```
bin/flink list
```

- Cancel a job:  
`bin/flink cancel <jobID>`
- Stop a job (streaming jobs only):  
`bin/flink stop <jobID>`

 NOTE

The difference between cancelling and stopping a (streaming) job is the following:

- Cancel a job: On a cancel call, the operators in a job immediately receive a cancel() method call to cancel them as soon as possible. If operators are not stopping after the cancel call, Flink will start interrupting the thread periodically until it stops.
  - Stop a job: Stop is only available for jobs which use sources that implement the `StoppableFunction` interface. The job will keep running until all sources properly shut down. Stop a job is more graceful than cancel, but it may cause the job to stop failing.
- Run the following command to obtain other parameters of Flink commands:  
`bin/flink --help`

## Precautions

- If `yarn-session.sh` uses `-z` to configure the specified ZooKeeper NameSpace, you need to use `-yid` to specify the application ID and use `-yz` to specify the ZooKeeper NameSpace when using `flink run`. The NameSpaces must the same.

Example:

```
bin/yarn-session.sh -z YARN101  
bin/flink run -yid application_****_*** -yz YARN101 examples/streaming/WindowJoin.jar
```

- If `yarn-session.sh` does not use `-z` to configure the specified ZooKeeper NameSpace, do not use `-yz` to specify the ZooKeeper NameSpace when using `flink run`.

Example:

```
bin/yarn-session.sh  
bin/flink run examples/streaming/WindowJoin.jar
```

- You can use `-yz` to specify a ZooKeeper NameSpace when using `flink run -m yarn-cluster` to start a cluster.
- A NameSpace cannot be shared by multiple clusters.
- If you use `-z` to specify a ZooKeeper NameSpace when starting a cluster or submitting a job, you need to use `-z` again to specify the NameSpace when deleting, stopping, or querying the job or triggering the savepoint.

## 1.8.5.5 FAQ

### 1.8.5.5.1 Savepoints-related Problems

1. Should I assign IDs to all operators of the job?

Strictly speaking, you can assign IDs to only operators with statuses because savepoints save only statuses of operators that have statuses and not operators without statuses.

However, in actual situations, you are advised to allocate IDs to all operators because some internal operators, such as window operators of Flink have statuses. Whether an operator has status or not is not obvious. If you are specific that an operator does not have status, you do not need to call `uid()` to allocate an ID to the operator.

2. What would be the impact if I add an operator with status while upgrading the job?

If you add an operator with status to the job, the status of the operator is not saved in the savepoint and thus the status cannot be recovered. The operator is processed as an operator without status and is executed from the start.

3. What would be the impact if I delete an operator with status while upgrading the job?

By default, savepoints attempt to recover all saved statuses. If the savepoint saves the status of the deleted operator, recovery fails.

You can run the following command and use the `-allowNonRestoredState (-n` in the following command) parameter to skip recovering the status of the deleted operator:

```
$ bin/flink run -s savepointPath -n [runArgs]
```

4. What would be the impact if I rearrange the sequence of operators with statuses?

- If you have allocated IDs to the operators, the statuses would be recovered normally.
- If you do not allocate IDs to the operators, IDs would be automatically allocated to the operators in the new sequence. Then, the status recovery would fail.

5. What would be the impact if I delete or add an operator without status or rearrange the sequence of operators without statuses?

- If you have allocated IDs to operators with statuses, operators without statuses do not affect status recovery from savepoints.
- If you do not allocate IDs to operators, operators with statuses may be allocated with new IDs due to the sequence change. This would cause status recovery failure.

6. What would be the impact if I change the operator concurrency during the status recovery?

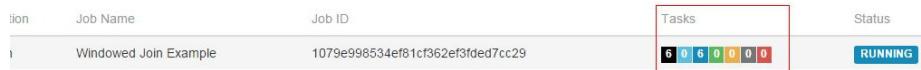

If the Flink version is higher than 1.2.0 and discarded status APIs, such as `checkpointed`, are not used, you can recover statuses from savepoints. Otherwise, statuses cannot be recovered.

### 1.8.5.5.2 What If the Chrome Browser Cannot Display the Title

#### Question

What to do if the title is not displayed when I use Chrome browser to access the Apache Flink Dashboard? This section takes the Tasks field as an example. When the pointer is placed on a colorful box in Tasks, the title of the box is not displayed, as shown in [Figure 1-100](#). [Figure 1-101](#) shows the normal situation when the title is displayed.

**Figure 1-100** Title not displayed on the page

**Figure 1-101** Title displayed normally

## Answer

If the Chrome browser does not display the title, perform the following procedure:

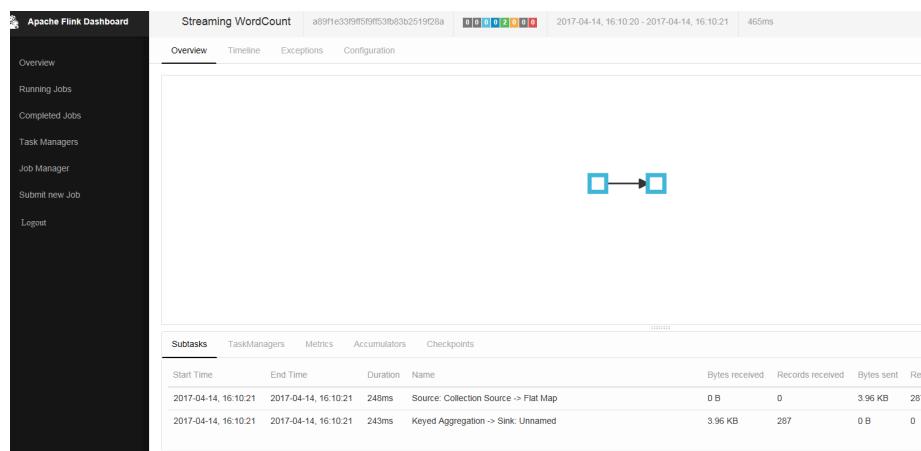

Check whether a tool that affects the tooltip display by the Chrome browser is running. If so, shut down the tool.

### 1.8.5.5.3 What If the Page Is Displayed Abnormally on Internet Explorer 10/11

## Question

What to do if Internet Explorer 10/11 does not display operator texts, as shown in [Figure 1-102](#)?

**Figure 1-102** Page displayed abnormally on Internet Explorer 10/11

## Answer

Flink uses the `foreignObject` element to draw scalable vector graphics (SVGs) but Internet Explorer 10/11 does not support `foreignObject` and thus operators cannot be displayed normally. Google Chrome browser is recommended.

#### 1.8.5.5.4 What If Checkpoint Is Executed Slowly in RocksDBStateBackend Mode When the Data Amount Is Large

##### Question

What to do if checkpoint is executed slowly in RocksDBStateBackend mode when the data amount is large?

##### Cause Analysis

Customized windows are used and the window state is ListState. There are many values under the same key. In the case of a new value, the merge operation of RocksDB is used. When calculation is triggered, all values under the key are read.

- The RocksDB mode is `merge() > merge() ... > merge() > read()`. Data reading in this mode consumes much time, as shown in [Figure 1-103](#).
- The source operator sends a large amount of data in a short period of time and the data keys are the same. The window operator fails to process data fast enough and barriers accumulate in the cache. The time consumed for snapshot preparation is too long and the window operator cannot report snapshot completion to CheckpointCoordinator in the specified time. Therefore, CheckpointCoordinator determines snapshot preparation failure, as shown in [Figure 1-104](#).

```

2 million pieces of data are sent within 466 ms

40S+  
39.7s is spent on reading data from RocksDB

Figure 1-104 Relationship

## Answer

Flink introduces the third-party software package RocksDB, whose defect causes the problem. You are advised to set checkpoint to FsStateBackend mode.

Set checkpoint to FsStateBackend mode in the application code as follows:

```
env.setCheckpointInterval(1000);
```

### 1.8.5.5.5 What If yarn-session Start Fails When blob.storage.directory Is Set to /home

## Question

When **blob.storage.directory** is set to **/home**, the **blobStore-UUID** file cannot be created in **/home**. This causes yarn-session start failure

## Answer

**Step 1** It is recommended that **blob.storage.directory** be set to **/tmp** or **/opt/huawei/Bigdata/tmp**.

**Step 2** When you set **blob.storage.directory** to a customized directory, manually grant permissions to the directory. This section takes the **admin** user of FusionInsight as an example.

1. Modify **conf/flink-conf.yaml** on the Flink client and run the **blob.storage.directory: /home/testdir/testdirdir/xxx** command.
2. Create the **/home/testdir** directory (level 1 is enough) and set the directory to be managed by the **admin** user.

```
SZV1000064084:/home # id admin  
uid=20000(admin) gid=9998(ficcommon) groups=9998(ficcommon),8003(SystemAdministrator_186)  
SZV1000064084:/home # chown admin:ficcommon testdir/ -R
```

### NOTE

The **testdirdir/xxx** directory under the **/home/testdir/** directory is automatically created on each node when Flink cluster starts.

3. Run `./bin/yarn-session.sh -jm 2048 -tm 3072` on the client to check that yarn-session is normally started and the directory is successfully created.

```
SV1000064084:/home # ll testdir/
total 4
drwxr-x--- 3 admin ficommon 4096 Mar 13 11:55 testdirdir
SV1000064084:/home # ll testdir/testdirdir/
total 4
drwxr-x--- 4 admin ficommon 4096 Mar 13 11:55 xxx
SV1000064084:/home # ll testdir/testdirdir/xxx/
total 8
drwxr-x--- 2 admin ficommon 4096 Mar 13 11:55 blobStore-6fb3f049-ecf3-49ac-9fc9-95ad0aeeffd3
drwxr-x--- 2 admin ficommon 4096 Mar 13 11:55 blobStore-ad89b118-8545-4ece-8cae-1334b01de857
```

----End

### 1.8.5.5.6 Why Does Non-static KafkaPartitioner Class Object Fail to Construct FlinkKafkaProducer010?

#### Question

After Flink kernel is upgraded to 1.3.0 or later versions, if Kafka calls the FlinkKafkaProducer010 that contains the non-static KafkaPartitioner class object as parameter to construct functions, an error is reported.

The error message is as follows:

```
org.apache.flink.api.common.InvalidProgramException: The implementation of the FlinkKafkaPartitioner is not serializable. The object probably contains or references non serializable fields.
```

#### Answer

In the 1.3.0 version of Flink, the FlinkKafkaDelegatePartitioner class is added, so that Flink allows APIs that use KafkaPartitioner, for example, FlinkKafkaProducer010 that contains KafkaPartitioner object, to construct functions.

The FlinkKafkaDelegatePartitioner class defines the member variable kafkaPartitioner.

```
private final KafkaPartitioner<T> kafkaPartitioner;
```

When Flink input parameter KafkaPartitioner constructs FlinkKafkaProducer010, the call stack is as follows:

```
FlinkKafkaProducer010(String topicId, KeyedSerializationSchema<T> serializationSchema, Properties
producerConfig, KafkaPartitioner<T> customPartitioner)
-> FlinkKafkaProducer09(String topicId, KeyedSerializationSchema<IN> serializationSchema, Properties
producerConfig, FlinkKafkaPartitioner<IN> customPartitioner)
---> FlinkKafkaProducerBase(String defaultTopicId, KeyedSerializationSchema<IN> serializationSchema,
Properties producerConfig, FlinkKafkaPartitioner<IN> customPartitioner)
-----> ClosureCleaner::clean(Object func, boolean checkSerializable)
```

Run the KafkaPartitioner object to construct a FlinkKafkaDelegatePartitioner object, and then check whether the object can be serializable. The ClosureCleaner::clean function is a static function. If the KafkaPartitioner object in a case is non-static, the ClosureCleaner::clean function cannot access the non-static member variable kafkaPartitioner in the KafkaDelegatePartitioner class and an exception is reported.

Either of the following methods can be used to solve the problem:

- Change the KafkaPartitioner class into static class.
- Use the FlinkKafkaProducer010 that contains FlinkKafkaPartitioner as the parameter to construct functions. In this case, FlinkKafkaDelegatePartitioner is not constructed and the exception about member variable is avoided.

### 1.8.5.5.7 When I Use a Newly Created Flink User to Submit Tasks, Why Does the Task Submission Fail and a Message Indicating Insufficient Permission on ZooKeeper Directory Is Displayed?

#### Question

When I use a newly-created Flink user to submit tasks, the task submission fails because of insufficient permission on the ZooKeeper directory. The error message in the log is as follows:

```
NoAuth for /flink_base/flink/application_1499222480199_0013
```

#### Answer

1. Check whether the permission on the /flink\_base directory in ZooKeeper is 'world,'anyone: cdrwa; If no, change the permission on the /flink\_base directory to 'world,'anyone: cdrwa and go to **step 2**. If yes, go to **step 2**.
2. In the configuration file of Flink, the default value of `high-availability.zookeeper.client.acl` is `creator`, indicating that only the creator of the directory has permission on it. The user created later has no access to the /flink\_base/flink directory in ZooKeeper because only the user created earlier has permission on it.

To solve the problem, perform the following operation as the newly-created user:

- a. Check the configuration file `conf/flink-conf.yaml` on the client.
- b. Modify the parameter `high-availability.zookeeper.path.root` to the corresponding ZooKeeper directory, for example, `/flink2`.
- c. Submit tasks again.

### 1.8.5.5.8 Why Cannot I Access the Apache Flink Dashboard?

#### Question

Why cannot I access the Apache Flink Dashboard through the URL: `http://IP address of JobManager:port of JobManager`.

#### Answer

The IP address of the computer you used has not been added to the whitelist of Apache Flink Dashboard. To solve this problem, modify the `conf/flink-conf.yaml` configuration file as follows:

1. Check whether the value of `jobmanager.web.ssl.enabled` is `false`. If not, set it to `false`.
2. Check whether the IP address of the computer you used has been added to the values of `jobmanager.web.access-control-allow-origin` and

**jobmanager.web.allow-access-address.** If the IP address has not been added, add it to the two parameters:

jobmanager.web.access-control-allow-origin:*IP address of the computer where the browser is installed*  
jobmanager.web.allow-access-address:*IP address of the computer where the browser is installed*

### 1.8.5.5.9 How Do I View the Debugging Information Printed Using System.out.println or Export the Debugging Information to a Specified File?

#### Question

System.out.println is added to the Flink service codes for printing debugging information. How do I view the debugging log? How do I export service logs to a specified file to differentiate service logs from run logs?

#### Answer

All run logs of Flink are printed to the local directory of Yarn. By default, all logs are exported to **taskmanager.log** in the local directory of Yarn container. All logs generated by invoking System.out will be exported to the **taskmanager.out** file. You can perform as follows to view the logs:

1. Log in to the native Flink web page.
2. Choose **Task Managers > Logs** or **Task Managers > Stdout** on the left to view log information.

The screenshot shows the Apache Flink Dashboard. On the left, there's a sidebar with links for Overview, Running Jobs, Completed Jobs, Task Managers (which is highlighted with a red box), and Job Manager. The main area is titled 'Task Manager' and shows a 'Last Heartbeat: 2019-01-17, 11:35:47' and ' akka.tcp'. Below this, there are tabs for Metrics, Logs (which is highlighted with a red box), and Stdout. The 'Overview' section contains a table with three columns: Data Port, All Slots, and Free Slots. The values are 32391, 1, and 0 respectively.

Configure the function of printing service logs and Task Manager run logs separately:

#### NOTE

If service logs and Task Manager run logs are separately printed, service logs are not exported to the **taskmanager.log** file and cannot be viewed on the web page.

1. Modify the configuration file **logback.xml** in the **conf** directory of the client. Add the following log configuration information to the file. Modify the information in bold according to the actual situation.

```
<appender name="TEST" class="ch.qos.logback.core.rolling.RollingFileAppender">
    <file>/path/test.log</file>
    <rollingPolicy class="ch.qos.logback.core.rolling.FixedWindowRollingPolicy">
        <fileNamePattern>/path/test.log.%i</fileNamePattern>
        <minIndex>1</minIndex>
        <maxIndex>20</maxIndex>
    </rollingPolicy>
    <triggeringPolicy class="ch.qos.logback.core.rolling.SizeBasedTriggeringPolicy">
        <maxFileSize>20MB</maxFileSize>
    </triggeringPolicy>
    <encoder>
```

```
<pattern>%d{"yyyy-MM-dd HH:mm:ss,SSS"} | %m %n</pattern>
</encoder>
</appender>

<logger name="com.huawei.bigdata.flink.examples" additivity="false">
    <level value="INFO"/>
    <appender-ref ref="TEST"/>
</logger>
```

2. Run **yarn-session.sh** to submit the task.

If the configuration file **logback.xml** contains `<file>/path/test.log</file>`, ensure that the user (configured **flink-conf.yaml**) used for running the task has the write and read permissions on the directory.

### 1.8.5.5.10 Incorrect GLIBC Version

#### Question

When **State Backend** is set to **RocksDB** for a Flink task, the following error message is displayed:

```
Caused by: java.lang.UnsatisfiedLinkError: /srv/BigData/hadoop/data1/nm/usercache/**/appcache/application_****/rocksdb-lib-****/librocksdbjni-linux64.so: /lib64/libpthread.so.0: version `GLIBC_2.12` not found (required by /srv/BigData/hadoop/**/librocksdbjni-linux64.so)
at java.lang.ClassLoader$NativeLibrary.load(Native Method)
at java.lang.ClassLoader.loadLibrary0(ClassLoader.java:1965)
at java.lang.ClassLoader.loadLibrary(ClassLoader.java:1890)
at java.lang.Runtime.load0(Runtime.java:795)
at java.lang.System.load(System.java:1062)
at org.rocksdb.NativeLibraryLoader.loadLibraryFromJar(NativeLibraryLoader.java:78)
at org.rocksdb.NativeLibraryLoader.loadLibrary(NativeLibraryLoader.java:56)
at
org.apache.flink.contrib.streaming.state.RocksDBStateBackend.ensureRocksDBIsLoaded(RocksDBStateBackend.java:734)
... 11 more
```

#### Possible Causes

The version of the system where the task runs and the version of the system where the compilation environment locates are different, resulting in the incompatibility of GLIBC versions.

#### Troubleshooting Method

Run the **strings /lib64/libpthread.so.0 | grep GLIBC** command to check whether the GLIBC version is earlier than 2.12.

#### Procedure

If the version of the GLIBC is too early, use the file of later version (2.12) to replace **libpthread-\* .so**. (This is a link file. You need to replace only the file that is linked to this link file.)

#### References

None

# 1.9 GraphBase Development Guide

## 1.9.1 Overview

### 1.9.1.1 Application Development Overview

#### GraphBase Introduction

FusionInsight GraphBase is a distributed graph database based on HBase and Elasticsearch. It builds a property graph model for storage and provides powerful graph query, analysis, and traversal capabilities. It has the following features:

- The HBase-based distributed storage mechanism is provided to process massive data.
- The Spark distributed memory computing technology is provided to support quick data import.
- The Elasticsearch-based index mechanism is provided to quickly query data based on indexes.

#### Interface Type Introduction

- REST API Interface

REST APIs are developed using the Java language that is simple and easy. Therefore, you are advised to use the Java language to develop upper-layer applications. For details, see **GraphBase** in *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

The following table describes the functions provided by GraphBase after REST API is invoked.

Function	Description
User login and logout	This function can be used for access authentication.
Metadata read/write	This function can be used to add, delete, modify, and query metadata.
Metadata-based operations on vertices and edges	This function can be used to add, delete, modify, and query vertices and edges.
Filtering and querying relationships for a large amount of data	This function can be used for full graph query, conditional query, line expansion query, and path query for vertices and edges.
Index management	This function can be used to create and query full graph indexes and edge indexes, and query the status of asynchronous index tasks.

- Gremlin API Interface

Gremlin is the graph traversal language of Apache TinkerPop. Gremlin is a functional, data-flow language that enables users to succinctly express complex traversals on (or queries of) their application's property graph. Every Gremlin traversal is composed of a sequence of (potentially nested) steps. A step performs an atomic operation on the data stream. For details about Gremlin, visit <http://tinkerpop.apache.org/docs/3.3.2/reference/#traversal>.

Gremlin has the following three types of basic operations:

- map-step: converts objects in a data flow.
- filter-step: filters objects in a data flow.
- sideEffect-step: calculates data flows.

### 1.9.1.2 Basic Concepts

Like most graph databases, GraphBase uses property graphs for modeling. Based on the property graph models, GraphBase has the following basic concepts:

- **Vertex**: A vertex is also called a node, which is used to specify an entity object in the real world, such as a person.
- **Vertex label**: A vertex label indicates a node type that specifies the type of an entity object in the real world. Example: person. In GraphBase, a node has only one vertex label. The default value is **vertex**.
- **Edge**: An edge, also known as a relationship that is used to specify the connections between two entity objects (vertices in a graph) in the real world. For example, the relationship between two persons is friend. Edges in GraphBase are unidirectional, which starts from a vertex and ends at another. Therefore, a bidirectional edge has an incoming and an outgoing edge.
- **Edge label**: An edge label specifies the type of a relationship in the real world. For example, the relationship is friend.
- **Property**: A property describes some attribute of either a vertex or an edge in the format of key-value pair. Property key is used to describe the key in the key-value pair, property value describes a specific value. For example, a property key is **name**, the property value is **Zhang San**.

### 1.9.1.3 Development Process

This section describes how to develop a GraphBase application based on GraphBase REST API and Gremlin API.

**Figure 1-105** shows the development process, and **Table 1-65** describes each phase.

Figure 1-105 GraphBase application development process

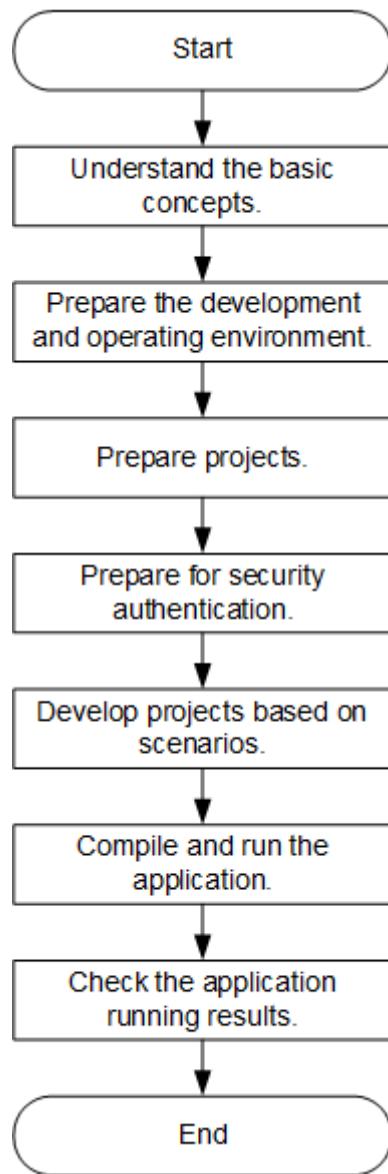

Table 1-65 GraphBase application development process

Phase	Description	Reference Document
Understand basic concepts about GraphBase.	Before application development, learn basic concepts of GraphBase, understand the scenario requirements, and design tables.	<a href="#">Basic Concepts</a>

Phase	Description	Reference Document
Prepare the development and running environment.	REST APIs and the Gremlin language are recommended for GraphBase application development. You can use the IntelliJ IDEA tool. The GraphBase running environment is the GraphBase client. Install and configure the client according to the guide.	<ul style="list-style-type: none"><li>For details about how to prepare the development environment for the REST API, see <a href="#">Preparing Development and Operating Environment</a>.</li><li>For details about how to prepare the development environment for the Gremlin API, see <a href="#">Preparing Development and Operating Environment</a>.</li></ul>
Prepare a project.	GraphBase provides sample projects for different scenarios. You can import a sample project to learn the application.	<ul style="list-style-type: none"><li>For details about how to prepare a project for the REST API, see <a href="#">Configuring and Importing Sample Projects</a>.</li><li>For details about how to prepare a project for the Gremlin API, see <a href="#">Configuring and Importing a Piece of Sample Code</a>.</li></ul>
Preparing for security authentication.	The security authentication is mandatory if security clusters are used.	<ul style="list-style-type: none"><li>For details about how to perform security authentication for the REST API, see <a href="#">Preparing for Security Authentication</a>.</li><li>For details about how to perform security authentication for the Gremlin API, see <a href="#">Preparing for Security Authentication</a>.</li></ul>

Phase	Description	Reference Document
Develop a project based on the scenario.	<ul style="list-style-type: none"><li>Sample projects for developing REST APIs are provided, including projects for creating and deleting graphs and performing full graph query, path query, and line expansion query.</li><li>The Gremlin syntax scenario is provided, including syntax scenarios for querying a specified graph object, querying one or more properties, traversing graph objects and paths.</li></ul>	<a href="#">Developing an Application</a>
Compile and run applications.	You can compile the developed application and submit it for running.	<ul style="list-style-type: none"><li><a href="#">Compiling and Running an Application</a></li><li><a href="#">Compiling and Running an Application</a></li></ul>
Check the application running results.	Application running results are exported to a path you specify. You can also view the application running status on the UI.	<ul style="list-style-type: none"><li><a href="#">Viewing Windows Commissioning Results</a></li><li><a href="#">Viewing Linux Commissioning Results</a></li></ul>

## 1.9.2 Environment Preparation

### 1.9.2.1 REST API Development Environment Preparation

#### 1.9.2.1.1 Preparing Development and Operating Environment

[Table 1-66](#) describes the development and operating environment required for secondary development.

**Table 1-66** Environment

Preparation Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows 7 or later</li><li>• Operating environment: Windows OS or Linux OS. If the program needs local debugging, the operating environment must be able to communicate with the cluster service plane.</li></ul>
JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– Oracle JDK 1.8</li><li>– IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>– BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA	<p>Tool used for developing GraphBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you are using an IBM JDK, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If you are using an Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If you are using an OpenJDK, ensure that the JDK configured in IntelliJ IDEA is the OpenJDK.</li></ul>
Maven	Basic configuration of the development environment. This tool is used for project management throughout the lifecycle of software development.

Preparation Item	Description
JUnit plug-ins	Basic configuration of the development environment.
User development	See <a href="#">Preparing a Developer Account</a> for configuration.
7-Zip	Tool used to decompress *.zip and *.rar files. <b>7-Zip 16.04</b> is supported.

## Preparing the Operating Environment

During application development, prepare the environment for running and commissioning code to verify that the application can run properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required for commissioning; configure the network connection, and commission the application in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#) and click **Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar**. Then, decompress this file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.
  - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\GraphBase\config** and import the configuration file to the configuration file directory (usually the **conf** folder) of the GraphBase sample project.

The keytab file obtained during [Preparing a Developer Account](#) is also stored in this directory. **Table 1-67** describes the main configuration files.

**Table 1-67** Configuration files

File	Description
graphbase.properties	Parameters required for the GraphBase sample code
Person.xml	Files required by Schema
user.keytab	User information for Kerberos security authentication

File	Description
krb5.conf	Kerberos Server configuration

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored, for example, in **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, install the client in the **/opt/hadoopclient** directory.

The difference between the client time and the cluster time must be less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).

- b. [Accessing FusionInsight Manager of an MRS Cluster](#). Download the cluster client software package to the active management node and decompress it. Then log in to the active management node as user **root**. Go to the decompression directory of the cluster client, and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/GraphBase/config** directory to the client node to the **conf** directory where the compiled JAR package is stored, for example, **/opt/hadoopclient/conf**, for subsequent commissioning.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active OMS node, run the following commands:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp GraphBase/config/* root@IP address of the client node:/opt/  
hadoopclient/conf
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. [Table 1-68](#) describes the main configuration files.

**Table 1-68** Configuration files

File	Description
graphbase.properties	Parameters required for the GraphBase sample code
Person.xml	Files required by Schema
user.keytab	User information for Kerberos security authentication
krb5.conf	Kerberos Server configuration

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If there is no required information, copy the content of the **hosts** file in the decompression directory to the **hosts** file on the node where the client is deployed, to ensure that the local host can communicate with each host in the cluster.

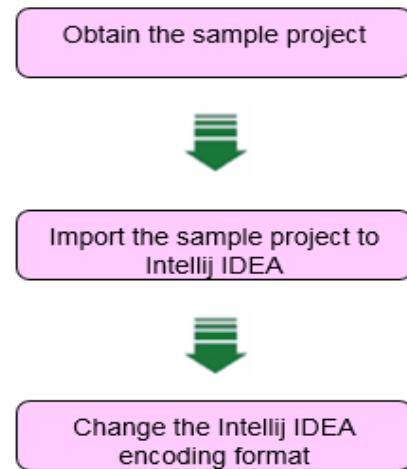

### 1.9.2.1.2 Configuring and Importing Sample Projects

#### Prerequisites

The GraphBase client has been installed.

#### Scenario

GraphBase provides sample projects for multiple scenarios to help you quickly master RESTful APIs. The following describes how to import the sample code to IntelliJ IDEA. [Figure 1-106](#) shows the operation process.

**Figure 1-106** Procedure of importing sample projects

## Procedure

- Step 1** Obtain the sample project folder **graphbase-examples** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

Download the sample project **graphbase-core-example** to the local PC.

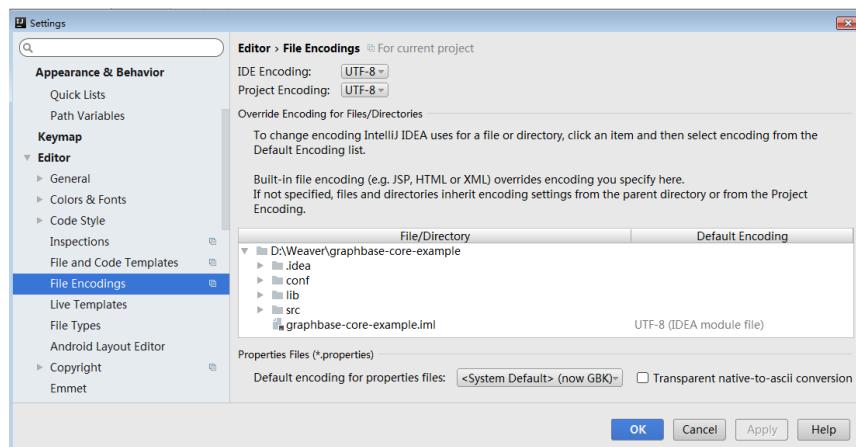

- Step 2** Import the sample project to the IntelliJ IDEA development environment.

1. Open IntelliJ IDEA and choose **File > New > Project from Existing Sources....**
2. Select the sample project folder **graphbase-core-example** and click **OK**.
3. In the **Import Project** window, select **Create project from existing sources**.
4. Click **Next** until JDK is set to jdk1.8.0\_402. Then click **Next** and **Finish**.

- Step 3** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

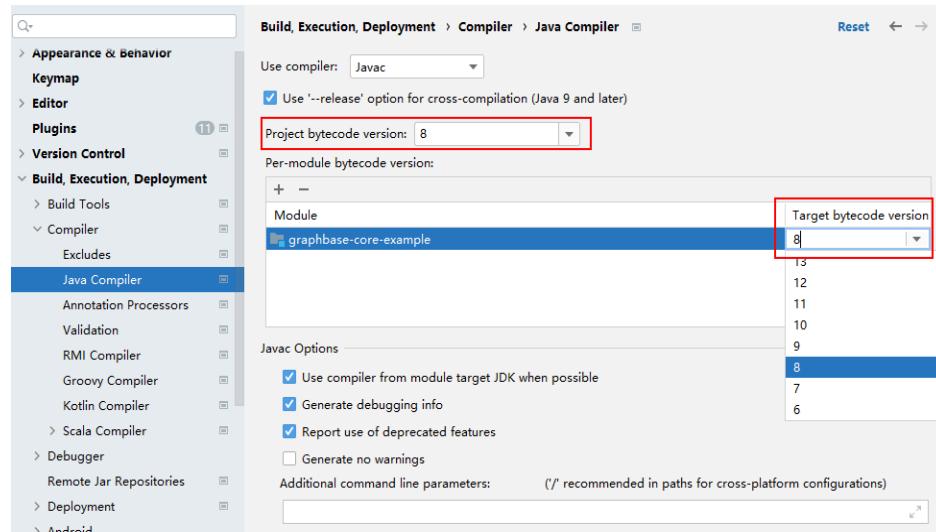

1. On the IntelliJ IDEA menu bar, choose **File > Settings....**
2. In the displayed **Settings** window, choose **Editor > File Encoding** in the navigation pane on the left, set the parameter to **UTF-8**, click **Apply**, and click **OK**.

**Figure 1-107** Setting the IntelliJ IDEA encoding format

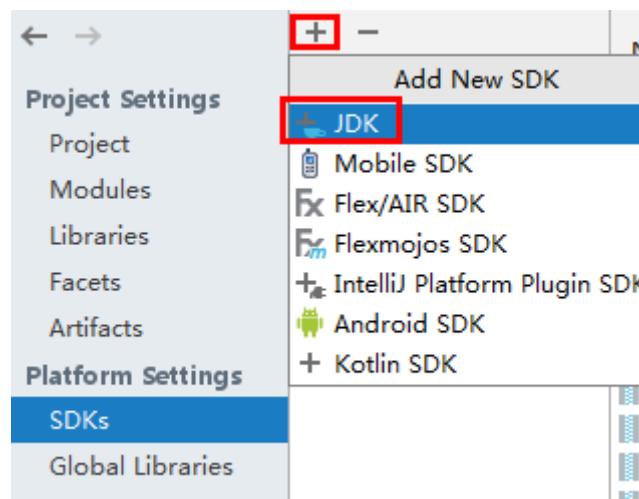

- Step 4** Set the JDK of the project.

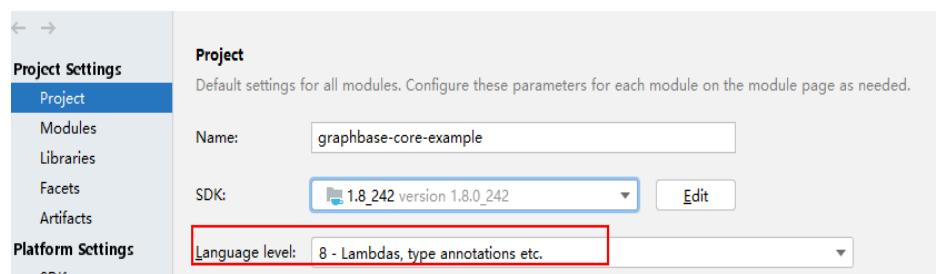

1. On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler** and select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** in **graphbase-core-example** to **8**.

3. Click **Apply** then **OK**.
4. On the menu bar of IntelliJ IDEA, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Choose **SDKs**, click the plus sign (+), and select **JDK**.

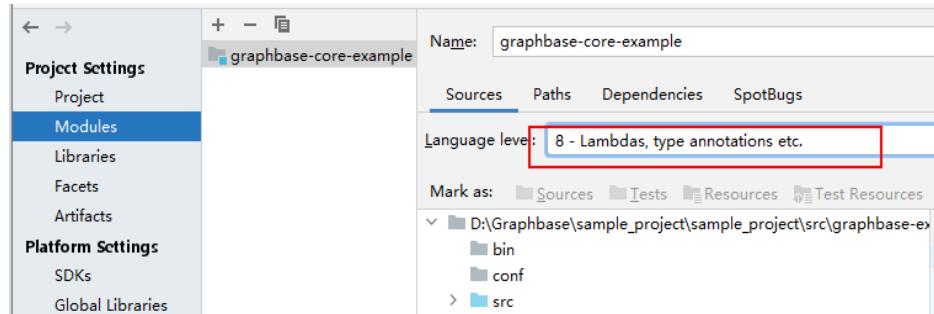

6. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.
7. Click **Apply**.
8. Select **Project**, select the JDK added in **SDKs** from the **Project SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Project language level** drop-down list box.

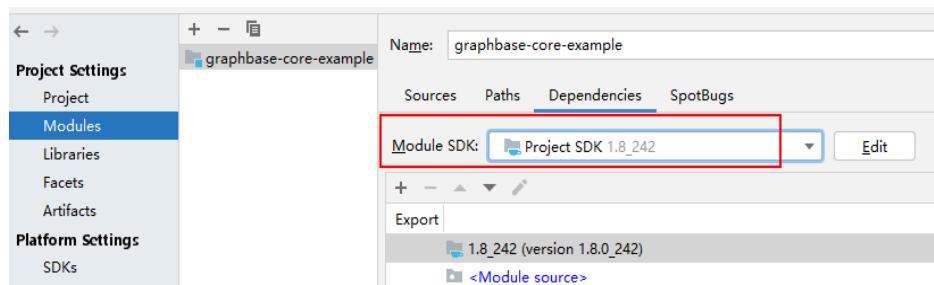

9. Click **Apply**.

- Choose **Modules**. On the **Sources** tab page, change the value of **Language level** to **8 - Lambdas, type annotations etc.**

On the **Dependencies** tab page, change the value of **Module SDK** to the JDK added in **SDKs**.

- Click **Apply** and then **OK**.

----End

### 1.9.2.1.3 Preparing for Security Authentication

GraphBase uses keytab authentication which never expires. You are advised to use keytab files for authentication on the client.

- Modify the configuration data.

- In the **conf** directory of the root directory of the sample project, set the **graphbase.properties** configuration file, IP address, port number, and username as you need.

#### NOTE

The IP address and port number of the GraphBase service is the floating IP address and port number specified when the GraphBase component is installed. Log in to FusionInsight Manager, choose **Cluster > Name of the desired cluster > Services > GraphBase > Configurations > All Configurations**, and search for **loadbalancer.floatip**. The value of **loadbalancer.floatip** is the floating IP address, the value of **loadbalancer.https.port** is the port number.

Parameter	Value
* loadbalancer.floatip	10 . 5 . 89 . 50
loadbalancer.https.port	22380

**Note:** In an IPv6 network, the floating IP address must be enclosed by square brackets, for example, [*/IPv6 address*].

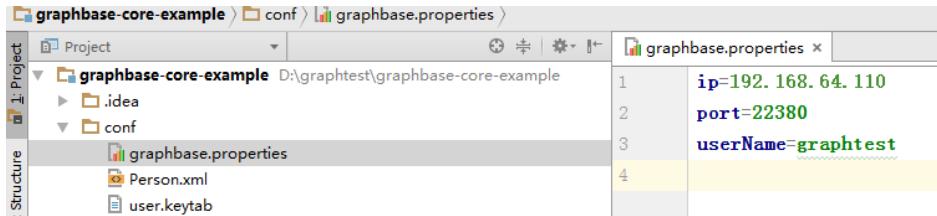

- Download the keytab file of the human-machine user and copy it to the **conf** directory in the root directory of the sample project.

Log in to FusionInsight Manager, click **System**, and choose **Permission > User**. On the displayed page, click **More > Download Authentication Credential** to obtain the **user.keytab** authentication file.

#### NOTE

The authentication credential contains the **krb5.conf** file of Kerberos. If there are multiple clusters, select the **krb5.conf** file of the corresponding cluster.

- c. Modify the configuration file as follows.

2. Obtain Keytab authentication code.

Construct an HTTP client, log in to it with Kerberos authentication, obtain CSRF TOKEN information, and call RESTful APIs. The following code snippets are in the **GraphHttpClient** class of the **com.huawei.security** package.

```
/* step 1: create http client */
final X509TrustManager trustManager = new X509TrustManager() {
    @Override
    public final X509Certificate[] getAcceptedIssuers() {
        return null;
    }

    @Override
    public final void checkClientTrusted(X509Certificate ax509certificate[], String s) throws CertificateException {
        // to do nothing.
    }

    @Override
    public final void checkServerTrusted(X509Certificate ax509certificate[], String s) throws CertificateException {
        // to do nothing.
    }
};

final javax.net.ssl.SSLContext context = javax.net.ssl.SSLContext.getInstance("TLS");
context.init(null, new TrustManager[]{trustManager}, null);
final ThreadSafeClientConnManager connectionManager = new ThreadSafeClientConnManager();
connectionManager.setMaxTotal(100);
connectionManager.getSchemeRegistry().register(new Scheme("https", 443, new SSLSocketFactory(
    context, SSLSocketFactory.ALLOW_ALL_HOSTNAME_VERIFIER)));

CloseableHttpClient httpclient = new DefaultHttpClient(connectionManager);

/*
 * step 2:
 * usage: kerberos login based on username and keytab,
 * note: Password never expired
 */
HttpPost loginPost = new HttpPost(httpAuthInfo.getBaseUrl() + "/login");
MultipartEntityBuilder entityBuilder = MultipartEntityBuilder.create();
entityBuilder.addPart("username", new StringBody(httpAuthInfo.getUsername(),
ContentType.create("text/plain", Consts.UTF_8)));
entityBuilder.addBinaryBody("keytabfile", new File(httpAuthInfo.getKeytabFilePath()));
loginPost.setEntity(entityBuilder.build());
loginRsp = httpclient.execute(loginPost);
RestHelper.checkHttpRsp(loginRsp);

/* step 3: get CSRF-Token */
```

```
HttpGet httpGet = new HttpGet(httpAuthInfo.getBaseUrl() + "/graph/user/me");
CloseableHttpResponse csrfTokenRsp = httpClient.execute(httpGet);
}
```

## 1.9.2.2 Gremlin API Development Environment Preparation

### 1.9.2.2.1 Preparing Development and Operating Environment

**Table 1-69** describes the development and operating environment required for secondary development.

**Table 1-69** Environment

Preparation Item	Description
OS	<ul style="list-style-type: none"><li>Development environment: Windows 7 or later</li><li>Operating environment: Windows OS or Linux OS. If the program needs local debugging, the operating environment must be able to communicate with the cluster service plane.</li></ul>
JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>Oracle JDK 1.8</li><li>IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>For security purposes, the server supports only TLS V1.2 or later.</li><li>By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls</a>.</li><li>For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>

Preparation Item	Description
IntelliJ IDEA	<p>Tool used for developing GraphBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you are using an IBM JDK, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If you are using an Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If you are using an OpenJDK, ensure that the JDK configured in IntelliJ IDEA is the OpenJDK.</li></ul>
Maven	Basic configuration of the development environment. This tool is used for project management throughout the lifecycle of software development.
JUnit plug-ins	Basic configuration of the development environment.
User development	See <a href="#">Preparing a Developer Account</a> for configuration.
7-Zip	Tool used to decompress *.zip and *.rar files. <b>7-Zip 16.04</b> is supported.

## Preparing the Operating Environment

During application development, prepare the environment for running and commissioning code to verify that the application can run properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required for commissioning; configure the network connection, and commission the application in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#) and click **Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar**. Then, decompress this file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.

    - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\GraphBase\config** and import the configuration file to the configuration file directory (usually the **conf** folder) of the GraphBase sample project.

The keytab file obtained during [Preparing a Developer Account](#) is also stored in this directory. [Table 1-70](#) describes the main configuration files.

**Table 1-70** Configuration files

File	Description
graphbase.properties	Parameters required for the GraphBase sample code
Person.xml	Files required by Schema
user.keytab	User information for Kerberos security authentication
krb5.conf	Kerberos Server configuration

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 **NOTE**

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
  - The local **hosts** file in a Windows environment is stored, for example, in **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, install the client in the **/opt/hadoopclient** directory.

The difference between the client time and the cluster time must be less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).
  - b. **Accessing FusionInsight Manager of an MRS Cluster**. Download the cluster client software package to the active management node and decompress it. Then log in to the active management node as user **root**. Go to the decompression directory of the cluster client, and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/GraphBase/config** directory to the client node to the **conf** directory where the compiled JAR package is stored, for example, **/opt/hadoopclient/conf**, for subsequent commissioning.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active OMS node, run the following commands:

```
cd /tmp/FusionInsight-Client
tar -xvf FusionInsight_Cluster_1_Services_Client.tar
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar
cd FusionInsight_Cluster_1_Services_ClientConfig
```

```
scp GraphBase/config/* root@IP address of the client node:/opt/hadoopclient/conf
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. [Table 1-71](#) describes the main configuration files.

**Table 1-71** Configuration files

File	Description
log4j.properties	Gremlin log related parameters
remote-objects.yaml	Detailed parameters for Gremlin query
user.keytab	User information for Kerberos security authentication
krb5.conf	Kerberos Server configuration

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If there is no required information, copy the content of the **hosts** file in the decompression directory to the **hosts** file on the node where the client is deployed, to ensure that the local host can communicate with each host in the cluster.

### 1.9.2.2 Configuring and Importing a Piece of Sample Code

1. Obtain the sample project folder **gremlin-demo4j** in the **graphbase-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
2. Import the sample code to IntelliJ IDEA. For details, see [Configuring and Importing Sample Projects](#).
3. Configure the **krb5.conf** and **user.keytab** files and copy the **krb5.conf** and keytab files that you applied for to the **gremlin-demo4j\conf** directory in the sample program.

### 1.9.2.3 Preparing for Security Authentication

In a secure cluster environment, the Gremlin client and server need to authenticate each other to ensure communication security. The LoginUtil-related interfaces are provided to complete such authentication configuration. In the following sample code, you only need to configure the account name (applied by the user) and keytab file name. For details about the sample code, see the LoginUtil class in the **com.huawei.graphbase.gremlin.util** package of the sample project.

Authentication sample code:

```
/*
 * kerberos authentication
 * @throws IOException
 */
```

```
private static void krbLogin() throws IOException{
    /**
     * Account name applied by the user.
     */
    String user_principal = "Account name applied by the user";
    String krb5Path = System.getProperty("user.dir") + File.separator + "conf" + File.separator +
"krb5.conf";
    File userKrb5File = FileUtils.getFile(krb5Path);
    if (!userKrb5File.exists())
    {
        throw new RuntimeException("userKrb5File(" + userKrb5File.getAbsolutePath() + ") does not
exist.");
    }
    //Set the krb5 file.
    System.setProperty("java.security.krb5.conf", userKrb5File.getAbsolutePath());

    //Set keytab, jaasconf
    String keytab = System.getProperty("user.dir") + File.separator + "conf" + File.separator + "user.keytab";
    LoginUtil.setJaasConf("gremlinclient", user_principal, keytab);
}
```

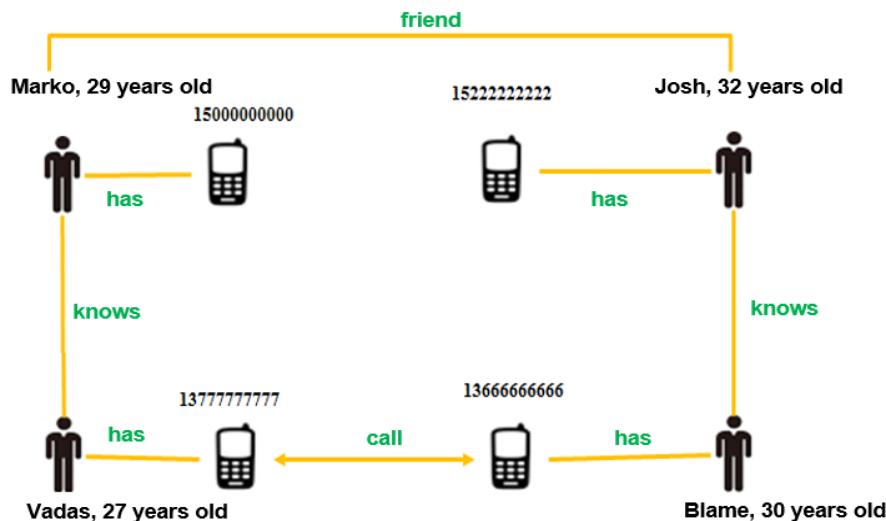

## 1.9.3 Developing an Application

### 1.9.3.1 Typical Application Scenario

You can quickly learn and master the GraphBase development process and know key interface functions in a typical application scenario.

#### Actual Scenario

Typical social relationships:

In the scenario, there are eight real world entities, four persons and four mobile phones.

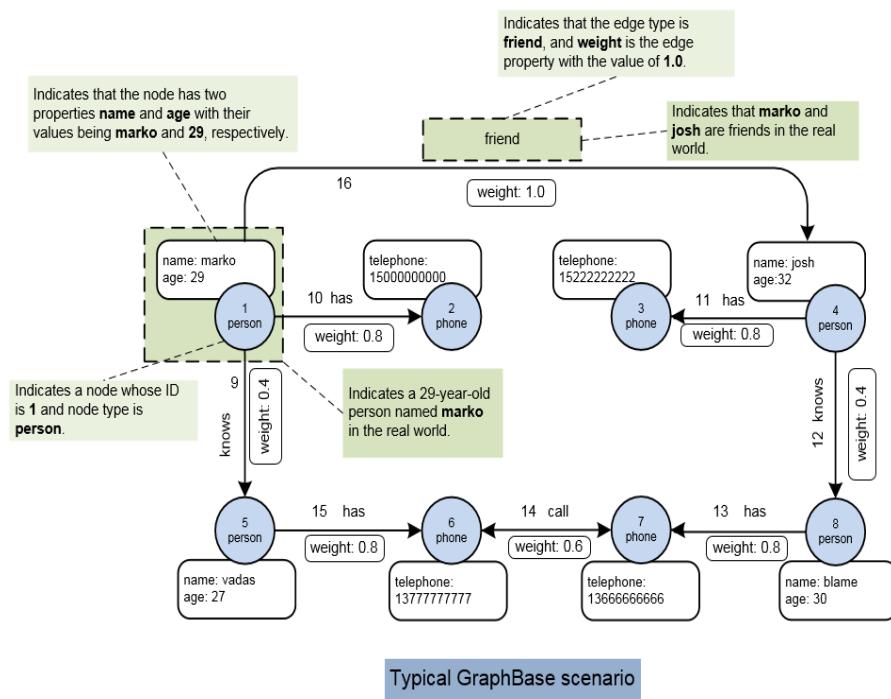

There are eight relationships between the entity objects, including **friend**, **knows**, **call**, and **has**.

## Graph Modeling Scenario

The purpose of graph modeling is to map the real world relationships to GraphBase using a graph:

- **Vertex:** maps persons and mobile phones in the real world to GraphBase using vertices.
- **Vertex label:** defines the types of persons and mobile phone in the real world in GraphBase. That is, people are labeled as **person**, and mobile phones are defined as **phone** in the graph.
- **Edge:** maps the relationships between people and people, people and mobile phones, and mobile phones and mobile phones in the real world to GraphBase using edges.
- **Edge label:** defines the relationships between entity objects in the real world in GraphBase. The definitions of these relationships in this scenario are as follows:
  - The friend relationship between people is defined as the edge label **friend**.
  - The acquaintance relationship is defined as the edge label **knows**.
  - The ownership between mobile phones and people is defined as **has**.
  - The communication relationship between mobile phones is defined as the edge label **call**.
- **Property:** defines the feature information of each entity object in the real world in GraphBase. The name and age of a person is defined as the property **name** and **age**, respectively, and the mobile phone number is defined as the property **telephone**.
- **New property:** Considering that GraphBase supports the value properties obtained by the evaluation system, the relationship weight property definition is added to indicate the importance of relationships. That is, the **weight** property is defined. It is considered that the value property has been obtained.

The graph model is as follows:

## Development Guidelines

Based on the preceding scenario description, the basic operation process of creating a GraphBase service and querying data using the created service are as follows:

- Take **node 1 > node 2** in the scenario as an example, there are three elements included: node 1, node 2, and edge 10.
  - Create a schema using the two nodes, see instructions provided in [Creating a Schema](#).  
You need to create two vertex labels, **person** and **phone**, and an edge label, **has**.  
You need to create the properties of all nodes and edges: **name**, **age**, **telephone**, and **weight**.
  - (Optional) Create indexes for properties to improve query efficiency. For details, see [Creating an Index](#).
  - Create vertices and edges.  
Create vertex 1, vertex 2, and the edge 10. For details about how to create vertices and edges, see [Creating and Querying a Vertex or an Edge](#).
  - Query data.  
Method 1: Invoke a REST API for query.  
Invoke the full graph query interface to query vertices and edges. For details, see [Performing a Full Graph Query](#).  
Method 2: Perform data query using Gremlin statements. For details, see [Gremlin Console](#), [Gremlin Java](#) and [Gremlin Application Scenarios](#).  
You can create other nodes and edges in the same way.

- If the data volume is large, you can import the data in batches. The procedure is as follows:
  - a. Create a schema.  
Compile an XML file. For details, see [Compiling a Schema File \(XML\)](#).  
Create a schema by uploading the XML file. For details, see [Creating a Schema by Uploading an XML File](#).
  - b. Import data.  
Compile a data file (CSV), data description file (DESC), and a graph mapping rule file (.mapper). For details, see [Preparing Data Files](#).  
Import data in real time or in batches. For details, see [Importing Data](#).
  - c. Query data.  
Method 1: Invoke a REST API for query.  
Invoke the full graph query interface to query vertices and edges. For details, see [Performing a Full Graph Query](#).  
Method 2: Perform data query using Gremlin statements. For details, see [Gremlin Console](#), [Gremlin Java](#) and [Gremlin Application Scenarios](#).
- During data query, except vertex and edge query, you can query paths between vertices and perform line expansion queries. For details, see [Performing a Path Query](#) and [Performing a Line Expansion Query](#).

### 1.9.3.2 Preparing Data Files

#### 1.9.3.2.1 Compiling a Schema File (XML)

##### Defining the Schema File (XML)

In GraphBase, vertices and edges are entities. You need to create the metadata information for the entity labels, such as vertex labels, edge labels, property names, property value types. Such metadata information is the schema information of a graph.

1. Define a schema file **person.xml** based on the scenario described in [Typical Application Scenario](#) to create a schema file (containing vertexLabel, edgeLabel, and propertyKey).

The following code snippets are used as an example. For complete codes, see [GraphBase.examples.person-demo](#).

```
<?xml version="1.0" encoding="UTF-8"?>
<schema>
    <vertexLabelList>
        <vertexLabel name="person"/>
        <vertexLabel name="phone"/>
    </vertexLabelList>
    <edgeLabelList>
        <edgeLabel name="friend"/></edgeLabel>
        <edgeLabel name="knows"/></edgeLabel>
        <edgeLabel name="call"/></edgeLabel>
        <edgeLabel name="has"/></edgeLabel>
    </edgeLabelList>
    <propertyKeyList>
        <propertyKey name="name" dataType="STRING"/>
        <propertyKey name="age" dataType="INTEGER"/>
        <propertyKey name="telephone" dataType="STRING"/>
        <propertyKey name="weight" dataType="FLOAT"/>
    </propertyKeyList>
</schema>
```

```
</propertyKeyList>
<graphIndexList>
    <graphIndex name="name_index" elementCategory="VERTEX" type="COMPOSITE">
        <keyTextTypeList name="name" textType="" />
    </graphIndex>
    <graphIndex name="age_index" elementCategory="VERTEX" type="MIXED">
        <keyTextTypeList name="age" textType="DEFAULT" />
    </graphIndex>
    <graphIndex name="telephone_index" elementCategory="VERTEX" type="COMPOSITE">
        <keyTextTypeList name="telephone" textType="" />
    </graphIndex>
    <graphIndex name="weight_index" elementCategory="EDGE" type="MIXED">
        <keyTextTypeList name="weight" textType="DEFAULT" />
    </graphIndex>
</graphIndexList>
</schema>
```

- **vertexLabelList**: indicates the vertex label set. These labels are optional in the preceding XML file, and the label content can be empty.

**vertexLabel**: indicates the vertex label. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name**: indicates the vertex label name, which is mandatory.

- **edgeLabelList**: indicates the edge label list. This parameter can be missing from the preceding XML file, and the parameter value can also be left blank.

**edgeLabel**: indicates an edge label. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name**: indicates the edge label name, which is mandatory.

**primaryKeys**: indicates the primary key to which EdgeLabel are bound with. Multiple primary keys can be specified. This parameter is optional. If there are multiple edges between two vertices and they have the same primaryKeys value, the edges can be considered as the same. For example:

```
<edgeLabel name="friend">
    <primaryKeys>p1</primaryKeys>
    <primaryKeys>p2</primaryKeys>
</edgeLabel>
```

- **propertyKeyList**: indicates the property key set. This parameter can be missing from the preceding XML file, and the parameter value can also be left blank.

**propertyKey**: indicates a property key. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name**: indicates the property name, which is mandatory.

**dataType**: indicates the property value data type, which is optional. The default value is **STRING**.

- **graphIndexList**: indicates the index set. This parameter can be missing from the preceding XML file, and the parameter value can also be left blank.

**graphIndex**: indicates the index. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name**: indicates the index name, which is mandatory.

**elementCategory:** indicates the index entity type, which is mandatory. The options are **VERTEX** and **EDGE**, which is case insensitive.

**type:** indicates the index type, which is mandatory. The options are as follows: **COMPOSITE** (Composite index: internal exact match index with index data stored in HBase) or **MIXED** (mixed index: external mixed match index with index data stored in Elasticsearch) which is case insensitive.

The analyzer cannot be configured by using COMPOSITE indexes.

- If the property key of this index does not contain any Chinese, you do not need to configure the analyzer.
- You can configure the analyzer only for data types, such as TEXT and TEXTSTRING.
- The analyzer can be set for MIXED indexes:
  - ik\_max\_word (fine-grained)
  - ik\_smart (coarse-grained, recommended)

**keyTextTypeList:** indicates the property key list in text format. This parameter can be missing from the preceding XML file, but the parameter value cannot be left blank once the parameter exists.

**name:** indicates the property name, which is mandatory.

**textType:** indicates the index data type. The options are as follows:

- **TEXT:** indicates that the index data is of the text type.
- **TEXTSTRING:** indicates that the index data is of the text string type.
- **PREFIX\_TREE:** indicates that the index is of the geographical location type.
- **DEFAULT:** indicates the default index type. The value is case insensitive and can be empty. If this parameter is left empty, the default type is used.

## NOTICE

- GraphBase index categories:
  - Composite index: is the internal exact match index with the index data stored in HBase and does not support full-text search or splitter.
  - Mixed Index: is the external mixed match index with the index data stored in Elasticsearch and supports full-text search and splitter.
- Suggestions for using GraphBase indexes:
  - When a property is the vertex primary key, an internal index (Composite Index) must be created.
  - You are advised to create mixed indexes in common cases because the index search performance is better and the functions are and richer than the composite index.
- The field definitions in the XML file labels are the same as those in the preceding labels. For details, see "Adding a Vertex Label", "Adding an Edge Label", "Adding a Property Key", "Adding a Graph Index", and "Vertex-centric Index Management" in "GraphBase" of the *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

## 2. Create metadata using the schema file.

REST APIs can be used to upload the schema file. For details, see [Creating a Schema by Uploading an XML File](#) in the sample project.

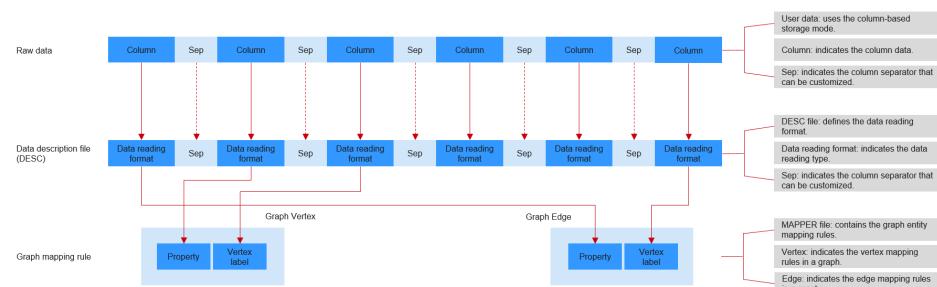

### 1.9.3.2.2 Compiling a Data File (CSV)

#### Data-Related Files

Data-related files are classified into the following types:

1. User data files, also called raw data files that are in CSV format.
2. Data description file is used to define the schema mapping relationship for data, and the file format is DESC.
3. Graph mapping rule file, which defines the mapping between raw data and entities in the graph database. The file format is MAPPER.

The following figure shows the relationship between the three types of files.

## Compiling Raw Data Files

Based on the instructions provided in [Typical Application Scenario](#), define the raw data file as follows (The following code snippets are used as an example. For complete codes, see [GraphBase.examples.person-demo](#)):

Note: The data in each column corresponds to the **index** value of properties in the graph mapping file (.mapper).

```
marko,29,,vadas,27,,knows,0.4,  
marko,29,150000000000,,,0.8,,  
josh,32,1522222222,,0.8,,  
josh,32,,blame,30,,knows,0.4,  
blame,30,136666666666,,,0.8,,  
,,136666666666,,137777777777,,0.6  
,,137777777777,,136666666666,,,0.6  
vadas,27,137777777777,,0.8,,  
marko,29,,josh,32,,friend,1.0,
```

### 1.9.3.2.3 Compiling a Data Description File (DESC)

#### Scenarios

Data description files (in DESC or HVDE format) corresponding to CSV data files are required during data reading.

Based on the information provided in [Typical Application Scenario](#), design data description files as follows (The following code snippets are used as an example. For complete codes, see [GraphBase.examples.person-demo](#)):

```
{"delim":",",  
"includeRowHead":false,  
"attributes": [  
 {"name":"attr_0","type":"STRING","nominalList":[]},  
 {"name":"attr_1","type":"INTEGER","nominalList":[]},  
 {"name":"attr_2","type":"STRING","nominalList":[]},  
 {"name":"attr_3","type":"STRING","nominalList":[]},  
 {"name":"attr_4","type":"INTEGER","nominalList":[]},  
 {"name":"attr_5","type":"STRING","nominalList":[]},  
 {"name":"attr_6","type":"REAL","nominalList":[]},  
 {"name":"attr_7","type":"STRING","nominalList":[]},  
 {"name":"attr_8","type":"REAL","nominalList":[]},  
 {"name":"attr_9","type":"REAL","nominalList":[]} ]}
```

#### File Format Description

For details about the data description files (in DESC format) corresponding to CSV data files, see [Table 1-72](#).

**Table 1-72** Data description file examples

File Format	Description
DESC	<p>The file contains <b>delim</b> and <b>attributes</b>.</p> <ul style="list-style-type: none"><li>• <b>delim</b>: defines the delimiter for data in the CSV data file. Ensure that you use the same delimiter in the CSV data file, otherwise, data fails to be imported, including commas (,), spaces, tabs, and user-defined delimiters. For example, a slash (/) or a colon (:).</li><li>• <b>includeRowHead</b>: specifies whether a header is included. If it is set to <b>false</b>, no header is included. If it is set to <b>true</b>, a header is included.</li><li>• <b>attributes</b>: includes <b>name</b>, <b>type</b>, <b>nominalList</b>, and <b>valueFormat</b>.</li><li>• <b>type</b>: specifies the feature data type, which can be String, Integer, Real, Date, Time, or Timestamp.</li><li>• <b>name</b>: specifies the feature name.</li><li>• <b>nominalList</b>: specifies the enumerated value list.</li><li>• <b>valueFormat</b>: specifies the date format when <b>type</b> is set to <b>DateTime</b>, for example, yyyy-MM-dd HH:mm:ss.</li></ul> <p>Metadata is defined as follows:</p> <pre>{   "delim": ",",   "includeRowHead": false,   "attributes": [     {"name": "name", "type": "STRING", "nominalList": []},     {"name": "date", "type": "DATETIME", "nominalList": [], "valueFormat": "yyyy-MM-dd HH:mm:ss"}   ] }</pre>

 NOTE

- A column name cannot contain special characters, for example, #@\*.
- The yyyyMMdd time format corresponds to year, month, and day. A complete time format is yyyyMMdd HH:mm:ss, corresponding to year, month, day, hour, minute, and second. The common time formats are yyyy/MM/dd and yyyy-MM-dd.

#### 1.9.3.2.4 Compiling a Graph Mapping Rule File (.mapper)

A graph mapping rule describes the mapping between the columns of a data set and the graph elements.

### Scenarios

Based on [Typical Application Scenario](#), design the graph mapping rule file as follows (The following code snippets are used as an example. For complete codes, see [GraphBase.examples.person-demo](#)):

```
{
  "entities": {
    "entity1": {
      "conceptIRI": "person",
```

```
"primaryKey": "name",
"properties": {
    "name": {
        "index": 0
    },
    "age": {
        "index": 1
    }
},
"entity2": {
    "conceptIRI": "phone",
    "primaryKey": "telephone",
    "properties": {
        "telephone": {
            "index": 2
        }
    }
},
"entity3": {
    "conceptIRI": "person",
    "primaryKey": "name",
    "properties": {
        "name": {
            "index": 3
        },
        "age": {
            "index": 4
        }
    }
},
"entity4": {
    "conceptIRI": "phone",
    "primaryKey": "telephone",
    "properties": {
        "telephone": {
            "index": 5
        }
    }
},
"relationships": [
    {
        "source": "entity1",
        "target": "entity2",
        "unique": true,
        "label": "has",
        "properties": {
            "weight": {
                "index": 6
            }
        }
    },
    {
        "source": "entity1",
        "target": "entity3",
        "unique": true,
        "labelType": "columnLookup",
        "labelColumn": {
            "index": 7
        },
        "properties": {
            "weight": {
                "index": 8
            }
        }
    },
    {
        "source": "entity2",
        "target": "entity4",
        "unique": true,
        "label": "isUsedFor"
    }
]
```

```
        "unique": true,
        "label": "call",
        "properties": [
            "weight": {
                "index": 9
            }
        ]
    }
}
```

## File Structure

The basic structure is as follows:

(The texts in bold are the defined property names, which are set by users.) The italic words can be entered by users based on scenarios and requirements. The underscored italic words indicate that the corresponding schemas must be created in the graph in advance.)

```
{
    "entities": {
        "entityName1": {
            "conceptIRI": "conceptName1",
            "primaryKey": "primaryKeyName1",
            "properties": {
                "propertyName1": {
                    "type": "propertyValueType",
                    "": ":{ }"
                },
                "propertyName2": {
                    "type": "propertyValueType",
                    "": ":{ }"
                }
            }
        },
        "entityName2": {
            "conceptIRIType": "constant",
            "conceptIRI": "conceptName2",
            "primaryKey": "primaryKeyName2",
            "properties": {
                "propertyName1": {
                    ...
                }
            }
        }
    },
    "relationships": [
        {
            "source": "entityName1",
            "target": "entityName2",
            "label": "labelName1"
        },
        {
            "source": "entityName3",
            "target": "entityName4",
            "label": "labelName2",
            "properties": {
                "propertyName1": {
                    "type": "propertyValueType",
                    "": ":{ }"
                },
                "propertyName2": {
                    "type": "propertyValueType",
                    "": ":{ }"
                }
            }
        }
    ]
}
```

- **entities** (mandatory): specifies entity sets. Entities indicate vertices in a graph. An entity set contains multiple entities.
- **relationships** (mandatory): specifies relationship sets. Relationships indicate edges in a graph.
- **entityName** (mandatory): specifies the entity name, which identifies an entity object and is referenced when a relationship is defined. In a mapping rule, entities cannot use the same name.

---

**NOTICE**

The entity that is defined after a used name in the graph overwrites the previously defined entity with the same name.

- **conceptIRIType** (optional): specifies the conceptIRI (entity label) definition mode. The available values are **constant** and **columnLookup**. If this parameter is not defined, the default value **constant** is used.
  - **constant**  
Specifies that a constant is defined as conceptIRI.  
Parameter:  
**conceptIRI** (mandatory): specifies an entity label, that is, an entity category. For example, conceptIRI can be a person or an item. **conceptIRI** is a string.
  - **columnLookup**  
Defines a value as the **conceptIRI**.  
Parameter:  
**concept** (mandatory): specifies a label value. The definition method is the same as that used for defining a property value.
- **primaryKey** (mandatory): specifies a primary key, which is the unique identifier of an entity (vertex). For example, the ID card number of a person. The value of **primaryKey** must be a property name in properties, and the property must be of the single type or a combination of required and single. That is, the property value must be a column of values in the input data rather than a multi-condition combination value. In addition, Built-in indexes must be created for the property that is used as a primary key. Currently, only one value can be specified for **primaryKey**, and the value cannot contain multiple primary keys.
- **createIfAbsent** (optional): specifies whether to create an entity when the entity does not exist. That is, whether the entity needs to be imported again. If this parameter is not set, the default value **true** is used.
  - **true**  
If this parameter is set to **true**, the common process is used. Check whether each entity has been imported. If yes, update the properties. If no, create required entities and add corresponding properties for the entities.
  - **false**  
If this parameter is set to **false**, the entity does not need to be imported. You can skip the entity query and property update. If some entities in the

data are not imported before, the entities will not be imported, and the relationships associated with the entities are not imported. If an entity has been imported before, the relationships associated with the entity can still be imported.

Setting this parameter to **false** improves the data import speed and reduces unnecessary query verification. However, you need to set this parameter based on the actual service scenario. In the following two typical scenarios, you are advised to set this parameter to **false**.

- If an exception occurs when data is imported. After the exception is handled, you are advised to import the data again. For example, if an exception occurs when the second entity is imported after the first entity is successfully imported. In this case, you can set this parameter to **false** in the mapping rule of the first entity for the second import. After this configuration, the first entity will be skipped and the data import will start from the second entity where the exception occurred. If the last exception occurs during the relationship import, you can set this parameter to **false** in the mapping rules of all entities for this import. After this configuration, the task will skip the phase of importing entity data, and only the relationship data is imported. In this way, data import speed is greatly improved and the data integrity is not affected.
- Some entities of the data have been imported for other data before. In this case, you must ensure that the entity type IDs of the data exist in the graph and that you do not need to update the property values this time. For example, to import the data relationship table of a transaction, the card numbers in the table have been imported when the card number table is imported. In this case, the card numbers in the transaction exist in the graph, and you do not need to update other property values of the card number. You can set **createIfAbsent** to **false** in the mapping rule of the card number to speed up the import.
- **properties** (mandatory): specifies properties of entities, such as the height and gender of a person. When defining an entity, you must define at least one property as the primary key. Property names, values, and rules must be provided. **propertyName** is defined by users. Property values have multiple types which can be specified by **propertyValueType**. Currently, the following nine types are supported: **single**, **required**, **constant**, **formattedMultiColumn**, **geopoint**, and **geocircle** (mandatory), **geobox**, **mappedMultiColumn**, and **fallback**. If the type is not specified, the default value **single** is used. Multiple property types can be nested. The following uses **ColumnValue** as an example to describe how to nest a property method.
  - **single**  
A column of values in the data set is used as the property values. This is the most common scenario.  
Parameter:  
**index** (mandatory): specifies a column of subscripts corresponding to the property value.
  - **required**

If a property value is defined as **required**, the value cannot be empty. If the value is not defined as **required**, the value can be empty. This definition method needs to be nested with other definition methods.

Parameter:

**Column** (mandatory). The value is **ColumnValue**. This parameter is used to define a value that cannot be empty.

- **constant**

Specifies that the property value is a constant.

Parameter:

**value** (mandatory): The value must be a constant. The value data type can only be a basic type, for example, numeric, string, or Boolean.

- **formattedMultiColumn**

Multiple property values are combined in sequence based on the defined format.

Parameter:

**columns** (mandatory): specifies the definition of multiple values in List[*ColumnValue*] format. Note that the definition sequence is related to the combination sequence.

**format** (mandatory): specifies the combination format. Placeholders are used, for example, %s-%s, indicates that two strings are connected using a hyphen. %d indicates an integer, and %f indicates a floating point number.

- **geopoint**

Specifies the geographical location that indicates the location of a point.

Parameter:

**latitudeColumn** (mandatory): *ColumnValue* Specifies the latitude. The value must be a numeral ranging from -90 to 90.

**longitudeColumn** (mandatory): *ColumnValue* Specifies the longitude. The value must be a numeral ranging from -180 to 180.

- **geocircle**

Specifies a geographical circle, which is determined by the location of a point and its radius.

Parameter:

**latitudeColumn** (mandatory): *ColumnValue* Specifies the latitude. The value must be a numeral ranging from -90 to 90.

**longitudeColumn** (mandatory): *ColumnValue* Specifies the longitude. The value must be a numeral ranging from -180 to 180.

**radiusColumn** (mandatory): *ColumnValue* Specifies the radius. The value must be a numeral. The unit is km.

- **geobox**

Specifies a geographical frame (a trapezoid on a sphere). You can determine the scope of the trapezoid by using the latitude and longitude values in the lower left corner of the rectangle and those in the upper right corner of the trapezoid.

Parameter:

**southWestLatitudeColumn** (mandatory): *ColumnName* Specifies the latitude of the southwest point. The value must be a numeral ranging from -90 to 90.

**southWestLongitudeColumn** (mandatory): *ColumnName* Specifies the longitude of the southwest point. The value must be a numeral ranging from -180 to 180.

**northEastLatitudeColumn** (mandatory): *ColumnName* Specifies the latitude of the northeast point. The value must be a numeral ranging from -90 to 90.

**northEastLongitudeColumn** (mandatory): *ColumnName* Specifies the longitude of the northeast point. The value must be a numeral ranging from -180 to 180.

- **mappedMultiColumn**

Combines multiple values in sequence to obtain a property value. Based on the defined mapping relationship, if the property value meets the mapping relationship, obtain the mapping value based on rules described in the mapping and use the mapping value as the final property value. If the mapping relationship cannot be found, delete the last property value and then search for the mapping relationship. Repeat this operation until only the first property value is left. If no mapping relationship is found still, the default value **null** is returned.

Parameter:

**keyColumns** (mandatory): specifies the definition of multiple values in List[*ColumnName*] format. Note that the definition sequence is related to the combination sequence.

**valueMap** (mandatory): The mapping relationship is in the following format: Map<*String*, *String*>. If a combined value does not meet the mapping requirement, the default value **null** is used. If you want to set the property value to a default value when the mapping rules are not met, you can set a null string as the key in the mapping relationship and set value to the default value.

**separator** (optional): specifies the separator. Separators are connectors between properties. **If this parameter is not specified, a colon (:) is used as the separator by default.**

If the property value is empty, the separator is also used. For example, if three values are defined for **keyColumns**, which are A, B, and C, the processing sequence is as follows:

- i. Combine the three values to obtain **A:B:C**.
- ii. Check whether there is a property whose key is **A:B:C** exists in the mapping. If the property exists, the mapping value is returned. If the property does not exist, delete the last value in the combination to obtain **A:B**.
- iii. Check whether there is a property whose key is **A:B** exists in the mapping. If the property exists, the mapping value is returned. If the property does not exist, delete the last value in the combination to obtain **A**.
- iv. Check whether the property whose key is **A** exists in the mapping. If the property does not exist, delete the last value **A**. In this case, an empty string is left.

- v. Check whether there is a null string mapping in the mapping (that is, the default value). If the mapping exists, the default value is returned. If no mapping is found, the **null** value is returned.
- **fallback**

In this definition method, two *ColumnValue* can be defined. One is active, and the other is the standby. If the active value is null or the value matches the corresponding **fallbackIf** condition, the standby value is used.

Parameter:

**Primarycolumn** (mandatory): *Columnvalue*. Specifies the first value. The property value takes precedence over the value of this parameter. Then, the system determines whether to obtain the standby value based on the condition.

**fallbackColumn** (required): *ColumnValue*. Specifies the standby value. When the primary value is empty or the value meets the **fallbackIf** condition, the value is used as the property value.

**fallbackIf** (mandatory): specifies the predicate, that is, the matching criteria. The following code uses Predicate as an example. Example:

```
"fallbackIf": {  
    "op": "stringEq",  
    "value": "unknown"  
}
```

Currently, the following nine basic conditional expression predicates are supported: **and**, **or**, **isNull**, **not**, **eq**, **stringEq**, **emptyStr**, **moreThan**, and **lessThan**.

- **and**

If multiple conditions are matched at the same time, the value is **true**.

Parameter:

**predicates** (mandatory): List[*Predicate*]: Specifies multiple conditions.

- **or**

If any condition is matched, the value is **true**.

Parameter:

**predicates** (mandatory): List[*Predicate*]: Specifies multiple conditions.

- **isNull**

If the value is empty, the value is **true**.

Specifies that no parameter is set.

- **not**

If criteria is not matched, the value is **true**.

Parameter:

**predicate** (mandatory): specifies the predicate, that is, a single condition.

- **eq**

If the values are the same, the value is **true**.

Parameter:

**value** (mandatory): specifies the value for judgment, which can be a basic type value.

- **stringEq**

If the strings are the same, the value is **true**. You can define whether the strings are case sensitive.

Parameter:

**value** (mandatory): specifies the value for judgment, which is a string.

**caseSensitive** (optional): specifies whether the value is case sensitive. The default value is **false** that is case insensitive.

- **emptyStr**

Checks whether the entered string is empty or all characters are spaces.  
Note: Empty strings are not null.

Specifies that no parameter is set.

- **moreThan**

Checks whether the entered value is greater than the specified value.

Parameter:

Value (mandatory): Specifies the value for judgment. The value must be a number, and the entered value must be a number too.

- **lessThan**

Checks whether the entered value is less than the specified value.

Parameter:

Value (mandatory): Specifies the value for judgment. The value must be a number, and the entered value must be a number too.

- **action**

A property rule is used to perform operations on the property value. The parameter is defined as an action. Currently, the following actions are supported:

**assign**: specifies that the property value is updated.

**assignIfAbsent**: specifies if the property does not exist, the property is updated. If the property does not exist, the property is not updated.

**assignIfBigger**: compares the existing value and a new value of the property to obtain the larger value and then updates the value. Only the numeric type and date type are supported.

**assignIfSmaller**: compares the existing value and a new value of the property to obtain the smaller value and then updates the value. Only the numeric type and date type are supported.

**assignSum**: sums up the existing value and a new value of the property, and then updates the value. Only the numeric type is supported.

If the property field is not set to **action**, the default value **assign** is used.

- The rules for filling in **relationships** are as follows:
- *source* (mandatory): specifies the start entity. The value must be an entity name defined above.
- *target* (mandatory): specifies the target entity. The value must be an entity name defined above.
- *labelType* (optional): specifies the label (relationship) definition mode. The available values are **constant** and **columnLookup**. If this parameter is not defined, the default value **constant** is used.

- **constant**  
Specifies that a constant is defined as conceptIRI.  
Parameter:  
**label** (mandatory): specifies the edge label. The value must be an edge label defined in the graph.
  - **columnLookup**  
Defines a value as the label.  
Parameter:  
**labelColumn** (mandatory): specifies the edge label value. The definition method is the same as that for property values described in the previous content. For details, see the related information provided above.
  - **unique** (optional): specifies whether modification is required based on the original relationship. If this parameter is not set, the default value **false** is used.
    - **true**  
If this parameter is set to **true**, the system checks whether the label relationship exists between the source entity and target entity before you import the relationship. If no, add an edge. If yes, update the attribute based on the original relationship. If there are multiple label relationships between two entities, you can set the **uniqueFilter** field to update a relationship. If the field is not set, the attribute of a relationship corresponding to the label is used for update. If all relationships do not meet the condition, you need to add an edge and ignore the update. The **uniqueFilter** field contains **propertyKey** and **propertyValue**, which respectively indicate the key and value of a special attribute of the edge. Multiple attribute keys can be set in the **uniqueFilter** field. Use commas (,) to separate multiple attribute keys. You can set only **propertyKey** but not **propertyValue**.
- The query rule description is as follows:
- i. If **propertyKey** is configured but **propertyValue** is not configured, the corresponding column value in the data is used for query. If the column value is null, keys are used for query.
  - ii. If **propertyKey** and **propertyValue** are both configured but the value is not null, use the value. If the value is null, replace it with the data in the CSV file.
  - iii. If **propertyKey** and **propertyValue** are both configured but the value is null, only keys are used for query.
- The following is a configuration example of the uniqueFilter in common scenarios:
- The configuration of **uniqueFilter** in common scenarios is as follows:
- ```
"uniqueFilter" : {  
    "propertyKey" : "p1,p2"  
}
```
- **false**  
No query operation is performed before the relationship is imported. The relationship of the corresponding label is directly added, and the original relationship is not changed.

- **optimizeUniqueCheck** (optional): specifies whether to optimize the check of **unique**. This parameter is valid only when **unique** is set to **true**. If this parameter is not set, the default value **false** is used.
  - **true**  
If this parameter is set to **true**, the label relationships to be added between the entities are queried in batches, reducing the number of HBase requests and accelerating the query of **unique**.
  - **false**  
If this parameter is set to **false**, the query is performed only when a relationship is added for two entities.

### NOTICE

Note: When an entity has a large number of identical label relationships (for example, the call between a person and another), setting this parameter to **true** may lead to slow query speed because the amount of returned data is too large or even may cause query failure for insufficient memory. In practical use, estimate the number of entity edges based on the service and data. Use this parameter with caution.

- **Properties** (optional): specifies the properties corresponding to the label. The parameter setting rule is the same as that for the entity property.

## Example

Assume that the node input mapping rules are as follows. For the meanings of the mapping rules, see the comments on the right of these rules.

```
{  
    "entities": {  
        "person": { // Defines an entity and is named as person. This name is used only when relationships is defined and it does not need to be defined in the schema.  
            "conceptIRI": "person", // The entity label is person, and conceptIRIType is omitted here. The default value is constant, that is, the value of conceptIRI is directly defined. The other islabel is columnLookup. For details, see the employer entity described below.  
            "primaryKey": "UID", // The entity ID is the property value whose name is UID in properties below. You can use this ID to uniquely identify an entity in the graph.  
            "properties": { // Defines the properties of person. UID and Name are property names, and their values are property values.  
                "UID": {  
                    "type": "required", // If this parameter is set to required, the value cannot be empty. If the value is empty, an error is reported.  
                    "column": {  
                        "index": 0,  
                    }  
                },  
                "Name": {  
                    "type": "formattedMultiColumn", // formattedMultiColumn indicates that Name is composed of the values whose subscript are 1 and 2, respectively, in the format of %s-%s. For example, the values whose subscripts are 1 and 2 are zhang and san, respectively. Name is zhang-san.  
                    "columns": [  
                        {  
                            "index": 1  
                        },  
                        {  
                            "index": 2  
                        }  
                    ]  
                }  
            }  
        }  
    }  
}
```

```

        ],
        "format": "%s-%s"
    },
    "shortName": {
        "type": "mappedMultiColumn",      // mappedMultiColumn indicates that the value of shortName
is composed of the value whose subscript is 1 and the value whose subscript is 2, and the two values are
separated by a colon (:). It is used to check whether the combination result has a mapping in valueMap.
        "keyColumns": [      // If the mapping exists, use the mapping value. For example, if the value
whose subscript 1 is zhang and the value whose subscript is 2 is san, the combination is zhang:san. In
valueMap, the value of zhang:san is zs. Therefore, the value of shortName is zs.
9           {      // If the mapping does not exist, remove the last value of the combination result and then
search for the mapping. For example, if the value whose subscript is 1 is zhao, and the value whose
subscript is 2 is wu, the combination is zhao:wu.
        "index": 1      // If valueMap does not contain zhao:wu, remove wu, and only zhao is left.
valueMap still does not contain the keyword zhao. Delete zhao to obtain an empty string.
        },      // The value corresponding to an empty string in valueMap is no short name. Therefore,
the value of shortName is no short name.
        {      // If the mapping corresponding to an empty string is not defined in valueMap, the value of
shortName is null.
            "index": 2
        }
    ],
    "valueMap": {
        "": "no short name",
        "zhang:san": "zs",
        "li:si": "ls"
    },
    "separator": ":"      // This parameter is optional. If separator is not defined, the default value is a
colon(:).
},
"BIRTH DATE": {
    "type": "single",      // single indicates that the value of BIRTH DATE is the value whose subscript is
3. The property value type is single by default, which can be omitted. For example, the following property
Married, its property type is ommited.
    "index": 3
},
"Married": {
    "index": 4      // The type single is omitted.
},
"Deceased": {
    "type": "constant",      // constant indicates that all Deceased properties are set to false.
    "value": "false"
},
"Home Address": {
    "type": "geopoint",      // geopoint indicates that the value of Home Address is the location
corresponding to the combination of the value whose latitude is the value of subscript 5 and the value
whose longitude is the value of subscript 6.
    "latitudeColumn": {
        "index": 5
    },
    "longitudeColumn": {
        "index": 6
    }
},
"Home Area": {
    "type": "geocircle",      // geocircle indicates that the value of Home Area is the scope that the
latitude is subscript 7, the longitude is subscript 8, and the radius is subscript 9.
    "latitudeColumn": {
        "index": 7
    },
    "longitudeColumn": {
        "index": 8
    },
    "radiusColumn": {
        "index": 9
    }
},
"Country Area": {
    "type": "geobox",      // geobox indicates that the value of Country Area is a geographical area
}

```

with the latitude ranges from the value of subscript 10 to that of subscript 12, the longitude ranges from the value of subscript 11 to that of subscript 13.

```

    "southWestLatitudeColumn": {
        "index": 10
    },
    "southWestLongitudeColumn": {
        "index": 11
    },
    "northEastLatitudeColumn": {
        "index": 12
    },
    "northEastLongitudeColumn": {
        "index": 13
    }
},
"employer": { // Defines an entity named employer
    "conceptIRIType": "columnLookup", // If conceptIRIType is set to columnLookup, a value is defined to indicate the conceptIRI. For example, the value of the subscript 14 is used as the conceptIRI.
        "concept": {"index": 14},
        "primaryKey": "companyName",
        "properties": {
            "companyName": {
                "index": 15
            },
            "locationAddress": {
                "type": "geopoint",
                "latitudeColumn": {

                "index": 21
            }
        }
    },
    "social utility": {
        "conceptIRI": "utility",
        "primaryKey": "userID",
        "properties": {
            "userID": {
                "index": 23
            }
        }
    },
    "relationships": [
        {
            "source": "person", // indicates the relationship that the person lives at home.
            "target": "home",
            "label": "livesAt"
        },
        {
            "source": "employer",
            "target": "person",
            "label": "employs",
            "unique": true, // This parameter is optional. If unique is not defined, the default value false is used, indicating that an employs relationship is added. If this parameter is set to true, the full-time property is updated in the original relationship when the employs relationship already exists between employer and person.
            "uniqueFilter":{} //This parameter is optional when unique is set to true. Based on this filter condition, update an edge between the two vertices in the same label. This parameter is left blank when unique is set to false.
            "propertyKey": "place",
            "propertyValue": "xian"
        },
        "properties": {} // Properties are not mandatory. For example, the preceding relationship does not have properties.
        "full-time": {
            "index": 24
        }
    ],
    {
        "source": "person",
        "target": "social utility",
        "labelType": "columnLookup", // If labelType is set to columnLookup, a value is defined to indicate the label. For example, the value of the subscript 27 is defined and used as the label.
        "labelColumn": {
            "index": 27
        },
        "properties": {
            "twitter": {
                "index": 25
            },
            "facebook": {
                "index": 26
            }
        }
    }
]
```

### 1.9.3.3 Importing Data

### 1.9.3.3.1 Importing Data in Batches Using Tools

#### ⚠ CAUTION

Data inconsistency occurs when GraphBase imports and deletes data at the same time. If you are using a data ingestion tool on the client, ensure that no batch deletion is executed at the same time.

The system automatically checks whether there are other asynchronous tasks when tasks are submitted through a REST API. You are advised to use the REST API **graphwriter** to submit batch import tasks.

## Prerequisites

1. Install clients for all components in the cluster.
2. A graph has been created. For details about how to create a graph, see [Creating or Deleting a Graph](#).
3. A schema file (for example, an XML file) has been prepared and uploaded. For details about how to upload a schema file, see [Creating a Schema by Uploading an XML File](#).
4. You have prepared the data file (for example, a CSV file). For details about how to prepare a data file, see the example on the GraphBase client in the `/opt/hadoopclient/GraphBase/examples/person-demo/` directory.  
For details about the data description file (DESC file), see [Compiling a Data Description File \(DESC\)](#).  
The graph mapping rule file (.mapper file) has been uploaded. For details, see [Compiling a Graph Mapping Rule File \(.mapper\)](#).
5. Required users have been created and the authentication files have been downloaded. For details about how to create a user, see [Preparing a Developer Account](#).

#### 📖 NOTE

The created user must have the rights of the **graphbaseadmin** user group.

## (Optional) Change the default username

Spark and the username are configured in the configuration **resource.properties** in the `/opt/hadoopclient/GraphBase/graphwriter/conf/` directory, as shown in the following:

```
USERNAME = graphtest  
BINDING_SPARK_SERVICE = Spark  
RESOURCE = --executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2 --conf  
spark.yarn.security.credentials.hbase.enabled=true --conf spark.inputFormat.cache.enabled=false
```

1. If the created username is **graphtest**, you do not need to change the username. Otherwise, change the username to the created username.
2. Configure the **RESOURCE** parameter as required. You can also add Spark advanced parameters, for example **--conf spark.default.parallelism** that is set to **105**.

When data is imported in batches, the Yarn resource queue in Spark parameters is the default queue. To change the default resource queue, add

the **--conf spark.yarn.queue** parameter and set it to the specified queue name in the **RESOURCE** parameter. For details about how to configure Yarn resource queues, see section "Tenant Resources" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1) in the MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

## Upload related files

1. Upload user authentication files.

Use WinSCP to upload the downloaded user authentication files **krb5.conf** and **user.keytab** to the **/opt/hadoopclient/GraphBase/graphwriter/conf** directory on the GraphBase client, as shown in the following figure.

```
[root@hd-184 conf]#ll
total 16
-rwxr-xr-x 1 root root 1178 Nov 25 15:58 janusgraph-loading.properties
-rw-r--r-- 1 root root 1255 Nov 26 19:02 krb5.conf
-rwxr-xr-x 1 root root 108 Nov 25 15:58 resource.properties
-rw-r--r-- 1 root root 142 Nov 26 19:02 user.keytab
```

2. Upload data files to the HDFS.

Switch to the **/graphwriter** directory in the installation directory of the GraphBase client.

```
cd /opt/hadoopclient/GraphBase/graphwriter
```

Run the following command to execute environment variables:

```
source /opt/hadoopclient/bigdata_env
```

Log in to the system as a GraphBase user and enter the password (specified by the user).

```
kinit graphtest
```

Create a directory storing HDFS files. (If the directory exists, skip this operation.)

```
hdfs dfs -mkdir /user/graphtest
```

Upload the data files to the **/user/graphtest** directory (for example, **person-demo**) of the HDFS.

```
hdfs dfs -put ..//examples/person-demo/Person.csv ..//examples/person-demo/Person.csv.mapper ..//examples/person-demo/Person.desc /user/graphtest
```

The details are shown in the following figure.

```
hadoopNode2:/opt/graphbaseClient/GraphBase/graphwriter # hdfs dfs -ls /user/graphtest
Found 7 items
-rw-r--r-- 3 root hadoop 100 2018-08-04 14:47 /user/graphtest/Person.csv
-rw-r--r-- 3 root hadoop 740 2018-08-04 14:47 /user/graphtest/Person.csv.mapper
-rw-r--r-- 3 root hadoop 368 2018-08-04 14:47 /user/graphtest/Person.desc
```

## Importing Data

Execute the following script and transfer the *graphName* parameter (*graphName* is user-defined that must exist. If it does not exist, create the graph first.)

```
./bin/graphWriter.sh graphName /user/graphtest/Person.csv /user/graphtest/Person.csv.mapper /user/graphtest/Person.desc
```

Note: The data file path must be an HDFS path that is in the following format:  
*Data file/Data mapping file.mapper/Metadata file.desc*

If no metadata file exists, the file path is: *Data file/Data mapping file.mapper*

After the script is executed, the following information is displayed:

```
hadoopNode2:/opt/graphbaseclient/graphBase/graphWriter # ./bin/graphWriter.sh graphName /user/graphtest/Person.csv /user/graphtest/Person.csv.mapper /user/graphtest/Person.desc
RESOURCE= -executor-memory 5g -driver-memory 5g --num-executors 5 --executor-cores 5
USERNAME= graphtest
spark.yarn.am.cores is set but does not apply in cluster mode.
spark.yarn.am.cores is set but does not apply in cluster mode.
2018-08-06 11:31:09.510 | WARN | main | Unable to load native-hadoop library for your platform... using builtin-java classes where applicable | org.apache.hadoop.util.N
der.<clinit>(NativeCodeLoader.java:62)

```

#### NOTE

During data import, if the feature data type (type attribute in attributes) configured in the data description file (.desc file) is different from the data type in the data file (for example, .csv file) to be imported, the batch import tool ignores data of different data types by default and imports only the data of the same type in the data description file and data file. For example, the type of data in a column defined in the data description file is "REAL", as indicated by the following: {"name": "Attr\_0", "type": "REAL", "nominalList": []}. In the data file to be imported, the data of the corresponding column is the character string "mary". The data type of "mary" is STRING, which is inconsistent with the "REAL" type in the description file. In this case, when the batch import tool is used to import data, the data of this error type is ignored and will not be imported.

### 1.9.3.3.2 Importing Data in Real Time Using Tool

Data import in real time is implemented by using SparkStreaming. After SparkStreaming is started, data is read from the corresponding topic based on the configuration and then imported to GraphBase.

#### CAUTION

Data inconsistency occurs when GraphBase imports and deletes data at the same time. If you are using a data ingestion tool on the client, ensure that no batch deletion is executed at the same time.

## Prerequisites

1. Install clients for all components in the cluster.
2. The schema file (that is, the XML file) has been uploaded. For details, see [Creating a Schema by Uploading an XML File](#).
3. The graph mapping rule file (.mapper file) has been uploaded. For details, see [Compiling a Graph Mapping Rule File \(.mapper\)](#).
4. Required users have been created and the authentication files have been downloaded. For details about how to create a user, see [Preparing a Developer Account](#).

#### NOTE

The created user must have the rights of the **graphbaseadmin** user group.

5. The Kafka parameter **allow.everyone.if.no.acl.found** has been set to **true**, and the Kafka service has been restarted.

| Parameter                      | Value   |
|--------------------------------|---|
| <b>Kafka-&gt;Broker</b>        |   |
| allow.everyone.if.no.acl.found | <input checked="" type="radio"/> true <input type="radio"/> false |

## Modify the configuration file

The configuration file directory is **/opt/hadoopclient/GraphBase/graphstream/conf/**.

1. Modify the **graph-streaming.properties** file.

The parameter configuration is listed in the following table.

| Parameter                            | Description  | Example  |
|--------------------------------------|--|--|
| graph.user.name                      | Specifies the name of the user to be created.  | graphtest  |
| spark.streaming.checkpoint.directory | Specifies the HDFS directory of the SparkStreaming checkpoint. If the directory does not exist, create it in advance. (It is recommended that this directory be created separately because a large number of checkpoint files are generated during the program running.) | /user/graphtest/graphstreaming/checkpoint          |
| spark.streaming.batch.time           | Specifies the time spent by SparkStreaming on data processing in batches. The unit is s.   | 1  |
| spark.streaming.partition.number     | Specifies the number of partitions of the node where SparkStreaming resides.   | 50   |
| kafka.topic.name                     | Specifies the name of the topic where data needs to be consumed.   | Person.csv   |
| kafka.metadata.broker.list           | Specifies the IP address of the node where Kafka metadata resides (manual configuration is not required).  | 10.3.70.133:21005,10.3.1.67:21005,10.3.71.24:21005 |

| Parameter                     | Description  | Example  |
|-------------------------------|--|--|
| csv.mapper.hdfs.file          | Specifies the path of the Mapper file in the HDFS.   | /user/graphtest/graphstreaming/Person.csv.mapper |
| kafka.save.failed.message     | Specifies whether to save failure messages. The available values are <b>false</b> and <b>true</b> . <b>false</b> indicates that the failure message is not saved, and <b>true</b> indicates the reverse. | false  |
| kafka.save.failed.to.pic.name | Specifies that the failure messages are saved as Kafka topic names.  | default  |
| kafka.topic.message.separator | Specifies a separator of Kafka messages.   | ,  |

- Set the **RESOURCE** parameter.

In **resource.properties**, allocate resources based on YARN resource usage. Ensure that the resources to be allocated do not exceed the total resources of YARN.

```
RESOURCE='--executor-memory 4g --driver-memory 2g --num-executors 5 --executor-cores 5'.
```

When data is imported in batches, the Yarn resource queue in Spark parameters is the default queue. To change the default resource queue, add the **--conf spark.yarn.queue** parameter and set it to the specified queue name in the **RESOURCE** parameter.

## Upload related files

- Upload user authentication files.

Use WinSCP to upload the downloaded user authentication files **krb5.conf** and **user.keytab** to the **/opt/hadoopclient/GraphBase/graphstream/conf** directory on the GraphBase client.

- Upload the customized Mapper file to the HDFS.

Execute environment variables as user **root** (**/opt/hadoopclient/** is the installation directory of the cluster client).

```
source /opt/hadoopclient/bigdata_env
```

Log in to the system as user **weaver** using the user account and password (specified by the user).

```
kinit graphtest
```

Create a directory storing HDFS files. (If the directory exists, skip this operation.)

```
hdfs dfs -mkdir /user/graphtest/graphstreaming
```

Upload the MAPPER data file to the **/user/graphtest/graphstreaming** directory of HDFS (Take the **person-demo** directory as an example).

```
hdfs dfs -put /opt/hadoopclient/GraphBase/examples/person-demo/  
Person.csv.mapper /user/graphtest/graphstreaming
```

## Create a topic

The APIs or scripts of Kafka can be used to create topics. For details, see "Managing Kafka Themes" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

## Importing Data

1. Go to the **graphstream** directory.

```
cd /opt/hadoopclient/GraphBase/graphstream
```

2. Execute the following script and transfer the *graphbase* parameter (*graphbase* is user-defined that must exist. If it does not exist, create the graph first. Before you create the graph, ensure that all prerequisites have been completed):

```
./bin/graphStreaming.sh graphbase
```

If you need to customize the path of the configuration file, you can specify a local absolute path for the configuration file and copy the information in **graph-streaming.properties** to the configuration file. If the path is not specified, the **graph-streaming.properties** file in the **conf/** directory is used as the configuration file by default. Example:

```
./bin/graphStreaming.sh graphbase /opt/hadoopclient/GraphBase/  
graphstream/conf/graph-streaming.properties
```

3. (Optional) Send a message to the **Person.csv** topic.

Send the message by following the following procedure:

- a. Upload data files. If the HDFS directory does not exist, create it in advance.

```
hdfs dfs -put ..//examples/person-demo/Person.csv /user/graphtest/  
graphstreaming/data
```

Run the **vi conf/graph-producer.properties** command to configure the **graph-producer.properties** file in **conf**. The parameter configuration in this file is listed as follows.

| Parameter        | Description  | Example          |
|------------------|--|------------------|
| graph.user.name  | Specifies the name of the user to be created.                    | <b>graphtest</b> |
| kafka.topic.name | Specifies the name of the topic where data needs to be consumed. | Person.csv       |

| Parameter                  | Description   | Example   |
|----------------------------|---|---|
| kafka.metadata.broker.list | Specifies the IP address of the node where Kafka metadata resides (manual configuration is not required). | 10.3.70.133:21005,10.3.71.67:21005,10.3.71.24:21005 |
| csv.data.hdfs.directory    | Specifies the directory for storing data in the HDFS.   | /user/graphtest/graphstreaming/data                 |

- b. Run the following command to send a message to a specified Kafka topic:

**./bin/graphProducer.sh**

This mode is used to test the production data. You can use other methods too.

## Monitor tasks

1. Click **ApplicationMaster** on the YARN task page to go to the Spark task page.

2. Click **Streaming**.

3. Check the processing progress.

| Batch Time          | Input Size     | Scheduling Delay <small>(?)</small> | Processing Time <small>(?)</small> | Total Delay <small>(?)</small> |
|---------------------|----------------|-------------------------------------|------------------------------------|--------------------------------|
| 2018/07/19 11:43:40 | 3579000 events | 42 min                              | 3.6 min                            | 45 min                         |
| 2018/07/19 11:43:30 | 3690000 events | 38 min                              | 3.9 min                            | 42 min                         |
| 2018/07/19 11:43:20 | 3608500 events | 34 min                              | 3.7 min                            | 38 min                         |
| 2018/07/19 11:43:10 | 3294500 events | 31 min                              | 3.4 min                            | 35 min                         |
| 2018/07/19 11:43:00 | 3675000 events | 27 min                              | 3.9 min                            | 31 min                         |
| 2018/07/19 11:42:50 | 9673500 events | 24 min                              | 3.8 min                            | 28 min                         |

## Tune parameters

- The product of the number of executors and the number of cores of each executor determines the task concurrency capability. The value of **spark.streaming.partition.number** determines the total number of tasks that can be started.  
If the resources are sufficient, you can set the executor and partition quantities to the same.
- spark.streaming.batch.time** of SparkStreaming and the data traffic of Kafka messages determine the amount of data that can be processed by SparkStreaming at a certain time. The data is distributed on each partition.  
The data traffic value is negatively correlated with the batchtime value. If the data traffic is small, set **batchtime** to a larger value. Otherwise, set **batchtime** to a small value. In this way, the amount of data to be processed can be ensured moderate.

## Stop a job

After a SparkStreaming task is submitted, it keeps running and reads messages from Kafka. To stop the task, perform the following operations: Obtain the submitted task ID on the YARN web client. Run the **yarn application -kill \${appid}** command to kill the task. Example: **yarn application -kill \$Application\_1530539359099\_0053** If no data is queried after the data import, kill the task and collect logs. Search for **ERROR** in the logs, and identify the cause. Run the following command to collect logs:

```
yarn logs -applicationId ${appid} > log
```

### 1.9.3.3.3 Using the Hive Data Import Tool

 CAUTION

Data inconsistency occurs when GraphBase imports and deletes data at the same time. If you are using a data ingestion tool on the client, ensure that no batch deletion is executed at the same time.

## Prerequisites

1. Install clients for all components in the cluster.
2. Create a graph by referring to [Creating or Deleting a Graph](#).
3. Prepare and upload a schema file (for example, an XML file) by referring to [Creating a Schema by Uploading an XML File](#).
4. The Hive component has been installed in the cluster.
5. Prepare a Hive table. The field names in the figure can be different from those in the Hive table. Compile a graph mapping rule file (**.mapper** file) based on the data columns of vertices and edges in Hive. For details, see [Compiling a Graph Mapping Rule File \(.mapper\)](#).
6. Create a user (with the Hive permission) and download the authentication file to **/opt/hadoopclient/GraphBase/graphwriter/conf**. For details, see section [Preparing a Developer Account](#).
7. For details about how to create Hive data, see section [Developing an Application](#).

## Modify the configuration file

The configuration file directory is **/opt/hadoopclient/GraphBase/graphwriter/conf/**.

1. Modify the **hiveTable.properties** file.

The parameter configuration is listed in the following table.

| Parameter        | Description   | Example       |
|------------------|---|---------------|
| table.namespace  | Indicates the namespace where the Hive table is located. Retain the <b>default</b> value.   | default       |
| table.tablename  | Indicates the Hive table name.  | table1        |
| table.columns    | Indicates the columns to be selected in the table. By default, the asterisk (*) indicates a global column. Multiple column names are separated by commas (,). | * or name,age |
| table.conditions | Indicates that you can write a condition expression to select the column that meets the condition. The format is the same as that of the WHERE clause.        | age=20        |

## 2. Set the **RESOURCE** parameter.

In **resource.properties**, allocate resources based on YARN resource usage. Ensure that the resources to be allocated do not exceed the total resources of YARN.

`RESOURCE="--executor-memory 4g --driver-memory 2g --num-executors 5 --executor-cores 5"`

When data is imported in real time, the YARN resource queue in Spark parameters is the default queue. To change the default resource queue, add the **--conf spark.yarn.queue=default** parameter and set it to the specified queue name in the **RESOURCE** parameter.

## Import data

Run the following script that contains the graph name (*graphName* is a user-defined graph name and must exist. If the graph name does not exist, create it first.) and the mapper file path (the mapper file path must be an HDFS path).

`./bin/hiveWriter.sh graphName /user/graphtest/xxx.mapper`

Example description:

```
CREATE EXTERNAL TABLE IF NOT EXISTS table1  
(
```

```
sourcelD STRING,  
targetId STRING,  
attr1 STRING,  
attr2 STRING  
)  
ROW FORMAT delimited fields terminated by ','  
STORED AS TEXTFILE;
```

Create the preceding Hive table. **sourcelD** corresponds to the primary key attribute of the start vertex, and **targetId** corresponds to the primary key attribute of the end vertex. If the start vertex and end vertex are not of the same type (for example, the start vertex is an ID card number and the end vertex is a mobile number), **entities** in the mapper file are defined as follows:

```
"entities": {  
  "entity1": {  
    "conceptIRI": "person",  
    "primaryKey": "idCard",  
    "properties": {  
      "name": {  
        "index": 0  
      }  
    }  
  },  
  "entity2": {  
    "conceptIRI": "phone",  
    "primaryKey": "phoneNum",  
    "properties": {  
      "name": {  
        "index": 1  
      }  
    }  
  }  
}
```

If the start vertex and end vertex are of the same type (for example, the start vertex is a mobile number and the end vertex is a mobile number), entities in the mapper file are defined as follows:

```
"entities": {  
  "entity1": {  
    "conceptIRI": "phone",  
    "primaryKey": "phoneNum",  
    "properties": {  
      "name": {  
        "index": 0  
      }  
    }  
  },  
  "entity2": {  
    "conceptIRI": "phone",  
    "primaryKey": "phoneNum",  
    "properties": {  
      "name": {  
        "index": 1  
      }  
    }  
  }  
}
```

#### 1.9.3.4 Data Export

##### NOTE

When exporting data, check whether the specified HDFS path exists. If it does not, check whether the default HDFS path exists. If it does, delete the path. Otherwise, an error is reported and the task fails.

## Prerequisites

1. Install clients for all components in the cluster.
2. Create a user and download the authentication file. For details, see section [Preparing a Developer Account](#).

## Uploading User Authentication Files

Use WinSCP to upload the downloaded user authentication files **krb5.conf** and **user.keytab** to the **/opt/graphbaseClient/GraphBase/graphwriter/conf** directory on the GraphBase client, as shown in the following figure.

```
[root@8-5-199-1 conf]# ll
total 24
-rwxr-xr-x 1 root root 171 Mar  2 17:39 edge.properties
-rwxr-xr-x 1 root root 1347 Mar  2 17:39 janusgraph-loading.properties
-rwxr-xr-x 1 root root 1239 Mar  2 17:36 krb5.conf
-rwxr-xr-x 1 root root 223 Mar  2 17:36 resource.properties
-rwxr-xr-x 1 root root 122 Mar  2 17:36 user.keytab
-rwxr-xr-x 1 root root 99 Mar  2 17:38 vertex.properties
```

## Configuring Data Collection

The mapper file is used to collect the parameter information required during the export. The following figure shows the relationships between the vertex with label set to Person and Tag and the edge with label set to hasInterest:

The mapper file of the Person vertex is as follows:

```
{
  "entities": {
    "entity1": {
      "conceptIRI": "Person",           ----- This item specifies label (type) of the vertex.
      "primaryKey": "personId",        ----- This item specifies primaryKey of the vertex.
      "properties": {
        "personId": {                 ----- This item specifies the attribute key of the vertex.
          "index": 0
        },
        "firstName": {                ----- This item specifies the attribute key of the vertex.
          "index": 1
        },
        "lastName": {                  ----- This item specifies the attribute key of the vertex.
          "index": 2
        },
        "gender": {                   ----- This item specifies the attribute key of the vertex.
          "index": 3
        },
        "birthDay": {                  ----- This item specifies the attribute key of the vertex.
          "index": 4
        },
        "creationDate": {             ----- This item specifies the attribute key of the vertex.
          "index": 5
        },
        "locationIP": {               ----- This item specifies the attribute key of the vertex.
          "index": 6
        },
        "browserUsed": {              ----- This item specifies the attribute key of the vertex.
          "index": 7
        }
      }
    }
}
```

```
    }
}
}
```

The mapper file of the Tag vertex is as follows:

```
{
  "entities": {
    "entity1": {
      "conceptIRI": "Tag",           ----- This item specifies label (type) of the vertex.
      "primaryKey": "tagId",        ----- This item specifies primaryKey of the vertex.
      "properties": {
        "tagId": {                  ----- This item specifies the attribute key of the vertex.
          "index": 0
        },
        "name": {                   ----- This item specifies the attribute key of the vertex.
          "index": 1
        },
        "url": {                    ----- This item specifies the attribute key of the vertex.
          "index": 2
        }
      }
    }
}
```

The mapper file of the hasInterest edge is as follows:

```
{
  "entities": {
    "sourceEntity": {             ----- This item specifies the attribute of the outvertex.
      "conceptIRI": "Person",     ----- This item specifies the label (type) of the outvertex.
      "primaryKey": "personId",  ----- This item specifies the primaryKey of the outvertex.
      "createIfAbsent": false,
      "properties": {
        "personId": {            ----- This item specifies the attribute key of the outvertex.
          "index": 0
        }
      }
    },
    "targetEntity": {             ----- This item specifies the attribute of the invertex.
      "conceptIRI": "Tag",       ----- This item specifies the label (type) of the invertex.
      "primaryKey": "tagId",    ----- This item specifies the primaryKey of the invertex.
      "createIfAbsent": false,
      "properties": {
        "tagId": {              ----- This item specifies the attribute key of the invertex.
          "index": 1
        }
      }
    },
    "relationships": [
      {
        "source": "sourceEntity",  ----- This item specifies the entity of the outvertex.
        "target": "targetEntity",  ----- This item specifies the entity of the invertex.
        "labelType": "constant",  ----- This item specifies the labelType of the edge
        "label": "hasInterest"
      }
    ]
}
```

## Modifying Configuration Files

The configuration file directory is **/opt/hadoopclient/GraphBase/graphreader/conf/**.

1. Modify the **vertex.properties** file.

The parameter configurations are listed in the following table.

| Parameter         | Definition   | Example                    |
|-------------------|--|----------------------------|
| graphname         | Name of the graph instance to be operated. This parameter is mandatory.  | graphbase                  |
| label             | Type of the vertex to be exported. This parameter is mandatory.  | Forum                      |
| propertykeylist   | Property key list of the vertex to be exported. This parameter is mandatory. The primary key must be specified. If multiple properties need to be exported, separate the property keys by commas (,). The primary key must be placed in the first place.   | forumId,title,creationDate |
| dest.storage.path | HDFS path for storing the data to be exported. This parameter is optional and not recommended. Assume that the current domain name is HADOOP.COM, by default, the data is stored in <b>/user/graphtest@HADOO P.COM/graphbase/vertex/Person</b> . In the preceding directory, <b>graphtest</b> indicates the user name, <b>graphbase</b> indicates the graph name, and <b>Person</b> indicates the vertex type. | /user/vertex               |

| Parameter | Definition  | Example   |
|-----------|---|---|
| delimiter | Separator between properties of the data to be exported. The separator can be a common character, a special character, or a unicode. The separators specified for exporting the incoming and outgoing vertices must be the same. If you do not configure this parameter, commas (,) are used as the separators by default. This parameter is optional.    | \u002a  |
| filters   | Filtering conditions of properties in the data to be exported. The data format is JSONArray. For details, see the description for <i>PropertyFilter</i> in section "GraphBase" > "REST" > "Performing Full Graph Query on Vertices" in <i>MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)</i> . This parameter is optional | [<br>{"propertyName":"age","predicate":">>","values":[27]},<br>{"propertyName":"name","predicate":}"string_contains _prefix","values":["m"]}] |

## 2. Modify the **edge.properties** file.

The parameter configuration is listed in the following table.

| Parameter | Definition  | Example   |
|-----------|---|-----------|
| graphname | Name of the diagram instance to be operated. This parameter is mandatory. | graphbase |

| Parameter            | Definition  | Example   |
|----------------------|---|-----------|
| label                | Type of the edge to be exported. This parameter is mandatory.   | hasMember |
| outvertex.label      | Type of the outvertex at the two vertices corresponding to the edge to be exported. This parameter is mandatory.  | Forum     |
| invertex.label       | Type of the invertex at the two vertices corresponding to the edge to be exported. This parameter is mandatory.   | Person    |
| nvertex.primarykey   | The primary key of the incoming vertex of the edge to be exported. This parameter is mandatory.   | forumId   |
| outvertex.primarykey | The primary key of the outgoing vertex of the edge to be exported. This parameter is mandatory.   | personId  |
| propertykeylist      | Attribute key list of the edge to be exported. This parameter is optional. If multiple attributes need to be exported, use commas (,) to separate all attribute keys. | joinDate  |

| Parameter         | Definition   | Example    |
|-------------------|--|------------|
| dest.storage.path | HDFS path for storing the data to be exported. This parameter is optional and not recommended. Assume that the current domain name is HADOOP.COM, by default, the data is stored in <b>/user/graphtest@HADOO P.COM/graphbase/edge/friend</b> . In the preceding path, <b>graphtest</b> is the created username, <b>graphbase</b> is the graph name, and <b>friend</b> is the type of the edge. | /user/edge |
| delimiter         | Separator between attributes of the data to be exported. The separator can be a common character, a special character, or a unicode. The separators specified for exporting the incoming and outgoing vertices must be the same. If you do not configure this parameter, commas (,) are used as the separators by default. This parameter is optional.   | \u002a     |

| Parameter | Definition   | Example   |
|-----------|--|---|
| filters   | Filtering conditions of properties in the data to be exported. The data format is JSONArray. For details, see the description for <i>PropertyFilter</i> in section "GraphBase" > "REST" > "Performing Full Graph Query on Vertices" in <i>MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)</i> . This parameter is optional. | [<br>{"propertyName":"age","predicate":">>","values":[27]},<br>{"propertyName":"name","predicate":}"string_contains _prefix","values":["m"]}<br>] |

### 3. Modify the **resource.properties** file.

The parameter configurations are listed in the following table.

| Parameter             | Definition   | Example   |
|-----------------------|--|---|
| USERNAME              | Name of a user to be created.                                      | graphtest                                       |
| BINDING_SPARK_SERVICE | Bound Spark service, which is used to adapt to multiple instances. | Spark   |
| RESOURCE              | --executor-memory  | Memory size allocated to each executor in Spark |
|                       | --driver-memory  | Memory size allocated to driver in Spark        |
|                       | --num-executors  | Number of executors started by Spark            |
|                       | --executor-cores   | Number of cores started in each executor        |

| Parameter | Definition  | Example |
|-----------|---|---------|
|           | --conf spark.hbase.obtainToken.enabled<br>Whether to dynamically obtain the token information of the HBase. | true    |
|           | --conf spark.inputFormat.cache.enabled<br>Whether to enable the HBase cache                                 | false   |

### NOTE

The following special characters can be used as separators.

\u0020 Space  
\u0021 ! Exclamation mark  
\u0022 " Double quotation marks  
\u0023 # Pond key  
\u0024 \$ Currency symbol  
\u0025 % Percentage symbol  
\u0026 & And sign  
\u0027 ' Single quotation mark  
\u0028 ( Open parenthesis  
\u0029 ) Close parenthesis  
\u002a \* Asterisk  
\u002b + Plus sign  
\u002c , Comma  
\u002d - Hyphen

## Parameter Optimization

### 1. Parameter Description

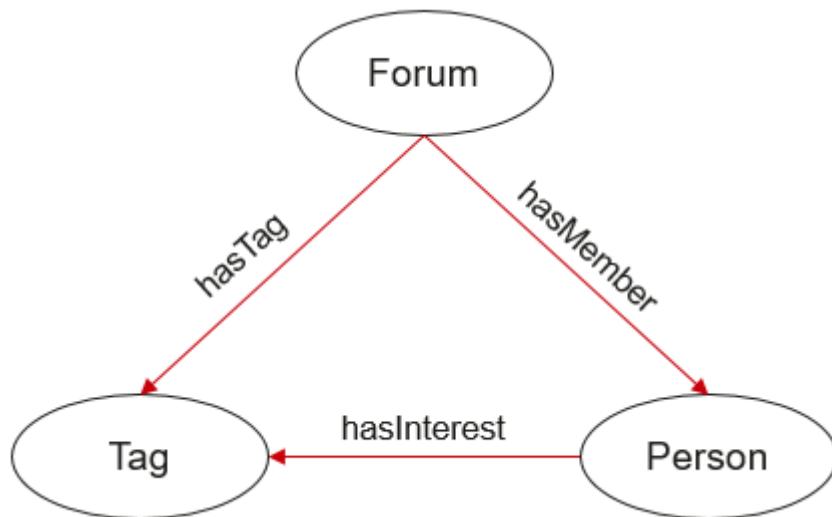

- In the **RESOURCE** configuration, the product of **num-executors** and **executor-cores** is the total number of **executor-core**, which determines the task concurrency capability.
- The product of the number of partitions and the number of nodes in the configuration item **graph.regions-per-server** in GraphBase is the total number of partitions, which determines the total number of started tasks.
- In the **RESOURCE** configuration, the product of **num-executors** and **executor-memory** is the total memory required by the task. The **yarn.nodemanager.resource.memory-mb** configuration item in Yarn determines the total memory that can be used.
- In the RESOURCE configuration, the value of **executor-memory** divided by **executor-cores** is the memory that can be used by each executor-core.

### 2. Parameter Optimization

- If the resources are sufficient, you can set the total number of executor-cores to be the same as the total number of partitions. In practice, you are advised to set **executor-cores** to a smaller value and increase the value of **num-executors**.
- The total memory configured for a task cannot exceed the total memory configured for Yarn, preventing memory overflow.
- If the memory is sufficient, you can increase the value of **executor-memory** to increase the memory size of each executor-core. You can also increase the value of **spark.yarn.executor.memoryOverhead** to dynamically increase executor memory to prevent performance deterioration caused by long GC time.

## Exporting Data

For example, the graph name is **graphbase** and the username is **graphtest**. The following figure shows the relationships between the vertex with label set to Forum, Person and Tag and the edge with label set to hasMember, hasInterest and hasTag.

1. Export the vertex.

Access the **graphreader** directory:

```
cd /opt/hadoopclient/GraphBase/graphreader
```

Run the following command to execute the environment variable:

```
source /opt/hadoopclient/bigdata_env
```

Authenticate the user and enter the user password.

```
kinit graphtest
```

- Export a vertex whose type is Forum.

Copy the configuration file:

```
cp conf/vertex.properties conf/Forum.properties
```

Modify the **Forum.properties** configuration file.

```
vim conf/vertex.properties
```

For example:

```
propertykeylist = forumId,title,creationDate  
dest.storage.path =  
graphname = graphbase  
label = Forum  
delimiter = \u002a  
filters =
```

Run the script to export data:

**./bin/graphReader.sh vertex Forum.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh vertex Forum.properties  
-----  
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2  
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false  
username=graphtest  
graphName=graphbase  
type=vertex  
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/Forum.properties  
delimiter=\u002a  
-----  
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your  
platform... using builtin-java classes where applicable |  
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)  
spark.yarn.am.memory is set but does not apply in cluster mode.  
spark.yarn.am.cores is set but does not apply in cluster mode.

cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)  
[root@10-5-199-1 graphreader]#
```

- Export the vertex whose type is Person.

Copy the configuration file:

**cp conf/vertex.properties conf/Person.properties**

Modify the **Person.properties** configuration file:

**vim conf/Person.properties**

For example:

```
propertykeylist = personId,firstName,lastName,gender,birthDay  
dest.storage.path =  
graphname = graphbase  
label = Person  
delimiter = \u002a  
filters =
```

Run the script to export data:

**./bin/graphReader.sh vertex Person.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh vertex Person.properties  
-----  
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2  
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false  
username=graphtest  
graphName=graphbase  
type=vertex  
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/Person.properties  
-----  
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your  
platform... using builtin-java classes where applicable |

```

```
cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)
[root@10-5-199-1 graphreader]#
```

- Export the vertex whose type is Tag.

Copy the configuration file:

**cp conf/vertex.properties conf/Tag.properties**

Modify the **Tag.properties** configuration file:

**vim conf/Tag.properties**

For example:

```
propertykeylist = tagId,name,url
dest.storage.path =
graphname = graphbase
label = Tag
delimiter = \u002a
filters =
```

Run the script to export data:

**./bin/graphReader.sh vertex Tag.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh vertex Tag.properties
```

```
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false
username=graphtest
graphName=graphbase
type=vertex
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/Tag.properties
```

```
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your
platform... using builtin-java classes where applicable |
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)
```

spark.yarn.am.memory is set but does not apply in cluster mode.

spark.yarn.am.cores is set but does not apply in cluster mode.

```
2019-03-07 10:26:49,315 | WARN | main | spark.yarn.am.extraJavaOptions will not take effect in
cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)
```

```
[root@10-5-199-1 graphreader]#
```

## 2. Export the edge.

Access **graphreader** directory:

**cd /opt/hadoopclient/GraphBase/graphreader**

Run the following command to execute the environment variable:

**source /opt/hadoopclient/bigdata\_env**

Authenticate the user and enter the user password.

**kinit graphtest**

- Export the edge whose type is hasMember.

Copy the configuration file:

**cp conf/edge.properties conf/hasMember.properties**

Modify the **hasMember.properties** configuration file.

**vim conf/hasMember.properties**

For example:

```
invertex.primarykey = personId
outvertex.primarykey = forumId
propertykeylist =
invertex.label = Person
```

```
dest.storage.path =
graphname = graphbase
outvertex.label = Forum
label = hasMember
delimiter = \u002a
filters =
```

Run the script to export data:

**./bin/graphReader.sh edge hasMember.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh edge hasMember.properties
-----
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false
username=graphtest
graphName=graphbase
type=edge
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/hasMember.properties
-----
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your
platform... using builtin-java classes where applicable |
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)
spark.yarn.am.memory is set but does not apply in cluster mode.
spark.yarn.am.cores is set but does not apply in cluster mode.
2019-03-07 10:26:49,315 | WARN | main | spark.yarn.am.extraJavaOptions will not take effect in
cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)
[root@10-5-199-1 graphreader]#
```

- Export the edge whose type is hasInterest.

Copy the configuration file:

**cp conf/edge.properties conf/hasInterest.properties**

Modify the **hasInterest.properties** configuration file:

**vim conf/hasInterest.properties**

For example:

```
invertex.primarykey = tagId
outvertex.primarykey = personId
propertykeylist =
invertex.label = Tag
dest.storage.path =
graphname = graphbase
outvertex.label = Person
label = hasInterest
delimiter = \u002a
filters =
```

Run the script to export data:

**./bin/graphReader.sh edge hasInterest.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh edge hasInterest.properties
-----
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false
username=graphtest
graphName=graphbase
type=edge
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/hasInterest.properties
-----
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your
platform... using builtin-java classes where applicable |
org.apache.hadoop.util.NativeCodeLoader.<clinit>(NativeCodeLoader.java:60)
```

```
spark.yarn.am.memory is set but does not apply in cluster mode.
spark.yarn.am.cores is set but does not apply in cluster mode.
2019-03-07 10:26:49,315 | WARN | main | spark.yarn.am.extraJavaOptions will not take effect in
cluster mode | org.apache.spark.Logging$class.logWarning(Logging.scala:71)
[root@10-5-199-1 graphreader]#
```

- Export the edge whose type is hasTag.

Copy the configuration file:

**cp conf/edge.properties conf/hasTag.properties**

Modify the **hasTag.properties** configuration file:

**vim conf/hasTag.properties**

For example:

```
invertex.primarykey = tagId
outvertex.primarykey = forumId
propertykeylist =
invertex.label = Tag
dest.storage.path =
graphname = graphbase
outvertex.label = Forum
label = hasTag
delimiter = \u002a
filters =
```

Run the script to export data:

**./bin/graphReader.sh edge hasTag.properties**

If the command is executed successfully, the following information is displayed:

```
[root@10-5-199-1 graphreader]# ./bin/graphReader.sh edge hasTag.properties
-----
resourceInfo=--executor-memory 2g --driver-memory 2g --num-executors 20 --executor-cores 2
--conf spark.hbase.obtainToken.enabled=true --conf spark.inputFormat.cache.enabled=false
username=graphtest
graphName=graphbase
type=edge
propertyFile=/opt/hadoopClient/GraphBase/graphreader/conf/hasTag.properties
-----
2019-03-07 10:26:36,684 | WARN | main | Unable to load native-hadoop library for your

```

## Viewing Execution Results

1. Check the execution process on Yarn.
  - a. Log in to FusionInsight Manager, choose **Cluster > Name of the desired cluster > Services > Yarn**, and select **ResourceManager (Active)** in **Basic Information** on the **Overview** page. The Yarn WebUI is displayed.

- b. Click the task ID to view the task overview.

The screenshot shows the Hadoop Application Overview page for application ID application\_1552331280773\_0007. It displays various metrics such as Application Owner (root), Queue (Default), Application Name (graphbase\_1552331280773), Application Type (Non-MapReduce), and Application Status (RUNNING). The Application Metrics section includes counters for Total Resource Requested (10.00 GB), Total Number of Map Tasks Executed (0), Total Number of All Executors Preempted (0), Resource Requested from Current Attempt (0.00 GB), and Number of Non-All-Committed Task Attempts (0). The Application Resource Allocation section shows 1.000 MB seconds, 100 msec seconds, and 100% Resource Usage.

- c. Click **ApplicationMaster** to view the task execution progress.

The screenshot shows the Spark Jobs page with a single job listed. The job has a status of "Submitted" and is currently at step 0 of 1. The progress bar indicates 0% completion. The table below shows the stages of the job, with the first stage having 100% completed and the second stage having 0% completed.

2. Check the exported data on HDFS.

Log in to FusionInsight Manager, choose **Cluster > Name of the desired cluster > Services > HDFS**, and select **NameNode (Active)** in **Basic Information** on the **Overview** page. On the HDFS WebUI that is displayed, choose **Utilities > Browse the file system** to go to the root directory.

- Go to the Person vertex export directory and check the Person data.

The screenshot shows the HDFS Browse Directory page for the path /user/hive/graphbase\_157/vertices/Person. A table lists 11 files, all of which are part of the SUCCESS file. The files have sizes ranging from 0.8 KB to 22.1 KB and were last modified on Tue Mar 12 07:29:37 2019.

| Permission | Owner | Group  | Size     | Last Modified            | Replication | Block Size | Name       |
|------------|-------|--------|----------|--------------------------|-------------|------------|------------|
| -rw-r--r-- | dbc   | hadoop | 0.8      | Tue Mar 12 07:29:37 2019 | 3           | 128 MB     | _SUCCESS   |
| -rw-r--r-- | dbc   | hadoop | 16.23 KB | Tue Mar 12 07:29:21 2019 | 3           | 128 MB     | part-00000 |
| -rw-r--r-- | dbc   | hadoop | 17.5 KB  | Tue Mar 12 07:29:21 2019 | 3           | 128 MB     | part-00001 |
| -rw-r--r-- | dbc   | hadoop | 18.19 KB | Tue Mar 12 07:29:21 2019 | 3           | 128 MB     | part-00002 |
| -rw-r--r-- | dbc   | hadoop | 19.41 KB | Tue Mar 12 07:29:35 2019 | 3           | 128 MB     | part-00003 |
| -rw-r--r-- | dbc   | hadoop | 14.3 KB  | Tue Mar 12 07:29:21 2019 | 3           | 128 MB     | part-00004 |
| -rw-r--r-- | dbc   | hadoop | 14.37 KB | Tue Mar 12 07:29:21 2019 | 3           | 128 MB     | part-00005 |
| -rw-r--r-- | dbc   | hadoop | 15.05 KB | Tue Mar 12 07:29:35 2019 | 3           | 128 MB     | part-00006 |

### NOTE

Data export formats of the Date and Geoshape are as follows:

- Date

During the import, the data may be the time of the long type: 1552894952164 or time of the date type: Mon Mar 18 15:43:34 GMT+08:00 2019.

During the export, the format is 2016-03-18 15:45:18.

- Geoshape

Data to be imported may be longitude and latitude: 23,52 (latitude, longitude) or a circle area: 23,52,18 (latitude,longitude,radius).

After the data export, if a comma (,) is used as the separator, the data format remains unchanged: 23,52 (latitude, longitude) or 23,52,18 (latitude,longitude,radius).

### 1.9.3.5 REST API Development

REST APIs are provided by GraphBase 8.3.1 and used by developers for secondary development based on the GraphBase platform.

The GraphBase API provides unified access for upper-layer applications and encapsulates the unified operations performed on the GraphBase platform through highly flexible REST APIs.

When an HTTP requester sets up a connection to the server and sends an HTTP request, no other requests can be sent from the connection until responses to the sent request are received.

## 1.9.3.6 REST API Invocation Examples and Running Results

### 1.9.3.6.1 Example

This section describes an example of creating a PropertyKey API. For details about how to create other APIs, see **GraphBase** in *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*. The code snippet is in the `GraphBaseRestExample` class in the `com.huawei.util` package of the sample project. After code is run, the result is returned on the console.

#### NOTE

1. Ensure that the input parameters and the invoked URL are correct.
2. Ensure that the entered IP address, port number, username, and password are correct.
1. Initialize the configuration of `graphbase.properties`. For details, see [Preparing for Security Authentication](#).
2. Obtain the connection information and perform security authentication.

```
GraphHttpClient client = null;
InputStream inputStream = null;
inputStream = new FileInputStream(System.getProperty("user.dir") + File.separator +
DEFAULT_CONFIG_FILE);
Properties p = new Properties();
p.load(inputStream);
HttpAuthInfo httpAuthInfo = HttpAuthInfo.newBuilder()
.setIp(p.getProperty("ip"))
.setPort(Integer.valueOf(p.getProperty("port")))
.setService(RestApi.SERVICE)
.setUsername(p.getProperty("userName"))
/*.setPassword(p.getProperty("password"))*/
.setKeytabFile(System.getProperty("user.dir") + File.separator + KEY_TAB)
.build();
client = GraphHttpClient.newKeytabClient(httpAuthInfo);
RestApi api = new RestApi(client);
```

3. Prepare the metadata-related classes, including `PropertyKey`, `EdgeLabel`, and `VertexLabel` in `com.huawei.entity` of the sample code.
4. Create the related REST APIs, for example, a property key API. (For details, see the sample project `com.huawei.graphbase.RestApi`.)

```
//Create a propertyKey interface.
public boolean addPropertyKey(PropertyKey propertyKey, String graphName) {
    JSONObject rspJson = null;
    try {
        //Invoke the REST API URL and transfer the request parameter propertyKey.
        rspJson = sendHttpPostReq("/graph/" + graphName + "/schema/property-key",
        RestHelper.toJsonString(propertyKey));
    } catch (JsonProcessingException e) {
        LOG.info(ERROR_MSG);
    }
    //Parse the returned rspJson parameter.
    final boolean isSuccessfully = (null == rspJson ? false : rspJson.getString("code").equals("0"));
    //Print logs to the console.
    String log = String.format("[%s]: create property key[%s] %s",
        (isSuccessfully ? "SUCCESS" : "FAIL"),
        propertyKey.getName(),
        (isSuccessfully ? "successfully." : "fail."));
    System.out.println(log);
    return isSuccessfully;
}
```

```
}

//Send a request containing CSRF_TOKEN.
private JSONObject sendHttpPutReq(String uri, JSONObject reqJson) {
    return sendHttpPutReq(uri, reqJson.toString());
}

private JSONObject sendHttpPutReq(String uri) {
    return sendHttpPutReq(uri, "");
}

private JSONObject sendHttpPutReq(String uri, String reqJsonStr) {
    String fullUrl = buildUrl(uri);
    HttpPut httpPut = new HttpPut(fullUrl);
    httpPut.addHeader(CSRF_TOKEN, this.client.csrfToken);

    CloseableHttpResponse response = null;
    JSONObject rspJson = null;

    try {
        if (reqJsonStr != null && !reqJsonStr.isEmpty()) {
            httpPut.setEntity(new StringEntity(reqJsonStr, ContentType.create("text/plain",
Consts.UTF_8)));
        }
        printHttpReqHeader(httpPut);
        printHttpReqBody(reqJsonStr);

        response = client.httpClient.execute(httpPut);
        RestHelper.checkHttpRsp(response);

        rspJson = new JSONObject(EntityUtils.toString(response.getEntity(), Charset.forName("UTF-8")));
        printHttpRspBody(rspJson);
    } catch (Exception e) {
        LOG.info(e.getMessage());
        return null;
    } finally {
        if (null != response) {
            try {
                response.close();
            } catch (IOException e) {
                // nothing to do
            }
        }
    }
}

return rspJson;
}
```

### 1.9.3.6.2 Creating or Deleting a Graph

To invoke Rest APIs to perform operations on graphs, refer to the following examples provided in com.huawei.graphbase.GraphBaseRestExample:

Create a graph.

```
String graphName = "graphbase";
api.createGraph(graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph HTTP/1.1
REQ BODY: {"graphName":"graphbase"}
RSP BODY: {
    "msg": "create graph success.",
    "code": "0"
}
[SUCCESS]: create graph[graphbase] successfully.
```

Delete a graph.

```
String graphName = "graphbase";
api.deleteGraph(graphName);
```

The command output is as follows:

```
REQ HEADER: DELETE https://10.7.66.150:22380/graphbase/graph?graphName=graphbase HTTP/1.1
REQ BODY: null
RSP BODY: {
    "msg": "delete graph success.",
    "code": "0"
}
[SUCCESS]: delete graph[graphbase] successfully.
```

### 1.9.3.6.3 Creating a Schema by Uploading an XML File

**graphName** specifies the name of a graph. This parameter is required when the specified REST API is invoked.

In the example, the com.huawei.graphbase.GraphBaseRestExample class has defined global variables. You can modify the configuration as required.

```
String graphName = "graphbase";
```

1. Save the XML file defined in [Compiling a Schema File \(XML\)](#) to a local directory.
2. Import the sample project. For details, see [Configuring and Importing Sample Projects](#).
3. Invoke the REST API of the addSchema class in **com.huawei.graphbase.GraphBaseRestExample**.

```
File file = new File(System.getProperty("user.dir") + File.separator + SCHEMA_FILE);
api.addSchema(file, graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema HTTP/1.1
RSP BODY: {
    "msg": "Make schema file successful",
    "code": "0"
}
[SUCCESS]: create schema successfully.
```

### 1.9.3.6.4 Creating a Schema

The following code snippets are used as an example. For complete codes, see **com.huawei.graphbase.GraphBaseRestExample**.

- Create a property key.

```
PropertyKey propertyKey = new PropertyKey();
propertyKey.setDataType(DataType.String);
propertyKey.setName("name");
api.addPropertyKey(propertyKey, graphName);
propertyKey = new PropertyKey();
propertyKey.setDataType(DataType.Integer);
propertyKey.setName("age");
api.addPropertyKey(propertyKey, graphName);
propertyKey = new PropertyKey();
propertyKey.setDataType(DataType.String);
propertyKey.setName("telephone");
api.addPropertyKey(propertyKey, graphName);
propertyKey = new PropertyKey();
propertyKey.setDataType(DataType.Float);
propertyKey.setName("weight");
api.addPropertyKey(propertyKey, graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/property-key  
HTTP/1.1  
REQ BODY: {"name":"name","dataType":"String"}  
RSP BODY: {  
    "msg": "success",  
    "code": "0",  
    "data": {  
        "dataType": "String",  
        "name": "name",  
        "cardinality": "SINGLE"  
    }  
}  
[SUCCESS]: create property key[name] successfully.
```

- Query a property key based on the name.  
api.queryPropertyKey("name",graphName);

The command output is as follows:

```
REQ HEADER: GET https://10.7.66.150:22380/graphbase/graph/graphbase/schema/property-key/  
p_name HTTP/1.1  
RSP BODY: {  
    "msg": "success",  
    "code": "0",  
    "data": {  
        "dataType": "String",  
        "name": "name",  
        "cardinality": "SINGLE",  
        "ttl":0  
    }  
}  
[SUCCESS]: query property key[name] successfully.
```

- Query all property keys.  
api.queryAllPropertyKey(graphName);

The command output is as follows:

```
REQ HEADER: GET https://10.7.66.150:22380/graphbase/graph/graphbase/schema/property-key  
HTTP/1.1  
RSP BODY: {  
    "msg": "success",  
    "code": "0",  
    "data": {"propertyKeyList": [  
        {  
            "dataType": "String",  
            "name": "name",  
            "cardinality": "SINGLE",  
            "ttl":0  
        },  
        {  
            "dataType": "Integer",  
            "name": "age",  
            "cardinality": "SINGLE",  
            "ttl":0  
        },  
        {  
            "dataType": "String",  
            "name": "telephone",  
            "cardinality": "SINGLE",  
            "ttl":0  
        },  
        {  
            "dataType": "Float",  
            "name": "weight",  
            "cardinality": "SINGLE",  
            "ttl":0  
        }  
    ]}  
}  
[SUCCESS]: query all property key successfully.  
===== Description of the JSON data result
```

```
=====
|---msg          message
|---code         code
|---data         Result data storage location
|---propertyKeyList   Property key list.
|---dataType      Data type of the property value.
|---name          Property name.
|---cardinality   Property value types. The values are as follows: SINGLE, SET, and LIST.
SINGLE specifies that there is only one property value. SET specifies that there are multiple different values for a property. LIST specifies that there are multiple repeated values for a property.
=====
```

- Create a vertex label.

```
api.addVertexLabel("person",graphName);
api.addVertexLabel("phone",graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/vertex-label
HTTP/1.1
REQ BODY: {"name":"person"}
RSP BODY: {
  "msg": "success",
  "code": "0",
  "data": {
    "name": "person"
  }
}
[SUCCESS]: create vertex label[person] successfully.
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/vertex-label
HTTP/1.1
REQ BODY: {"name":"person"}
RSP BODY: {
  "msg": "success",
  "code": "0",
  "data": {
    "name": "phone"
  }
}
[SUCCESS]: create vertex label[phone] successfully.
```

- Query a vertex label based on the name.

```
api.queryVertexLabel("person",graphName);
```

The command output is as follows:

```
REQ HEADER: GET https://10.7.66.150:22380/graphbase/graph/graphbase/schema/vertex-label/person
HTTP/1.1
RSP BODY: {
  "msg": "success",
  "code": "0",
  "data": {
    "name": "person"
  }
}
[SUCCESS]: query vertex label[person] successfully.
```

- Query all vertex labels.

```
api.queryAllVertexLabel(graphName);
```

The command output is as follows:

```
REQ HEADER: GET https://10.5.199.50:22380/graphbase/graph/graphbase/schema/vertex-label
HTTP/1.1
RSP BODY: {
  "msg": "success",
  "code": "0",
  "data": {"vertexLabelList": [
    {
      "name": "person"
    },
    {
      "name": "phone"
    }
  ]
}
```

```
        }
    ]
}
[SUCCESS]: query all vertex label successfully.
```

- Create an edge label.

```
EdgeLabel edgeLabel = new EdgeLabel();
edgeLabel.setName("friend");
api.addEdgeLabel(edgeLabel,graphName);
edgeLabel = new EdgeLabel();
edgeLabel.setName("knows");
api.addEdgeLabel(edgeLabel,graphName);
edgeLabel = new EdgeLabel();
edgeLabel.setName("call");
api.addEdgeLabel(edgeLabel,graphName);
edgeLabel = new EdgeLabel();
edgeLabel.setName("has");
api.addEdgeLabel(edgeLabel,graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/edge-label
HTTP/1.1
REQ BODY: {"name":"friend"}
RSP BODY: {

  "code": "0",
  "data": {
    "multiplicity": "MULTI",
    "name": "friend",
    "ttl": 0
  }
}
[SUCCESS]: create edge label[friend] successfully.
```

- Query an edge label based on the name.

```
api.queryEdgeLabel("friend",graphName);
```

The command output is as follows:

```
REQ HEADER: GET https://10.7.66.150:22380/graphbase/graph/graphbase/schema/edge-label/
friend
HTTP/1.1
RSP BODY: {
  "msg": "success",
  "code": "0",
  "data": {
    "multiplicity": "MULTI",
    "name": "friend",
    "ttl": 0
  }
}
[SUCCESS]: query edge label[friend] successfully.
```

## Periodic Data Deletion

GraphBase provides the following periodic data deletion functions:

1. When creating a property key, you can set the **ttl** parameter for the property. The value must be an integer, in seconds. For example, if you set **ttl** for the **name** property to **120**, the **name** property of all vertices will be deleted 120s later after being created.

This parameter takes effect only for vertex properties, and does not take effect for edge properties.

Note: If a vertex has only one property and the **ttl** parameter is set for the property, the vertex cannot be queried using this property after the property is deleted. However, this vertex can be queried by performing full-graph traversal, and the vertex ID is also recorded on the corresponding edge of the

vertex. You are not advised to configure **ttl** for the unique property of a vertex.

2. When creating an edge label, you can set the **ttl** parameter for the edge label. The value must be an integer, in seconds. For example, if you set **ttl** for the **know** label to **120**, edges labeled by the **know** label will be deleted 120s later after being created.

Note: The **ttl** parameter is not allowed for data stored in Elasticsearch. For example, if a MIXED index is created for the property of an edge labeled by **know**, the index data of the edge cannot be deleted with the edge 120s later, and the deleted edge cannot be found using the index. To delete the index data, you are advised to create a MIXED index for the corresponding edge property and recreate the index. After the index is successfully recreated, delete the original MIXED index.

#### NOTICE

If **ttl** is set to **0** or a negative number, the corresponding property or edges are not deleted. The default value is **0**.

### 1.9.3.6.5 Creating an Index

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

- Create an index.

#### NOTE

MIXED: specifies the mixed index that is a kind of external hybrid match index. This type of indexes searches vertices and edges using any combination of indexes created in the databases. The property key corresponding to such indexes is in the `<key, value>` format. The options of `value` are as follows: **TEXT**, **TEXTSTRING**, **PREFIX\_TREE**, and **DEFAULT** (these values are case insensitive.) External indexes are used for non-exact match queries.

COMPOSITE: specifies the composite index that is a kind of internal exact match index. This type of indexes retrieve vertices or edges using a fixed combination of one or more properties. Such indexes are accurate, simple, and efficient, and can greatly accelerate the retrieval speed, but have high requirements on the property sequence in the combination. The property key corresponding to such indexes is in the `<key, "">` format. Built-in indexes are used for exact match queries.

You can create an index only after a schema is created and before a vertex or edge is created. Otherwise, data cannot be queried. You need to recreate indexes to query data.

```
//Create indexes for all vertices and edges.  
addIndex(api, graphName);  
private static void addIndex(RestApi api, String graphName) {  
//Create a built-in index for the vertex property name.  
    GraphIndexReqObj graphIndexReqObj = new GraphIndexReqObj();  
    graphIndexReqObj.setElementCategory(ElementCategory.VERTEX);  
    graphIndexReqObj.setName("name_index");  
    graphIndexReqObj.setType(IndexType.COMPOSITE);  
    List<KeyTextType> keyTextTypeList1 = new ArrayList<>();  
    KeyTextType keyTextType = new KeyTextType();  
    keyTextType.setName("name");  
    KeyTextType.setTextType(""); //If IndexType is set to COMPOSITE, TextType is empty.  
    keyTextTypeList1.add(keyTextType);  
    graphIndexReqObj.setKeyTextTypeList(keyTextTypeList1);
```

```
api.addGraphIndex(graphIndexReqObj, graphName);
//Create a built-in index for the vertex property age.
graphIndexReqObj = new GraphIndexReqObj();
graphIndexReqObj.setElementCategory(ElementCategory.VERTEX);
graphIndexReqObj.setName("age_index");
graphIndexReqObj.setType(IndexType.COMPOSITE);
List<KeyTextType> keyTextTypeList2 = new ArrayList<>();
keyTextType = new KeyTextType();
keyTextType.setName("age");
keyTextType.setTextType(""); //If IndexType is set to COMPOSITE, TextType is empty.
keyTextTypeList2.add(keyTextType);
graphIndexReqObj.setKeyTextTypeList(keyTextTypeList2);
api.addGraphIndex(graphIndexReqObj, graphName);
//Create a mixed index for the vertex property telephone.
graphIndexReqObj = new GraphIndexReqObj();
graphIndexReqObj.setElementCategory(ElementCategory.VERTEX);
graphIndexReqObj.setName("telephone_index");
graphIndexReqObj.setType(IndexType.COMPOSITE);
List<KeyTextType> keyTextTypeList3 = new ArrayList<>();
keyTextType = new KeyTextType();
keyTextType.setName("telephone");
keyTextType.setTextType(""); //If IndexType is set to COMPOSITE, TextType is empty.
keyTextTypeList3.add(keyTextType);
graphIndexReqObj.setKeyTextTypeList(keyTextTypeList3);
api.addGraphIndex(graphIndexReqObj, graphName);
...//Creates a mixed index for the edge property weight.
graphIndexReqObj = new GraphIndexReqObj();
graphIndexReqObj.setElementCategory(ElementCategory.EDGE);
graphIndexReqObj.setName("weight_index");
graphIndexReqObj.setType(IndexType.MIXED);
List<KeyTextType> keyTextTypeList4 = new ArrayList<>();
keyTextType = new KeyTextType();
keyTextType.setName("weight");
keyTextType.setTextType("DEFAULT"); //If IndexType is set to MIXED, TextType is transferred based
on the information provided in the interface document.
keyTextTypeList4.add(keyTextType);
graphIndexReqObj.setKeyTextTypeList(keyTextTypeList4);
api.addGraphIndex(graphIndexReqObj, graphName);
}
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/schema/index/graph

}

[SUCCESS]: query all index successfully.
```

### 1.9.3.6.6 Creating and Querying a Vertex or an Edge

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

- Create a vertex.

```
//Create four nodes labeled as person 1, person 4, person 5, and person 8.
addVertexPerson(api, graphName);
private static void addVertexPerson(RestApi api, String graphName) {
...//Create the node person 1.
    AddVertexReqObj addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("person");
    List<PropertyReqObj> propertyReqObjList1 = new ArrayList<>();
    PropertyReqObj propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("name");
    propertyReqObj.setValue("marko");
    propertyReqObjList1.add(propertyReqObj);
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("age");
    propertyReqObj.setValue(29);
    propertyReqObjList1.add(propertyReqObj);
    addVertexReqObj.setPropertyList(propertyReqObjList1);
    api.addVertex(addVertexReqObj, graphName);
//Create the node person 4.
    addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("person");
    List<PropertyReqObj> propertyReqObjList2 = new ArrayList<>();
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("name");
    propertyReqObj.setValue("josh");
    propertyReqObjList2.add(propertyReqObj);
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("age");
    propertyReqObj.setValue(32);
```

```
propertyReqObjList2.add(propertyReqObj);
addVertexReqObj.setPropertyList(propertyReqObjList2);
api.addVertex(addVertexReqObj, graphName);
...//Create the node person 5.
addVertexReqObj = new AddVertexReqObj();
addVertexReqObj.setVertexLabel("person");
List<PropertyReqObj> propertyReqObjList3 = new ArrayList<>();
propertyReqObj = new PropertyReqObj();
propertyReqObj.setName("name");
propertyReqObj.setValue("vadas");
propertyReqObjList3.add(propertyReqObj);
propertyReqObj = new PropertyReqObj();
propertyReqObj.setName("age");
propertyReqObj.setValue(27);
propertyReqObjList3.add(propertyReqObj);
addVertexReqObj.setPropertyList(propertyReqObjList3);
api.addVertex(addVertexReqObj, graphName);
...//Create the node person 8.
addVertexReqObj = new AddVertexReqObj();
addVertexReqObj.setVertexLabel("person");
List<PropertyReqObj> propertyReqObjList4 = new ArrayList<>();
propertyReqObj = new PropertyReqObj();
propertyReqObj.setName("name");
propertyReqObj.setValue("blame");
propertyReqObjList4.add(propertyReqObj);
propertyReqObj = new PropertyReqObj();
propertyReqObj.setName("age");
propertyReqObj.setValue(30);
propertyReqObjList4.add(propertyReqObj);
addVertexReqObj.setPropertyList(propertyReqObjList4);
api.addVertex(addVertexReqObj, graphName);
}
//Create four nodes labeled as phone 2, phone 3, phone 6, and phone 7, respectively.
addVertexPhone(api, graphName);
private static void addVertexPhone(RestApi api, String graphName) {
    //Create the node phone 2.
    AddVertexReqObj addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("phone");
    List<PropertyReqObj> propertyReqObjList1 = new ArrayList<>();
    PropertyReqObj propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("telephone");
    propertyReqObj.setValue("15000000000");
    propertyReqObjList1.add(propertyReqObj);
    addVertexReqObj.setPropertyList(propertyReqObjList1);
    api.addVertex(addVertexReqObj, graphName);
    //Create the node phone 3.
    addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("phone");
    List<PropertyReqObj> propertyReqObjList2 = new ArrayList<>();
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("telephone");
    propertyReqObj.setValue("1522222222");
    propertyReqObjList2.add(propertyReqObj);
    addVertexReqObj.setPropertyList(propertyReqObjList2);
    api.addVertex(addVertexReqObj, graphName);
    //Create the node phone 6.
    addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("phone");
    List<PropertyReqObj> propertyReqObjList3 = new ArrayList<>();
    propertyReqObj = new PropertyReqObj();
    propertyReqObj.setName("telephone");
    propertyReqObj.setValue("13777777777");
    propertyReqObjList3.add(propertyReqObj);
    addVertexReqObj.setPropertyList(propertyReqObjList3);
    api.addVertex(addVertexReqObj, graphName);
    //Create the node phone 7.
    addVertexReqObj = new AddVertexReqObj();
    addVertexReqObj.setVertexLabel("phone");
    List<PropertyReqObj> propertyReqObjList4 = new ArrayList<>();
```

```
propertyReqObj = new PropertyReqObj();
propertyReqObj.setName("telephone");
propertyReqObj.setValue("13666666666");
propertyReqObjList4.add(propertyReqObj);
addVertexReqObj.setPropertyList(propertyReqObjList4);
api.addVertex(addVertexReqObj, graphName);
}
```

The command output is as follows:

### 1.9.3.6.7 Performing a Full Graph Query

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

- Perform full graph query for vertices.

```
//Perform full graph query for vertices in the following scenario: To query the users who are older than 29 years old and list the users by age in ascending order. The upper limit of the number of users is 3.
```

```
VertexSearchReqObj vertexSearchReqObj = new VertexSearchReqObj();
vertexSearchReqObj.setVertexLabel("person");
List<PropertyFilter> propertyFilterList = new ArrayList<>();
PropertyFilter propertyFilter = new PropertyFilter();
propertyFilter.setPropertyName("age");
propertyFilter.setPredicate(PropertyPredicate.GREATER_THAN);
List<Integer> values = new ArrayList();
values.add(29);
propertyFilter.setValues(values);
propertyFilterList.add(propertyFilter);
vertexSearchReqObj.setFilterList(propertyFilterList);
List<PropertyKeySort> sortList = new ArrayList<>();
```

```
PropertyKeySort propertyKeySort = new PropertyKeySort();
propertyKeySort.setPropertyKeyName("age");
propertyKeySort.setSortType("ASC");
sortList.add(propertyKeySort);
vertexSearchReqObj.setPropertyKeySortList(sortList);
vertexSearchReqObj.setLimit(3);
//Perform full graph query for vertices.
api.searchVertex(vertexSearchReqObj, graphName);
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/graph/graphbase/vertex/search HTTP/1.1
REQ BODY: {"filterList":[{"propertyName":"age","predicate":">>","values":
[29]}],"vertexLabel":"person","propertyKeySortList":
[{"propertyKeyName":"age","sortType":"ASC"}],"limit":3}
RSP BODY: {
    "msg": "success",
    "code": "0",
    "data": {
        "totalHits": 2,
        "vertexList": [
            {
                "propertyList": [
                    {
                        "name": "name",
                        "id": "atc7-vozc-4if9",
                        "value": "blame"
                    },
                    {
                        "name": "age",
                        "id": "dmh3-vozc-5wzp",
                        "value": "30"
                    }
                ],
                "id": "1478712",
                "vertexLabel": "person"
            },
            {
                "propertyList": [
                    {

=====

### 1.9.3.6.8 Performing a Path Query

- Graph traversal: Access the vertices of the graph along the side from any vertex of the graph. Graph traversal is a basic operation in graph databases, and it is similar to tree traversal. In a narrow sense, a vertex can be accessed only once in a graph traversal. The graph traversal described in this document is that in a broad sense.
- Graph path: indicates the set of vertices and edges that passed by during graph traversal. The number of edges in a path is called the path depth.

Use marko in [Typical Application Scenario](#) as an example, the paths formed by the vertices and edges found based on the first layer expansion query are as follows:

- marko -[friend]-> josh
- marko -[has]-> 15000000000
- marko -[knows]-> vadas

In this example, the person name or mobile number indicates the entity object. -[relationship]-> is used to indicate the edge, and the relationship in the square brackets([]) indicates the edge label. The depth of these paths is 1.

Continue traversing based on the preceding path result, and obtain a second layer edge and a vertex of marko to form a new path. The original path is named the parent path of the new path, and the new path is named the sub-path of the original path.

Example:

- Original path (path A): marko -[friend]-> josh
- New path (path B): marko -[friend]-> josh -[has]-> 1522222222
- Path A is the parent path of path B, and path B is the sub-path of path A.

- Full path: indicates all graph paths between two vertices that meet specified conditions.

Scenario 1: Query the full path between node 1 and node 8.

The following code snippets are used as an example. For complete codes, see [com.huawei.graphbase.GraphBaseRestExample](#).

```
allPathSearch(api, graphName);
private static void allPathSearch(RestApi api, String graphName) {
    PathSearchReqObj pathSearchReqObj = new PathSearchReqObj();
    List<String> vertexIdList = new ArrayList<>();
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "marko"));
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "blame"));
    pathSearchReqObj.setVertexIdList(vertexIdList);
    pathSearchReqObj.setLayer(7);
    api.searchPath(pathSearchReqObj, graphName);
}
```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/default/paths HTTP/1.1
```

```

=====
Description of the JSON data result
format=====
|---msg           message
|---code          code
|---data          Result data storage location
|---pathSet       All path data. Multiple vertex pairs correspond to multiple data structures.
|---start         Start node ID
|---end           End node ID
|---edgeList      Detailed data of all relationships in the data result
|---vertexList    Detailed data of all vertices included in the current data result
|---pathList      Path set. Each path stores only the relationship access sequence table. Only
relationship IDs are recorded.
=====
```

Build a path based on the path result (applicable to all paths):

- Find a path from the path list. For example:

```
[
    "cy23-12g60-2sb9-17808",
    "6kdl-17808-46vp-1ox94"
]
```

- Find an edge from the edge list based on the edge ID. For example:

Find the edge with the ID of cy23-12g60-2sb9-17808:

```
{
    "propertyList": [
        {
            "name": "weight",
            "value": "1.0"
        }
    ],
    "start": "1793880",
}
```

```

    "end": "2016584",
    "id": "cy23-12g60-2sb9-17808",
    "label": "friend",
    "type": "edge"
}

```

- c. Identify the start vertex, obtain the end node ID based on the edge data in **b**, and obtain the vertex data from the vertex list. For example:

Start from the edge with the ID of cy23-12g60-2sb9-17808 to find the end node with the vertex ID of 2016584

```

{
    "labelList": ["person"],
    "propertyList": [
        {
            "name": "name",
            "value": "josh"
        },
        {
            "name": "age",
            "value": "32"
        }
    ],
    "id": "2016584",
    "type": "vertex"
}

```

- d. Repeat **b** and **c** until the data in **a** is exhausted.

The path in the preceding example is simplified as follows:

```
(1793880,marko) -[cy23-12g60-2sb9-17808:friend]-> (2016584,josh)
-[6kdl-17808-46vp-1ox94:knows]-> (2842456:blame)
```

Vertices are marked in parentheses and in the format of (Vertex ID, Person name). Edges are marked in square brackets and in the format of -[Edge ID:Edge type]->

- Shortest path

It indicates the shortest path between two vertices, specifically the path with the smallest sum of relationship weights. This document considers that the path with the smallest sum of path relationship weights is not the shortest path. Instead, the shortest path must comply with the specified weight rule. If the weight calculation rule is not specified, the shortest path is the path with the minimum path depth by default. The shortest path complying with the relationship weighting rule is the weight-based shortest path.

Scenario 2: Query the shortest path from node 1 to node 8.

The following code snippets are used as an example. For complete codes, see **com.huawei.graphbase.GraphBaseRestExample**.

```

shortestPathSearch(api, graphName);
private static void shortestPathSearch(RestApi api, String graphName) {
    PathSearchReqObj pathSearchReqObj = new PathSearchReqObj();
    List<String> vertexIdList = new ArrayList<>();
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "marko"));
    vertexIdList.add(getVertexIdByProperty(api, graphName, "person", "name", "blame"));
    pathSearchReqObj.setVertexIdList(vertexIdList);
    pathSearchReqObj.setLayer(7);
    ...PathSearchReqObj.setOption("shortest");//If option is not transferred, the default value is all, that
    is, the full path.
    api.searchPath(pathSearchReqObj, graphName);
}

```

The command output is as follows:

```
REQ HEADER: POST https://10.7.66.150:22380/graphbase/default/paths HTTP/1.1
```

```
REQ BODY: {"vertexIdList":["1793880","2842456"],"layer":7,"option":"shortest"}
```

```
RSP BODY: {
```

### 1.9.3.6.9 Performing a Line Expansion Query

- Line Expansion Query
  - Similar to graph traversal, a line expansion query starts from a specified vertex and traverses the incident edges to find the target vertex. In a graph traversal, the process of finding the vertices that have direct connection with the specified vertex is the first layer expansion for the vertex.
  - The graph traversal proceeds with the query from these vertices directly connected with the start vertex to find the vertices that are indirectly connected with the start vertex. This process is called second layer expansion. In this way the graph traversal will expand n layers to find all vertices that are directly and indirectly connected with the start vertex.

```

//Scenario: Satrt from node 1 and expand two layers.
//Layer 1 query condition: To query the vertices whose age is equal to or less than 29.
//Layer 2 query condition: To query the verticeswhose vertexlabel is phone.
lineSearch(api, graphName);
private static void lineSearch(RestApi api, String graphName) {
    LineSearchReqObj lineSearchReqObj = new LineSearchReqObj();
    List<Integer> vertexIdList = new ArrayList<>();
    String vertexId = getVertexIdByProperty(api, graphName, "person", "name", "marko");
    vertexIdList.add(Integer.valueOf(vertexId));
    lineSearchReqObj.setVertexIdList(vertexIdList);
    List<VertexFilter> vertexFilterList = new ArrayList<>();
    VertexFilter vertexFilter = new VertexFilter();
    List<PropertyFilter> propertyFilterList1 = new ArrayList<>();
    PropertyFilter propertyFilter = new PropertyFilter();
    propertyFilter.setProperty("age");
    propertyFilter.setPredicate(PropertyPredicate.LESS_THAN_EQUAL);
    List<Integer> values2 = new ArrayList();
    values2.add(29);
    propertyFilter.setValues(values2);
    propertyFilterList1.add(propertyFilter);
    vertexFilter.setFilterList(propertyFilterList1);
    vertexFilterList.add(vertexFilter);
    vertexFilter = new VertexFilter();
    List<String> vertexLabelList = new ArrayList<>();
    vertexLabelList.add("phone");
    vertexFilter.setVertexLabelList(vertexLabelList);
    vertexFilterList.add(vertexFilter);
    lineSearchReqObj.setVertexFilterList(vertexFilterList);
    lineSearchReqObj.setLayer(2);
    lineSearchReqObj.setLimit(5);
    api.searchLines(lineSearchReqObj, graphName);
}
```

The command output is as follows:

```

### 1.9.3.6.10 Analyzing the Typical Application Scenario

#### Direct Contact Search

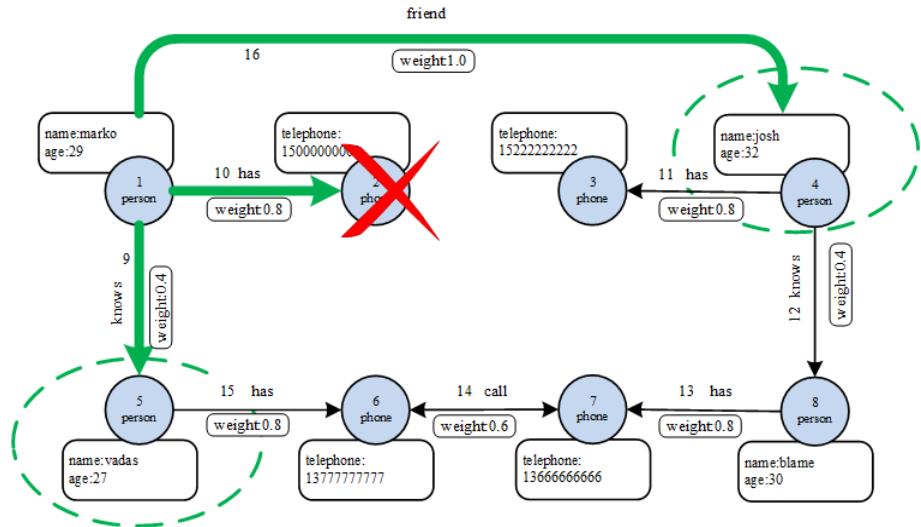

Direct contact: A person who has direct contact with a specified person.

The following graph shows the relationship between persons and their direct contacts in the typical scenario. (marko is used as an example. The direct contacts of marko are marked using the red dotted ovals.)

In GraphBase, the line expansion query function can be used to implement this scenario. [Figure 1-108](#) shows how to find the direct contacts for marko. (The green arrows indicate the expansion direction, the red cross mark indicates that the vertex does not meet the search condition, and the green dotted ovals indicate the search result.)

**Figure 1-108 Direct contact search in GraphBase**

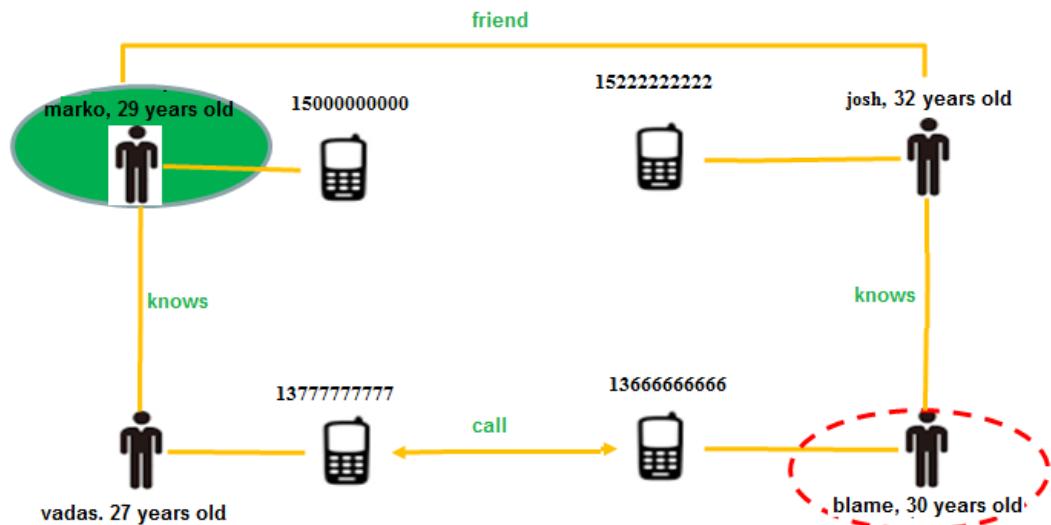

As shown in the preceding graph, josh and vadas are directly connected with marko. The related code is as follows:

```
/*
 * <p> Search for the direct contact</p>
 * @param api REST API encapsulation
 * @param graphName Graph name
 * @param startNodeId Start node ID
 * NOTE: The search result is the response data of the end node.
 */
static String findDirectRelations(RestApi api, String graphName, String startNodeId)
{
    // Node preparation
    LineSearchReqObj lineSearchReqObj = new LineSearchReqObj();
    List<Integer> vertexIdList = new ArrayList<>();
    vertexIdList.add(Integer.valueOf(startNodeId));
    lineSearchReqObj.setVertexIdList(vertexIdList);
    // Query depth
    lineSearchReqObj.setLayer(1);
    // End node condition (the label is person)
    List<VertexFilter> vertexFilterList = new ArrayList<>();
    VertexFilter vertexFilter = new VertexFilter();
    List<String> vertexLabelList = new ArrayList<>();
    vertexLabelList.add("person");
    vertexFilter.setVertexLabelList(vertexLabelList);
    vertexFilterList.add(vertexFilter);
    lineSearchReqObj.setVertexFilterList(vertexFilterList);
    // Perform line expansion query. (The query result is displayed as strings in JSON format.)
    String result = api.searchLines(lineSearchReqObj, graphName);
    return result;
}
```

## Indirect Contact Search

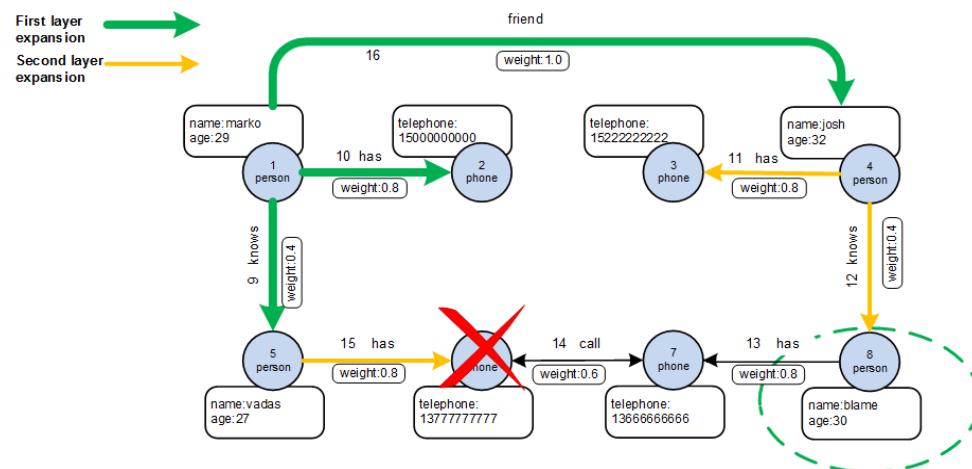

Indirect contact: A person who has indirect contact with a specified person.

The following graph shows the relationship between persons and their indirect contacts in the typical scenario. (marko is used as an example. The indirect contacts of marko are marked using the red dotted ovals.)

In GraphBase, the line expansion query can be used to find the indirect contact of marko in this scenario. [Figure 1-109](#) shows how the indirect contacts are searched in GraphBase. In the scenario, two layers are expanded: the green arrows indicate the query at the first layer, the yellow arrows indicate the query at the second layer. The red cross indicates that the vertex does not meet the search criteria, and the green dotted oval marks out the search result.

**Figure 1-109** Graph example of indirect contact search

As shown in the preceding graph, only one link between marko and blame meets the search criteria. The related code is as follows:

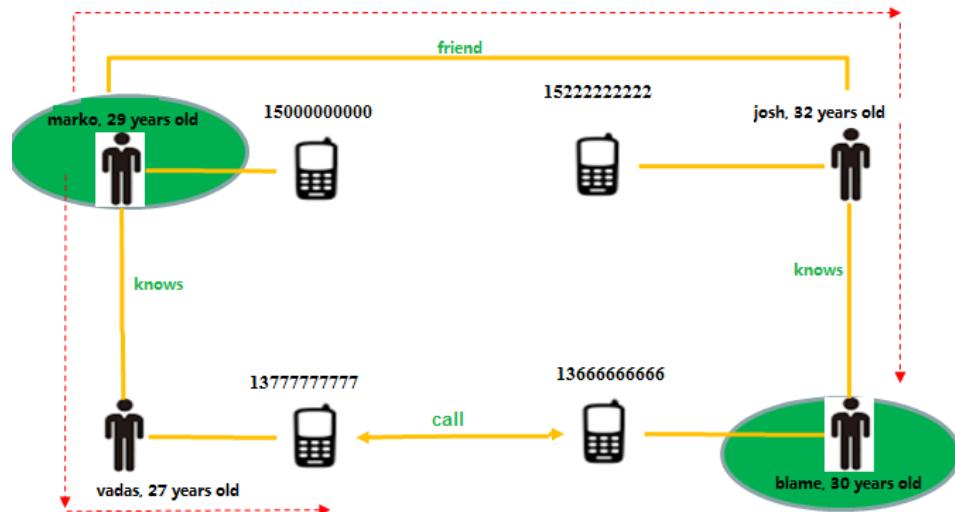

```
/*
 * <p> Search for the indirect contact</p>
 * @param api REST API encapsulation
 * @param graphName Graph name
 * @param startNodeID Start node ID
 * NOTE: The search result is the response data of the end node.
 */
static String findIndirectRelations(RestApi api, String graphName, String startNodeID)
{
    // Node preparation
    LineSearchReqObj lineSearchReqObj = new LineSearchReqObj();
    List<Integer> vertexIdList = new ArrayList<>();
    vertexIdList.add(Integer.valueOf(startNodeID));
```

```
lineSearchReqObj.setVertexIdList(vertexIdList);
// Query depth
lineSearchReqObj.setLayer(2);
// End node condition (the vertex label is person)
List<VertexFilter> vertexFilterList = new ArrayList<>();
VertexFilter vertexFilter = new VertexFilter();
List<String> vertexLabelList = new ArrayList<>();
vertexLabelList.add("person");
vertexFilter.setVertexLabelList(vertexLabelList);
vertexFilterList.add(vertexFilter);
lineSearchReqObj.setVertexFilterList(vertexFilterList);
// Perform line expansion query. (The query result is displayed as strings in JSON format.)
String result = api.searchLines(lineSearchReqObj, graphName);
return result;
}
```

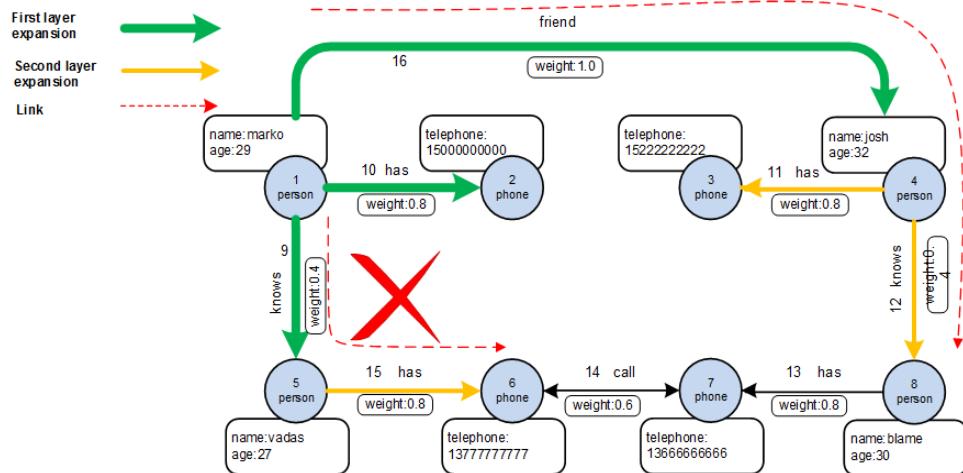

## Search for Link

Link refers to the link between two real world entities.

In the real world, the link between two persons is shown in the following graph. (The link between marko and blame is used as an example. The red dashed arrows indicate the link directions.)

In the link search scenario, the full path query function needs to be used. The following graph shows how to search for links in GraphBase. In this graph, the link between marko and blame is used as an example, and the path depth must be within two layers. The green arrows indicate the first layer expansion, the yellow arrow indicate the line expansion at the second layer, the red dotted arrows indicate the link direction, and the red cross indicates that the link does not meet the requirements.

As shown in the preceding graph, only one link between marko and blame meets the search conditions. The related code is as follows:

```

/*
 * <p> Search for links </p>
 * @param api      REST API encapsulation
 * @param graphName Graph name
 * @param startNodeID Start node ID
 * @param endNodeID End node ID
 * NOTE: The result data is the path set of the response data.
 */
static String findLinkedPaths(RestApi api, String graphName, String startNodeID, String endNodeID) {
    // Node preparation
    PathSearchReqObj pathSearchReqObj = new PathSearchReqObj();
    List<String> vertexIdList = new ArrayList<>();
    vertexIdList.add(startNodeID);
    vertexIdList.add(endNodeID);
    pathSearchReqObj.setVertexIdList(vertexIdList);
    // Query depth.
    pathSearchReqObj.setLayer(2);
    // Perform full path query. (The query result is displayed as strings in JSON format).
    String result = api.searchPath(pathSearchReqObj, graphName);
    return result;
}

```

### 1.9.3.7 Gremlin Console

#### Prerequisites

You have installed all component clients required in the cluster.

#### Performing Query Using Gremlin Statements

1. Use PuTTY to log in to the node where the client is installed as user **root**.
2. Go to the **/GraphBase/gremlinserver/gremlin-console** directory where the GraphBase client is installed.

`cd /opt/hadoopclient/GraphBase/gremlinserver/gremlin-console`

In this example, the GraphBase client is installed in the **/opt/hadoopclient** directory.

3. Run the required environment variables as user **root**.

- ```
source /opt/hadoopclient/bigdata_env
```
4. Perform the kinit security authentication.  
**kinit Component service user**
  5. Enter the Gremlin operation block.  
**sh bin/gremlin.sh**
  6. Connect to the remote GraphBase.  
**:remote connect tinkerpop.server conf/remote-graphbase-gremlinserver.yaml**
  7. Omit the remote command ">".  
**:remote console** (This operation is optional. If you perform this operation, you do not need to add ">" before the Gremlin language.)
  8. Traverse a specified graph.  
**:remote config alias g Graph name**
  9. Query a vertex, as shown in the following example. (For other application scenarios, see [Gremlin Application Scenarios](#).)  
gremlin> :>  
=>[name:[zhangsan],age:[30]]  
gremlin> :remote console  
=>All scripts will now be sent to Gremlin Server - [szvphicprb00285/10.4.64.123:22375] - type  
'remote console' to return to local mode  
gremlin> g.V(13464736).valueMap()  
=>[name:[zhangsan],age:[30]]

```
[root@hd-123 gremlin-console]#source /opt/graphbaseClient/bigdata_env
[root@hd-123 gremlin-console]#kinit zky
Password for zky@HADOOP.COM:
[root@hd-123 gremlin-console]#sh bin/gremlin.sh
..../
(o o)
.....o0Oo-(3)-o0Oo-----
plugin activated: tinkerpop.server
plugin activated: tinkerpop.utilities
gremlin> :remote connect tinkerpop.server conf/remote-graphbase-gremlinserver.yaml
=>Configured hd-123/187.4.64.123:22381, hd-184/187.4.64.184:22381, HD-10/187.4.65.10:22381
gremlin> :remote config alias g gremlintest_1109
=>g=gremlintest_1109
gremlin> :remote console
=>All scripts will now be sent to Gremlin Server - [hd-123/187.4.64.123:22381, hd-184/187.4.64.184:22381, HD-10/187.4.65.10:22381]
gremlin> g.V().valueMap().limit(10)
=>[name:[blame], age:[30]]
=>[telephone:[13612493615]]
=>[telephone:[137235842111]]
=>[telephone:[13612493615]]
=>[telephone:[15023614521]]
=>[telephone:[15291463258]]
=>[name:[blame], age:[30]]
=>[name:[blame], age:[30]]
=>[telephone:[13612493615]]
=>[telephone:[15023614521]]
gremlin> 
```

### 1.9.3.8 Gremlin Java

#### 1.9.3.8.1 Connecting Gremlin Servers and Clients

- Modify the Gremlin client configuration file **remote-objects.yaml**.

Change the host name in hosts to the actual IP address.

```
hosts:[10.7.66.111,10.7.66.151,10.7.66.220]
```

```
port: 22381
```

```
connectionPool: {
    maxContentLength: 65536000,
    maxInProcessPerConnection: 60,
    maxSize: 16,
    resultIterationBatchSize: 960
}
protocol: gremlinserver
jaasEntry: GremlinConsole
serializer:
```

```
{ className: org.apache.tinkerpop.gremlin.driver.ser.GryoMessageSerializerV3d0, config:  
{ ioRegistries: [org.janusgraph.graphdb.tinkerpop.JanusGraphIoRegistry] } }  
serializer:  
{ className: org.apache.tinkerpop.gremlin.driver.ser.GryoMessageSerializerV3d0, config:  
{ serializeResultToString: true } }
```

- Configure the mapping between the service IP Address of GraphServer and the host name in the local HOSTS file.

Directory of the HOSTS file on the Windows OS: **C:\Windows\|System32\drivers\etc\hosts**

Directory of the HOSTS file on the Linux OS: **/etc/hosts**

```
#Mapping between the IP address and host name.  
10.7.66.111 hd-111  
10.7.66.151 hd-151  
10.7.66.220 hd-220
```

- Connect the server and client.

Method 1:

```
//Connect the client and one or more Gremlin server instances.  
Cluster cluster = GremlinClient.getInstance().getCluster();  
//Create a client based on a cluster object.  
Client client = cluster.connect().alias ("Graph name");
```

Method 2:

```
//Connect the client and one or more Gremlin server instances.  
Cluster cluster = GremlinClient.getInstance().getCluster();  
//Configure a remote graph traversal object on the client.  
Graph graph = GremlinClient.getInstance().getGraph();  
GraphTraversalSource g = graph.traversal().withRemote(DriverRemoteConnection.using (cluster,  
"Graph name"));
```

### 1.9.3.8.2 Running Gremlin Java API Example Code

- Submit Gremlin DSL statements as a client object.

```
//Submit Gremlin DSL statements synchronously.  
ResultSet resultSet = Client.submit("g.V().has('propertyKey', 'huawei').valueMap().limit(10)");  
//Submit Gremlin DSL statements asynchronously.  
Future<ResultSet> resultSet =  
Client.submitAsync("g.V().hasLabel('person').valueMap('name','age').limit(10)");  
//Generate the result.  
==>{name=[vadas], age=[27]}  
==>{name=[josh], age=[32]}  
==>{name=[blame], age=[30]}  
==>{name=[marko], age=[29]}
```

- Perform a graph traversal.

```
//Perform vertex traversal.  
Iterator<Map<String,Object>> iterator = g.V(ids).valueMap(properties).limit(10)  
//Perform edge traversal.  
Iterator<Map<String,Object>> iterator = g.E(ids).valueMap(properties).limit(10)  
//Generate the result.  
==>{name=[vadas], age=[27]}  
==>{name=[josh], age=[32]}  
==>{name=[blame], age=[30]}  
==>{name=[marko], age=[29]}
```

### 1.9.3.9 Gremlin Application Scenarios

#### 1.9.3.9.1 Querying a Specified Graph Object

- Query a specified vertex.

```
//Taverse all properties of the vertex based on the vertex ID.  
gremlin> g.V(1151560,1195696).valueMap()
```

```
==>{name=[vadas], age=[27]}\n==>{name=[josh], age=[32]}
```

- **Query a specified edge.**  
gremlin> g.E('fryh-oojs-93th-108hc', '102fq-pmls-6aol-vegw').valueMap()  
==>{weight=0.8}\n==>{weight=0.4}

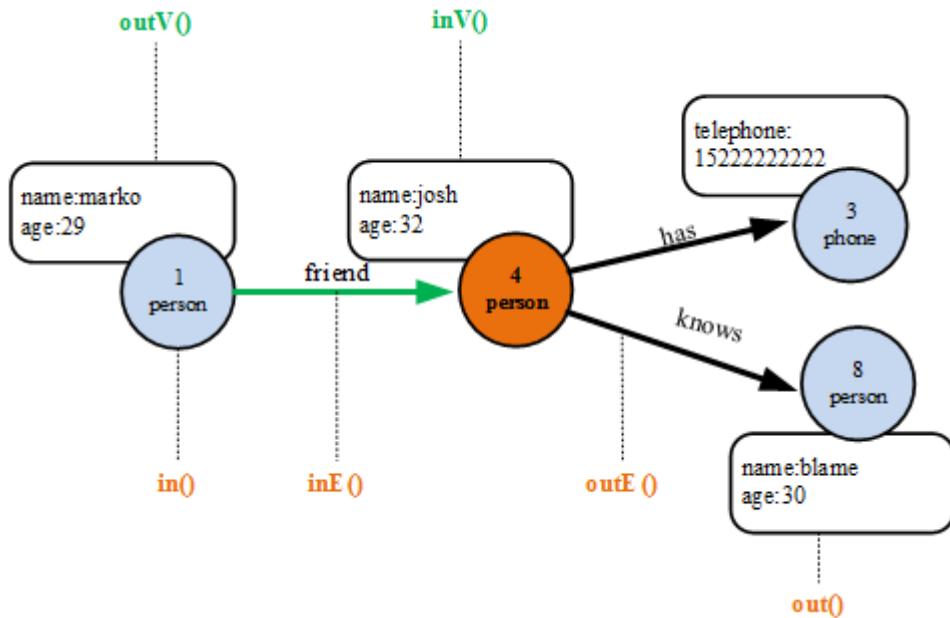

### 1.9.3.9.2 Queries One or More Properties

Querying one or more properties of a graph object.

```
gremlin> g.V().hasLabel('person').valueMap('name','age')\n==>{name=[vadas], age=[27]}\n==>{name=[josh], age=[32]}\n==>{name=[blame], age=[30]}\n==>{name=[marko], age=[29]}
```

### 1.9.3.9.3 Traversing a Graph Object

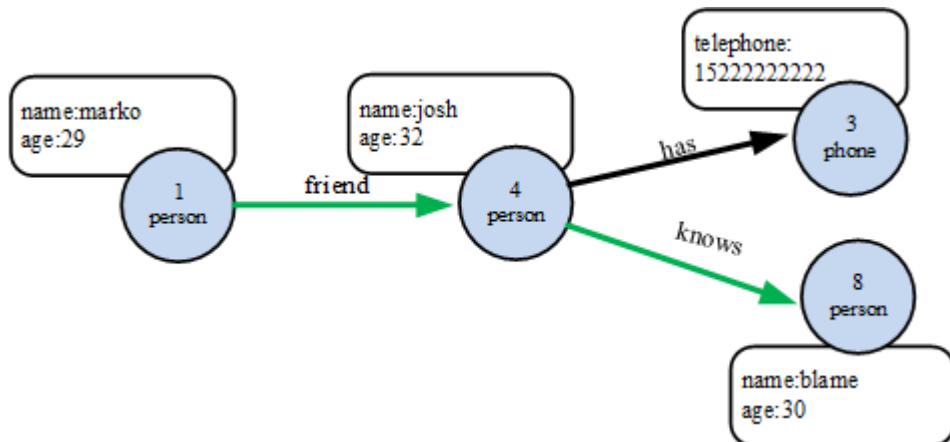

Graph Object Traversal	Description
Out(string )	Move to the outgoing adjacent vertices given the edge labels.
In(string )	Move to the incoming adjacent vertices given the edge labels.
Both(string )	Move to both the incoming and outgoing adjacent vertices given the edge labels.
OutE(string )	Move to the outgoing incident edges given the edge labels.
InE(string )	Move to the incoming incident edges given the edge labels.
BothE(string )	Move to both the incoming and outgoing incident edges given the edge labels.
outV()	Move to the outgoing vertex.
inV()	Move to the incoming vertex.
bothV()	Move to both vertices.

```

//Start from vertex 4 and traverse the edge to the out direction to obtain the incoming vertex of the edge.
gremlin> g.V(4).outE().inV()
==>v[3]
==>v[8]
//Move from vertex 4 to the out direction to obtain the peer vertex.
gremlin> g.V(4).out()
==>v[3]
==>v[8]
//Start from vertex 4 and traverse all edges to the out direction.
gremlin> g.V(4).outE()
==>e[10][4-has->3]
==>e[11][4-knows->8]
//Start from vertex 4 and traverse the edge to the out or in direction. The edge labels must be of a
specified edge type, such as knows, has, or friend.
gremlin> g.V(4).bothE('knows','has','friend')
==>e[10][4-has->3]
==>e[11][4-knows->8]
==>e[8][1-friend->4]
  
```

#### 1.9.3.9.4 Traversing a Path

Function: path()

```
//Start from vertex 1 and traverse two layers to the out direction to obtain the peer vertex of the second layer.  
gremlin> g.V(1).out().out().values('name')  
==>blame  
//Start from vertex 1 and traverse two layers to the out direction to return the track path of the traversal.  
gremlin> g.V(1).out().out().values('name').path()  
==>[v[1],v[4],v[8],blame]
```

### 1.9.3.9.5 Filtering by Condition

- Filtering function: has()

has	Description
has(key, value)	Remove the traverser if its element does not have the provided key/value property.
has(label, key, value)	Remove the traverser if its element does not have the specified label and provided key/value property.
has(key, predicate)	Remove the traverser if its element does not have a key value that satisfies the predicate.
HasLabel(labels )	Remove the traverser if its element does not have any of the labels.
HasId(ids )	Remove the traverser if its element does not have any of the IDs.
HasKey(keys )	Remove the traverser if the property does not have all of the provided keys.
HasValue(values )	Remove the traverser if its property does not have all of the provided values.
has(key)	Remove the traverser if its element does not have a value for the key.
hasNot(key)	Remove the traverser if its element has a value for the key.

- Expression: predicate

Predicate	Description
eq(object)	Is the incoming object equal to the provided object?
neq(object)	Is the incoming object not equal to the provided object?
lt(number)	Is the incoming number less than the provided number?
lte(number)	Is the incoming number less than or equal to the provided number?
gt(number)	Is the incoming number greater than the provided number?

Predicate	Description
gte(number)	Is the incoming number less than or equal to the provided number?
inside(number, number)	Is the incoming number greater than the first provided number and less than the second?
outside(number, number)	Is the incoming number less than the first provided number or greater than the second?
between(number, number)	Is the incoming number greater than or equal to the first provided number and less than the second?
Within(objects )	Is the incoming object in the array of provided objects?
Without(objects )	Is the incoming object not in the array of the provided objects?
TextP.startsWith(string)	Does the incoming String start with the provided String?
TextP.endsWith(string)	Does the incoming String end with the provided String?
TextP.contains(string)	Does the incoming String contain the provided String?
TextP.notStartingWith(string)	Does the incoming String not start with the provided String?
TextP.notEndingWith(string)	Does the incoming String not end with the provided String?
TextP.notContaining(string)	Does the incoming String not contain the provided String?

```
//Traverse the vertices that are of the person type.
gremlin> g.V().hasLabel('person')
==>v[1151560]
==>v[1195696]
==>v[1465088]
==>v[1421128]
//Traverse the vertices with the age property.
gremlin> g.V().properties().hasKey('age').value()
==>27
==>32
==>30
==>29
//Traverse the vertices where the values of the age properties are within the range from 20 to 30.
gremlin> g.V().has('age',inside(20,30)).values('age')
==>29
==>27
//Traverse the veretxes where the value of the name property is josh or marko.
gremlin> g.V().has('name',within('josh','marko')).valueMap()
==>{name=[josh], age=[32]}
==>{name=[marko], age=[29]}
```

### 1.9.3.9.6 Sorting the Result

```
//Sort the result based on the value of the age property in ascending order.
gremlin> g.V().hasLabel('person').order().by('age', incr).valueMap('name','age')
==>{name=[vadas], age=[27]}
==>{name=[marko], age=[29]}
==>{name=[blame], age=[30]}
==>{name=[josh], age=[32]}
//Sort the result based on the value of the age property in descending order.
gremlin> g.V().hasLabel('person').order().by('age', decr).valueMap('name','age')
==>{name=[josh], age=[32]}
==>{name=[blame], age=[30]}
==>{name=[marko], age=[29]}
==>{name=[vadas], age=[27]}
```

### 1.9.3.9.7 Displaying the Result in Multiple Pages

```
//Sort the result based on the value of the age property in ascending order and only obtain the first two data records.
gremlin> g.V().hasLabel('person').order().by('age', incr).limit(2).valueMap('name','age')
==>{name=[vadas], age=[27]}
==>{name=[marko], age=[29]}
//Sort the result based on the value of the age property in ascending order and obtain data from the third to the fourth records.
gremlin> g.V().hasLabel('person').order().by('age', incr).range(2,4).valueMap('name','age')
==>{name=[blame], age=[30]}
==>{name=[josh], age=[32]}
```

### 1.9.3.9.8 Calculating the Intersection Between Two Data Sets

```
//During the traversal, the concept of the intersection between two data sets must be differentiated from the join operation in the SQL syntax.
gremlin> g.V().hasLabel('person').match(
    __.as('c').values('name').as('name') //Data set 1. The column alias is name.
    __.as('c').out('friend','knows').values('name').as('friend_or_knows') //Data set 2. The column alias is friend_or_knows.
    ).select('name', 'friend_or_knows') //Calculate the intersection between the two data sets.
==>{name=josh, friend_or_knows=blame}
==>{name=marko, friend_or_knows=josh}
==>{name=marko, friend_or_knows=vadas}
```

### 1.9.3.9.9 Calculating the Union of Two Data Sets

```
//During the traversal, calculate the union of the following two data sets.
gremlin> g.V().has('name','josh').union(
    __.in('friend').values('name'), //Data set 1
    __.out('knows').values('name')) //Data set 2
==>marko
==>blame
```

### 1.9.3.9.10 Using Statistical Functions

Function	Description
count()	Collects data.
max()	Calculates the maximum value.
min()	Calculates the minimum value.
mean()	Calculates the average value.
sum()	Sums up data.

```
//Calculate the number of vertices whose type is person
gremlin> g.V().hasLabel('person').count()
==>4
//Traverse all vertices to obtain the maximum value of the age property.
gremlin> g.V().values('age').max()
==>32
```

## 1.9.4 Application Commissioning

### 1.9.4.1 Commissioning an Application in Windows

#### 1.9.4.1.1 Compiling and Running an Application

##### Scenario

After the code development is complete, you can run the application in the Windows development environment. If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

If IBM JDK is used in the Windows environment, the application cannot be run in the Windows environment.

##### Procedure

In the development environment (for example, running the REST API on the IntelliJ IDEA environment), right-click **GraphBaseRestExample.java** and choose **Run > GraphBaseRestExample.main()**.

#### 1.9.4.1.2 Viewing Windows Commissioning Results

##### Scenario

After the running of GraphBase application completes, you can view the running results in the IntelliJ IDEA running result.

##### Procedure

The following information is displayed in the running results:

```
REQ HEADER: POST https://10.4.64.110:22380/graphbase/graph HTTP/1.1
REQ BODY: {"graphName":"graphbase"}
RSP BODY: {
    "msg": "create graph success.",
    "code": "0"
}
[SUCCESS]: create graph[graphbase] successfully.
REQ HEADER: POST https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1
REQ BODY: {"name":"person"}
RSP BODY: {
    "msg": "Success.",
    "code": "0",
    "data": {
        "name": "person"
    }
}
```

```
[SUCCESS]: create vertex label[person] successfully.  
REQ HEADER: POST https://10.154.4.90:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1  
REQ BODY: {"name":"phone"}  
RSP BODY: {  
    "msg": "Success.",  
    "code": "0",  
    "data": {  
        "name": "phone"  
    }  
}  
[SUCCESS]: create vertex label[phone] successfully.  
REQ HEADER: GET https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label/person  
HTTP/1.1  
RSP BODY: {  
    "msg": "Success.",  
    "code": "0",  
    "data": {  
        "name": "person"  
    }  
}  
[SUCCESS]: query vertex label[person] successfully.  
REQ HEADER: GET https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1  
RSP BODY: {  
    "msg": "Success.",  
    "code": "0",  
    "data": {"vertexLabelList": [  
        {  
            "name": "person"  
        },  
        {  
            "name": "phone"  
        }  
    ]}  
}  
[SUCCESS]: query all vertex label successfully.  
...
```

## 1.9.4.2 Commissioning an Application in Linux

### 1.9.4.2.1 Compiling and Running an Application

#### Scenario

GraphBase applications can run in a Linux OS. After application code development is complete, you can upload a JAR file to the Linux environment to run applications.

#### Prerequisites

- A JDK has been installed in the Linux environment. The version of the JDK must be consistent with that of the JDK used by the JAR package exported by IntelliJIDEA.
- If the Linux host is not a node in the cluster, set the mapping between the host name and the IP address in the **hosts** file on the node. The host name and IP address must be in one-to-one mapping.

#### Procedure

##### Step 1 Export a JAR package.

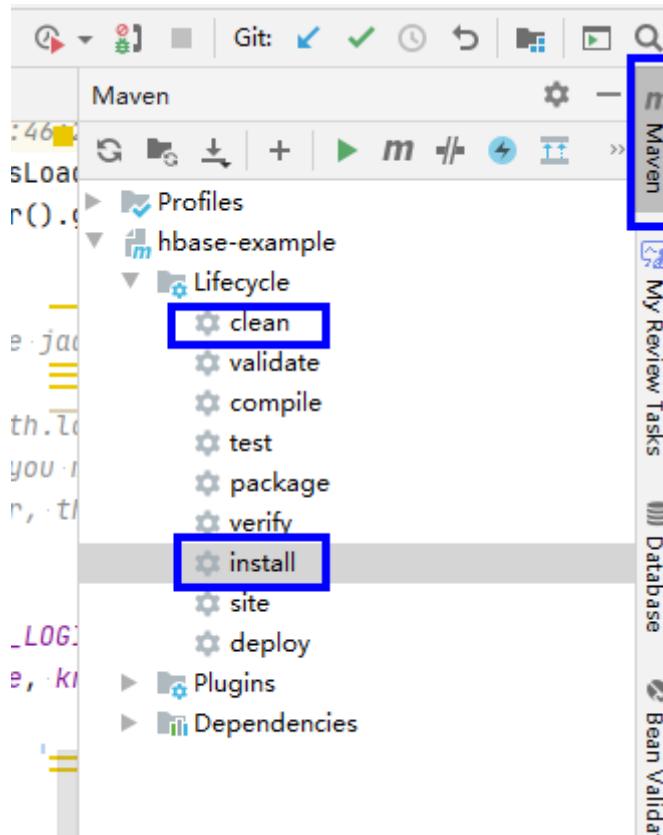

You can build a JAR package in either of the following ways:

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean**. Double-click **clean** to run the clean command of Maven.

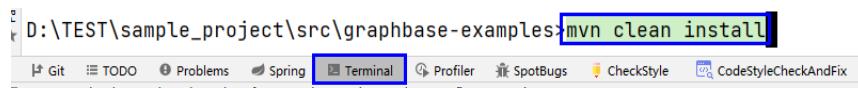

Choose **Maven** > *Sample project name* > **Lifecycle** > **install**. Double-click **install** to run the install command of Maven.

**Figure 1-110** clean and install

- Method 2: Access the directory where the **pom.xml** file is located in the **Terminal** window at the bottom of the IDEA. Run the **mvn clean install** command to compile the file.

**Figure 1-111** mvn clean install

After the compilation is complete, "Build Success" is printed, and the target directory is generated. The generated JAR package is stored in the target directory.

## Step 2 Export the JAR package on which the sample project depends.

Access the directory where the pom.xml file is located in the Terminal window or other command line tools at the bottom of the IDEA, and then run the following command:

```
mvn dependency:copy-dependencies -DoutputDirectory=lib
```

The lib folder is generated in the pom.xml directory, which contains the JAR package on which the sample project depends.

**Step 3** Prepare for the required JAR packages and configuration files.

1. In the Linux environment, create a directory, for example, **/opt/test**, and create subdirectories**conf** and **lib**. Upload the JAR packages in **Step 1** and **Step 2** to the **lib** directory in Linux. Upload the conf configuration files in the sample project to the **conf** directory in Linux.
2. Import the user authentication credential files.

Import the authentication credential files (**user.keytab** and **krb5.conf**) of the current user to the **conf** directory. On the FusionInsight Manager page, choose **System > Permission > User** to obtain the authentication credential files. Locate the row that contains the user whose authentication credentials need to be exported, and choose **More > Download Authentication Credential**.

3. In **/opt/test**, create the**GraphBase.sh** script, modify the following content, and save the file:

```
function Startup()
{
    SCRIPT_PATH=$(cd $(dirname $(readlink -f "${BASH_SOURCE[0]}")) && pwd )
    for f in ${SCRIPT_PATH}/lib/*.jar;
    do
        CLASSPATH=${CLASSPATH}:$f
    done
    JAVA_EXE=java
    JAVA_OPTS="$JAVA_OPTS -Xms2G -Xmx4G"
    ${JAVA_EXE} ${JAVA_OPTS} -classpath ${CLASSPATH}
    com.huawei.graphbase.example.GraphBaseRestExample
}
Startup
```

In the preceding content, "com.huawei.graphbase.example.GraphBaseRestExample" is used as an example.

**Step 4** Go to **/opt/test** and run the following commands to run the JAR packages:

**./graphbase.sh**

**----End**

#### 1.9.4.2.2 Viewing Linux Commissioning Results

##### Scenario

After an GraphBase application is run, you can check the running result through one of the following methods:

- Viewing the command output.
- Viewing GraphBase logs.

##### Procedure

The following information is displayed in the running results:

```
REQ HEADER: POST https://10.4.64.110:22380/graphbase/graph HTTP/1.1
REQ BODY: {"graphName":"graphbase"}
RSP BODY: {
```

```
"msg": "create graph success.",
"code": "0"
}
[SUCCESS]: create graph[graphbase] successfully.
REQ HEADER: POST https://10.4.64.110:22380/graphbase/graph/graphbase/schema/vertex-label HTTP/1.1
REQ BODY: {"name":"person"}
RSP BODY: {
    "msg": "Success.",
    "code": "0",
    "data": {
        "name": "person",
        "isPartitioned": "false"
    }

## 1.9.5 More Information

### 1.9.5.1 Common APIs

#### 1.9.5.1.1 REST API

For details about the complete and detailed description of GraphBase REST APIs, see *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

### 1.9.5.1.2 Gremlin API

For details about the GraphBase Gremlin API, see [Gremlin Console](#), [Gremlin Java](#) and [Gremlin Application Scenarios](#).

## 1.10 HBase Development Guide

### 1.10.1 Overview

#### 1.10.1.1 Application Development Overview

##### HBase Introduction

HBase is a column-oriented scalable distributed storage system featuring high reliability and high performance. HBase is designed to break through the limitation when relational databases are used to process massive data.

HBase applies to the following application scenarios:

- Massive data processing (higher than the TB or PB level).
- Scenarios that require high throughput.
- Scenarios that require efficient random read of massive data.
- Scenarios that require good scalability.
- Structured and unstructured data is concurrently processed.
- The Atomicity, Consistency, Isolation, Durability (ACID) feature supported by traditional relational databases is not required.
- HBase tables provide the following features:
  - Large: One table contains a hundred million rows and one million columns.
  - Column-oriented: Storage and rights control is implemented based on columns (families), and columns (families) are independently retrieved.
  - Sparse: Null columns do not occupy storage space, so a table is sparse.

##### Interface Type Introduction

The Java language is recommended for HBase application development because HBase is developed based on Java and Java is a concise, universal, and easy-to-understand language.

HBase adopts the same interfaces as those of Apache HBase.

**Table 1-73** describes the functions that HBase can provide by invoking interfaces.

**Table 1-73** Functions provided by HBase interfaces

Function	Description
Data CRUD function	Data creating, retrieving, updating, and deleting
Advanced feature	Filter, secondary index, and coprocessor
Management function	Table management and cluster management

### 1.10.1.2 Common Concepts

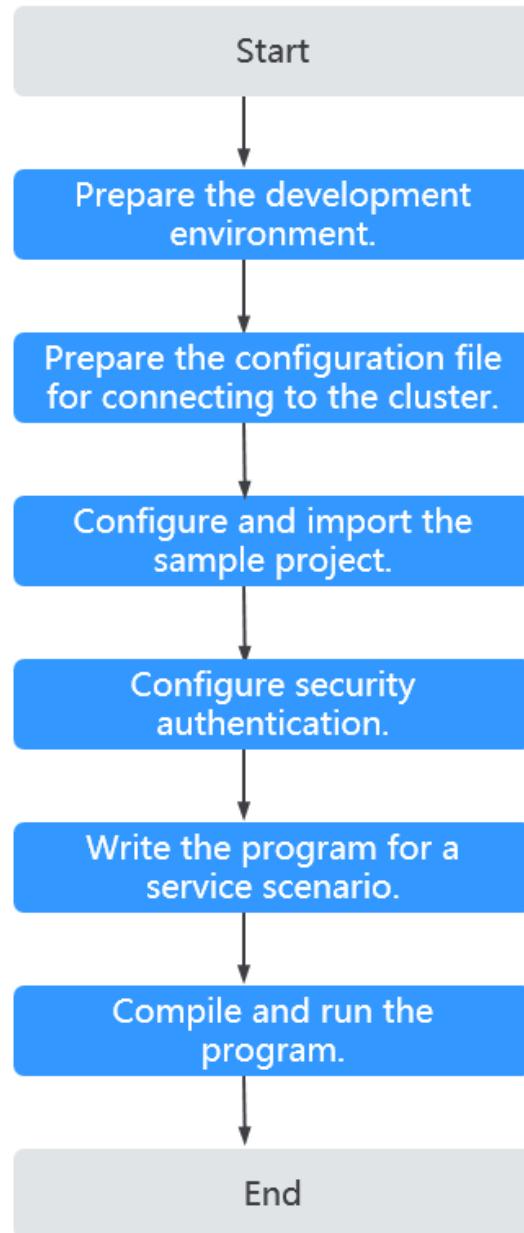

- **Filter**  
Filters provide powerful features to help users improve the table data processing efficiency of HBase. Users can use the filters predefined in HBase and customized filters.
- **Coprocessor**  
Coprocessors enable users to perform region-level operations and provide functions similar to those of triggers in relational database management systems (RDBMSs).
- **keytab file**  
The keytab file is a key file that stores user information. In security mode, applications use the key file for API authentication on HBase.
- **Client**  
Users can access the server from the client through the Java API, HBase Shell or WebUI to read and write HBase tables. The HBase client in this document indicates the HBase client installation package, see [External Interfaces](#).

### 1.10.1.3 Development Process

This document describes HBase application development based on the Java API.

For information about each phase in the development process, see [Figure 1-112](#) and [Table 1-74](#).

Figure 1-112 HBase application development process

**Table 1-74** HBase application development process description

Phase	Description	Reference Document
Prepare the development environment.	Before developing an application, you need to prepare the development environment. You are advised to use the Java language and IntelliJ IDEA tool for development. In addition, you need to complete the initial configuration of the JDK and Maven.	<a href="#">Preparing for Development Environment</a>
Prepare the Configuration File for Connecting to the Cluster.	During application development or running, you need to connect to the MRS cluster through cluster configuration files. Configuration files include cluster component information files and user files used for security authentication. You can obtain related content from the created MRS cluster. Nodes used for program commissioning or running must be able to communicate with nodes in the MRS cluster and the hosts domain name must be configured.	<a href="#">Preparing the Connection Cluster Configuration File</a>
Configure and import the sample project.	HBase provides multiple sample programs in different scenarios. You can obtain sample projects and import them to the local development environment for program learning.	<a href="#">Configuring and Importing Sample Projects</a>
Configure security authentication.	If you are using an MRS cluster with Kerberos authentication enabled, you need to perform security authentication.	<a href="#">Preparing for Security Authentication</a>

Phase	Description	Reference Document
Develop programs based on business scenarios.	Develop programs based on actual service scenarios and invoke component interfaces to implement corresponding functions.	<a href="#">Developing an Application</a>
Compile and run the application.	You can commission and run the program in the local Windows development environment, or compile the program into a JAR package and submit it to the Linux node for running.	<a href="#">Application Commissioning</a>

#### 1.10.1.4 HBase Sample Project Introduction

To obtain the MRS sample project, visit <https://github.com/huaweicloud/huaweicloud-mrs-example>. Switch to the version branch that matches the MRS cluster, download the package to the local PC, and decompress the package to obtain the sample code project of each component.

Currently, MRS provides the following HBase-related sample projects. You can select an example based on the actual service scenario:

**Table 1-75** HBase-related sample projects

Sample Project Location	Function Description
hbase-examples/hbase-example	<p>Application development example of HBase data read/write operations and global secondary indexes. The following functions can be implemented by calling HBase APIs:</p> <ul style="list-style-type: none"><li>• You can call HBase APIs to create user tables, import user data, add user information, query user information, and create secondary indexes for user tables. For details, see <a href="#">Service Scenario Description</a>.</li><li>• Creates and deletes global secondary indexes, modifies the status of global secondary indexes, and queries data based on global secondary indexes. For details about related service scenarios, see <a href="#">Service Scenario Description</a>.</li><li>• When multiple threads concurrently read data from or write data into an HBase table, region information can be preloaded. For details about related service scenarios, see <a href="#">Sample Program for Preloading Meta Tables When Request Concurrency Is High</a>.</li></ul>
hbase-examples/hbase-rest-example	<p>HBase REST API development sample. Using REST APIs to query clusters, obtain tables, operate Namespaces, and operate tables. For details, see <a href="#">HBase Rest API Invoking Sample Program</a>.</p>
hbase-examples/hbase-thrift-example	<p>Access the HBase ThriftServer development sample. Accessing ThriftServer to operate tables, writing data to tables, and reading data from tables. For details, see <a href="#">Accessing the HBase ThriftServer Sample Program</a>.</p>

Sample Project Location	Function Description
hbase-examples/hbase-zk-example	Application development example for HBase to access ZooKeeper. The same client process accesses both the FusionInsight ZooKeeper and third-party ZooKeeper. The HBase client accesses the FusionInsight ZooKeeper, and the customer application accesses the third-party ZooKeeper. For details, see <a href="#">Sample Program for HBase to Access Multiple ZooKeepers</a> .
springboot/hbase-examples	Provide an example of connecting Phoenix to SpringBoot. This example describes how to interconnect HBase with Phoenix with Spring Boot. For details, see <a href="#">Security Authentication for Interconnecting HBase/Phoenix with Spring Boot</a> .

## 1.10.2 Environment Preparation

### 1.10.2.1 Preparing for Development Environment

[Table 1-76](#) describes the environment required for secondary development.

**Table 1-76** Development environment

Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows OS. Windows 7 or later is supported.</li><li>• Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul>

Item	Description
Installing JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>Tool used for developing HBase applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>
JUnit plug-in installation	Basic configuration for the development environment.

Item	Description
Installation of Maven	Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development.  Huawei provides Huawei Mirrors for you to download all dependency JAR files of sample projects. However, you need to download the rest dependency open-source JAR files from the Maven central repository or other custom repository address. For details, see <a href="#">Configuring Huawei Open-Source Mirrors</a> .
7-zip	Used to decompress .zip and .rar packages. The 7-Zip 16.04 is supported.

### 1.10.2.2 Preparing the Connection Cluster Configuration File

#### Preparing a Developer Account

For an MRS cluster with Kerberos authentication enabled, you need to prepare a user who has the permission to perform operations on related components for program authentication.

The following HBase permission configuration example is for reference only. You can adjust the permission configuration based on service requirements in actual service scenarios.

**Step 1** Log in to FusionInsight Manager.

**Step 2** Choose **Cluster > Services > HBase > More > Enable Ranger**, and check whether this parameter is dimmed.

- If yes, create a user and grant related operation rights to the user in Ranger.
  - a. Choose **System > Permission > User > Create**. On the Create user page, create a Machine-Machine user, for example, **developuser**. The user group must be added to the **hadoop** user group.
  - b. Log in to the Ranger management page as the Ranger administrator **rangeradmin**.
  - c. On the home page, click a component plug-in name in the **HBASE** area, for example, HBase.
  - d. Click  in the Operation column of **all - table, column-family, column** for Policy Name.
  - e. In the **Allow Conditions** area, add a policy condition, select the new user name in the **Select User** column, and select **Select All** in the **Permissions** column.
  - f. Click **Save**.
- If no, create a user and grant related operation permissions to the user on FusionInsight Manager.
  - a. Choose **System > Permission > Role > Create Role**.

- i. Enter the role name, for example, **developrole**.
- ii. In **Configure Resource Permission**, choose *Name of the desired cluster* > **HBase** > **HBase Scope** > **global**, select the **admin**, **create**, **read**, **write**, and **execute** permissions, and click **OK**.
- iii. Choose **User** > **Create**. On the Create user page, create a Machine-Machine user, for example, **developuser**.
  - o The user group must be added to the **hadoop** user group.
  - o Add the new role to **Role**.

**Step 3** Log in to FusionInsight Manager as the **admin** user and choose **System** > **Permission** > **User**. In the Operation column of the user named **developuser**, choose **More** > **Download Authentication Credential** to download the authentication credential file. Save the file and decompress it to obtain the **user.keytab** and **krb5.conf** files for security authentication in the sample project.

----End

## Preparing an Operating Environment

During application development or running, you need to connect to the MRS cluster through cluster configuration files. Configuration files include cluster component information files and user files for security authentication. You can obtain related content from the created MRS cluster.

Nodes used for program commissioning or running must be able to communicate with nodes in the MRS cluster and the hosts domain name must be configured.

- Scenario 1: Prepare the configuration files required by the commissioning program in the local Windows development environment.
  - a. Log in to the FusionInsight Manager, click **Download Client** in the upper right corner of the Homepage, set **Select Client Type** to **Configuration Files Only** and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client configuration file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** file.
  - b. Go to the client configuration file decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles\HBase\config**, obtain related configuration files from the [Table 1-77](#).

**Table 1-77** Configuration files

file	Function
core-site.xml	Configures Hadoop Core parameters.
hbase-site.xml	Configures HBase parameters.

file	Function
hdfs-site.xml	Configures HDFS parameters.

 NOTE

To obtain the configuration file required by the HBase ThriftServer sample project, see [Preparing the ThriftServer Instance Configuration File](#).

- c. Copy the content in the **hosts** file in the decompression directory to the local **hosts** file.

 NOTE

- During application development, if you need to commission applications in the local Windows system, ensure that the local node can communicate with the hosts listed in the hosts file.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.
- When configuring IPv6 hosts on the local PC running Windows, add % and InterfaceIndex of the network interface card (NIC) to the end of the IPv6 address. The InterfaceIndex can be obtained by running the **ipconfig** command.

Example:

fec1:0:0:e505:8:99:5:1%10

- Scenario 2: Prepare the configuration file required for running programs in the Linux environment.
  - a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.
  - b. To obtain the configuration file.
    - i. Log in to the FusionInsight Manager, click **Download Client** in the upper right corner of the Homepage, set **Select Client Type** to **Configuration Files Only** and click **OK**. Download the client configuration file to the active OMS node in the cluster.
    - ii. Log in to the active OMS node as user **root**, go to the directory where the client configuration file is stored (the default directory is **/tmp/FusionInsight-Client/**), and decompress the software package to obtain the configuration files in the [Table 1-77](#) in the *FusionInsight\_Cluster\_1\_Services\_ClientConfig/HBase/config* directory.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, the download path is **/tmp/FusionInsight-Client** on the active management node.

**cd /tmp/FusionInsight-Client**

**tar -xvf FusionInsight\_Cluster\_1\_Services\_Client.tar**

**tar -xvf**

**FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar**

**cd FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles**

 NOTE

HBase ThriftServer sample project, see [Preparing the ThriftServer Instance Configuration File](#).

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

## Preparing the ThriftServer Instance Configuration File

To access HBase ThriftServer and perform table-related operations, perform the following steps:

- Step 1** Log in to FusionInsight Manager, choose **Cluster > Service > HBase > Configuration** and click **All Configurations**, search for and modify the parameter **hbase.thrift.security.qop** of the ThriftServer instance. The value of this parameter must be the same as that of **hbase.rpc.protection**. Save the configuration and restart the node service for the configuration to take effect.

 NOTE

The mapping between **hbase.rpc.protection** and **hbase.thrift.security.qop** is as follows:

- "privacy" - "auth-conf"
- "authentication" - "auth"
- "integrity" - "auth-int"

- Step 2** Obtain the configuration file of the ThriftServer instance in the cluster.

- Method 1: Choose **Cluster > Service > HBase > Instance**, click the ThriftServer instance to go to the details page. In the **Configuration File** area of the **Dashboard** page, click the names of the configuration files **hdfs-site.xml**, **core-site.xml**, and **hbase-site.xml** to obtain the configuration files.
- Method 2: Obtain the configuration files by decompressing the client file in [Preparing an Operating Environment](#). Manually add the following configuration to **hbase-site.xml**. The value of **hbase.thrift.security.qop** must be the same as that in [Step 1](#).

```
<property>
<name>hbase.thrift.security.qop</name>
<value>auth</value>
</property>
<property>
<name>hbase.thrift.kerberos.principal</name>
<value>thrift/hadoop.hadoop.com@HADOOP.COM</value>
</property>
<property>
<name>hbase.thrift.keytab.file</name><value>/opt/huawei/Bigdata/FusionInsight_HD_8.3.1/install/FusionInsight-HBase-2.4.14/keytabs/HBase/thrift.keytab</value>
</property>
```

----End

### 1.10.2.3 Configuring and Importing Sample Projects

#### Background

Obtain the HBase development example project. Import the project to IntelliJ IDEA for learning.

#### Prerequisites

- Ensure that the difference between the local PC time and the MRS cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the MRS cluster time in the bottom-right corner on FusionInsight Manager.
- The development environment and MRS cluster configuration files have been prepared. For details, see [Preparing for Development Environment](#).

#### Procedure

- Step 1** Obtain the sample project from the `src` directory in the directory where the sample code is decompressed by referring to [Obtaining Sample Projects from Huawei Mirrors](#). You can select an example based on the actual service scenario. For details about the example, see [HBase Sample Project Introduction](#).
- Step 2** If you need to commission the HBase sample code on the local Windows operating system, you need to place the configuration files and authentication files required by each sample project by referring to the following table:

**Table 1-78** Place the configuration files/authentication files required for each sample project

Sample Project Location	Configuration/authentication files to be placed
hbase-examples/hbase-example (single cluster)	Place the following files in the <code>../src/main/resources/conf</code> directory of the sample project: <ul style="list-style-type: none"><li>• The configuration files are <code>core-site.xml</code>, <code>hbase-site.xml</code>, and <code>hdfs-site.xml</code> obtained in <a href="#">Preparing an Operating Environment</a>.</li><li>• The authentication files are the keytab authentication files <code>user.keytab</code> and <code>krb5.conf</code> obtained by <a href="#">Preparing a Developer Account</a>.</li></ul>

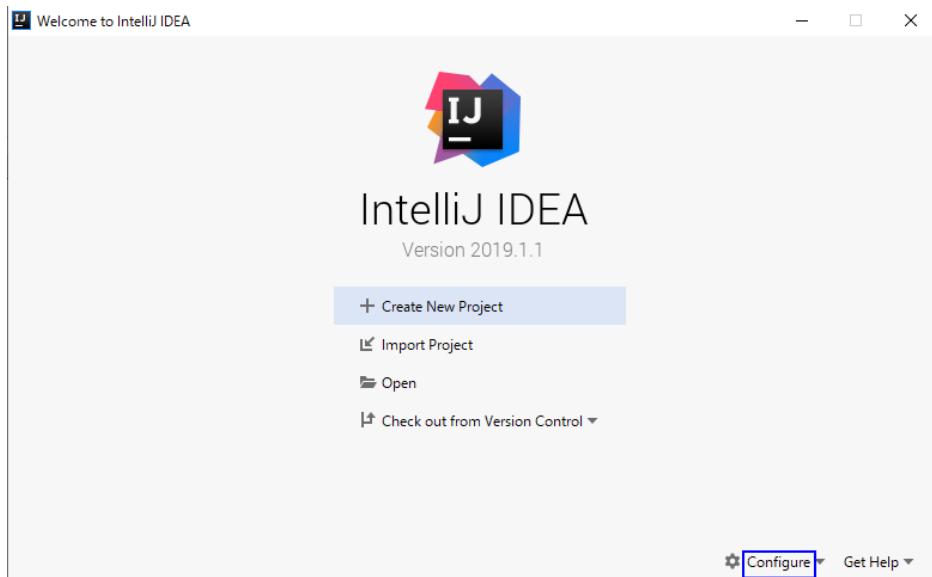

Sample Project Location	Configuration/authentication files to be placed
hbase-examples/hbase-example (multi-cluster)	<p>Place the authentication credential and configuration file of a cluster with the same user name in the mutual trust scenario to the <b>..src/main/resources/hadoopDomain</b> directory, and place the configuration file of the other cluster to the <b>..src/main/resources/hadoop1Domain</b> directory.</p> <ul style="list-style-type: none"><li>The configuration files are <b>core-site.xml</b>, <b>hbase-site.xml</b>, and <b>hdfs-site.xml</b> obtained in section <a href="#">Preparing an Operating Environment</a>.</li><li>The authentication files are the keytab authentication files <b>user.keytab</b> and <b>krb5.conf</b> obtained by <a href="#">Preparing a Developer Account</a>.</li></ul>
hbase-examples/hbase-rest-example	<p>Place the keytab authentication files <b>user.keytab</b> and <b>krb5.conf</b> obtained in <a href="#">Preparing a Developer Account</a> to the <b>..src/main/resources/conf</b> directory. If the conf directory does not exist, create it.</p>
hbase-examples/hbase-thrift-example	<p>Place the following files in the <b>..src/main/resources/conf</b> directory of the sample project:</p> <ul style="list-style-type: none"><li>The configuration files are <b>core-site.xml</b>, <b>hbase-site.xml</b>, and <b>hdfs-site.xml</b> obtained in <a href="#">Preparing the ThriftServer Instance Configuration File</a>.</li><li>The authentication files are the keytab authentication files <b>user.keytab</b> and <b>krb5.conf</b> obtained by <a href="#">Preparing a Developer Account</a>.</li></ul>

Sample Project Location	Configuration/authentication files to be placed
hbase-examples/hbase-zk-example	<p>Place the following files in the <code>./src/main/resources/conf</code> directory of the sample project:</p> <ul style="list-style-type: none"> <li>The configuration files are <code>core-site.xml</code>, <code>hbase-site.xml</code>, and <code>hdfs-site.xml</code> obtained in <a href="#">Preparing an Operating Environment</a>.</li> <li>The authentication files are the keytab authentication files <code>user.keytab</code> and <code>krb5.conf</code> obtained by <a href="#">Preparing a Developer Account</a>.</li> <li>Ensure that the <code>zoo.cfg</code> and <code>jaas.conf</code> files required for authentication in the <a href="#">Security Authentication for Accessing Multiple ZooKeepers</a> exist in the directory.</li> </ul>
springboot/hbase-examples	<p>The following files need to be placed on your local Windows:</p> <ul style="list-style-type: none"> <li>The configuration files are <code>core-site.xml</code>, <code>hbase-site.xml</code>, and <code>hdfs-site.xml</code> obtained in <a href="#">Preparing an Operating Environment</a>.</li> <li>The authentication files are the keytab authentication files <code>user.keytab</code> and <code>krb5.conf</code> obtained by <a href="#">Preparing a Developer Account</a>.</li> </ul>

**Step 3** After the IntelliJ IDEA and JDK are installed, configure the JDK in IntelliJ IDEA.

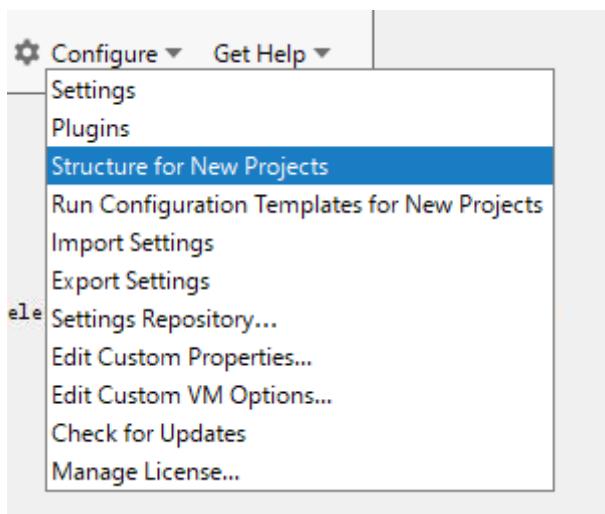

1. Start the IntelliJ IDEA and click **Configure**.

Figure 1-113 Quick Start

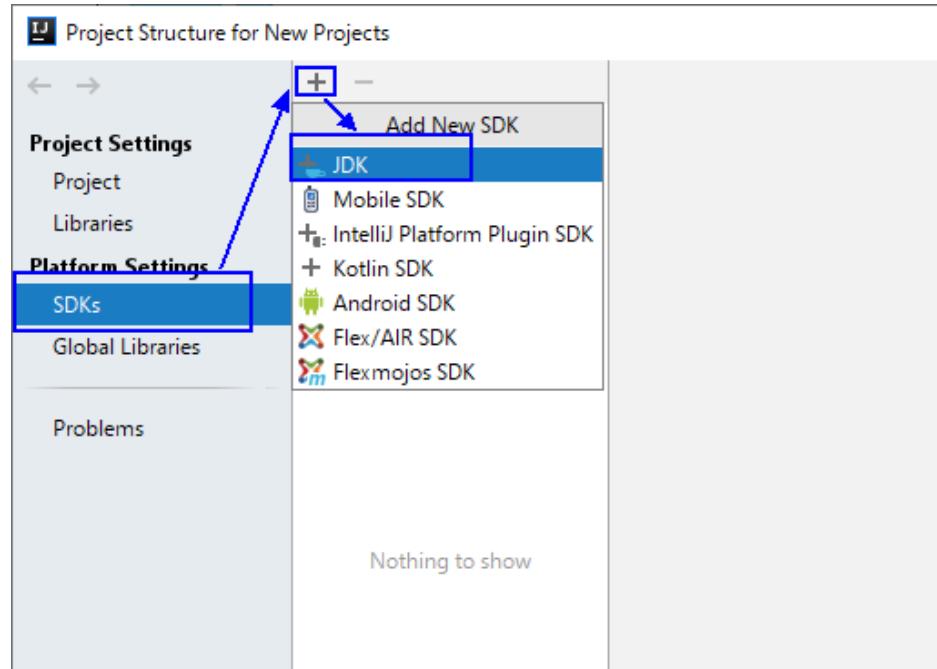

2. Click **Structure for New Projects** from the drop-down list.

Figure 1-114 Configure

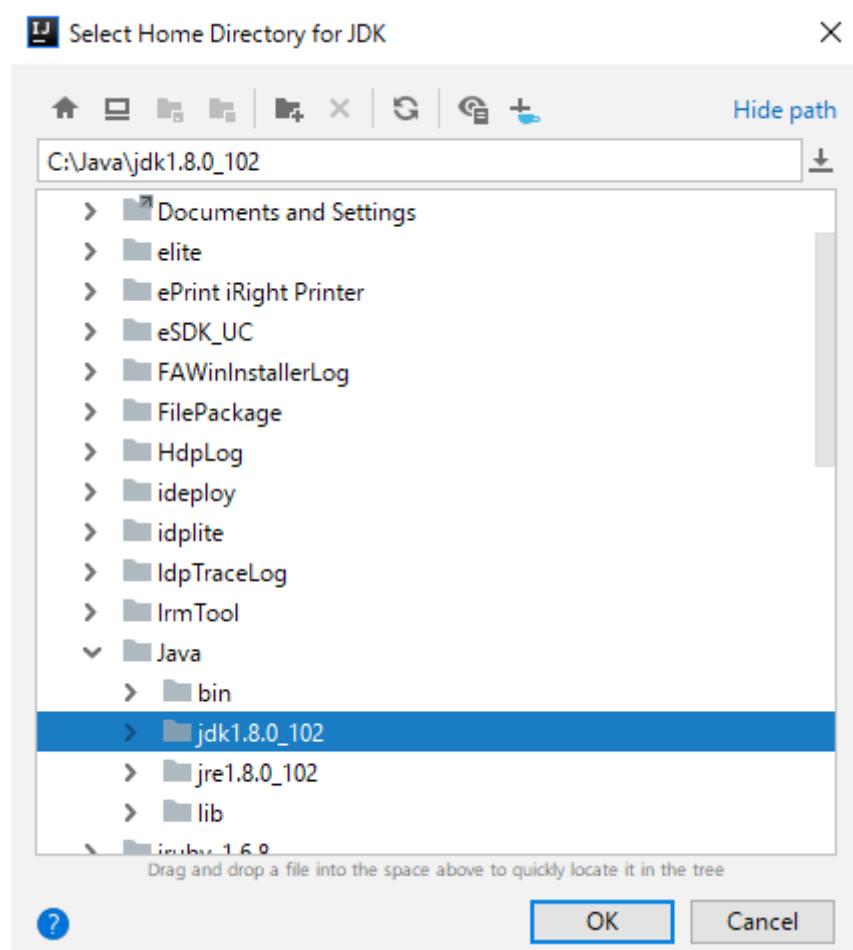

3. On the displayed **Project Structure for New Projects** page, select **SDKs** and click the plus sign (+) to add the **JDK**.

Figure 1-115 Project Structure for New Projects

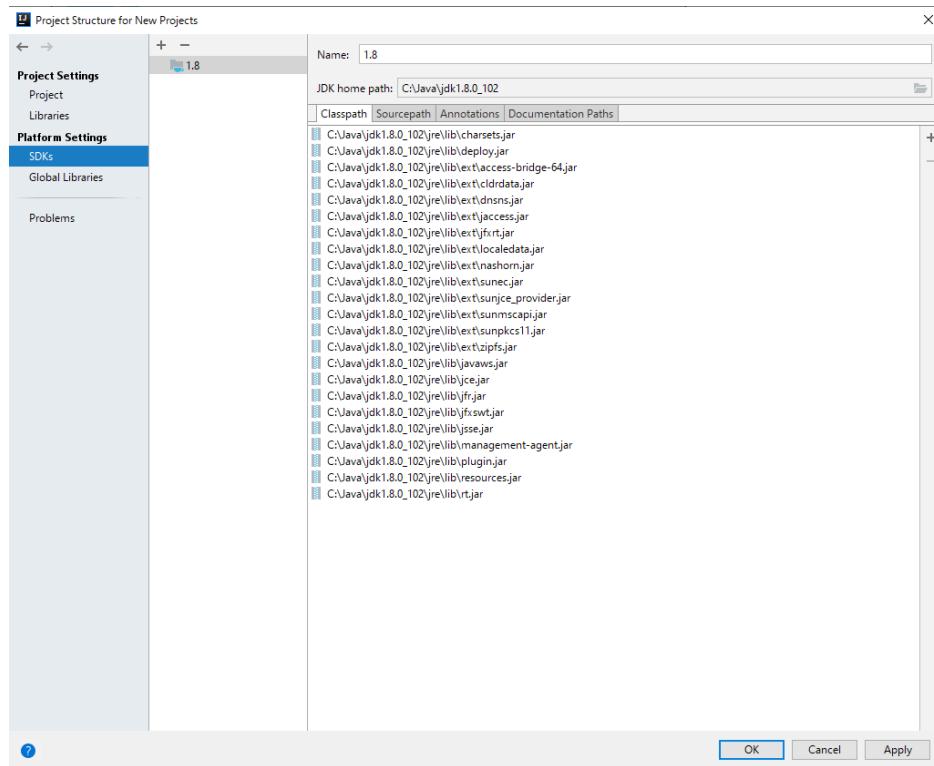

4. In the **Select Home Directory for JDK** window that is displayed, select the JDK directory, and click **OK**.

Figure 1-116 Select Home Directory for JDK

5. After selecting the JDK, click **OK** to complete the configuration.

Figure 1-117 Complete JDK configuration

NOTE

The operations vary by the IDEA version. The operation procedure varies according to the actual version.

**Step 4** Import the example project to the IntelliJ IDEA development environment.

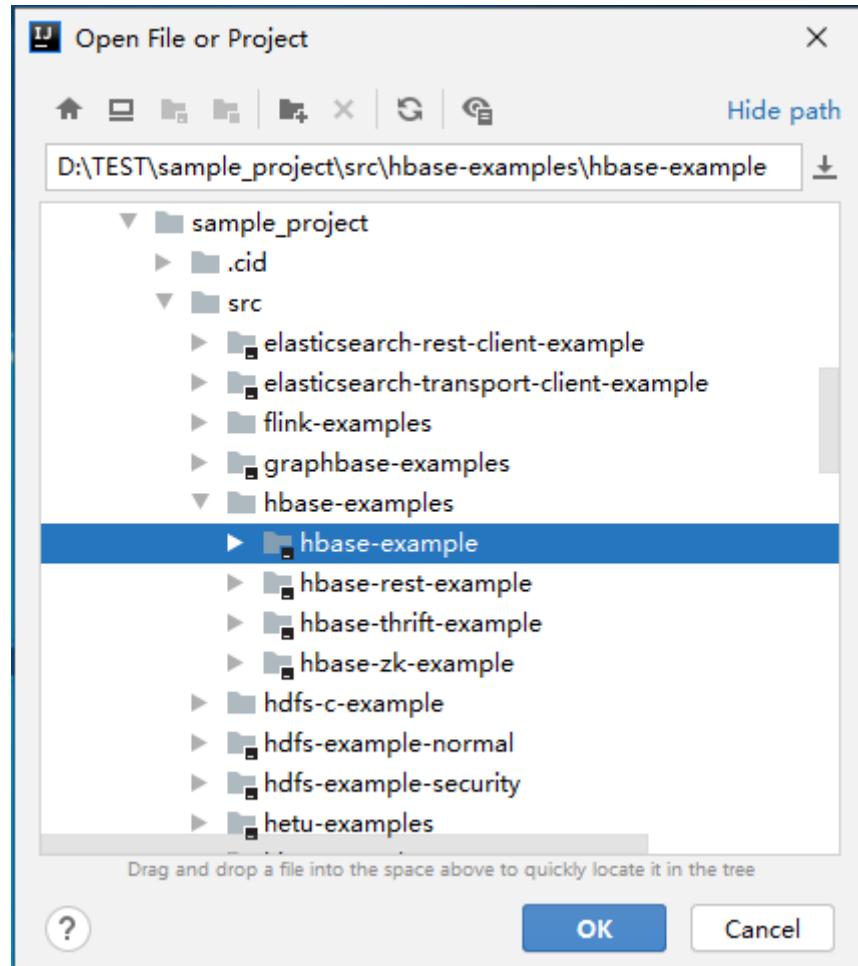

1. Start the IntelliJ IDEA, and click **Import Project** on the Open or Import.
- For the IDEA tool that has been used, you can choose **File > Import project...** on the main interface to import the sample project.

Figure 1-118 Open or Import (Quick Start page)

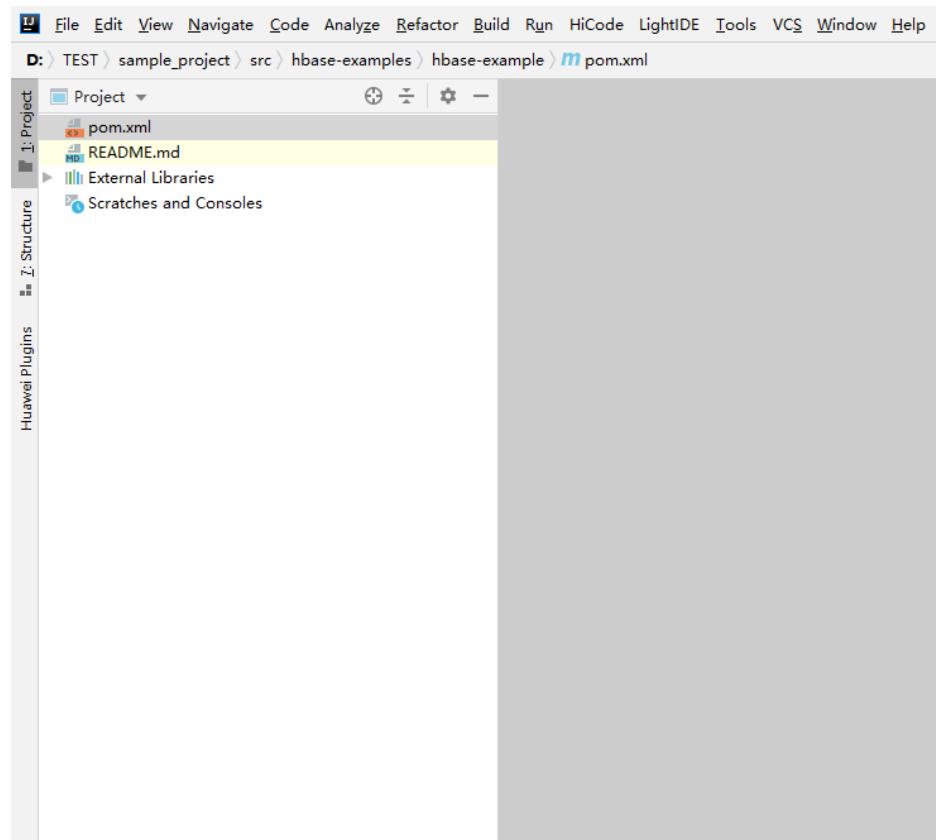

2. Select the example project folder **hbase-example**, and click **OK**.

**Figure 1-119** Select File or Directory to Import

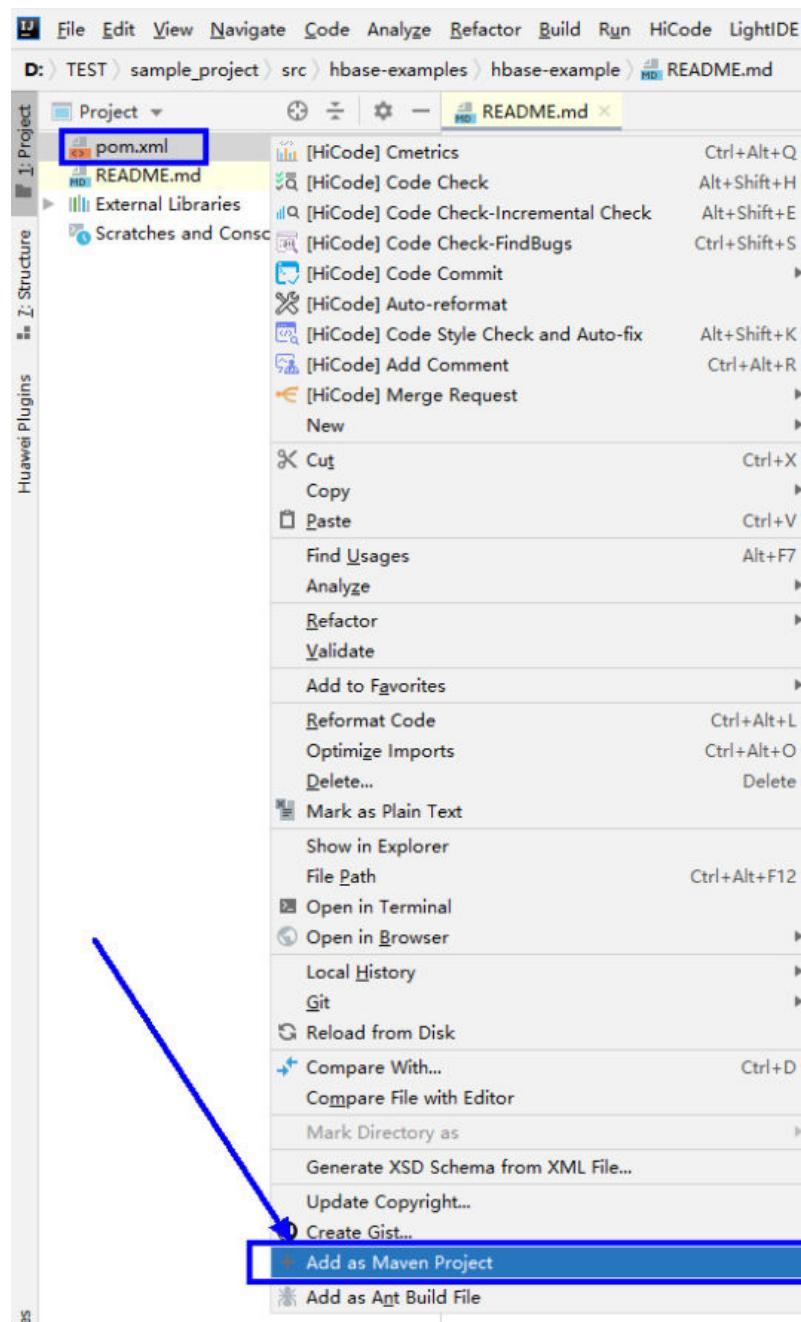

3. After the import, the imported sample project is displayed on the IDEA home page.

Figure 1-120 Successfully importing the sample project

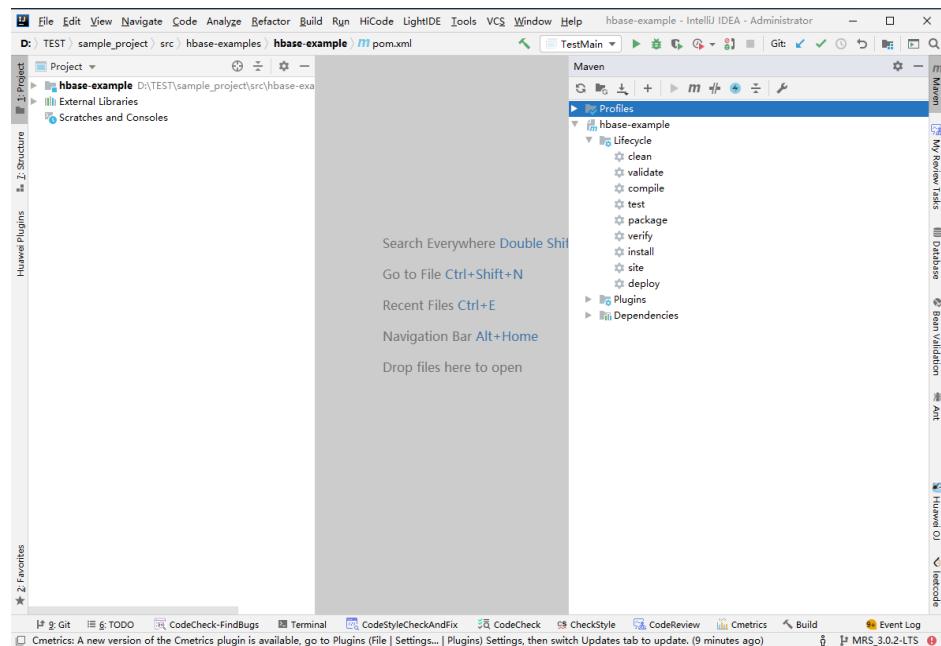

4. Right-click **pom.xml** and choose **Add as Maven Project** from the shortcut menu to add the project as a Maven Project. If the **pom.xml** icon is as shown in , go to the next step.

Figure 1-121 Add as Maven Project

In this case, the IDEA can identify the project as a Maven project.

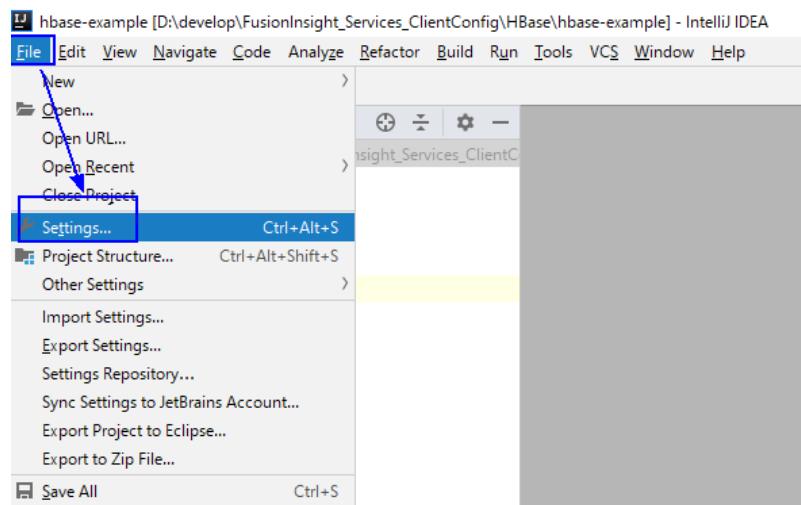

**Figure 1-122** Sample project displayed in IDEA as a Maven project

### Step 5 Set the Maven version used by the project.

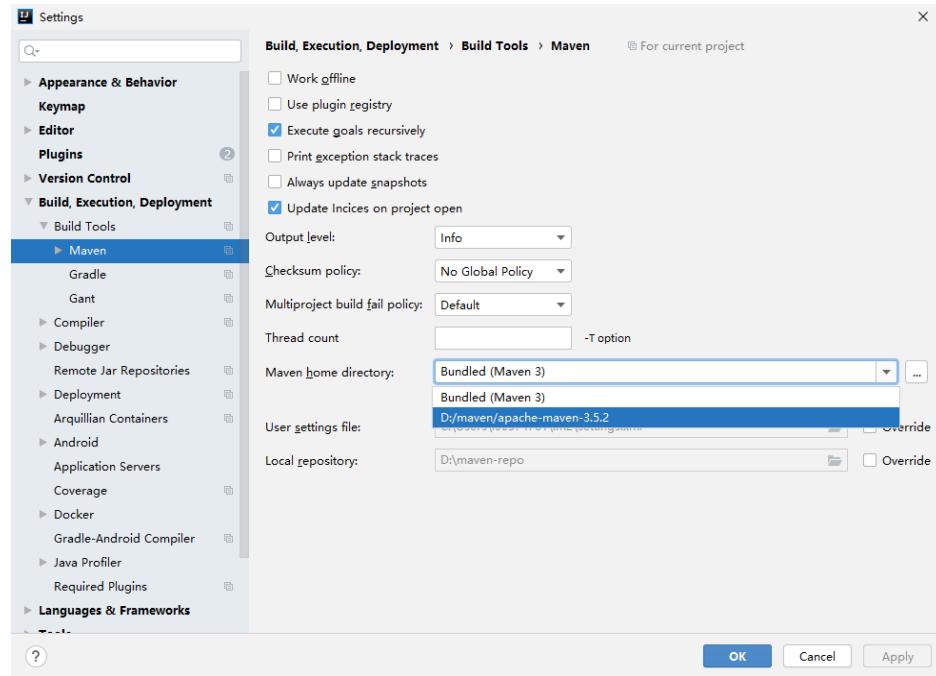

- Choose **File > Settings...** from the main menu of IntelliJ IDEA.

**Figure 1-123** Settings

- Choose **Build,Execution,Deployment > Maven** and set **Maven home directory** to the Maven version installed on the local host.  
Set **User settings file** and **Local repository** parameters based on the site requirements, and choose **Apply > OK**.

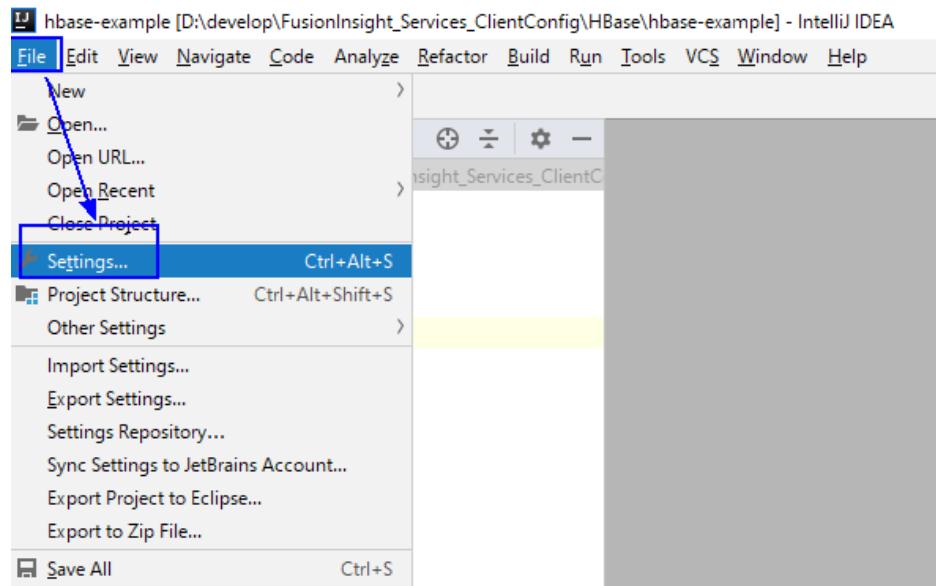

Figure 1-124 Selecting the local Maven installation directory

**Step 6** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

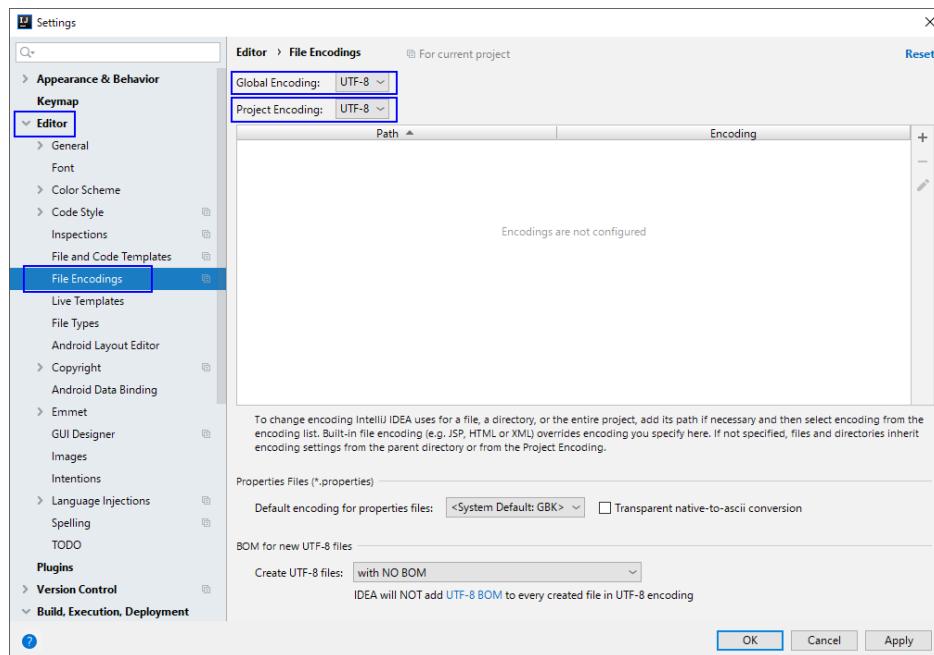

1. On the IntelliJ IDEA menu bar, choose **File > Settings....**

Figure 1-125 Settings

2. In the navigation tree of the **Settings** page, choose **Editor > File Encodings**, and select **UTF-8** for **Global Encoding** and **Project Encoding**.

Figure 1-126 File Encodings

3. Click **Apply** and **OK** to complete the encoding configuration.

----End

#### 1.10.2.4 Preparing for Security Authentication

##### 1.10.2.4.1 Security Authentication for HBase Data Read and Write and Global Secondary Index Example (Single-Cluster Scenario)

###### Scenario

In a security cluster environment, the components must be mutually authenticated before communicating with each other to ensure communication security. ZooKeeper and Kerberos security authentications are required for HBase application development. The **jaas.conf** file is used for ZooKeeper authentication, and the **keytab** and **krb5.conf** files are used for Kerberos security authentication.

The code authentication mode is used for security authentication. Oracle Java and IBM Java are supported.

 NOTE

- Before using an IBM JDK on a client, check whether the MRS cluster runs one of the following versions. If not, upgrade the cluster version first.
  - MRS 8.2.0 or later
  - MRS 8.1.2.5 or later 8.1.x
  - MRS 8.0.2.6 or later 8.0.2.x
- SASL of IBM JDKs is incompatible with JDKs such as OpenJDK. As a result, the authentication fails. In this case, you need to check the client parameters and then perform the authentication. To perform the authentication, perform the following steps:
  1. Open the HBase configuration file **hbase-site.xml** to be loaded on the client or to an application.
  2. Check the **hbase.rpc.client.impl** value.
  3. If the value is **org.apache.hadoop.hbase.ipc.NettyRpcClient**, go to [Changing the Configuration Value](#) to modify the configuration. Otherwise, no further action is required.
  4. Change the **hbase.rpc.client.impl** value to **org.apache.hadoop.hbase.ipc.BlockingRpcClient** or **org.apache.hadoop.hbase.ipc.RpcClientImpl**.

The following code snippet belongs to the **TestMain** class of the **com.huawei.bigdata.hbase.examples** packet.

- Code authentication

```
try {  
    init();  
    login();  
}  
catch (IOException e) {  
    LOG.error("Failed to login because ", e);  
    return;  
}
```

- Initializing configuration

```
private static void init() throws IOException {  
    // Default load from conf directory  
    conf = HBaseConfiguration.create();  
    //In Windows environment  
    String userdir = TestMain.class.getClassLoader().getResource("conf").getPath() + File.separator;  
    [1] //In Linux environment  
    //String userdir = System.getProperty("user.dir") + File.separator + "conf" + File.separator;  
    conf.addResource(new Path(userdir + "core-site.xml"), false);  
    conf.addResource(new Path(userdir + "hdfs-site.xml"), false);  
    conf.addResource(new Path(userdir + "hbase-site.xml"), false);  
}
```

[1] **userdir** obtains the **conf** directory in the resource path after compilation.

## Prerequisites

You have obtained the configuration file and authentication file required for running the sample project. For details, see [Preparing the Connection Cluster Configuration File](#).

## Configuring Secure Login

Modify the following parameters in the **TestMain** class of the **com.huawei.bigdata.hbase.examples** package based on the site requirements:

- Change the value of **userName** to the username you actually use, for example, **developuser**.
- Change the value of **ZOOKEEPER\_DEFAULT\_SERVER\_PRINCIPAL** to **zookeeper/hadoop**.*Cluster domain name*. To obtain the value of cluster domain name, log in to FusionInsight Manager, choose **System > Permission > Domain and Mutual Trust**, and view the value of **Local Domain**.

```
private static void login() throws IOException {
    if (User.isHBaseSecurityEnabled(conf)) {
        userName = "developuser";

        //In Windows environment
        String userdir = TestMain.class.getClassLoader().getResource("conf").getPath() + File.separator;
        //In Linux environment
        //String userdir = System.getProperty("user.dir") + File.separator + "conf" + File.separator;

        /*
         * if need to connect zk, please provide jaas info about zk. of course,
         * you can do it as below:
         * System.setProperty("java.security.auth.login.config", confDirPath +
         * "jaas.conf"); but the demo can help you more : Note: if this process
         * will connect more than one zk cluster, the demo may be not proper. you
         * can contact us for more help
         */
        LoginUtil.setJaasConf(ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME, userName, userKeytabFile);
        LoginUtil.setZookeeperServerPrincipal(ZOOKEEPER_SERVER_PRINCIPAL_KEY,
ZOOKEEPER_DEFAULT_SERVER_PRINCIPAL);
        LoginUtil.login(userName, userKeytabFile, krb5File, conf);
    }
}
```

#### 1.10.2.4.2 Security Authentication for HBase Data Read and Write and Global Secondary Index Example (Mutual Trust Scenarios)

### Description

When multiple clusters in different security modes need to access each other's resources, the administrator can set up a mutual trust system so that users of external systems can use the system. The usage range of users in each system is called a **domain**. Each Manager system must have a unique domain name. Cross-Manager access means users to be used across domains. For details about how to configure mutual trust between clusters, see "Managing Mutual Trust Relationships Between Managers" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

As a user that meets the cross-domain access requirements, you can use the keytab and principal files for Kerberos security authentication obtained from one Manager system and the client configuration files of multiple Manager systems to access and invoke the HBase service of multiple clusters after one authentication login in the multi-cluster mutual trust scenario.

The following code snippets belong to the **TestMultipleLogin** class in the **com.huawei.bigdata.hbase.examples** package of the **hbase-example** sample project.

- Code authentication

```
List<String> confDirectories = new ArrayList<>();
List<Configuration> confs = new LinkedList<>();
try {
    // conf directory
```

```
confDirectories.add("hadoopDomain");[1]
confDirectories.add("hadoop1Domain");[2]

for (String confDir : confDirectories) {
    confs.add(init(confDir));[3]
}

login(confs.get(0), confDirectories.get(0));[4]
} catch (IOException e) {
    LOG.error("Failed to login because ", e);
    return;
}
```

[1] **hadoopDomain** indicates the name of the directory for storing user credentials and the configuration file of a cluster. The relative path of the directory is **hbase-example/src/main/resources/hadoopDomain**, which can be changed as required.

[2] **hadoop1Domain** is the name of the directory for storing the configuration file of the other cluster. The relative path of the directory is **hbase-example/src/main/resources/hadoop1Domain**, which can be changed as required.

[3] Initialize the conf objects in sequence.

[4] Perform login authentication.

- Initialization configuration

```
private static Configuration init(String confDirectoryName) throws IOException {
    // Default load from conf directory
    Configuration conf = HBaseConfiguration.create();
    //In Windows environment
    String userdir = TestMain.class.getClassLoader().getResource(confDirectoryName).getPath() +
File.separator;
    //In Linux environment
    //String userdir = System.getProperty("user.dir") + File.separator + confDirectoryName +
File.separator;
    conf.addResource(new Path(userdir + "core-site.xml"), false);
    conf.addResource(new Path(userdir + "hdfs-site.xml"), false);
    conf.addResource(new Path(userdir + "hbase-site.xml"), false);
    return conf;
}
```

## Prerequisites

You have obtained the configuration file and authentication file required for running the sample project. For details, see [Preparing the Connection Cluster Configuration File](#).

## Configuring Secure Login

Change **userName** in the **TestMultipleLogin** class in the **com.huawei.bigdata.hbase.examples** package of the **hbase-example** sample project to the actual user name, for example, **developuser**.

```
private static void login(Configuration conf, String confDir) throws IOException {

    if (User.isHBaseSecurityEnabled(conf)) {
        userName = " developuser ";

        //In Windows environment
        String userdir = TestMain.class.getClassLoader().getResource(confDir).getPath() + File.separator;
        //In Linux environment
        //String userdir = System.getProperty("user.dir") + File.separator + confDir + File.separator;

        userKeytabFile = userdir + "user.keytab";
```

```
    krb5File = userdir + "krb5.conf";

    /*
     * if need to connect zk, please provide jaas info about zk. of course,
     * you can do it as below:
     * System.setProperty("java.security.auth.login.config",confDirPath +
     * "jaas.conf"); but the demo can help you more : Note: if this process
     * will connect more than one zk cluster, the demo may be not proper. you
     * can contact us for more help
     */

    LoginUtil.setJaasConf(ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME, userName,userKeytabFile);
    LoginUtil.login(userName, userKeytabFile, krb5File, conf);
}
```

### 1.10.2.4.3 Accessing HBase REST Service Security Authentication

#### Description

When installing the HBase service, you can optionally deploy the RESTServer instance. You can access the HBase REST service to invoke HBase operations, including operations on namespaces and tables. Kerberos authentication is also required for accessing the HBase REST service.

#### Prerequisites

You have obtained the configuration file and authentication file required for running the sample project. For details, see [Preparing the Connection Cluster Configuration File](#).

#### Configuring Secure Login

In this scenario, initial configuration is not required. Only the **keytab** and **krb5.conf** files used for Kerberos security authentication are required.

The following code snippets belong to the **HBaseRestTest** class in the **com.huawei.bigdata.hbase.examples** package of the **hbase-rest-example** sample project.

- Code authentication

Change **principal** to the actual user name, for example, **developuser**.

```
//In Windows environment
String userdir = HBaseRestTest.class.getClassLoader().getResource("conf").getPath() +
File.separator+[1]
//In Linux environment
//String userdir = System.getProperty("user.dir") + File.separator + "conf" + File.separator;
String principal = "developuser";
login(principal, userKeytabFile, krb5File);
// RESTServer's hostname.
String restHostName = "10.120.16.170";[2]
String securityModeUrl = new
StringBuilder("https://").append(restHostName).append(":21309").toString();
String nonSecurityModeUrl = new
StringBuilder("http://").append(restHostName).append(":21309").toString();
HBaseRestTest test = new HBaseRestTest();

//If cluster is non-security mode,use nonSecurityModeUrl as parameter.
test.test(securityModeUrl);[3]
```

[1] **userdir** obtains the **conf** directory in the resource path after compilation.

[2] Change the value of **restHostName** to the IP address of the node where the RestServer instance to be accessed is located, and configure the node IP address in the hosts file on the local host where the sample code is run. To obtain the IP address of the RestServer instance, log in to FusionInsight Manager and choose **Cluster > Services > HBase > Instance**.

[3] In security mode, access the HBase REST service in HTTPS mode and use **nonSecurityModeUrl** as the **test.test()** parameter.

- Security login

```
private static void login(String principal, String userKeytabFile, String krb5File) throws
LoginException {
    Map<String, String> options = new HashMap<>();
    options.put("useTicketCache", "false");
    options.put("useKeyTab", "true");
    options.put("keyTab", userKeytabFile);

    /**
     * Krb5 in GSS API needs to be refreshed so it does not throw the error
     * Specified version of key is not available
     */

    options.put("refreshKrb5Config", "true");
    options.put("principal", principal);
    options.put("storeKey", "true");
    options.put("doNotPrompt", "true");
    options.put("isInitiator", "true");
    options.put("debug", "true");
    System.setProperty("java.security.krb5.conf", krb5File);
    Configuration config = new Configuration() {
        @Override
        public AppConfigurationEntry[] getAppConfigurationEntry(String name) {
            return new AppConfigurationEntry[] {
                new AppConfigurationEntry("com.sun.security.auth.module.Krb5LoginModule",
                    AppConfigurationEntry.LoginModuleControlFlag.REQUIRED, options)
            };
        }
    };
    subject = new Subject(false, Collections.singleton(new KerberosPrincipal(principal)),
    Collections.EMPTY_SET,
    Collections.EMPTY_SET);
    LoginContext loginContext = new LoginContext("Krb5Login", subject, null, config);
    loginContext.login();
}
```

#### 1.10.2.4.4 Security Authentication for Accessing the ThriftServer Service

##### Scenario

HBase combines Thrift to provide HBase services for external applications. The ThriftServer instance is optional during HBase service installation. The ThriftServer system can access HBase users and has the read, write, execute, creation, and management permissions on all HBase namespaces and tables. Kerberos authentication is also required for accessing the ThriftServer service. HBase implements two sets of Thrift Server services. **hbase-thrift-example** is used to call the ThriftServer instance service.

##### Prerequisites

You have obtained the configuration file and authentication file required for running the sample project. For details, see [Preparing the Connection Cluster Configuration File](#).

## Sample Configuration

- Code authentication

The following code snippets belong to the **TestMain** class in the **com.huawei.bigdata.hbase.examples** package of the **hbase-thrift-example** sample project.

```
private static void init() throws IOException {
    // Default load from conf directory
    conf = HBaseConfiguration.create();

    String userdir = TestMain.class.getClassLoader().getResource("conf").getPath() + File.separator;
[1]   //In Linux environment
    //String userdir = System.getProperty("user.dir") + File.separator + "conf" + File.separator;
    conf.addResource(new Path(userdir + "core-site.xml"), false);
    conf.addResource(new Path(userdir + "hdfs-site.xml"), false);
    conf.addResource(new Path(userdir + "hbase-site.xml"), false);
}
```

[1] **userdir** obtains the **conf** directory in the resource path after compilation.

- Security login

Set **userName** to the actual username based on the actual situation, for example, **developuser**.

```
private static void login() throws IOException {
    if (User.isHBaseSecurityEnabled(conf)) {
        userName = " developuser ";

        //In Windows environment
        String userdir = TestMain.class.getClassLoader().getResource("conf").getPath() +
File.separator;
        //In Linux environment
        //String userdir = System.getProperty("user.dir") + File.separator + "conf" + File.separator;

        userKeytabFile = userdir + "user.keytab";
        krb5File = userdir + "krb5.conf";

        /*
         * if need to connect zk, please provide jaas info about zk. of course,
         * you can do it as below:
         * System.setProperty("java.security.auth.login.config", confDirPath +
         * "jaas.conf"); but the demo can help you more : Note: if this process
         * will connect more than one zk cluster, the demo may be not proper. you
         * can contact us for more help
         */
        LoginUtil.setJaasConf(ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME, userName,
userKeytabFile);
        LoginUtil.login(userName, userKeytabFile, krb5File, conf);
    }
}
```

- Connecting to a ThriftServer instance

```
try {
    test = new ThriftSample();
    test.test("10.120.16.170", THRIFT_PORT, conf);[2]
} catch (TException | IOException e) {
    LOG.error("Test thrift error", e);
}
```

[2] The value of the input parameter **test.test()** is the IP address of the node where the target ThriftServer instance is deployed. Change the IP address to the actual one. The IP address of the node must be configured in the hosts file of the local host where the sample code is run.

**THRIFT\_PORT** is the value of **hbase.regionserver.thrift.port** configured for the ThriftServer instance. To obtain the IP address of the node where the

ThriftServer instance is deployed, log in to FusionInsight Manager, choose **Cluster > Services > HBase**, and click the **Instance** tab.

### 1.10.2.4.5 Security Authentication for Accessing Multiple ZooKeepers

#### Scenario

To avoid ZooKeeper authentication conflicts when a client process accesses a FusionInsight ZooKeeper and a third-party ZooKeeper at the same time, sample code is provided for the HBase client to access the FusionInsight ZooKeeper and for customer applications to access the third-party ZooKeeper.

#### Prerequisites

You have obtained the configuration file and authentication file required for running the sample project. For details, see [Preparing for Development Environment](#).

#### Sample Configuration

The following lists the authentication configuration files in the **src/main/resources** directory.

- **zoo.cfg**

```
# The configuration in jaas.conf used to connect fi
zookeeper.zookeeper.sasl.clientconfig=Client_new[1]
# Principal of fi zookeeper server side.
zookeeper.server.principal=zookeeper/hadoop.hadoop.com[2]
# Set true if the fi cluster is security mode.
# The other two parameters do not take effect if the value is false.
zookeeper.sasl.client=true[3]
```

[1] **zookeeper.sasl.clientconfig**: specifies the configuration in the **jaas.conf** file used for accessing FusionInsight ZooKeeper.

[2] **zookeeper.server.principal**: specifies the principal used by the ZooKeeper server. The format is **zookeeper/hadoop.System domain name**, for example, **zookeeper/hadoop.HADOOP.COM**. To obtain the system domain name, log in to FusionInsight Manager, choose **System > Permission > Domain and Mutual Trust**, and view the value of **Local Domain**.

[3] **zookeeper.sasl.client**: If the MRS cluster works in the security mode, set this parameter to **true**. Otherwise, set this parameter to **false**. If this parameter is set to **false**, the **zookeeper.sasl.clientconfig** and **zookeeper.server.principal** parameters do not take effect.
- **jaas.conf**

```
Client_new { [4]
    com.sun.security.auth.module.Krb5LoginModule required
    useKeyTab=true
    keyTab="D:\\work\\sample_project\\src\\hbase-examples\\hbase-zk-example\\target\\classes\\conf\\user.keytab" [5]
    principal="hbaseuser1"
    useTicketCache=false
    storeKey=true
    debug=true;
}
Client { [6]
    org.apache.zookeeper.server.auth.DigestLoginModule required
    username="bob"
    password="xxxxxx"; [7]
}
```

- [4] **Client\_new**: reads configuration specified in the **zoo.cfg** file. When the name is changed, the corresponding configuration in the **zoo.cfg** file must be modified accordingly.
- [5] **keyTab**: specifies the path for storing the **user.keytab** file used by the project on the host where the sample is run. Use an absolute path to better locate the file. Use \\ in the Windows and \ in Linux.
- [6] **Client**: A third-party ZooKeeper uses this configuration for access. The connection authentication configuration depends on the third-party ZooKeeper version.
- [7] **password**: Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or environment variables.

### 1.10.2.4.6 Security Authentication for Interconnecting HBase/Phoenix with Spring Boot

#### Scenario

Run Spring Boot interface sample code of MRS HBase/Phoenix.

#### Prerequisites

You have obtained the configuration file and authentication file required for running the sample project. For details, see [Preparing the Connection Cluster Configuration File](#).

#### Sample Configuration

**Step 1** In the IntelliJ IDEA development environment, click the **springclient.properties** file in the **src/springboot/hbase-examples/src/main/resources** directory and modify the parameters listed in [Table 1-79](#) as needed:

**Table 1-79** Configuration parameters

Parameter	Definition
principal	Username created when you prepare a developer account.
user.keytab.path	Path of the user authentication file <b>user.keytab</b> created during developer account preparation.
krb5.conf.path	Path of the user authentication file <b>krb5.conf</b> created during developer account preparation.
conf.path	Path of the HBase configuration file.

Parameter	Definition
zookeeper.server.principal	Principal of the ZooKeeper server, in <b>zookeeper/hadoop.System domain name</b> format. To obtain the system domain name, log in to FusionInsight Manager, choose <b>System &gt; Permission &gt; Domain and Mutual Trust</b> , and view the value of <b>Local Domain</b> .

----End

## 1.10.3 Developing an Application

### 1.10.3.1 HBase Data Read/Write Sample Program

#### 1.10.3.1.1 Service Scenario Description

Based on typical scenarios, users can quickly learn and master the HBase development process and know important interface functions.

#### Scenario

Develop an application to manage information about users who use service A in an enterprise. **Table 1-80** provides the user information. The operation process of service A is described as follows:

- Create a user information table.
- Add diplomas and titles to the user information table.
- Query user names and addresses by user ID.
- Query information by user name.
- Query information about users whose ages range from 20 to 29.
- Collect statistics on the number and the maximum, minimum, and average ages of users.
- Deregister users, and delete user data.
- Delete the user information table after service A ends.

**Table 1-80** User information

ID	Name	Gender	Age	Address
1200500020 1	Zhang San	Male	19	Shenzhen, Guangdong
1200500020 2	Li Wanting	Female	23	Shijiazhuang, Hebei
1200500020 3	Wang Ming	Male	26	Ningbo, Zhejiang

ID	Name	Gender	Age	Address
1200500020 4	Li Gang	Male	18	Xiangyang, Hubei
1200500020 5	Zhao Enru	Female	21	Shangrao, Jiangxi
1200500020 6	Chen Long	Male	32	Zhuzhou, Hunan
1200500020 7	Zhou Wei	Female	29	Nanyang, Henan
1200500020 8	Yang Yiwen	Female	30	Kaixian, Chongqing
1200500020 9	Xu Bing	Male	26	Weinan, Shaanxi
1200500021 0	Xiao Kai	Male	25	Dalian, Liaoning

## Data Planning

Proper design of the table structure, RowKeys, and column names can give full play to the advantages of HBase. In this example, the unique ID is used as the RowKey, and columns are stored in the **info** column family.

### CAUTION

HBase tables are stored in *Namespace:Table name* format. If no namespace is specified when a table is created, the table is stored in **default**. The **hbase** namespace is the system table namespace. Do not create service tables or read or write data in the system table namespace.

### 1.10.3.1.2 Application Development Approach

#### Function Decomposition

Functions are decomposed based on the preceding service scenario. [Table 1-81](#) provides the functions to be developed.

**Table 1-81** Functions to be developed in HBase

No.	Procedure	Code Implementation
1	Create a table based on <a href="#">Table 1-80</a> .	For details, see <a href="#">Creating a Table</a> .

No.	Procedure	Code Implementation
2	Import user data.	For details, see <a href="#">Inserting Data</a> .
3	Add the <b>Education</b> column family, and add diplomas and titles to the user information table.	For details, see <a href="#">Modifying a Table</a> .
4	Query user names and addresses by user ID.	For details, see <a href="#">Reading Data Using Get</a> .
5	Query information by user name.	For details, see <a href="#">Filtering Data</a> .
6	To improve query performance, create or delete secondary indexes.	For details, see <a href="#">Creating a Secondary Index</a> and <a href="#">Secondary Index-based Query</a> .
7	Deregister users, and delete user data.	For details, see <a href="#">Deleting Data</a> .
8	Delete the user information table after service A ends.	For details, see <a href="#">Deleting a Table</a> .

## Key Design Principle

HBase is a distributed database system based on the lexicographic order of RowKeys. The RowKey design has great impact on performance, so the RowKeys must be designed based on specific services.

### 1.10.3.1.3 Creating Configuration

#### Function

HBase obtain configuration items by using the login method. The configuration items include user login information and security authentication information.

#### Example Codes

The following code snippet belongs to the `createClientConf` method in the `createClientConf` class of the `com.huawei.bigdata.hadoop.security.examples` package.

```
public static Configuration createClientConf() {  
    // In Windows environment  
    String userDir = Utils.class.getClassLoader().getResource(CONF_DIRECTORY).getPath() + File.separator;  
    // In Linux environment  
    // String userDir = System.getProperty("user.dir") + File.separator + CONF_DIRECTORY + File.separator;  
    return createConfByUserDir(userDir);  
}  
public static Configuration createConfByUserDir(String userDir) {  
    // Default load from conf directory  
    Configuration conf = HBaseConfiguration.create();  
    if (userDir == null || userDir.isEmpty()) {
```

```
        return conf;
    }
    conf.addResource(new Path(userDir + CLIENT_CORE_FILE), false);
    conf.addResource(new Path(userDir + CLIENT_HDFS_FILE), false);
    conf.addResource(new Path(userDir + CLIENT_HBASE_FILE), false);
    return conf;
}
```

#### 1.10.3.1.4 Creating Connection

### Function

HBase creates a Connection object using the `ConnectionFactory.createConnection(configuration)` method. The transferred parameter is the Configuration created in the last step.

Connection encapsulates the connections between underlying applications and servers and ZooKeeper. Connection is instantiated using the `ConnectionFactory` class. Creating Connection is a heavyweight operation. Connection is thread-safe. Therefore, multiple client threads can share one Connection.

In a typical scenario, a client program uses a Connection, and each thread obtains its own Admin or Table instance and invokes the operation interface provided by the Admin or Table object. You are not advised to cache or pool Table and Admin. The lifecycle of Connection is maintained by invokers that frees up resources by invoking `close()`.

### Example Code

The following code snippet exemplifies login, creating Connection, and creating a table. It belongs to the `HbaseSample` method in the `HbaseSample` class of the `com.huawei.bigdata.hbase.examples` package.

```
private TableName tableName = null;
private Connection conn = null;

public HbaseSample(Configuration conf) throws IOException {
    this.tableName = TableName.valueOf("hbase_sample_table");
    this.conn = ConnectionFactory.createConnection(conf);
}
```

Avoid invoking login code repeatedly.

#### 1.10.3.1.5 Creating a Table

### Function

Create a table using the `createTable` method of the `org.apache.hadoop.hbase.client.Admin` object and specify the table name and column family name. Tables can be created in two modes. (The mode of creating a table using preassigned regions is strongly recommended.)

- Quickly create a table. A newly created table contains only one region which will be split into multiple new regions as data increases.

- Create a table using preassigned regions. Preassign multiple regions before creating a table. This mode accelerates data write at the beginning of massive data write.

 NOTE

The column name and column family name of an HBase table consists of letters, digits, and underscores and cannot contain any special characters.

## Example Code

The following code snippet belongs to the **testCreateTable** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testCreateTable() {  
    LOG.info("Entering testCreateTable.");  
    // Specify the table descriptor.  
    TableDescriptorBuilder htd = TableDescriptorBuilder.newBuilder(tableName);(1)  
  
    // Set the column family name to info.  
    ColumnFamilyDescriptorBuilder hcd =  
    ColumnFamilyDescriptorBuilder.newBuilder(Bytes.toBytes("info"));(2)  
  
    // Set data encoding methods, HBase provides DIFF,FAST_DIFF,PREFIX  
  
    hcd.setDataBlockEncoding(DataBlockEncoding.FAST_DIFF);  
    // Set compression methods, HBase provides two default compression  
    // methods:GZ and SNAPPY  
    // GZ has the highest compression rate, but low compression and  
    // decompression efficiency, fit for cold data  
    // SNAPPY has low compression rate, but high compression and  
    // decompression efficiency, fit for hot data.  
    // It is advised to use SNAPPY  
    hcd.setCompressionType(Compression.Algorithm.SNAPPY); //Note [1]  
    htd.setColumnFamily(hcd.build()); (3)  
    Admin admin = null;  
    try {  
        // Instantiate an Admin object.  
        admin = conn.getAdmin(); (4)  
        if (!admin.tableExists(tableName)) {  
            LOG.info("Creating table...");  
            admin.createTable(htd.build()); //Note [2] (5)  
            LOG.info(admin.getClusterMetrics().toString());  
            LOG.info(admin.listNamespaceDescriptors().toString());  
            LOG.info("Table created successfully.");  
        } else {  
            LOG.warn("table already exists");  
        }  
    } catch (IOException e) {  
        LOG.error("Create table failed " ,e);  
    } finally {  
        if (admin != null) {  
            try {  
                // Close the Admin object.  
                admin.close();  
            } catch (IOException e) {  
                LOG.error("Failed to close admin " ,e);  
            }  
        }  
    }  
    LOG.info("Exiting testCreateTable.");  
}
```

## Explanation

1. Create a table descriptor.

2. Create a column family descriptor.
3. Add the column family descriptor to the table descriptor.
4. Obtain an Admin object. The Admin object provides functions for creating a table, creating a column family, checking whether a table exists, modifying the table structure, modifying the column family structure, and deleting a table.
5. Invoke the table creation method of Admin.

## Precautions

- 1. The compression mode of a column family can be set. The code snippets are as follows:

```
// Set the encoding algorithm. HBase supports the DIFF, FAST_DIFF, PREFIX encoding algorithms.  
hcd.setDataBlockEncoding(DataBlockEncoding.FAST_DIFF);  
  
// Set the file compression mode. HBase provides the GZ and SNAPPY compression algorithms by default.  
// GZ provides a high compression rate but low compression and decompression performance. GZ is suitable for cold data.  
// SNAPPY provides a low compression rate but high compression and decompression performance. SNAPPY is suitable for hot data.  
// It is recommended that SNAPPY be enabled by default.  
hcd.setCompressionType(Compression.Algorithm.SNAPPY);
```
- 2. A table can be created by specifying the start and end RowKeys or preassigning regions using RowKey arrays. The code snippets are as follows:

```
// Create a table whose regions are preassigned.  
byte[][] splits = new byte[4][];  
splits[0] = Bytes.toBytes("A");  
splits[1] = Bytes.toBytes("H");  
splits[2] = Bytes.toBytes("O");  
splits[3] = Bytes.toBytes("U");  
admin.createTable(htd, splits);
```

### 1.10.3.1.6 Deleting a Table

#### Function

Delete a table using the **deleteTable** method of **org.apache.hadoop.hbase.client.Admin**.

#### Example Code

The following code snippet belongs to the **dropTable** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void dropTable() {  
    LOG.info("Entering dropTable.");  
    Admin admin = null;  
    try {  
        admin = conn.getAdmin();  
        if (admin.tableExists(tableName)) {  
            // Disable the table before deleting it.  
            admin.disableTable(tableName);  
            // Delete table.  
            admin.deleteTable(tableName); // Note[1]  
        }  
        LOG.info("Drop table successfully.");  
    } catch (IOException e) {  
        LOG.error("Drop table failed " ,e);  
    } finally {
```

```
if (admin != null) {  
    try {  
        // Close the Admin object.  
        admin.close();  
    } catch (IOException e) {  
        LOG.error("Close admin failed " ,e);  
    }  
}  
LOG.info("Exiting dropTable.");
```

## Precautions

A table can be deleted only when the table is disabled. Therefore, **deleteTable** is used together with **disableTable**, **enableTable**, **tableExists**, **isTableEnabled**, and **isTableDisabled**.

### 1.10.3.1.7 Modifying a Table

#### Function

Modify table information using the **modifyTable** method of **org.apache.hadoop.hbase.client.Admin**.

#### Example Code

The following code snippet belongs to the **testModifyTable** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testModifyTable() {  
    LOG.info("Entering testModifyTable.");  
  
    // Specify the column family name.  
    byte[] familyName = Bytes.toBytes("education");  
    Admin admin = null;  
    try {  
        // Instantiate an Admin object.  
        admin = conn.getAdmin();  
        // Obtain the table descriptor.  
        TableDescriptor htd = admin.getTableDescriptor(tableName);  
  
        // Check whether the column family is specified before modification.  
        if (!htd.hasColumnFamily(familyName)) {  
            // Create the column descriptor.  
            TableDescriptor tableBuilder = TableDescriptor.newBuilder(htd)  
                .setColumnFamily(ColumnFamilyDescriptor.newBuilder(familyName).build()).build();  
  
            // Disable the table to get the table offline before modifying  
            // the table.  
            admin.disableTable(tableName); // Note[1]  
            // Submit a modifyTable request.  
            admin.modifyTable(tableBuilder);  
            // Enable the table to get the table online after modifying the  
            // table.  
            admin.enableTable(tableName);  
        }  
        LOG.info("Modify table successfully.");  
    } catch (IOException e) {  
        LOG.error("Modify table failed " ,e);  
    } finally {  
        if (admin != null) {  
            try {
```

```
// Close the Admin object.  
admin.close();  
} catch (IOException e) {  
    LOG.error("Close admin failed " ,e);  
}  
}  
}  
LOG.info("Exiting testModifyTable.");  
}
```

## Precautions

**modifyTable** takes effect only when a table is disabled.

### 1.10.3.1.8 Inserting Data

#### Function

HBase is a column-oriented database. A row of data may have multiple column families, and a column family may contain multiple columns. When writing data, you must specify the columns (including the column family names and column names) to which data is written. In HBase, data (a row of data or data sets) is inserted using the **put** method of HTable.

#### Example Code

The following code snippet belongs to the **testPut** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testPut() {  
    LOG.info("Entering testPut.");  
  
    // Specify the column family name.  
    byte[] familyName = Bytes.toBytes("info");  
    // Specify the column name.  
    byte[][] qualifiers = {  
        Bytes.toBytes("name"), Bytes.toBytes("gender"), Bytes.toBytes("age"), Bytes.toBytes("address")  
    };  
  
    Table table = null;  
    try {  
        // Instantiate an HTable object.  
        table = conn.getTable(tableName);  
        List<Put> puts = new ArrayList<Put>();  
  
        // Instantiate a Put object.  
        Put put = putData(familyName, qualifiers,  
            Arrays.asList("012005000201", "Zhang San", "Male", "19", "Shenzhen, Guangdong"));  
        puts.add(put);  
  
        put = putData(familyName, qualifiers,  
            Arrays.asList("012005000202", "Li Wanting", "Female", "23", "Shijiazhuang, Hebei"));  
        puts.add(put);  
  
        put = putData(familyName, qualifiers,  
            Arrays.asList("012005000203", "Wang Ming", "Male", "26", "Ningbo, Zhejiang"));  
        puts.add(put);  
  
        put = putData(familyName, qualifiers,  
            Arrays.asList("012005000204", "Li Gang", "Male", "18", "Xiangyang, Hubei"));  
        puts.add(put);  
  
        put = putData(familyName, qualifiers,  
            Arrays.asList("012005000205", "Zhao Enru", "Female", "21", "Shangrao, Jiangxi"));  
    } catch (IOException e) {  
        LOG.error("Error occurred while performing testPut.", e);  
    } finally {  
        if (table != null) {  
            try {  
                table.close();  
            } catch (IOException e) {  
                LOG.error("Error occurred while closing table.", e);  
            }  
        }  
    }  
}
```

```
puts.add(put);

put = putData(familyName, qualifiers,
    Arrays.asList("012005000206", "Chen Long", "Male", "32", "Zhuzhou, Hunan"));
puts.add(put);

put = putData(familyName, qualifiers,
    Arrays.asList("012005000207", "Zhou Wei", "Female", "29", "Nanyang, Henan"));
puts.add(put);

put = putData(familyName, qualifiers,
    Arrays.asList("012005000208", "Yang Yiwen", "Female", "30", "Kaixian, Chongqing"));
puts.add(put);

put = putData(familyName, qualifiers,
    Arrays.asList("012005000209", "Xu Bing", "Male", "26", "Weinan, Shaanxi"));
puts.add(put);

put = putData(familyName, qualifiers,
    Arrays.asList("012005000210", "Xiao Kai", "Male", "25", "Dalian, Liaoning"));
puts.add(put);

// Submit a put request.
table.put(puts);

LOG.info("Put successfully.");
} catch (IOException e) {
    LOG.error("Put failed ", e);
} finally {
    if (table != null) {
        try {
            // Close the HTable object.
            table.close();
        } catch (IOException e) {
            LOG.error("Close table failed ", e);
        }
    }
}
LOG.info("Exiting testPut.");
}
```

## Precautions

Multiple threads are not allowed to use the same HTable instance at the same time. HTable is a non-thread safe class. If an HTable instance is used by multiple threads at the same time, concurrency problems will occur.

### 1.10.3.1.9 Deleting Data

#### Function

Delete data (a row of data or data sets) using the **delete** method of a Table instance.

#### Example Code

The following code snippet belongs to the **testDelete** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testDelete() {
    LOG.info("Entering testDelete.");

    byte[] rowKey = Bytes.toBytes("012005000201");
```

```
Table table = null;
try {
    // Instantiate an HTable object.
    table = conn.getTable(tableName);

    // Instantiate a Delete object.
    Delete delete = new Delete(rowKey);

    // Submit a delete request.
    table.delete(delete);

    LOG.info("Delete table successfully.");
} catch (IOException e) {
    LOG.error("Delete table failed " ,e);
} finally {
    if (table != null) {
        try {
            // Close the HTable object.
            table.close();
        } catch (IOException e) {
            LOG.error("Close table failed " ,e);
        }
    }
}
LOG.info("Exiting testDelete.");
```

 **NOTE**

If secondary index is created in the family of the column where the deleted cell is, the index data is synchronously deleted.

### 1.10.3.1.10 Reading Data Using Get

#### Function

Before reading data from a table, instantiate the Table instance of the table, and then create a Get object. You can also set parameters for the Get object, such as the column family name and column name. Query results are stored in the Result object that stores multiple Cells.

#### Example Code

The following code snippet belongs to the **testGet** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testGet() {
    LOG.info("Entering testGet.");
    // Specify the column family name.
    byte[] familyName = Bytes.toBytes("info");
    // Specify the column name.
    byte[][] qualifier = { Bytes.toBytes("name"), Bytes.toBytes("address") };
    // Specify RowKey.
    byte[] rowKey = Bytes.toBytes("012005000201");
    Table table = null;
    try {
        // Create the Table instance.
        table = conn.getTable(tableName);
        // Instantiate a Get object.
        Get get = new Get(rowKey);
        // Set the column family name and column name.
        get.addColumn(familyName, qualifier[0]);
        get.addColumn(familyName, qualifier[1]);
        // Submit a get request.
        Result result = table.get(get);
```

```
// Print query results.
for (Cell cell : result.rawCells()) {
    LOG.info("{}:{}:{}",
        Bytes.toString(CellUtil.cloneRow(cell)),
        Bytes.toString(CellUtil.cloneFamily(cell)), Bytes.toString(CellUtil.cloneQualifier(cell)),
        Bytes.toString(CellUtil.cloneValue(cell)));
}
LOG.info("Get data successfully.");
} catch (IOException e) {
    LOG.error("Get data failed " ,e);
} finally {
    if (table != null) {
        try {
            // Close the HTable object.
            table.close();
        } catch (IOException e) {
            LOG.error("Close table failed " ,e);
        }
    }
}
LOG.info("Exiting testGet.");
}
```

### 1.10.3.1.11 Reading Data Using Scan

#### Function

Before reading data from a table, instantiate the Table instance of the table, create a Scan object, and set parameters for the Scan object based on search criteria. To improve query efficiency, you are advised to specify **StartRow** and **StopRow**. Query results are stored in the ResultScanner object where each row of data is stored as a Result object that stores multiple Cells.

#### Example Code

The following code snippet belongs to the **testScanData** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testScanData() {
    LOG.info("Entering testScanData.");
    Table table = null;
    // Instantiate a ResultScanner object.
    ResultScanner rScanner = null;
    try {
        // Create the Configuration instance.
        table = conn.getTable(tableName);
        // Instantiate a Get object.
        Scan scan = new Scan();
        scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("name"));
        // Set the cache size.
        scan.setCaching(1000);

        // Submit a scan request.
        rScanner = table.getScanner(scan);
        // Print query results.
        for (Result r = rScanner.next(); r != null; r = rScanner.next()) {
            for (Cell cell : r.rawCells()) {
                LOG.info("{}:{}:{}",
                    Bytes.toString(CellUtil.cloneRow(cell)),
                    Bytes.toString(CellUtil.cloneFamily(cell)), Bytes.toString(CellUtil.cloneQualifier(cell)),
                    Bytes.toString(CellUtil.cloneValue(cell)));
            }
        }
        LOG.info("Scan data successfully.");
    } catch (IOException e) {
        LOG.error("Scan data failed " ,e);
    } finally {
```

```
if (rScanner != null) {  
    // Close the scanner object.  
    rScanner.close();  
}  
if (table != null) {  
    try {  
        // Close the HTable object.  
        table.close();  
    } catch (IOException e) {  
        LOG.error("Close table failed ",e);  
    }  
}  
LOG.info("Exiting testScanData.");  
}
```

## Precuations

1. You are advised to specify **StartRow** and **StopRow** to ensure good performance with a specified Scan scope.
2. You can set **Batch** and **Caching**.
  - **Batch**  
Indicates the maximum number of records returned each time when the **next** interface is invoked using Scan. This parameter is related to the number of columns read each time.
  - **Caching**  
Indicates the maximum number of **next** records returned for a remote procedure call (RPC) request. This parameter is related to the number of rows read by an RPC.

### 1.10.3.1.12 Filtering Data

#### Function

HBase Filter is used to filter data during Scan and Get. You can specify the filter criteria, such as filtering by RowKey, column name, or column value.

#### Example Code

The following code snippet belongs to the **testSingleColumnValueFilter** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testSingleColumnValueFilter() {  
    LOG.info("Entering testSingleColumnValueFilter.");  
    Table table = null;  
  
    ResultScanner rScanner = null;  
  
    try {  
        table = conn.getTable(tableName);  
  
        Scan scan = new Scan();  
        scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("name"));  
        // Set the filter criteria.  
        SingleColumnValueFilter filter = new SingleColumnValueFilter(  
            Bytes.toBytes("info"), Bytes.toBytes("name"), CompareOperator.EQUAL,  
            Bytes.toBytes("Xu Bing"));  
        scan.setFilter(filter);  
        // Submit a scan request.  
    }
```

```
rScanner = table.getScanner(scan);
// Print query results.
for (Result r = rScanner.next(); r != null; r = rScanner.next()) {
    for (Cell cell : r.rawCells()) {
        LOG.info("{{}:{}:{}:{}}", Bytes.toString(CellUtil.cloneRow(cell)),
            Bytes.toString(CellUtil.cloneFamily(cell)), Bytes.toString(CellUtil.cloneQualifier(cell)),
            Bytes.toString(CellUtil.cloneValue(cell)));
    }
}
LOG.info("Single column value filter successfully.");
} catch (IOException e) {
    LOG.error("Single column value filter failed " ,e);
} finally {
    if (rScanner != null) {
        // Close the scanner object.
        rScanner.close();
    }
    if (table != null) {
        try {
            // Close the HTable object.
            table.close();
        } catch (IOException e) {
            LOG.error("Close table failed " ,e);
        }
    }
}
LOG.info("Exiting testSingleColumnValueFilter.");
```

## Precautions

Currently, secondary indexes do not support the comparators that use objects of the SubstringComparator class as filters.

For example, the following sample code is not supported:

```
Scan scan = new Scan();
filterList = new FilterList(FilterList.Operator.MUST_PASS_ALL);
filterList.addFilter(new SingleColumnValueFilter(Bytes
.toBytes(columnFamily), Bytes.toBytes(qualifier),
CompareOperator.EQUAL, new SubstringComparator(substring)));
scan.setFilter(filterList);
```

### 1.10.3.1.13 Creating a Secondary Index

#### Function

You can manage HBase secondary indexes using methods provided in **org.apache.hadoop.hbase.hindex.client.HIndexAdmin**. This class provides methods of creating an index.

#### NOTE

Secondary indexes cannot be modified. If you need to modify them, delete old indexes and create new ones.

#### Example Code

The following code snippet belongs to the **createIndex** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void createIndex() {
    LOG.info("Entering createIndex.");
```

```

String indexName = "index_name";
// Create hindex instance
TableIndices tableIndices = new TableIndices();
IndexSpecification iSpec = new IndexSpecification(indexName);
iSpec.addIndexColumn(ColumnFamilyDescriptorBuilder.newBuilder(Bytes.toBytes("info")).build(),
    "name", ValueType.STRING); // Note[1]
tableIndices.addIndex(iSpec);

HIndexAdmin iAdmin = null;
Admin admin = null;
try {

    admin = conn.getAdmin();
    iAdmin = HIndexClient.newHIndexAdmin(admin);

    // add index to the table
    iAdmin.addIndices(tableName, tableIndices);

    LOG.info("Create index successfully.");
} catch (IOException e) {
    LOG.error("Create index failed ", e);
} finally {
    if (admin != null) {
        try {
            admin.close();
        } catch (IOException e) {
            LOG.error("Close admin failed ", e);
        }
    }
    if (iAdmin != null) {
        try {
            // Close IndexAdmin Object
            iAdmin.close();
        } catch (IOException e) {
            LOG.error("Close admin failed ", e);
        }
    }
}
LOG.info("Exiting createIndex.");
}

```

By default, newly created level-2 indexes are disabled. To enable a specified level-2 index, see the following code snippet. The following code snippet belongs to the `enableIndex` method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```

public void enableIndex() {
    LOG.info("Entering createIndex.");

    // Name of the index to be enabled
    String indexName = "index_name";

    List<String> indexNameList = new ArrayList<String>();
    indexNameList.add(indexName);

    HIndexAdmin iAdmin = null;
    Admin admin = null;
    try {
        admin = conn.getAdmin();
        iAdmin = HIndexClient.newHIndexAdmin(admin);

        // Alternately, enable the specified indices
        iAdmin.enableIndices(tableName, indexNameList);
        LOG.info("Successfully enable indices {} of the table {}", indexNameList, tableName);
    } catch (IOException e) {
        LOG.error("Failed to enable indices {} of the table {} . {}", indexNameList, tableName, e);
    } finally {
        if (admin != null) {
            try {

```

```
        admin.close();
    } catch (IOException e) {
        LOG.error("Close admin failed ", e);
    }
}
if (iAdmin != null) {
    try {
        iAdmin.close();
    } catch (IOException e) {
        LOG.error("Close admin failed ", e);
    }
}
}
```

## Precautions

Create a combination index.

HBase supports creation of secondary indexes on multiple fields, for example, the name and age columns.

```
HIndexSpecification iSpecUnite = new HIndexSpecification(indexName);
iSpecUnite.addIndexColumn(new HColumnDescriptor("info"), "name", ValueType.String, 10);
iSpecUnite.addIndexColumn(new HColumnDescriptor("info"), "age", ValueType.String, 3);
```

## Related Operations

### Create an index table by running a command.

You can also use the TableIndexer tool to create an index in an existing user table.

The <table\_name> user table must exist.

```
hbase org.apache.hadoop.hbase.hindex.mapreduce.TableIndexer -Dtablename.to.index=<table_name> -
Dindexspecs.to.add='IDX1=>cf1:[q1->datatype];cf2:[q2->datatype],[q3-
>datatype]#IDX2=>cf1:[q5->datatype]' -Dindexnames.to.build='IDX1'
```

A number sign "#" is used to separate indexes. A semicolon ";" is used to separate column families. A comma "," is used to separate columns.

**tablename.to.index:** indicates the name of the table where the index is created.

**indexspecs.to.add:** indicates the user table columns corresponding to the index.

The parameters in the command are described as follows:

- **IDX1:** indicates the index name.
- **cf1:** indicates the column family name.
- **q1:** indicates the column name.
- **datatype:** indicates the data type. Only the Integer, String, Double, Float, Long, Short, Byte and Char formats are supported.

### 1.10.3.1.14 Deleting an Index

#### Function

You can manage HBase secondary indexes using methods provided in **org.apache.hadoop.hbase.hindex.client.HIndexAdmin**. This class provides methods of querying and deleting an index.

#### Example Code

The following code snippet belongs to the **dropIndex** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void dropIndex() {
    LOG.info("Entering dropIndex.");
    String indexName = "index_name";
    List<String> indexNameList = new ArrayList<String>();
    indexNameList.add(indexName);

    IndexAdmin iAdmin = null;
    try {
        // Instantiate HIndexAdmin Object
        iAdmin = HIndexClient.newHIndexAdmin(conn.getAdmin());
        // Delete Secondary Index
        iAdmin.dropIndex(tableName, indexNameList);

        LOG.info("Drop index successfully.");
    } catch (IOException e) {
        LOG.error("Drop index failed.");
    } finally {
        if (iAdmin != null) {
            try {
                // Close Secondary Index
                iAdmin.close();
            } catch (IOException e) {
                LOG.error("Close admin failed.");
            }
        }
    }
    LOG.info("Exiting dropIndex.");
}
```

### 1.10.3.1.15 Secondary Index-based Query

#### Function

In user tables with secondary indexes, you can use Filter to query data. The data query performance is higher than that in user tables without secondary indexes.

#### NOTE

- For details about the secondary index principles, see "HIndex" in the "Product Introduction > Components > HBase > HBase Enhanced Open Source Features".
- HIndex supports three Filter types: SingleColumnValueFilter, SingleColumnValueExcludeFilter, and SingleColumnValuePartitionFilter.
- HIndex supports the following Comparator types: binary comparator, bit comparator, long comparator, decimal comparator, double comparator, float comparator, int comparator, and null comparator.

The secondary index usage rules are as follows:

- For scenarios in which a single index is created for one or multiple columns:
  - When you use this column for AND or OR query filtering, the index is used to improve the query performance.  
For example, Filter\_Condition(IndexCol1) AND/OR  
Filter\_Condition(IndexCol2).
  - When you use "Index Column AND Non-Index Column" for filtering in the query, this index is used to improve the query performance.  
For example, Filter\_Condition(IndexCol1) AND  
Filter\_Condition(IndexCol2) AND Filter\_Condition(NonIndexCol1).
  - When you use "Index Column OR Non-Index Column" for filtering in the query, the index is not used and the query performance is not improved.  
For example, Filter\_Condition(IndexCol1) AND/OR  
Filter\_Condition(IndexCol2) OR Filter\_Condition(NonIndexCol1).
- For scenarios in which a combination index is created for multiple columns:
  - When the columns used for query are all or part of the columns of the combination index and are in the same sequence with the combination index, the index is used to improve the query performance.  
For example, a combination index is created for C1, C2, and C3. The index takes effect in the following scenarios:  
Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol2) AND  
Filter\_Condition(IndexCol3)  
Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol2)  
Filter\_Condition(IndexCol1)  
The index does not take effect in the following scenarios:  
Filter\_Condition(IndexCol2) AND Filter\_Condition(IndexCol3)  
Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol3)  
Filter\_Condition(IndexCol2)  
Filter\_Condition(IndexCol3)
  - When you use "Index Column AND Non-Index Column" for filtering in the query, this index is used to improve the query performance.  
For example:  
Filter\_Condition(IndexCol1) AND Filter\_Condition(NonIndexCol1)  
Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol2) AND  
Filter\_Condition(NonIndexCol1)
  - When you use "Index Column OR Non-Index Column" for filtering in the query, the index is not used and the query performance is not improved.  
For example:  
Filter\_Condition(IndexCol1) OR Filter\_Condition(NonIndexCol1)  
(Filter\_Condition(IndexCol1) AND Filter\_Condition(IndexCol2))OR  
( Filter\_Condition(NonIndexCol1))
  - When multiple columns are used for query, a value range can be specified only for the last column in the combination index and the other columns can only be set to a specified value.

For example, a combination index is created for C1, C2, and C3. In range query, a value range can be set only for C3 and the filter criterion is "C1 = XXX, C2 = XXX, and C3 = value range".

- For scenarios in which secondary index is created in a user table, you can use Filter to query data. The query results of the single and combination index with filter are the same as those in the table without secondary index. The data query performance is higher than that in user tables without secondary indexes.

## Example Code

The following code snippet belongs to the **testScanDataByIndex** method in the **HbaseSample** class of the **com.huawei.hadoop.hbase.example** package.

### Example: Query data using secondary indexes.

```
public void testScanDataByIndex() {
    LOG.info("Entering testScanDataByIndex.");
    Table table = null;
    ResultScanner scanner = null;
    try {
        table = conn.getTable(tableName);

        // Create a filter for indexed column.
        Filter filter = new SingleColumnValueFilter(Bytes.toBytes("info"), Bytes.toBytes("name"),
            CompareOperator.EQUAL, "Li Gang".getBytes());
        Scan scan = new Scan();
        scan.setFilter(filter);
        scanner = table.getScanner(scan);
        LOG.info("Scan indexed data.");

        for (Result result : scanner) {
            for (Cell cell : result.rawCells()) {
                LOG.info("{}:{}:{}",
                    Bytes.toString(CellUtil.cloneRow(cell)),
                    Bytes.toString(CellUtil.cloneFamily(cell)), Bytes.toString(CellUtil.cloneQualifier(cell)),
                    Bytes.toString(CellUtil.cloneValue(cell)));
            }
        }
        LOG.info("Scan data by index successfully.");
    } catch (IOException e) {
        LOG.error("Scan data by index failed.");
    } finally {
        if (scanner != null) {
            // Close the scanner object.
            scanner.close();
        }
        try {
            if (table != null) {
                table.close();
            }
        } catch (IOException e) {
            LOG.error("Close table failed.");
        }
    }
    LOG.info("Exiting testScanDataByIndex.");
}
```

## Precaution

Create secondary indexes for the **name** field first.

## Related Operations

Query a table using a secondary index.

The following provides an example:

Add an index to the **name** column of the **info** column family in **hbase\_sample\_table**. Run the following command on the client:

```
hbase org.apache.hadoop.hbase.hindex.mapreduce.TableIndexer -Dtablename.to.index=hbase_sample_table -Dindexspecs.to.add='IDX1=>info:[name->String]' -Dindexnames.to.build='IDX1'
```

Query **info:name**. Run the following command on the HBase shell client:

```
>scan 'hbase_sample_table',  
{FILTER=>"SingleColumnValueFilter(family,qualifier,compareOp,comparator,filterIfMissing,latestVersionOnly)"}
```

Use APIs to perform complex query on the HBase shell client.

The parameters are described as follows:

- **family**: indicates the column family where the column to be queried locates, such as **info**.
- **qualifier**: indicates the column to be queried, such as **name**.
- **compareOp**: indicates the comparison operator, such as = and >.
- **comparator**: indicates the target value to be queried, such as **binary:Zhang San**.
- **filterIfMissing**: indicates whether a row is filtered if the column does not exist in this row. The default value is **false**.
- **latestVersionOnly**: indicates whether only values of the latest version are to be queried. The default value is **false**.

For example:

```
>scan 'hbase_sample_table',{FILTER=>"SingleColumnValueFilter('info','name',=,'binary:Zhang San',true,true)"}
```

### 1.10.3.1.16 Multi-Point Region Division

## Function

You can perform multi-point division by using **org.apache.hadoop.hbase.client.HBaseAdmin**. Note that the division operations take effect on empty regions only.

In this example, the multi-point division is performed on an HBase table by using **multiSplit**. The table will be split into 5 parts: "-∞~A", "A~D", "D~F", "F~H", and "H~+∞".

## Example Code

The following code snippet belongs to the **testMultiSplit** method in the **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
public void testMultiSplit() {  
    LOG.info("Entering testMultiSplit.");  
  
    Table table = null;  
    Admin admin = null;
```

```

try {
    admin = conn.getAdmin();

    // initialize a HTable object
    table = conn.getTable(tableName);
    Set<HRegionInfo> regionSet = new HashSet<HRegionInfo>();
    List<HRegionLocation> regionList = conn.getRegionLocator(tableName).getAllRegionLocations();
    for(HRegionLocation hrl : regionList){
        regionSet.add(hrl.getRegionInfo());
    }
    byte[][] sk = new byte[4][];
    sk[0] = "A".getBytes();
    sk[1] = "D".getBytes();
    sk[2] = "F".getBytes();
    sk[3] = "H".getBytes();
    for (RegionInfo regionInfo : regionSet) {
        admin.multiSplitSync(regionInfo.getRegionName(), sk);
    }
    LOG.info("MultiSplit successfully.");
} catch (Exception e) {
    LOG.error("MultiSplit failed.");
} finally {
    if (table != null) {
        try {
            // Close table object
            table.close();
        } catch (IOException e) {
            LOG.error("Close table failed " ,e);
        }
    }
    if (admin != null) {
        try {
            // Close the Admin object.
            admin.close();
        } catch (IOException e) {
            LOG.error("Close admin failed " ,e);
        }
    }
}
LOG.info("Exiting testMultiSplit.");
}

```

Note that the division operations take effect on empty regions only.

### 1.10.3.1.17 Creating a Phoenix Table

#### Function

Phoenix can be installed on HBase to enable it to support SQL and JDBC APIs. This way, SQL users can access the HBase cluster.

#### Example Code

The following code snippet belongs to the **testCreateTable** method in the **PhoenixSample** class of the **com.huawei.bigdata.hbase.examplespackage**.

```

/**
 * Create Table
 */
public void testCreateTable() {
    LOG.info("Entering testCreateTable.");
    String URL = "jdbc:phoenix:" + conf.get("hbase.zookeeper.quorum");
    // Create table
    String createTableSQL =
        "CREATE TABLE IF NOT EXISTS TEST (id integer not null primary key, name varchar, "
        + "account char(6), birth date)";

```

```
try (Connection conn = DriverManager.getConnection(url, props);
    Statement stat = conn.createStatement()) {
    // Execute Create SQL
    stat.executeUpdate(createTableSQL);
    LOG.info("Create table successfully.");
} catch (Exception e) {
    LOG.error("Create table failed.", e);
}
LOG.info("Exiting testCreateTable.");
}
/**
 * Drop Table
 */
public void testDrop() {
    LOG.info("Entering testDrop.");
    String URL = "jdbc:phoenix:" + conf.get("hbase.zookeeper.quorum");
    // Delete table
    String dropTableSQL = "DROP TABLE TEST";

    try (Connection conn = DriverManager.getConnection(url, props);
        Statement stat = conn.createStatement()) {
        stat.executeUpdate(dropTableSQL);
        LOG.info("Drop successfully.");
    } catch (Exception e) {
        LOG.error("Drop failed.", e);
    }
    LOG.info("Exiting testDrop.");
}
```

### 1.10.3.1.18 Writing Data to the PhoenixTable

#### Function

The Phoenix table enables data writing in HBase.

#### Example Code

The following code snippet belongs to the **testPut** method in the **PhoenixSample** class of the **com.huawei.bigdata.hbase.examples** package.

```
/*
 * Put data
 */
public void testPut() {
    LOG.info("Entering testPut.");
    String URL = "jdbc:phoenix:" + conf.get("hbase.zookeeper.quorum");
    // Insert
    String upsertSQL =
        "UPSERT INTO TEST VALUES(1,'John','100000', TO_DATE('1980-01-01','yyyy-MM-dd'))";
    try (Connection conn = DriverManager.getConnection(url, props);
        Statement stat = conn.createStatement()){
        stat.executeUpdate(upsertSQL);
        conn.commit();
        LOG.info("Put successfully.");
    } catch (Exception e) {
        LOG.error("Put failed.", e);
    }
    LOG.info("Exiting testPut.");
}
```

### 1.10.3.1.19 Reading the PhoenixTable

#### Function

The Phoenix table enables data reading.

#### Example Code

The following code snippet belongs to the `testSelect` method in the `PhoenixSample` class of the `com.huawei.bigdata.hbase.examples` package.

```
/*
 * Select Data
 */
public void testSelect() {
    LOG.info("Entering testSelect.");
    String URL = "jdbc:phoenix:" + conf.get("hbase.zookeeper.quorum");
    // Query
    String querySQL = "SELECT * FROM TEST WHERE id = ?";
    Connection conn = null;
    PreparedStatement preStat = null;
    Statement stat = null;
    ResultSet result = null;
    try {
        // Create Connection
        conn = DriverManager.getConnection(url, props);
        // Create Statement
        stat = conn.createStatement();
        // Create PrepareStatement
        preStat = conn.prepareStatement(querySQL);
        // Execute query
        preStat.setInt(1, 1);
        result = preStat.executeQuery();
        // Get result
        while (result.next()) {
            int id = result.getInt("id");
            String name = result.getString(1);
            System.out.println("id: " + id);
            System.out.println("name: " + name);
        }
        LOG.info("Select successfully.");
    } catch (Exception e) {
        LOG.error("Select failed.", e);
    } finally {
        if (null != result) {
            try {
                result.close();
            } catch (Exception e2) {
                LOG.error("Result close failed.", e2);
            }
        }
        if (null != stat) {
            try {
                stat.close();
            } catch (Exception e2) {
                LOG.error("Stat close failed.", e2);
            }
        }
        if (null != conn) {
            try {
                conn.close();
            } catch (Exception e2) {
                LOG.error("Connection close failed.", e2);
            }
        }
    }
}
```

```
    LOG.info("Exiting testSelect.");
}
```

### 1.10.3.1.20 Using HBase Dual-Read Capability

#### Scenario

The HBase client application loads the configuration items of the active and standby clusters by customization to implement the dual-read capability. HBase dual-read is a key feature that improves the high availability of the HBase cluster system. It applies to four query scenarios: reading data using **Get**, reading data in batches using **Get**, reading data using **Scan**, and querying data using a secondary index. HBase can read data from the active and standby clusters at the same time, reducing the query glitch time. The advantages are as follows:

- High success rate: The concurrent dual-read mechanism ensures a high success rate of read requests.
- High availability: When a single cluster is faulty, the query service is not interrupted. A short network jitter does not prolong the query time.
- High generality: The dual-read feature does not support dual-write, but does not affect the original real-time write scenario.
- Ease-of-use: Client encapsulation is performed, which is not sensed by services.

#### NOTE

Restrictions on HBase dual-read:

- The HBase dual-read feature is implemented based on replication. Data read from the standby cluster may be different from that from the active cluster. Therefore, only eventual consistency can be achieved.
- Currently, the HBase dual-read feature is used only for query. When the active cluster breaks down, the latest data cannot be synchronized. As a result, the latest data cannot be queried in the standby cluster.
- A **Scan** operation of HBase may be split into multiple RPC operations. Data may not be completely the same because related session information is not synchronized between different clusters. Therefore, the dual-read feature takes effect only when an RPC operation is performed for the first time. Requests before ResultScanner close access the cluster used for the first RPC operation.
- The HBase Admin API and real-time write API access only the active cluster. Therefore, after the active cluster breaks down, the Admin API and real-time write API are unavailable, and only the **Get** and **Scan** query services are available.

HBase dual-read supports the following two methods to configure the active/standby cluster:

- Add active/standby cluster configurations to the **hbase-dual.xml** file.
- Add the active/standby cluster configuration to **HBaseMultiClusterConnection**.

#### Add the Active/Standby Cluster Configuration to the hbase-dual.xml File

**Step 1** Save the keytab authentication files **user.keytab** and **krb5.conf** of the active cluster obtained when [Preparing a Developer Account](#) to the **src/main/resources/conf** secondary sample directory.

- Step 2** Obtain the client configuration files **core-site.xml**, **hbase-site.xml**, and **hdfs-site.xml** of the HBase active cluster and save them to the **src/main/resources/conf/active** directory. This directory needs to be created by yourself. For details, see [Preparing the Connection Cluster Configuration File](#).
- Step 3** Obtain the client configuration files **core-site.xml**, **hbase-site.xml**, and **hdfs-site.xml** of the standby cluster and save them to the **src/main/resources/conf/standby** directory. For details, see [Preparing the Connection Cluster Configuration File](#).
- Step 4** Create the **hbase-dual.xml** configuration file and save it to the **src/main/resources/conf/** directory. This directory needs to be created by yourself. For details about the configuration items in the configuration file, see [Table 1-83](#).

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration>
<!--Configuration file directory of the active cluster-->
<property>
    <name>hbase.dualclient.active.cluster.configuration.path</name>
    <value>{Sample code directory}\src\main\resources\active</value>
</property>
<!--Configuration file directory of the standby cluster-->
<property>
    <name>hbase.dualclient.standby.cluster.configuration.path</name>
    <value>{Sample code directory}\src\main\resources\standby</value>
</property>
<!--Connection implementation of the dual-read mode-->
<property>
    <name>hbase.client.connection.impl</name>
    <value>org.apache.hadoop.hbase.client.HBaseMultiClusterConnectionImpl</value>
</property>
<!--Security mode-->
<property>
    <name>hbase.security.authentication</name>
    <value>kerberos</value>
</property>
<!--Security mode-->
<property>
    <name>hadoop.security.authentication</name>
    <value>kerberos</value>
</property>
</configuration>
```

- Step 5** Create a dual-read Configuration and delete the comment of **testHBaseDualReadSample** from the **main** method of the **TestMain** class in the **com.huawei.bigdata.hbase.examples** package. Ensure that the value of **IS\_CREATE\_CONNECTION\_BY\_XML** in the **HBaseDualReadSample** class in the **com.huawei.bigdata.hbase.examples** package is **true**.

**Step 6** Determining the data source cluster

- GET request. The following code snippet belongs to the **testGet** method in **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```
Result result = table.get(get);
if (result instanceof DualResult) {
    LOG.info(((DualResult)result).getClusterId());
}
```

- Scan request. The following code snippet belongs to the **testScanData** method in **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```
ResultScanner rScanner = table.getScanner(scan);
if (rScanner instanceof HBaseMultiScanner) {
    LOG.info(((HBaseMultiScanner)rScanner).getClusterId());
}
```

**Step 7** The client can print metric information.

Add the following content to the **log4j.properties** file so that the client can export metric information to the specified file: For details about the metrics, see [Printing Metric Information](#).

```
log4j.logger.DUAL=debug,DUAL
log4j.appendender.DUAL=org.apache.log4j.RollingFileAppender
log4j.appendender.DUAL.File=/var/log/dual.log //Local dual-read log path on the client. Change the value to
the actual directory, but ensure that the directory has the write permission.
log4j.additivity.DUAL=false
log4j.appendender.DUAL.MaxFileSize=${hbbase.log.maxfilesize}
log4j.appendender.DUAL.MaxBackupIndex=${hbbase.log.maxbackupindex}
log4j.appendender.DUAL.layout=org.apache.log4j.PatternLayout
log4j.appendender.DUAL.layout.ConversionPattern=%d{ISO8601} %--5p [%t] %c{2}: %m%n
```

----End

## Configure the Active/Standby Cluster Configuration in HBaseMultiClusterConnection

- Step 1** Save the keytab authentication files **user.keytab** and **krb5.conf** of the active cluster obtained when [Preparing a Developer Account](#) to the **src/main/resources/conf** secondary sample directory.
- Step 2** Create a dual-read Configuration and delete the comment of **testHBaseDualReadSample** from the **main** method of the **TestMain** class in the **com.huawei.bigdata.hbase.examples** package. Ensure that the value of **IS\_CREATE\_CONNECTION\_BY\_XML** in the **HBaseDualReadSample** class in the **com.huawei.bigdata.hbase.examples** package is **false**.
- Step 3** Add related configurations to the **addHbaseDualXmlParam** method of the **HBaseDualReadSample** class. For details about related configuration items, see [HBase Dual-Read Configuration Items](#).

```
private void addHbaseDualXmlParam(Configuration conf) {
    // We need to set the optional parameters contained in hbase-dual.xml to conf
    // when we use configuration transfer solution
    conf.set(CONNECTION_IMPL_KEY, DUAL_READ_CONNECTION);
    // conf.set("", "");
}
```

- Step 4** Add configurations related to the Active cluster client to the **initActiveConf** method of the **HBaseDualReadSample** class.

```
private void initActiveConf() {
    // The hbase-dual.xml configuration scheme is used to generate the client configuration of the active
    // cluster.
    // In actual application development, you need to generate the client configuration of the active cluster.
    String activeDir =
        HBaseDualReadSample.class.getClassLoader().getResource(Utils.CONF_DIRECTORY).getPath()
            + File.separator + ACTIVE_DIRECTORY + File.separator;
    Configuration activeConf = Utils.createConfByUserDir(activeDir);
    HBaseMultiClusterConnection.setActiveConf(activeConf);
}
```

- Step 5** Add configurations related to the Standby cluster client to the **initStandbyConf** method of the **HBaseDualReadSample** class.

```
private void initStandbyConf() {
    // The hbase-dual.xml configuration scheme is used to generate the client configuration of the standby
    // cluster.
    // In actual application development, you need to generate the client configuration of the standby cluster.
    String standbyDir =
        HBaseDualReadSample.class.getClassLoader().getResource(Utils.CONF_DIRECTORY).getPath()
```

```
+ File.separator + STANDBY_DIRECTORY + File.separator;
Configuration standbyConf = Utils.createConfByUserDir(standbyDir);
HBaseMultiClusterConnection.setStandbyConf(standbyConf);
}
```

**Step 6** Determining the data source cluster.

- GET request. The following code snippet belongs to the **testGet** method in **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```
Result result = table.get(get);
if (result instanceof DualResult) {
    LOG.info(((DualResult)result).getClusterId());
}
```
- Scan request. The following code snippet belongs to the **testScanData** method in **HBaseSample** class of the **com.huawei.bigdata.hbase.examples** packet.

```
ResultScanner rScanner = table.getScanner(scan);
if (rScanner instanceof HBaseMultiScanner) {
    LOG.info(((HBaseMultiScanner)rScanner).getClusterId());
}
```

**Step 7** The client can print metric information.

Add the following content to the **log4j.properties** file so that the client can export metric information to the specified file: For details about the metrics, see [Printing Metric Information](#)

```
log4j.logger.DUAL=debug,DUAL
log4j.appendер.DUAL=org.apache.log4j.RollingFileAppender
log4j.appendер.DUAL.File=/var/log/dual.log //Local dual-read log path on the client. Change the value to
the actual directory, but ensure that the directory has the write permission.
log4j.additivity.DUAL=false
log4j.appendер.DUAL.MaxFileSize=${hbse.log.maxfilesize}
log4j.appendер.DUAL.MaxBackupIndex=${hbse.log.maxbackupindex}
log4j.appendер.DUAL.layout=org.apache.log4j.PatternLayout
log4j.appendер.DUAL.layout.ConversionPattern=%d{ISO8601} %-5p [%t] %c{2}: %m%n
```

----End

### 1.10.3.1.21 Configuring Log4j Log Output

#### Function Description

This section describes how to output HBase client logs to a specified log file separately from service logs to facilitate HBase problem analyzing and locating.

If the **log4j** configuration exists in the process, copy the RFA and RFAS configurations in **hbse-example\src\main\resources\log4j.properties** to the existing **log4j** configuration.

#### Sample Code

```
hbse.root.logger=INFO,console,RFA          //HBase client log output configuration. console: outputs to
the console; RFA: outputs to the log files.

```

## 1.10.3.2 HBase Global Secondary Index Sample Program

### 1.10.3.2.1 Service Scenario Description

HBase allows you to use global secondary indexes to accelerate conditional queries. This sample shows you how to manage and use global secondary indexes.

#### Scenario

Assume that you are developing an application that records user information and addresses. The following table lists the data to be recorded.

**Table 1-82** User information

<b>id</b>	<b>name</b>	<b>age</b>	<b>address</b>
1	Zhang	20	CityA
2	Li	30	CityB
3	Wang	35	CityC

#### Data Preparation

Proper design of a table structure, RowKeys, and column names enable you to make full use of HBase advantages. If you use a global secondary index in a scan condition query, the query is performed on an index table. You do not need to pay attention to the rowkeys of the user table. In this example, the rowkeys are in "r1", "r2", "r3"... format. All columns are stored in the **info** column family.

#### Sample Description

The examples in following content describe how to create and delete global secondary indexes, modify statuses, , and use them to accelerate queries.

### 1.10.3.2.2 Creating HBase Global Secondary Indexes

#### Function

Manage HBase global secondary indexes by calling the method in **org.apache.hadoop.hbase.hindex.global.GlobalIndexAdmin**. **addIndices** is used for creating global secondary indexes.

To create a global secondary index, you need to configure the index column, covering column (optional), and pre-created index table regions (recommended).

### NOTE

To create global secondary indexes on a table with existing data, you need to pre-create regions for the index table to prevent hot-spotting. The rowkeys of the index table data consists of index columns and separators. The format is `\x01/index value\x00`. Specify the format when you pre-create a region, for example, when the **id** and **age** columns are used as the index columns, both columns need to be integers. Use the **id** column to pre-create regions. You can specify the pre-created index table region as follows:

`\x010,\x011,\x012....`

## Code Sample

The following code snippets are in the **addIndices** method in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, an index named **index\_id\_age** is created for the **user\_table** data table. The **id** and **age** columns in the data are used as index columns and the **name** column is overwritten. (The query condition is not used, but the query result needs to return to this column).

```
/**  
 * createIndex  
 */  
public void testCreateIndex() {  
    LOG.info("Entering createIndex.");  
    // Create index instance  
    TableIndices tableIndices = new TableIndices();  
    // Create index spec  
    // idx_id_age covered info:name  
    HIndexSpecification indexSpec = new HIndexSpecification("idx_id_age");  
  
    // Set index column  
    indexSpec.addIndexColumn(Bytes.toBytes("info"), Bytes.toBytes("id"), ValueType.STRING);  
    indexSpec.addIndexColumn(Bytes.toBytes("info"), Bytes.toBytes("age"), ValueType.STRING);  
  
    // Set covered column  
    // If you want cover one column, use addCoveredColumn  
    // If you want cover all column in one column family, use addCoveredFamilies  
    // If you want cover all column of all column family, use setCoveredAllColumns  
    indexSpec.addCoveredColumn(Bytes.toBytes("info"), Bytes.toBytes("name"));  
  
    // Need specify index table split keys, it should specify by index column.  
    // Note: index data's row key has a same prefix "\x01"  
    // For example:  
    // Our index column include "id" and "age", "id" is a number, we  
    // could specify split key like \x010 \x011 \x012...  
    byte[][] splitKeys = new byte[10][];  
    for (int i = 0; i < 10; i++) {  
        splitKeys[i] = Bytes.toBytesBinary("\x01" + i);  
    }  
    indexSpec.setSplitKeys(splitKeys);  
    tableIndices.addIndex(indexSpec);  
  
    // iAdmin will close the inner admin instance  
    try (GlobalIndexAdmin iAdmin = GlobalIndexClient newIndexAdmin(conn.getAdmin())) {  
        // add index to the table  
        iAdmin.addIndices(tableName, tableIndices);  
        LOG.info("Create index successfully.");  
    } catch (IOException e) {  
        LOG.error("Create index failed.", e);  
    }  
    LOG.info("Exiting createIndex.");  
}
```

### 1.10.3.2.3 Querying Global Secondary Indexes

#### Function

Manage HBase global secondary index by calling the method in **org.apache.hadoop.hbase.hindex.global.GlobalIndexAdmin.listIndices** is used for querying indexes, including the definitions and status of all indexes related to the current user table.

#### Code Sample

The following code snippets are in the **listIndices** method in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, all indexes corresponding to the user table **user\_table** are queried.

```
/*
 * List indexes
 */
public void testListIndexes() {
    LOG.info("Entering testListIndexes.");
    try (GlobalIndexAdmin iAdmin = GlobalIndexClient.newIndexAdmin(conn.getAdmin())) {
        for (Pair<HIndexSpecification, IndexState> indexPair : iAdmin.listIndices(tableName)) {
            LOG.info("index spec:{} , index state:{}" , indexPair.getFirst(), indexPair.getSecond());
        }
        LOG.info("List indexes successfully.");
    } catch (IOException e) {
        LOG.error("List indexes failed." , e);
    }
    LOG.info("Exiting testListIndexes.");
}
```

### 1.10.3.2.4 Querying Based on Global Secondary Indexes

#### Function

When a user table with a global secondary index is used for query, the query can be converted to a range query of the index table. The query performance is higher than that of a user table without a secondary index. For details about global secondary indexes, see

"Introduction to Global Secondary Indexes" in MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1) in the MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1).

#### Code Sample

The following code snippets are in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, the values of **id**, **age**, and **name** of the specified **id** are queried, and the **idx\_id\_age** index is selected. The query results are completely overwritten. As a result, you do not need to query in the original table to achieve optimal query performance.

```
/*
 * Scan data by secondary index.
```

```

/*
public void testScanDataByIndex() {
    LOG.info("Entering testScanDataByIndex.");

    Scan scan = new Scan();
    // Create a filter for indexed column.
    SingleColumnValueFilter filter = new SingleColumnValueFilter(Bytes.toBytes("info"), Bytes.toBytes("id"),
        CompareOperator.EQUAL, Bytes.toBytes("3"));
    filter.setFilterIfMissing(true);
    scan.setFilter(filter);

    // Specify returned columns
    // If returned columns not included in index table, will query back user table,
    // it's not the fast way to get data, suggest to cover all needed columns.
    // If you want to confirm whether using index for scanning, please set hbase client log level to DEBUG.
    scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("id"));
    scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("age"));
    scan.addColumn(Bytes.toBytes("info"), Bytes.toBytes("name"));

    LOG.info("Scan indexed data.");
    try (Table table = conn.getTable(tableName); ResultScanner scanner = table.getScanner(scan)) {
        for (Result result : scanner) {
            for (Cell cell : result.rawCells()) {
                LOG.info("{}:{}:{},{}:{}:{}",
                    Bytes.toString(CellUtil.cloneRow(cell)),
                    Bytes.toString(CellUtil.cloneFamily(cell)), Bytes.toString(CellUtil.cloneQualifier(cell)),
                    Bytes.toString(CellUtil.cloneValue(cell)));
            }
        }
        LOG.info("Scan data by index successfully.");
    } catch (IOException e) {
        LOG.error("Scan data by index failed ", e);
    }
    LOG.info("Exiting testScanDataByIndex.");
}

```

### 1.10.3.2.5 Disabling Global Secondary Indexes

#### Function

The status of a global secondary index determines whether the index is valid. By modifying the index status, you can disable, enable, or discard an index (no index data will be generated). You can modify the index status by calling the method in **org.apache.hadoop.hbase.hindex.global.GlobalIndexAdmin**. For details, see "Introduction to Global Secondary Index APIs" in MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1) in the MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1).

#### Code Sample

The following code snippets are in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, the **idx\_id\_age** index is disabled. That is, the index is not used during query, but index data is generated.

```

/**
 * alter index to UNUSABLE state.
 */
public void testAlterIndex() {
    LOG.info("Entering testAlterIndex.");
    List<String> indexNameList = Lists.newArrayList("idx_id_age");
    // Instantiate HIndexAdmin Object
    try (GlobalIndexAdmin iAdmin = GlobalIndexClient newIndexAdmin(conn.getAdmin())) {
        iAdmin.alterGlobalIndicesUnusable(tableName, indexNameList);
    }
}

```

```
        LOG.info("Alter indices to UNUSABLE successfully.");
    } catch (IOException e) {
        LOG.error("Alter indices to UNUSABLE failed.", e);
    }
    LOG.info("Exiting testAlterIndex.");
}
```

### 1.10.3.2.6 Deleting Global Secondary Indexes

#### Function

Manage HBase global secondary indexes by calling the method in **org.apache.hadoop.hbase.hindex.global.GlobalIndexAdmin**.

**dropIndices** is used to delete indexes.

#### Code Sample

The following code snippets are in the **dropIndices** method in the **GlobalSecondaryIndexSample** class of the **com.huawei.bigdata.hbase.examples** package.

In this case, the **idx\_id\_age** index is deleted from the **user\_table** table.

```
/*
 * dropIndex
 */
public void testDropIndex() {
    LOG.info("Entering testDropIndex.");
    List<String> indexNameList = Lists.newArrayList("idx_id_age");
    // Instantiate HIndexAdmin Object
    try (GlobalIndexAdmin iAdmin = GlobalIndexClient newIndexAdmin(conn.getAdmin())) {
        // Delete Secondary Index
        iAdmin.dropIndices(tableName, indexNameList);
        LOG.info("Drop index successfully.");
    } catch (IOException e) {
        LOG.error("Drop index failed ", e);
    }
    LOG.info("Exiting testDropIndex.");
}
```

### 1.10.3.3 Sample Program for Preloading Meta Tables When Request Concurrency Is High

#### 1.10.3.3.1 Service Scenario Description

When there is a large number of concurrent access requests to a data table, the client caches the required region location information again after an application is restarted. Each thread waits until the cache is complete before executing the requests. If the client timeout is too short and the target table contains a large number of regions, a large number of requests will be retried due to timeout. To prevent this issue, you need to cache the region information in the table before the application threads run so that subsequent requests will not time out.

This sample contains HBase multi-thread read/write tasks. The meta table will be preloaded before the thread tasks are started.

 NOTE

In this sample, multiple threads concurrently access HBase, where:

- The number of regions of the HBase table is greater than or equal to 100.
- The data table is concurrently accessed by a single application.
- The HBase request timeout on the application side is less than 2s.

### 1.10.3.3.2 Preloading Meta Tables When Request Concurrency Is High

#### Function

Preload region location information in the scenario where multiple threads concurrently read and write HBase tables.

#### Code Sample

The following code snippets are in the **MultiThreadSample** class of the **com.huawei.bigdata.hbase.examples** package.

- Create a user table, pre-split 300 regions, and compress the table using SNAPPY.

```
private void createUserTable() {
    // Use number id as the first part of rowKey and pre-split 300 regions by the decimal string split
    // algorithm.
    ColumnFamilyDescriptor cf = ColumnFamilyDescriptorBuilder
        .newBuilder(Bytes.toBytes("f"))
        .setCompressionType(Compression.Algorithm.SNAPPY)
        .build();
    TableDescriptor td = TableDescriptorBuilder
        .newBuilder(tableName)
        .setColumnFamily(cf)
        .build();
    try (Admin admin = conn.getAdmin()) {
        if (!admin.tableExists(tableName)) {
            RegionSplitter.SplitAlgorithm splitAlgo = RegionSplitter
                .newSplitAlgoInstance(this.conn.getConfiguration(),
                    RegionSplitter.DecimalStringSplit.class.getName());
            admin.createTable(td, splitAlgo.split(REGION_NUMS));
            LOG.info("Create table success.");
        } else {
            LOG.warn("Table already exists.");
        }
    } catch (IOException e) {
        LOG.error("Create table failed!", e);
    }
}
```

- Preload the meta table and obtain the location information of all regions in the user table.

```
private void preLoadTableRegionLocations() {
    try (RegionLocator rl = conn.getRegionLocator(tableName)) {
        long startTime = System.currentTimeMillis();
        rl.getAllRegionLocations();
        LOG.info("Cache table region location success, cost {} ms.", System.currentTimeMillis() -
            startTime);
    } catch (IOException e) {
        LOG.error("Cache table region location failed!", e);
    }
}
```

- Perform multi-thread read and write operations.

```
private void doOperations() {
    int cores = Math.max(32, Runtime.getRuntime().availableProcessors());
```

```
// Pool for user service including HBase data read/write.
ThreadPoolExecutor pool = new ThreadPoolExecutor(cores, cores,
    60,
    TimeUnit.SECONDS,
    new LinkedBlockingQueue<>(cores * 100),
    new ThreadFactoryBuilder()
        .setDaemon(true)
        .setUncaughtExceptionHandler((t, e) ->
            LOG.warn("Thread:{} exited with Exception:{}", t, StringUtils.stringifyException(e)))
        .setNameFormat("Application-Pool-%d").build());

for (int i = 0; i < OPERATIONS_COUNT; i++) {
    pool.execute(() -> {
        try (Table table = conn.getTable(tableName)) {
            Put put = new Put(Bytes.toBytes(
                ThreadLocalRandom.current().nextLong(0, 100000L) + "#"
                    + RandomStringUtils.randomAlphabetic(5)));
            put.addColumn(Bytes.toBytes("f"), Bytes.toBytes("name"),
                Bytes.toBytes(RandomStringUtils.randomAlphabetic(10)));
            put.addColumn(Bytes.toBytes("f"), Bytes.toBytes("ts"),
                Bytes.toBytes(Long.toString(System.currentTimeMillis())));
            table.put(put);
        } catch (IOException e) {
            LOG.error("Put data failed ", e);
        }
    });
    pool.execute(() -> {
        Scan scan = new Scan()
            .withStartRow(Bytes.toBytes(
                ThreadLocalRandom.current().nextLong(0, 100000L) + "#"))
            .setLimit(1);
        try (Table table = conn.getTable(tableName);
            ResultScanner scanner = table.getScanner(scan)) {
            Result result;
            while ((result = scanner.next()) != null) {
                for (Cell cell : result.rawCells()) {
                    LOG.info("ROW:{};CF:{};CQ:{};VALUE:{}",
                        Bytes.toString(CellUtil.cloneRow(cell)),
                        Bytes.toString(CellUtil.cloneFamily(cell)),
                        Bytes.toString(CellUtil.cloneQualifier(cell)),
                        Bytes.toString(CellUtil.cloneValue(cell)));
                }
            }
        } catch (IOException e) {
            LOG.error("Scan data failed ", e);
        }
    });
}
shutDownPool(pool);
LOG.info("Finish do operations.");
}

private void shutDownPool(ThreadPoolExecutor pool) {
    pool.shutdown();
    try {
        if (!pool.awaitTermination(SHUT_DOWN_POOL_WAIT_TIMEOUT_SEC, TimeUnit.SECONDS)) {
            pool.shutdownNow();
        }
    } catch (InterruptedException e) {
        pool.shutdownNow();
    }
}
```

- Clear the user table.

```
private void dropUserTable() {
    try (Admin admin = conn.getAdmin()) {
        admin.disableTable(tableName);
        admin.deleteTable(tableName);
        LOG.info("Drop table success.");
    } catch (IOException e) {
        LOG.error("Drop table failed ", e);
    }
}
```

```
    }
```

### 1.10.3.4 HBase Rest API Invoking Sample Program

#### 1.10.3.4.1 Querying Cluster Information Using REST

##### Function

Use the REST service to transfer the URL consisting of the host and port to obtain the cluster version and status information through HTTPS.

##### Example Code

- Obtaining the cluster version information

The following code snippets are in the **getClusterVersion** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getClusterVersion(String url) {
    String endpoint = "/version/cluster";
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);
    handleNormalResult((Optional<ResultModel>) result);
}
```

- Obtaining the cluster status information

The following code snippets are in the **getClusterStatus** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getClusterStatus(String url) {
    String endpoint = "/status/cluster";
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);
    handleNormalResult(result);
}
```

#### 1.10.3.4.2 Obtaining All Tables Using REST

##### Function

Use the REST service and transfer the URL consisting of the host and port to obtain all tables using HTTPS.

##### Example Code

The following code snippets are in the **getAllUserTables** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getAllUserTables(String url) {
    String endpoint = "/";
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);
    handleNormalResult(result);
}
```

### 1.10.3.4.3 Operate Namespaces Using REST

#### Function

Use the REST service to import the URL consisting of the host and port and the specified namespace, Use HTTPS to create, query, and delete namespaces, and obtain tables in the specified namespace.

#### ⚠ CAUTION

HBase tables are stored in *Namespace.Table name* format. If no namespace is specified when a table is created, the table is stored in **default**. The **hbase** namespace is the system table namespace. Do not create service tables or read or write data in the system table namespace.

#### Example Code

- Invoking methods

```
// Namespace operations.  
createNamespace(url, "testNs");  
getAllNamespace(url);  
deleteNamespace(url, "testNs");  
getAllNamespaceTables(url, "default");
```

- Creating a namespace

The following code snippets are in the **createNamespace** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void createNamespace(String url, String namespace) {  
    String endpoint = "/namespaces/" + namespace;  
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.POST, null);  
    if (result.orElse(new ResultModel()).getStatusCode() == HttpStatus.SC_CREATED) {  
        LOG.info("Create namespace '{}' success.", namespace);  
    } else {  
        LOG.error("Create namespace '{}' failed.", namespace);  
    }  
}
```

- Querying all namespaces

The following code snippets are in the **getAllNamespace** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getAllNamespace(String url) {  
    String endpoint = "/namespaces";  
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);  
    handleNormalResult(result);  
}
```

- Deleting a specified namespace

The following code snippets are in the **deleteNamespace** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void deleteNamespace(String url, String namespace) {  
    String endpoint = "/namespaces/" + namespace;  
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.DELETE, null);  
    if (result.orElse(new ResultModel()).getStatusCode() == HttpStatus.SC_OK) {  
        LOG.info("Delete namespace '{}' success.", namespace);  
    } else {  
        LOG.error("Delete namespace '{}' failed.", namespace);  
    }  
}
```

```
        LOG.error("Delete namespace '{}' failed.", namespace);
    }
}
```

- Obtain tables in a specified namespace.

The following code snippets are in the **getAllNamespaceTables** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getAllNamespaceTables(String url, String namespace) {
    String endpoint = "/namespaces/" + namespace + "/tables";
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);
    handleNormalResult(result);
}
```

#### 1.10.3.4.4 Operate Tables Using REST

##### Function

Use the REST service to transfer the URL consisting of the host and port as well as the specified **tableName** and **jsonHTD** to query, modify, create, and delete table information through HTTPS.

##### Example Code

- Invoking methods

```
// Add a table with specified info.
createTable(url, "testRest",
    "{\"name\":\"default:testRest\",\"ColumnSchema\":[{\"name\":\"cf1\"},\"cf2\"]}");

// Add column family 'testCF1' if not exist, else update the 'VERSIONS' to 3.
// Notes: The unspecified property of this column family will be updated to default value.
modifyTable(url, "testRest",
    "{\"name\":\"testRest\",\"ColumnSchema\":[{\"name\":\"testCF1\",\"VERSIONS\":3}]}");

// Describe specific Table.
descTable(url, "default:testRest");

// delete a table with specified info.
deleteTable(url, "default:testRest",
    "{\"name\":\"default:testRest\",\"ColumnSchema\":[{\"name\":\"testCF1\",\"VERSIONS\":3}]");
```

- Querying table information

The following code snippets are in the **descTable** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void descTable(String url, String tableName) {
    String endpoint = "/" + tableName + "/schema";
    Optional<ResultModel> result = sendAction(url + endpoint, MethodType.GET, null);
    handleNormalResult((Optional<ResultModel>) result);
}
```

- Modifying table information

The following code snippets are in the **modifyTable** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void modifyTable(String url, String tableName, String jsonHTD) {
    LOG.info("Start modify table.");
    String endpoint = "/" + tableName + "/schema";
    JsonElement tableDesc = new JsonParser().parse(jsonHTD);
```

```
// Add a new column family or modify it.  
handleNormalResult(sendAction(url + endpoint, MethodType.POST, tableDesc));  
}
```

- Creating a table

The following code snippets are in the **createTable** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void createTable(String url, String tableName, String jsonHTD) {  
    LOG.info("Start create table.");  
    String endpoint = "/" + tableName + "/schema";  
    JsonElement tableDesc = new JsonParser().parse(jsonHTD);  
  
    // Add a table.  
    handleCreateTableResult(sendAction(url + endpoint, MethodType.PUT, tableDesc));  
}
```

- Deleting a table

The following code snippets are in the **deleteTable** method in the **HBaseRestTest** class of the **hbase-rest-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void deleteTable(String url, String tableName, String jsonHTD) {  
    LOG.info("Start delete table.");  
    String endpoint = "/" + tableName + "/schema";  
    JsonElement tableDesc = new JsonParser().parse(jsonHTD);  
  
    // delete a table.  
    handleNormalResult(sendAction(url + endpoint, MethodType.DELETE, tableDesc));  
}
```

### 1.10.3.5 Accessing the HBase ThriftServer Sample Program

#### 1.10.3.5.1 Accessing the ThriftServer Operation Table

##### Function

After importing the host where the ThriftServer instances are located and the port that provides services, you can create a Thrift client using the authentication credential and configuration file, access ThriftServer, and obtain table names, create a table, and delete a table based on the specified namespace.

##### Example Code

- Invoking methods

```
// Get table of specified namespace. getTableNamesByNamespace(client, "default");  
// Create table. createTable(client, TABLE_NAME);  
// Delete specified table.  
deleteTable(client, TABLE_NAME);
```

- Obtains table names based on the specified namespace.

The following code snippets are in the **getTableNamesByNamespace** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getTableNamesByNamespace(THBaseService.Iface client, String namespace) throws  
TException {  
    client.getTableNamesByNamespace(namespace)  
        .forEach(  
            tTableName -> LOGGER.info("{}: {}, TableName.valueOf(tTableName.getNs(),  
tTableName.getQualifier())));  
}
```

- Creating a table

The following code snippets are in the **createTable** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void createTable(THBaseService.Iface client, String tableName) throws TException, IOException {
    TTableName table = getTableName(tableName);
    TTableDescriptor descriptor = new TTableDescriptor(table);
    descriptor.setColumns(
        Collections.singletonList(new
        TColumnFamilyDescriptor(). setName(COLUMN_FAMILY.getBytes())));
    if (client.tableExists(table)) {
        LOGGER.warn("Table {} is exists, delete it.", tableName);
        client.disableTable(table);
        client.deleteTable(table);
    }
    client.createTable(descriptor, null);
    if (client.tableExists(table)) {
        LOGGER.info("Created {}.", tableName);
    } else {
        LOGGER.error("Create {} failed.", tableName);
    }
}
```

- Deleting a table

The following code snippets are in the **deleteTable** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void deleteTable(THBaseService.Iface client, String tableName) throws TException, IOException {
    TTableName table = getTableName(tableName);
    if (client.tableExists(table)) {
        client.disableTable(table);
        client.deleteTable(table);
        LOGGER.info("Deleted {}.", tableName);
    } else {
        LOGGER.warn("{} not exist.", tableName);
    }
}
```

### 1.10.3.5.2 Accessing ThriftServer to Write Data

#### Function

After importing the host where the ThriftServer instances are located and the port that provides services, you can create a Thrift client using the authentication credential and configuration file, access the ThriftServer, and use Put and putMultiple to write data.

#### Example Code

- Invoking methods

```
// Write data with put.
putData(client, TABLE_NAME);

// Write data with putlist.
putDataList(client, TABLE_NAME);
```

- Using Put to write data.

The following code snippets are in the **putData** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void putData(THBaseService.Iface client, String tableName) throws TException {
    LOGGER.info("Test putData.");
    TPut put = new TPut();
    put.setRow("row1".getBytes());

    TColumnValue columnValue = new TColumnValue();
    columnValue.setFamily(COLUMN_FAMILY.getBytes());
    columnValue.setQualifier("q1".getBytes());
    columnValue.setValue("test value".getBytes());
    List<TColumnValue> columnValues = new ArrayList<>(1);
    columnValues.add(columnValue);
    put.setColumnValues(columnValues);

    ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());
    client.put(table, put);
    LOGGER.info("Test putData done.");
}
```

- Using `putMultiple` to write data.

The following code snippets are in the `putDataList` method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void putDataList(THBaseService.Iface client, String tableName) throws TException {
    LOGGER.info("Test putDataList.");
    TPut put1 = new TPut();
    put1.setRow("row2".getBytes());
    List<TPut> putList = new ArrayList<>();

    TColumnValue q1Value = new TColumnValue(ByteBuffer.wrap(COLUMN_FAMILY.getBytes()),
        ByteBuffer.wrap("q1".getBytes()), ByteBuffer.wrap("test value".getBytes()));
    TColumnValue q2Value = new TColumnValue(ByteBuffer.wrap(COLUMN_FAMILY.getBytes()),
        ByteBuffer.wrap("q2".getBytes()), ByteBuffer.wrap("test q2 value".getBytes()));
    List<TColumnValue> columnValues = new ArrayList<>(2);
    columnValues.add(q1Value);
    columnValues.add(q2Value);
    put1.setColumnValues(columnValues);
    putList.add(put1);

    TPut put2 = new TPut();
    put2.setRow("row3".getBytes());

    TColumnValue columnValue = new TColumnValue();
    columnValue.setFamily(COLUMN_FAMILY.getBytes());
    columnValue.setQualifier("q1".getBytes());
    columnValue.setValue("test q1 value".getBytes());
    put2.setColumnValues(Collections.singletonList(columnValue));
    putList.add(put2);

    ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());
    client.putMultiple(table, putList);
    LOGGER.info("Test putDataList done.");
}
```

### 1.10.3.5.3 Accessing ThriftServer to Read Data

#### Function

After importing the host where the ThriftServer instances are located and the port that provides services, you can create a Thrift client using the authentication credential and configuration file, access the ThriftServer, and use **get** and **scan** methods to read data.

## Example Code

- Invoking methods

```
// Get data with single get.  
getData(client, TABLE_NAME);  
  
// Get data with getlist.  
getDataList(client, TABLE_NAME);  
  
// Scan data.  
scanData(client, TABLE_NAME);
```

- Using the **get** method to write data.

The following code snippets are in the **getData** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getData(THBaseService.Iface client, String tableName) throws TException {  
    LOGGER.info("Test getData.");  
    TGet get = new TGet();  
    get.setRow("row1".getBytes());  
  
    ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());  
    TResult result = client.get(table, get);  
    printResult(result);  
    LOGGER.info("Test getData done.");  
}
```

- Using the **getlist** method to write data.

The following code snippets are in the **getDataList** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void getDataList(THBaseService.Iface client, String tableName) throws TException {  
    LOGGER.info("Test getDataList.");  
    List<TGet> getList = new ArrayList<>();  
    TGet get1 = new TGet();  
    get1.setRow("row1".getBytes());  
    getList.add(get1);  
  
    TGet get2 = new TGet();  
    get2.setRow("row2".getBytes());  
    getList.add(get2);  
  
    ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());  
    List<TResult> resultList = client.getMultiple(table, getList);  
    for (TResult tResult : resultList) {  
        printResult(tResult);  
    }  
    LOGGER.info("Test getDataList done.");  
}
```

- Using the **scan** method to write data.

The following code snippets are in the **scanData** method in the **ThriftSample** class of the **hbase-thrift-example\src\main\java\com\huawei\hadoop\hbase\examples** packet.

```
private void scanData(THBaseService.Iface client, String tableName) throws TException {  
    LOGGER.info("Test scanData.");  
    int scannerId = -1;  
    try {  
        ByteBuffer table = ByteBuffer.wrap(tableName.getBytes());  
        TScan scan = new TScan();  
        scan.setLimit(500);  
        scannerId = client.openScanner(table, scan);  
        List<TResult> resultList = client.getScannerRows(scannerId, 100);  
        while (resultList != null && !resultList.isEmpty()) {  
            for (TResult tResult : resultList) {
```

```
        printResult(tResult);
    }
    resultList = client.getScannerRows(scannerId, 100);
}
} finally {
    if (scannerId != -1) {
        client.closeScanner(scannerId);
        LOGGER.info("Closed scanner {}.", scannerId);
    }
}
LOGGER.info("Test scanData done.");
}
```

## 1.10.3.6 Sample Program for HBase to Access Multiple ZooKeepers

### 1.10.3.6.1 Accessing Multiple ZooKeepers

#### Function

This function allows simultaneous access to FusionInsight ZooKeeper from the HBase client and third-party ZooKeeper from the customer application in the same client process.

#### Example code

The following code snippet is in the **TestZKSample** class of the **hbase-zk-example** **\src\main\java\com\huawei\hadoop\hbase\example**. You need to pay attention to the **login** and **connectApacheZK** methods.

```
private static void login(String keytabFile, String principal) throws IOException {
    conf = HBaseConfiguration.create();
    //In Windows environment
    String confDirPath = TestZKSample.class.getClassLoader().getResource("").getPath() + File.separator;
[1]    //In Linux environment
    //String confDirPath = System.getProperty("user.dir") + File.separator + "conf" + File.separator;

    // Set zoo.cfg for hbase to connect to fi zookeeper.
    conf.set("hbase.client.zookeeper.config.path", confDirPath + "zoo.cfg");
    if (User.isHBaseSecurityEnabled(conf)) {
        // jaas.conf file, it is included in the client package
        System.setProperty("java.security.auth.login.config", confDirPath + "jaas.conf");
        // set the kerberos server info, point to the kerberosclient
        System.setProperty("java.security.krb5.conf", confDirPath + "krb5.conf");
        // set the keytab file name
        conf.set("username.client.keytab.file", confDirPath + keytabFile);
        // set the user's principal
        try {
            conf.set("username.client.kerberos.principal", principal);
            User.login(conf, "username.client.keytab.file", "username.client.kerberos.principal",
                InetAddress.getLocalHost().getCanonicalHostName());
        } catch (IOException e) {
            throw new IOException("Login failed.", e);
        }
    }
}
private void connectApacheZK() throws IOException, org.apache.zookeeper.KeeperException {
    try {
        // Create apache zookeeper connection.
        ZooKeeper digestZk = new ZooKeeper("127.0.0.1:24002", 60000, null);
        LOG.info("digest directory: {}", digestZk.getChildren("/", null));
        LOG.info("Successfully connect to apache zookeeper.");
    } catch (InterruptedException e) {
        LOG.error("Found error when connect apache zookeeper ", e);
    }
}
```

```
}
```

- [1] **userdir** obtains the **conf** directory in the resource path after compilation. Save the **core-site.xml**, **hdfs-site.xml**, and **hbase-site.xml** configuration files required for initialization and the user credential file used for security authentication to the **src/main/resources** directory.
- The **jaas.conf** file specified by the **java.security.auth.login.config** parameter in the **login** method is used to set the authentication information for accessing ZooKeeper. The example code contains the Client\_new and Client configurations. The Client\_new configuration is used to access FusionInsight ZooKeeper and the Client configuration is used to access Apache ZooKeeper.
- The **hbase.client.zookeeper.config.path** parameter in the **login** method controls the access to the FusionInsight ZooKeeper client. The following parameters are involved:
  - **zookeeper.sasl.clientconfig**: Specifies the configuration in the **jaas.conf** file used for accessing FusionInsight ZooKeeper.
  - **zookeeper.server.principal**: Specifies the principle of the ZooKeeper server. The format is **zookeeper/hadoop.System domain name**, for example, **zookeeper/hadoop.HADOOP.COM**. To obtain the system domain name, log in to FusionInsight Manager, choose **System > Permission > Domain and Mutual Trust**, and view the value of Local Domain.
  - **zookeeper.sasl.client**: If the MRS cluster works in the security mode, set this parameter to **true**. Otherwise, set this parameter to **false**. If this parameter is set to **false**, the **zookeeper.sasl.clientconfig** and **zookeeper.server.principal** parameters do not take effect.

## 1.10.4 Application Commissioning

### 1.10.4.1 Commissioning an Application in Windows

#### 1.10.4.1.1 Compiling and Running an Application

##### Scenario

After the code development is complete, you can run the application in the Windows development environment.

If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

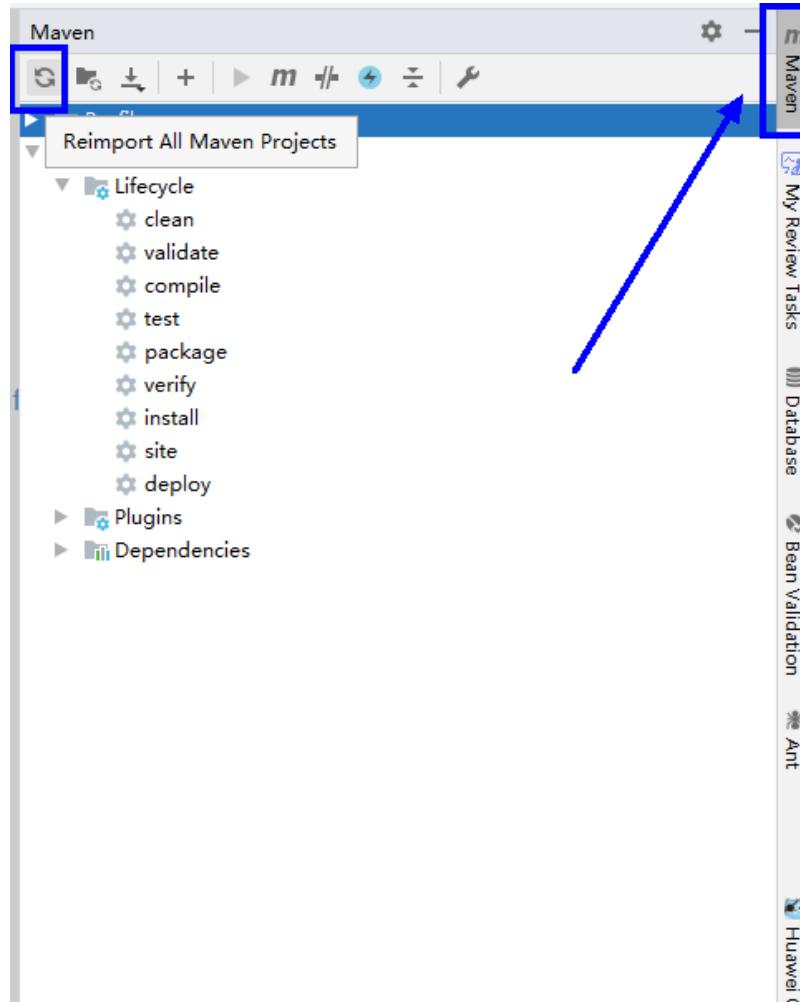

- NOTE**
- If IBM JDK is used in the Windows development environment, the application cannot be run in the Windows environment.
  - You need to set the mapping between the host names and IP addresses of the access nodes in the hosts file on the local host where the sample code is run. The host names and IP addresses must be mapped one by one.

## Procedure

**Step 1** Click **Reimport All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

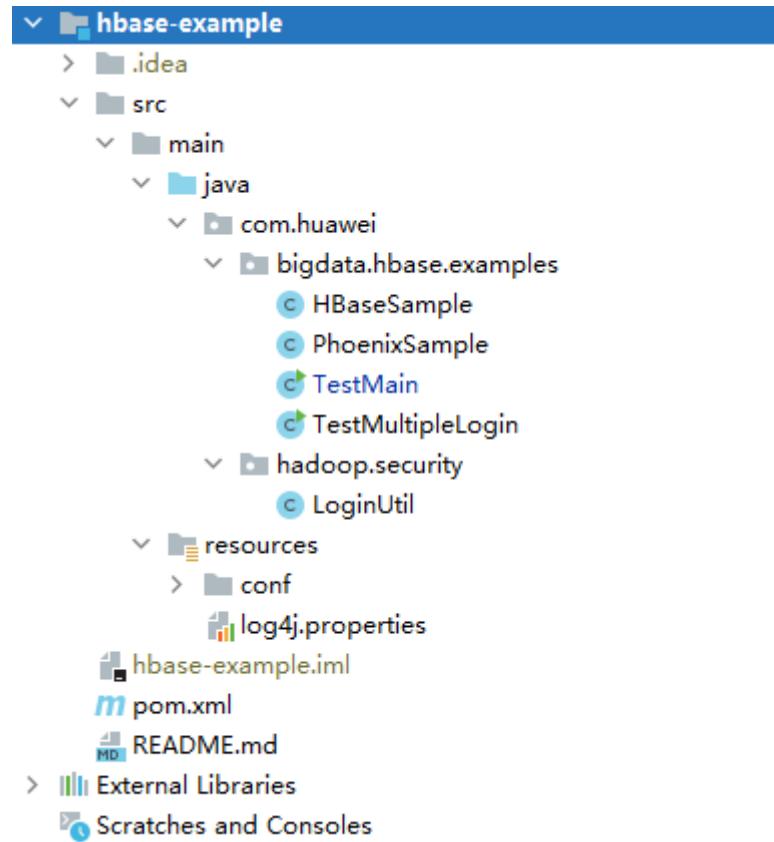

**Figure 1-127** reimport projects

**Step 2** Compile and run an application.

Place the configuration file directory and modify the code to match the login user.  
See [Figure 1-128](#).

Figure 1-128 Directory list of **hbase-example** to be compiled

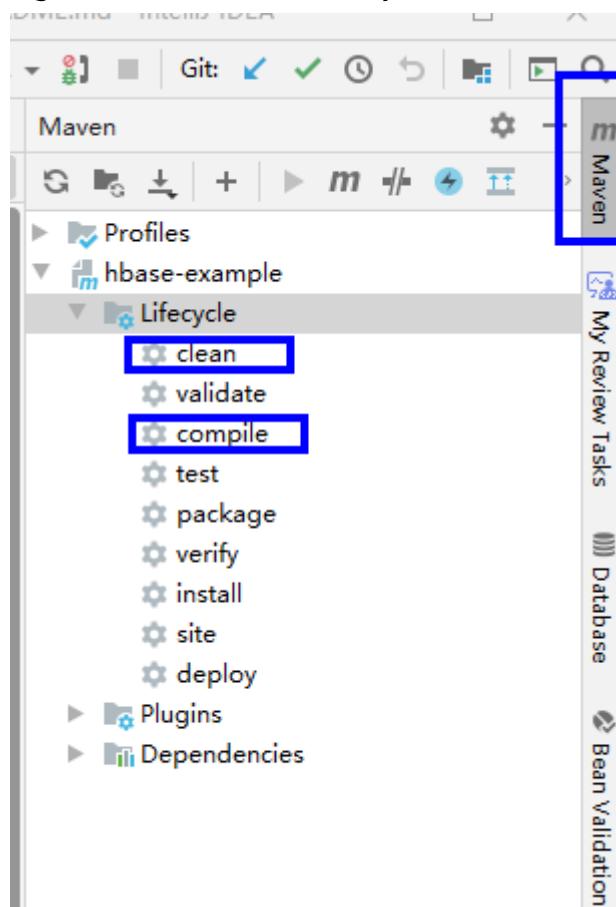

1. Compile an application.

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean** and double-click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **compile**, double click **compile** to run the **compile** command of Maven.

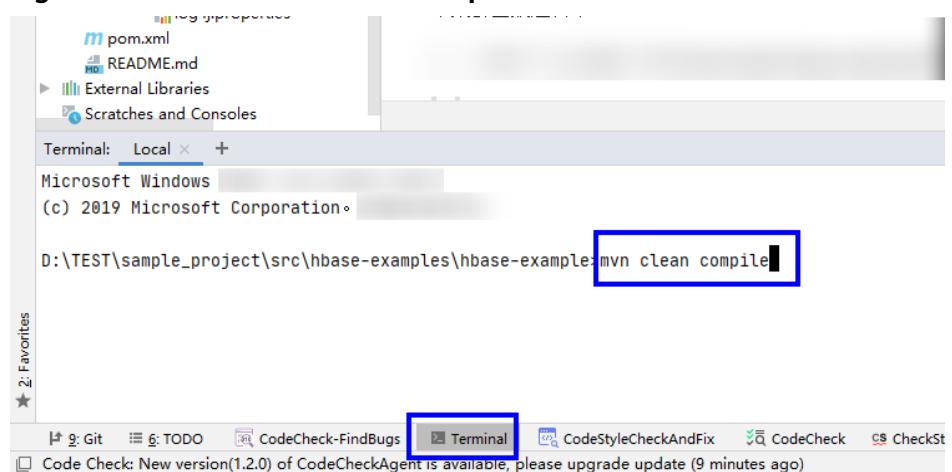

Figure 1-129 clean and compile tools of Maven

- Method 2:

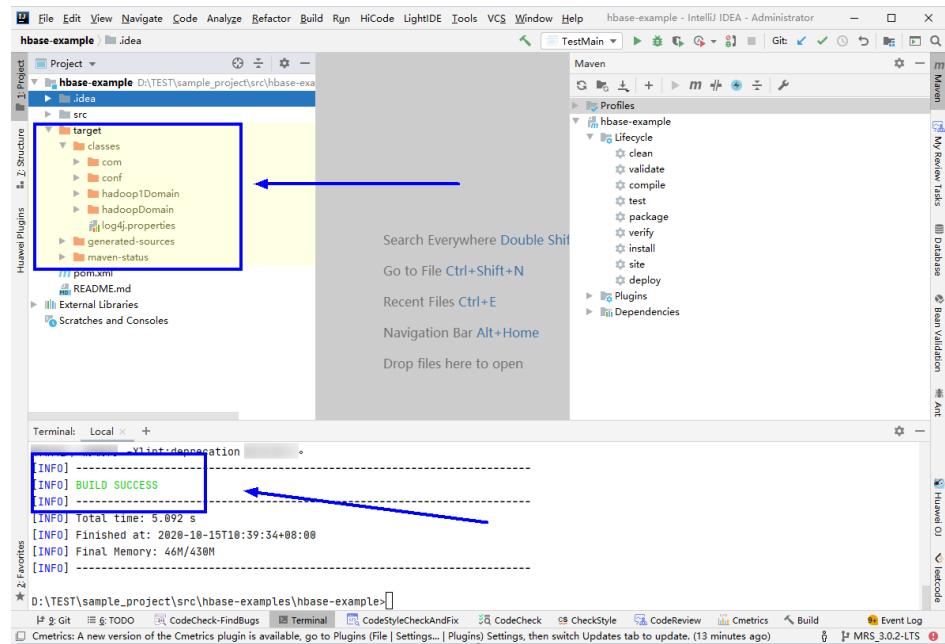

Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean compile** command to compile the **pom.xml** file.

Figure 1-130 Enter mvn clean compile in the IDEA Terminal text box.

2. After the compilation is complete, the message "Build Success" is displayed and the **target** directory is generated.

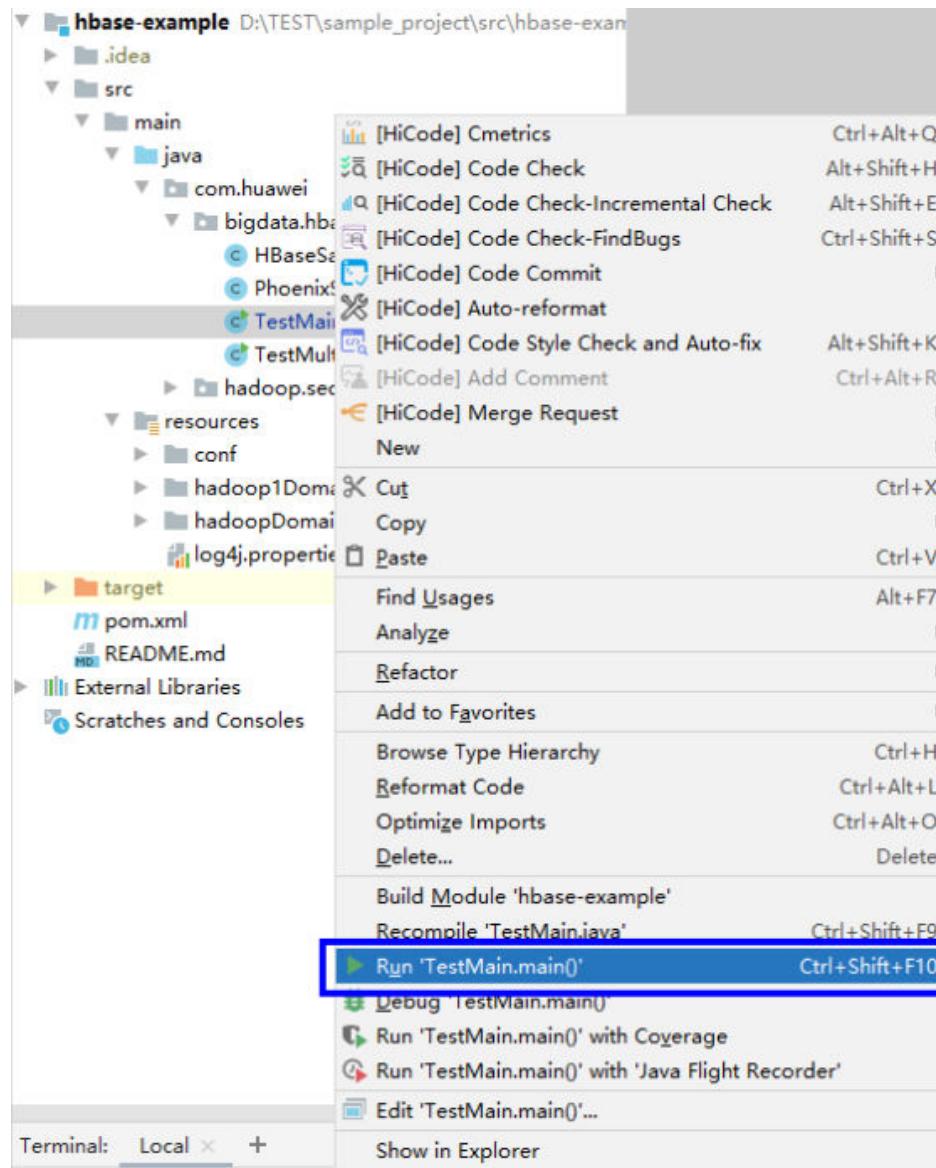

Figure 1-131 Compilation completed

3. Run the program.

Right-click the **TestMain.java** file and choose **Run'TestMain.main()'** from the shortcut menu.

Figure 1-132 Run the application.

----End

#### 1.10.4.1.2 Viewing Windows Commissioning Results

##### Scenario

After an HBase application is run, you can check the running result through one of the following methods:

- Viewing the IntelliJ IDEA running result.
- Viewing HBase logs.
- Logging in to the HBase WebUI, see **More Information > External Interfaces > WebUI**.
- Using HBase Shell command, see **More Information > External Interfaces > Shell**.

## Procedure

- After the **hbase-sample** is successfully executed, the following information is displayed:

```
...
2020-09-09 22:11:48,496 INFO [main] example.TestMain: Entering testCreateTable.
2020-09-09 22:11:48,894 INFO [main] example.TestMain: Creating table...

...
```

### NOTE

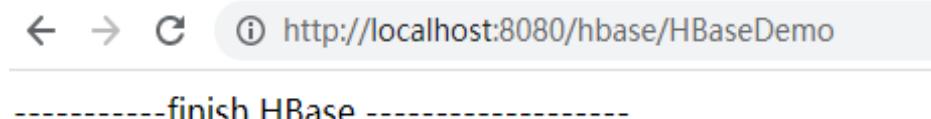

In the Windows environment, the following exception occurs but does not affect services.

java.io.IOException: Could not locate executable null\bin\winutils.exe in the Hadoop binaries.

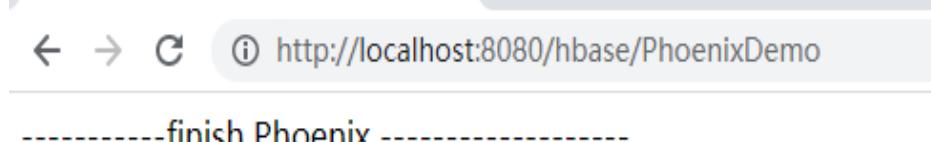

- Result of interconnecting HBase/Phoenix with SpringBoot:

Open a browser and access **http://IP address of the sample running node:8080/hbase/HBaseDemo** and **http://IP address of the sample running node:8080/hbase/PhoenixDemo**. IDEA prints logs normally, and "finish HBase" and "finish Phoenix" are returned.

**Figure 1-133 "finish HBase" displayed**

**Figure 1-134 "finish Phoenix" returned**

- Log description

The log level is **INFO** by default and more detailed information can be viewed by changing the log level (**DEBUG**, **INFO**, **WARN**, **ERROR**, and **FATAL**). You can modify the **log4j.properties** file to change log levels, for example:

```
hbase.root.logger=INFO,console  
...  
log4j.logger.org.apache.zookeeper=INFO  
#log4j.logger.org.apache.hadoop.fs.FSNamesystem=DEBUG  
log4j.logger.org.apache.hadoop.hbase=INFO  
# Make these two classes DEBUG-level. Make them DEBUG to see more zk debug.  
log4j.logger.org.apache.hadoop.hbase.zookeeper.ZKUtil=INFO  
log4j.logger.org.apache.hadoop.hbase.zookeeper.ZooKeeperWatcher=INFO  
...
```

## 1.10.4.2 Commissioning an Application in Linux

### 1.10.4.2.1 Compiling and Running an Application When a Client Is Installed

#### Scenario

In a Linux environment where an HBase client is installed, you can upload the JAR package to the prepared Linux running environment and then run an application after the code development is complete.

#### Prerequisites

- You have installed the HBase client.
- If the host where the client is installed is not a node in the cluster, set the mapping between the host name and the IP address in the **hosts** file on the node where the client locates. The host name and IP address must be in one-to-one mapping.

#### Procedure

##### Step 1 Export a JAR package.

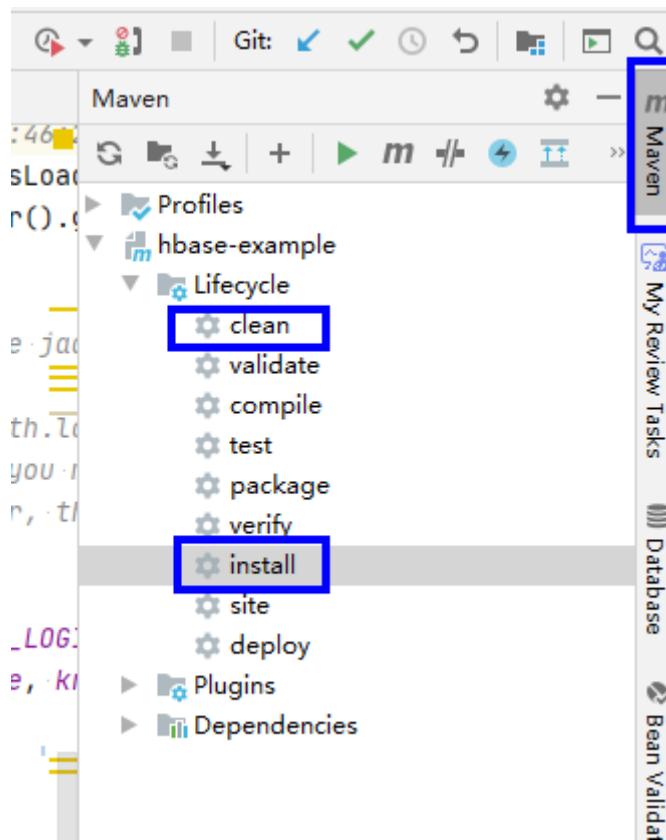

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven** > *Sample projectname* > **Lifecycle** > **clean**, double click **clean** to run the **clean** command of Maven.

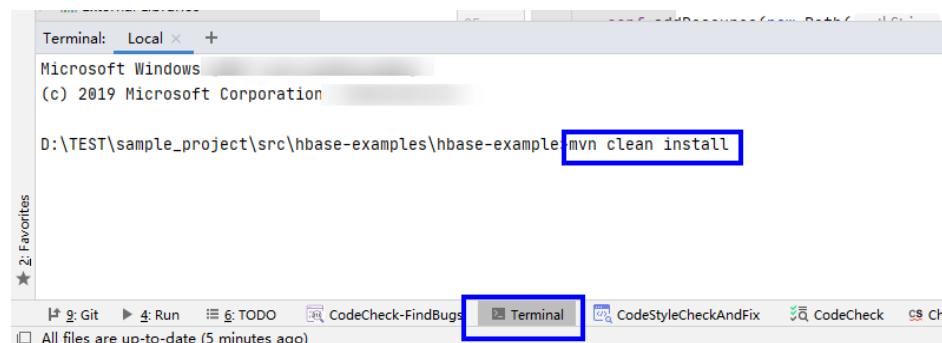

Choose **Maven** > *Sample project name* > **Lifecycle** > **install**, double click **install** to run the **install** command of Maven.

Figure 1-135 Maven tools: clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean install** command to compile the **pom.xml** file.

Figure 1-136 Enter mvn clean compile in the IDEA Terminal text box.

After the compilation is completed, the message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

#### Step 2 Example of whether to run HBase/Phoenix to interconnect with Spring Boot:

- If yes, perform the following steps to run the sample:
  - Create a running directory in the Linux environment and place **hbase-springboot-\*jar** in the target directory to the directory. Upload the

configuration file and user authentication file to the corresponding path specified in [Step 1](#).

- b. Switch to the running directory and run the following command to run the JAR package:

**java -jar hbase-springboot-\*.jar**

- If no, go to [Step 3](#).

**Step 3** Export the JAR file on which the sample project depends.

Access the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of IDEA or by using other command line tools.

Run the command **mvn dependency:copy-dependencies -DoutputDirectory=lib**.

The **lib** folder is generated in the directory where the **pom.xml** file is located. The **lib** folder contains the JAR files on which the sample project depends.

**Step 4** Run the JAR package.

1. Before running the JAR package on the Linux client, run the following command to go to the client directory:

**cd \$BIGDATA\_CLIENT\_HOME**

**\$BIGDATA\_CLIENT\_HOME** is the installation directory of the HBase client.

2. Then run the following command:

**source bigdata\_env**

After the multi-instance function is enabled, run the following command to switch to the client of the specified service instance before performing application development for the HBase service instance.

For example, for HBase2, run the **source /opt/hadoopclient/HBase2/component\_env** command.

3. Upload the JAR file (non-dependent JAR file) of the sample project generated in the application development environment to the *Client installation directory/HBase/hbase/lib* directory in the client running environment. If the HBase dual-read sample needs to be executed, Upload the hbase-dualclient JAR package exported in [Step 3](#) to the directory. In addition, you need to copy the configuration file and authentication file obtained in section [Preparing the Connection Cluster Configuration File](#) to the *Client installation directory/HBase/hbase/conf* directory.
4. Go to the **\$BIGDATA\_CLIENT\_HOME/HBase/hbase** directory and run the following command to run the JAR package. The task is complete.

**hbase com.huawei.bigdata.hbase.examples.TestMain**

In the preceding command, **hbase com.huawei.bigdata.hbase.examples.TestMain** is used as an example.

----End

### 1.10.4.2.2 Compiling and Running an Application When No Client Is Installed

#### Scenario

In a Linux environment where no HBase client is installed, you can upload the JAR package to the Linux and then run an application after the code development is complete.

#### Prerequisites

- A JDK has been installed in the Linux environment. The version of the JDK must be consistent with that of the JDK used by the JAR package exported by IntelliJ IDEA.
- If the Linux host is not a node in the cluster, set the mapping between the host name and the IP address in the **hosts** file on the node. The host name and IP address must be in one-to-one mapping.

#### Procedure

**Step 1** Export a JAR package. For details, see [Step 1](#) in section [Compiling and Running an Application When a Client Is Installed](#).

**Step 2** Example of whether to run HBase/Phoenix to interconnect with Spring Boot:

- If yes, perform the following steps to run the sample:
  - a. Create a running directory in the Linux environment and place **hbase-springboot-\*jar** in the target directory to the directory. Upload the configuration file and user authentication file to the corresponding path specified in [Step 1](#).
  - b. Switch to the running directory and run the following command to run the JAR package:  
**java -jar hbase-springboot-\*jar**
- If no, go to [Step 3](#).

**Step 3** Prepare for the required JAR packages and configuration files.

1. In the Linux environment, create a directory, for example, **/opt/test**, and create subdirectories **lib** and **conf**. Export the JAR package that the sample project depends on. For details about how to export the JAR package, see [Step 3](#) in [1.4.2.1 Compiling and Running an Application When a Client Is Installed](#). Upload this JAR file and that exported in [Step 1](#) to the **lib** directory on the Linux server. Upload the configuration file and authentication file obtained in section [Preparing for Development Environment](#) to the **conf** directory on Linux.

2. In **/opt/test**, create the **run.sh** script, modify the following content, and save the file:

```
#!/bin/sh  
BASEDIR=`cd $(dirname $0);pwd`  
cd ${BASEDIR}  
for file in ${BASEDIR}/lib/*.jar  
do  
i_cp=$i_cp:$file  
echo "$file"  
done  
for file in ${BASEDIR}/conf/*
```

```
do  
i_cp=$i_cp:$file  
done  
  
java -cp ${i_cp} com.huawei.bigdata.hbase.examples.TestMain
```

In the preceding content, *com.huawei.bigdata.hbase.examples.TestMain* is used as an example.

**Step 4** Go to **/opt/test** and run the following commands to run the JAR packages:

**sh run.sh**

**----End**

#### 1.10.4.2.3 Viewing Linux Commissioning Results

##### Scenario

After an HBase application is run, you can check the running result through one of the following methods:

- Viewing the command output.
- Viewing HBase logs.
- Logging in to the HBase WebUI, see **More Information > External Interfaces > WebUI**.
- Using HBase Shell command, see **More Information > External Interfaces > Shell**.

##### Procedure

- You can view the execution details of the submitted application in the run logs. For example, after the **hbase-sample** is successfully executed, the following information is displayed:

```
2280 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample- Entering testCreateTable.  
3091 [main] WARNcom.huawei.hadoop.hbase.example.HBaseSample- table already exists  
3091 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample- Exiting testCreateTable.  
3091 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample- Entering testPut.  
3264 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample- Put successfully.  
3264 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample- Exiting testPut.  
3264 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample- Entering testGet.  
3283 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample-  
012005000201:info,address,Shenzhen, Guangdong  
3283 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample-  
012005000201:info,name,yugeZhang San  
3283 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample- Get data successfully.  
3283 [main] INFOcom.huawei.hadoop.hbase.example.HBaseSample- Exiting testGet.  
3283 [main] INFOorg.apache.hadoop.hbase.client.ConnectionManager$HConnectionImplementation-  
Closing zookeeper sessionid=0xd000035eba278e9  
3297 [main] INFOorg.apache.zookeeper.ZooKeeper- Session: 0xd000035eba278e9 closed  
3297 [main-EventThread] INFOorg.apache.zookeeper.ClientCnxn- EventThread shut down  
-----finish HBase -----
```

- Result of interconnecting HBase/Phoenix with SpringBoot:

Open a browser and access **http://IP address of the sample running node:8080/hbase/HBaseDemo** and **http://IP address of the sample running node:8080/hbase/PhoenixDemo**. IDEA prints logs normally, and "finish HBase" and "finish Phoenix" are returned.

Figure 1-137 "finish HBase" displayed

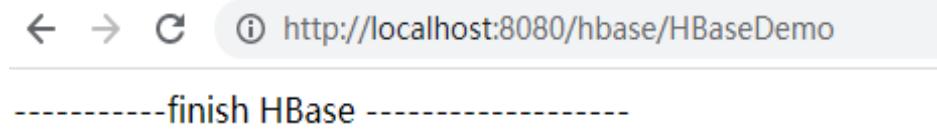

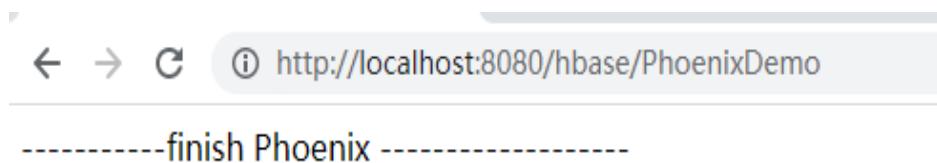

Figure 1-138 "finish Phoenix" returned

## 1.10.5 More Information

### 1.10.5.1 SQL Query

#### Function

Phoenix is an intermediate structured query language (SQL) layer built on HBase. Phoenix provides a JDBC driver that can be embedded in a client. The Phoenix query engine converts input SQL statements to one or multiple HBase scans, and compiles and executes the scan tasks to generate a standard JDBC result set.

#### Example Code

- The **hbase-example/conf/hbase-site.xml** file on the client is used to configure the temporary directory for storing query results. If the client program configures the temporary directory in a Linux environment, configure a Linux path. If the client program configures the temporary directory in a Windows environment, configure a Windows path.

```
<property>
    <name>phoenix.spool.directory</name>
    <value>[1] Temporary directory for storing intermediate query results</value>
</property>
```

- JAVA Example: Use the JDBC interface to access HBase.

```
public String getURL(Configuration conf)
{
    String phoenix_jdbc = "jdbc:phoenix";
    String zkQuorum = conf.get("hbase.zookeeper.quorum");
    return phoenix_jdbc + ":" + zkQuorum;
}

public void testSQL()
{
    String tableName = "TEST";
    // Create table
    String createTableSQL = "CREATE TABLE IF NOT EXISTS TEST(id integer not null primary key,
name varchar, account char(6), birth date)";

    // Delete table
    String dropTableSQL = "DROP TABLE TEST";

    // Insert
```

```
String upsertSQL = "UPSERT INTO TEST VALUES(1,'John','100000',  
TO_DATE('1980-01-01','yyyy-MM-dd'))";  
  
// Query  
String querySQL = "SELECT * FROM TEST WHERE id = ?";  
  
// Create the Configuration instance  
Configuration conf = getConfiguration();  
  
// Get URL  
String URL = getURL(conf);  
  
Connection conn = null;  
PreparedStatement preStat = null;  
Statement stat = null;  
ResultSet result = null;  
  
try  
{  
    // Create Connection  
    conn = DriverManager.getConnection(URL);  
    // Create Statement  
    stat = conn.createStatement();  
    // Execute Create SQL  
    stat.executeUpdate(createTableSQL);  
    // Execute Update SQL  
    stat.executeUpdate(upsertSQL);  
    // Create PrepareStatement  
    preStat = conn.prepareStatement(querySQL);  
    conn.commit();  
    // Execute query  
    preStat.setInt(1,1);  
    result = preStat.executeQuery();  
    // Get result  
    while (result.next())  
    {  
        int id = result.getInt("id");  
        String name = result.getString(1);  
    }  
}  
catch (Exception e)  
{  
    // handler exception  
}  
finally  
{  
    if(null != result){  
        try {  
            result.close();  
        } catch (Exception e2) {  
            // handler exception  
        }  
    }  
    if(null != stat){  
        try {  
            stat.close();  
        } catch (Exception e2) {  
            // handler exception  
        }  
    }  
    if(null != conn){  
        try {  
            conn.close();  
        } catch (Exception e2) {  
            // handler exception  
        }  
    }  
}
```

## Precaution

- You need to configure a temporary directory for storing intermediate query results in **hbase-site.xml**. The size of the query result set is restricted by the directory size.
- Phoenix provides most **java.sql** interfaces and follows the ANSI SQL standard.

### 1.10.5.2 HBase Dual-Read Configuration Items

This section provides the details of all the configurations required for the HBase dual-read feature.

## HBase Dual-Read Operations

**Table 1-83** Configuration items in hbase-dual.xml

Configuration Item	Description	Default Value	Level
hbase.dualclient.active.cluster.configuration.path	HBase client configuration directory of the active cluster	None	Mandatory
hbase.dualclient.standby.cluster.configuration.path	HBase client configuration directory of the standby cluster	None	Mandatory
dual.client.schedule.update.table.delay.second	DR table update interval	5	Optional
hbase.dualclient.gitchtimeout.ms	Maximum glitch time can be tolerated in the active cluster	50	Optional
hbase.dualclient.slow.query.timeout.ms	Slow query alarm log	180000	Optional
hbase.dualclient.active.cluster.id	Active cluster ID	ACTIVE	Optional
hbase.dualclient.standby.cluster.id	Standby cluster ID	STANDBY	Optional
hbase.dualclient.active.executor.thread.max	Maximum size of the thread pool for processing requests to the active cluster	100	Optional

Configuration Item	Description	Default Value	Level
hbase.dualclient.active.executor.thread.core	Core size of the thread pool for processing requests to the active cluster	100	Optional
hbase.dualclient.active.executor.queue	Queue size of the thread pool for processing requests to the active cluster	256	Optional
hbase.dualclient.standby.executor.thread.max	Maximum size of the thread pool for processing requests to the standby cluster	100	Optional
hbase.dualclient.standby.executor.thread.core	Core size of the thread pool for processing requests to the standby cluster	100	Optional
hbase.dualclient.standby.executor.queue	Queue size of the thread pool for processing requests to the standby cluster	256	Optional
hbase.dualclient.clear.executor.thread.max	Maximum size of the thread pool for clearing resources	30	Optional
hbase.dualclient.clear.executor.thread.core	Core size of the thread pool for clearing resources	30	Optional
hbase.dualclient.clear.executor.queue	Queue size of the thread pool for clearing resources	Integer.MAX_VALUE	Optional
dual.client.metrics.enable	Whether to print client metric information	true	Optional
dual.client.schedule.metrics.second	Interval for printing client metric information	300	Optional

Configuration Item	Description	Default Value	Level
dual.client.asyncronous.enable	Whether to asynchronously request the active and standby clusters	false	Optional

## Printing Metric Information

**Table 1-84** Basic specifications

Metric Name	Description	Log level
total_request_count	Total number of queries in a period	INFO
active_success_count	Number of successful queries in the active cluster in a period	INFO
active_error_count	Number of failed queries in the active cluster in a period	INFO
active_timeout_count	Number of query timeouts in the active cluster in a period	INFO
standby_success_count	Number of successful queries in the standby cluster in a period	INFO
standby_error_count	Number of failed queries in the standby cluster in a period	INFO
Active Thread pool	Periodically printed information about the thread pool for processing requests to the active cluster	DEBUG
Standby Thread pool	Periodically printed information about the thread pool for processing requests to the standby cluster	DEBUG

Metric Name	Description	Log level
Clear Thread pool	Periodically printed information about the thread pool for releasing resources	DEBUG

**Table 1-85** Histogram indicators for **GET**, **BatchGET**, and **SCAN** requests

Metric Name	Description	Log level
averageLatency(ms)	Average latency	INFO
minLatency(ms)	Minimum latency	INFO
maxLatency(ms)	Maximum latency	INFO
95thPercentileLatency(ms)	Maximum latency of 95% requests	INFO
99thPercentileLatency(ms)	Maximum latency of 99% requests	INFO
99.9PercentileLatency(ms)	Maximum latency of 99.9% requests	INFO
99.99PercentileLatency(ms)	Maximum latency of 99.99% requests	INFO

### 1.10.5.3 External Interfaces

#### 1.10.5.3.1 Shell

You can directly perform operations on HBase using Shell on the server. Versions of Shell interfaces of HBase need to be consistent with those in the open-source community. For details, see <http://learnhbase.wordpress.com/2013/03/02/hbase-shell-commands/>.

Methods of running the Shell command:

Go to any directory on the HBase client and run the following command:

**hbase shell**

Go to the running mode of the HBase command (also called CLI client connection).

```
hbase(main):001:0>
```

Run the **help** command to obtain the help information of the HBase command parameters.

## Precautions

The **count** command does not support conditional statistics. It supports only full table statistics.

## Command to retrieve HBase replication metrics

All the required metrics will be added for the shell command "status".

- Command to view replication source metrics.

**hbase(main):019:0> status 'replication', 'source'**

The output is as follows:

```
version 2.4.14
1 live servers
BLR1000006595:
SOURCE: PeerID=1, SizeOfLogQueue=0, ShippedBatches=0, ShippedOps=0, ShippedBytes=0,
LogReadInBytes=1389, LogEditsRead=4, LogEditsFiltered=4, SizeOfLogToReplicate=0,
TimeForLogToReplicate=0, ShippedHFiles=0, SizeOfHFileRefsQueue=0, AgeOfLastShippedOp=0,
TimeStampsOfLastShippedOp=Wed May 25 20:44:42 CST 2016, Replication Lag=0 PeerID=3,
SizeOfLogQueue=0, ShippedBatches=0, ShippedOps=0, ShippedBytes=0, LogReadInBytes=1389,
LogEditsRead=4, LogEditsFiltered=4, SizeOfLogToReplicate=0,
TimeForLogToReplicate=0, ShippedHFiles=0, SizeOfHFileRefsQueue=0, AgeOfLastShippedOp=0,
TimeStampsOfLastShippedOp=Wed May 25 20:44:42 CST 2016, Replication Lag=0,
FailedReplicationAttempts=0
```

- Command to view replication sink metrics.

**hbase(main):020:0> status 'replication', 'sink'**

The output is as follows:

```
version 2.4.14
1 live servers
BLR1000006595:
SINK : AppliedBatches=0, AppliedOps=0, AppliedHFiles=0, AgeOfLastAppliedOp=0,
TimeStampsOfLastAppliedOp=Wed May 25 17:55:21 CST 2016
```

- Command to view both replication source and replication sink metrics.

**hbase(main):018:0> status 'replication'**

The output is as follows:

```
version 2.4.14
1 live servers
BLR1000006595:
SOURCE: PeerID=1, SizeOfLogQueue=0, ShippedBatches=0, ShippedOps=0, ShippedBytes=0,
LogReadInBytes=1389, LogEditsRead=4, LogEditsFiltered=4, SizeOfLogToReplicate=0,
TimeForLogToReplicate=0, ShippedHFiles=0, SizeOfHFileRefsQueue=0, AgeOfLastShippedOp=0,
TimeStampsOfLastShippedOp=Wed May 25 20:43:24 CST 2016, Replication Lag=0 PeerID=3,
SizeOfLogQueue=0, ShippedBatches=0, ShippedOps=0, ShippedBytes=0, LogReadInBytes=1389,
LogEditsRead=4, LogEditsFiltered=4, SizeOfLogToReplicate=0,
TimeForLogToReplicate=0, ShippedHFiles=0, SizeOfHFileRefsQueue=0, AgeOfLastShippedOp=0,
TimeStampsOfLastShippedOp=Wed May 25 20:43:24 CST 2016, Replication Lag=0,
FailedReplicationAttempts=0
SINK : AppliedBatches=0, AppliedOps=0, AppliedHFiles=0, AgeOfLastAppliedOp=0,
TimeStampsOfLastAppliedOp=Wed May 25 17:55:21 CST 2016
```

### 1.10.5.3.2 Java API

For details about HBase APIs, see *MapReduce Service (MRS) 3.3.1-LTS API Reference (for Huawei Cloud Stack 8.3.1)*.

### API Usage Suggestions

- **org.apache.hadoop.hbase.Cell** rather than **org.apache.hadoop.hbase.KeyValue** is recommended as the KV data object.

- It is recommended that `Connection connection = ConnectionFactory.createConnection(conf)` be used to create a connection. The HTablePool is abandoned.
- `org.apache.hadoop.hbase.mapreduce` rather than `org.apache.hadoop.hbase.mapred` is recommended.
- You are advised to obtain the HBase client operation object using the `getAdmin()` method of the constructed Connection object.

## Common HBase APIs

Common HBase Java classes are as follows:

- Interface class Admin: It is the core class of HBase client applications, which encapsulates APIs for HBase management, such as table creation and table deletion. For details, see [Table 1-86](#).
- Interface class Table: It is a class for HBase read/write, which encapsulates APIs for reading and writing HBase tables. For details, see [Table 1-87](#).

**Table 1-86** org.apache.hadoop.hbase.client.Admin

Method	Description
<code>boolean tableExists(final TableName tableName)</code>	This method is used to check whether a specified table exists. If the table exists in the <b>hbase:meta</b> table, <b>true</b> is returned. Otherwise, <b>false</b> is returned.
<code>HTableDescriptor[] listTables(String regex)</code>	This method is used to view the user table that complies with the specified regular expression format. There are two other overload methods, one with the input parameter type of Pattern, and the other with the empty input parameter. When the input parameter is empty, all user tables are queried by default.
<code>HTableDescriptor[] listTables(final Pattern pattern, final boolean includeSysTables)</code>	The function of this method is similar to that of the previous method. Users can use this method to specify whether the returned result contains the system table. The previous method returns only the user table.

Method	Description
TableName[] listTableNames(String regex)	This method is used to view the user table that complies with the specified regular expression format. There are two other overload methods, one with the input parameter type of Pattern, and the other with the empty input parameter. When the input parameter is empty, all user tables are queried by default. The function of this method is similar to that of listTables. The only difference is that this method returns TableName[].
TableName[] listTableNames(final Pattern pattern, final boolean includeSysTables)	The function of this method is similar to that of the previous method. Users can use this method to specify whether the returned result contains the system table. The previous method returns only the user table.
void createTable(HTableDescriptor desc)	This method is used to create a table with only one region.
void createTable(HTableDescriptor desc, byte[] startKey, byte[] endKey, int numRegions)	This method is used to create a table with a specified number of regions. The endKey of the first region is the startKey, and the StartKey of the last region is the endKey. If there are a large number of regions, the invoking of this method may time out.
void createTable(final HTableDescriptor desc, byte[][] splitKeys)	This method is used to create a table. The number of regions in the table and the startKey of each region are determined by splitKeys. If there are a large number of regions, the invoking of this method may time out.
void createTable(final HTableDescriptor desc, final byte[][] splitKeys)	This method is used to create a table. The number of regions in the table and the startKey of each region are determined by splitKeys. This method uses asynchronous invoking, and does not wait for the created table to be online.
void deleteTable(final TableName tableName)	This method is used to delete a specified table.

Method	Description
public void truncateTable(final TableName tableName, final boolean preserveSplits)	This method is used to re-create a specified table. If the second parameter is set to <b>true</b> , the region of the reconstructed table is the same as that of the previous table. Otherwise, there is only one region.
void enableTable(final TableName tableName)	This method is used to enable a specified table. If there are a large number of regions in a table, the invoking of this method may time out.
void enableTableAsync(final TableName tableName)	This method is used to enable a specified table. This method uses asynchronous invoking, and does not wait for all regions to be online.
void disableTable(final TableName tableName)	This method is used to disable a specified table. If there are a large number of regions in a table, the invoking of this method may time out.
void disableTableAsync(final TableName tableName)	This method is used to disable a specified table. This method uses asynchronous invoking, and does not wait for all regions to be offline.
boolean isTableEnabled(TableName tableName)	This method is used to check whether a table is enabled. This method can be used with the enableTableAsync method to check whether the operation of enabling a table is complete.
boolean isTableDisabled(TableName tableName)	This method is used to check whether a table is disabled. This method can be used with the disableTableAsync method to check whether the operation of disabling a table is complete.
void addColumn(final TableName tableName, final HColumnDescriptor column)	This method is used to add a column family to a specified table.
void deleteColumn(final TableName tableName, final HColumnDescriptor column)	This method is used to delete a specified column family from a specified table.
void modifyColumn(final TableName tableName, final HColumnDescriptor column)	This method is used to modify a specified column family.

**Table 1-87** org.apache.hadoop.hbase.client.Table

Method	Description
boolean exists(Get get)	This method is used to check whether the specified rowkey exists in the table.
boolean[] existsAll(List<Get> gets)	This method is used to check whether the specified rowkey exists in the table. The returned Boolean array result corresponds to the input parameter position.
Result get(Get get)	This method is used to read data based on the specified rowkey.
Result[] get(List<Get> gets)	This method is used to read data in batches by specifying a batch of rowkeys.
ResultScanner getScanner(Scan scan)	This method is used to obtain a scanner object in the table. The query parameters can be specified by the input parameter scan, including <b>StartRow</b> , <b>StopRow</b> , and <b>caching</b> .
void put(Put put)	This method is used to write a data record to the table.
void put(List<Put> puts)	This method is used to write a batch of data records to the table.
void close()	This method is used to release the resources held by the table object.

 NOTE

The table [org.apache.hadoop.hbase.client.Admin](#) and [org.apache.hadoop.hbase.client.Table](#) list only some common methods.

#### 1.10.5.3.3 SQLLine

You can run **sqlline.py** on the client to perform SQL operations on HBase. The SQLLine APIs of Phoenix are the same as those of the open-source community. For details, see <http://phoenix.apache.org/>.

**Table 1-88** lists common SQLline syntax, **Table 1-89** lists common functions, and [Phoenix Command Line](#) describes how to use commands.

**Table 1-88** Common syntax

Command	Description	Example
<b>CREATE TABLE</b>	Creates a table.	CREATE TABLE MY_TABLE(id BIGINT not null primary key, name VARCHAR);
<b>ALTER</b>	Alters a table or a view.	ALTER TABLE MY_TABLE DROP COLUMN name;
<b>DROP TABLE</b>	Deletes a table.	DROP TABLE MY_TABLE;
<b>UPSERT VALUES</b>	Inserts or changes data.	UPSERT INTO MY_TABLE VALUES(1,'abc');
<b>SELECT</b>	Queries data.	SELECT * FROM MY_TABLE;
<b>CREATE INDEX</b>	Creates a global index.	CREATE INDEX MY_IDX ON MY_TABLE(name);
<b>CREATE LOCAL INDEX</b>	Creates a local index.	CREATE LOCAL INDEX MY_LOCAL_IDX ON MY_TABLE(id,name);
<b>ALTER INDEX</b>	Changes the index status.	ALTER INDEX MY_IDX ON MY_TABLE DISABLE;
<b>DROP INDEX</b>	Deletes an index.	DROP INDEX MY_IDX ON MY_TABLE;
<b>EXPLAIN</b>	Displays an execution plan.	EXPLAIN SELECT name FROM MY_TABLE;
<b>CREATE SEQUENCE</b>	Creates a sequence.	CREATE SEQUENCE MY_SEQUENCE;
<b>DROP SEQUENCE</b>	Deletes a sequence.	DROP SEQUENCE MY_SEQUENCE;
<b>CREATE VIEW</b>	Creates a view.	CREATE VIEW MY_VIEW AS SELECT * FROM MY_TABLE;
<b>DROP VIEW</b>	Deletes a view.	DROP VIEW MY_VIEW;
<b>CREATE SCHEMA</b>	Creates a schema.	CREATE SCHEMA MY_SCHEMA;
<b>USE</b>	Modifies the default schema.	USE MY_SCHEMA;
<b>DROP SCHEMA</b>	Deletes a schema.	DROP SCHEMA MY_SCHEMA;

**Table 1-89** Common functions

Function Type	Function	Description	Example
String functions	<b>SUBSTR</b>	Extracts a part of a string.	SUBSTR('[Hello]', 2, 5)
	<b>INSTR</b>	Queries the position of the first occurrence of a string in another string.	INSTR('Hello World', 'World')
	<b>TRIM</b>	Removes whitespaces from both ends of a string.	TRIM(' Hello ')
	<b>LTRIM</b>	Removes whitespaces found on the left-hand side of the string.	LTRIM(' Hello')
	<b>RTRIM</b>	Removes whitespaces found on the right-hand side of the string.	RTRIM('Hello ')
	<b>LPAD</b>	Left-pads a string with another string.	LPAD('John',30,'*')
	<b>LENGTH</b>	Gets the length of a given string.	LENGTH('Hello')
	<b>UPPER</b>	Converts all the characters in a string to uppercase characters.	UPPER('Hello')
	<b>LOWER</b>	Converts all the characters in a string to lowercase characters.	LOWER('HELLO')
	<b>REVERSE</b>	Reverses a string.	REVERSE('Hello')
	<b>REGEXP_SPLIT</b>	Splits a string using a regular expression.	REGEXP_SPLIT('ONE,TWO,THREE', ',')

Function Type	Function	Description	Example
	<b>REGEXP_REPLACE</b>	Returns a string by applying a regular expression and replacing the matches with the replacement string.	REGEXP_REPLACE('abc123ABC', '[0-9]+', '#')
	<b>REGEXP_SUBSTR</b>	Returns a substring from a string based on a regular expression pattern.	REGEXP_SUBSTR('na1-appsrv35-sj35', '[^-]+')
Aggregate functions	<b>AVG</b>	Gets the average value.	AVG(X)
	<b>COUNT</b>	Gets the number of data records.	COUNT(*)
	<b>MAX</b>	Gets the maximum value.	MAX(NAME)
	<b>MIN</b>	Gets the minimum value.	MIN(NAME)
	<b>SUM</b>	Gets the sum of all values.	SUM(X)
	<b>STDDEV_POP</b>	Gets the population standard deviation of all values.	STDDEV_POP( X )
	<b>STDDEV_SAMP</b>	Gets the sample standard deviation of all values.	STDDEV_SAMP( X )
	<b>NTH_VALUE</b>	Gets the Nth value in each distinct group ordered according to the <b>ORDER BY</b> specification.	NTH_VALUE( name, 2 ) WITHIN GROUP ( ORDER BY salary DESC )

Function Type	Function	Description	Example
Time and date functions	<b>NOW</b>	Returns the current date.	NOW()
	<b>CURRENT_TIME</b>	Returns the current time.	CURRENT_TIME()
	<b>CURRENT_DATE</b>	Returns the current date.	CURRENT_DATE()
	<b>TO_DATE</b>	Parses a string and returns a date.	TO_DATE('1970-01-01', 'yyyy-MM-dd', 'GMT+1')
	<b>TO_TIME</b>	Converts the given string into a <b>TIME</b> instance.	TO_TIME('1970-01-01', 'yyyy-MM-dd', 'GMT+1')
	<b>TO_TIMESTAMP</b>	Converts the given string into a <b>TIMESTAMP</b> instance.	TO_TIMESTAMP('1970-01-01', 'yyyy-MM-dd', 'GMT+1')
	<b>YEAR</b>	Returns the year of the specified date.	YEAR(TO_DATE('2015-6-05'))
	<b>MONTH</b>	Returns the month of the specified date.	MONTH(TO_TIMESTAMP('2015-6-05'))
	<b>WEEK</b>	Returns the week of the specified date.	WEEK(TO_TIME('2010-6-15'))
	<b>HOUR</b>	Returns the hour of the specified date.	HOUR(TO_TIMESTAMP('2015-6-05'))
	<b>MINUTE</b>	Returns the minute of the specified date.	MINUTE(TO_TIME('2015-6-05'))
	<b>SECOND</b>	Returns the second of the specified date.	SECOND(TO_DATE('2015-6-05'))

Function Type	Function	Description	Example
Numeric functions	<b>ROUND</b>	Rounds the numeric or timestamp expression to the nearest scale or time unit specified.	ROUND(2.56)
	<b>CEIL</b>	Rounds any fractional value up to the next even multiple.	CEIL(2.34)
	<b>FLOOR</b>	Rounds any fractional value down to the previous even multiple.	FLOOR(2.34)
	<b>TRUNC</b>	Rounds any fractional value down to the previous even multiple (same as <b>FLOOR</b> ).	TRUNC(2.34)
	<b>TO_NUMBER</b>	Formats a string as a number.	TO_NUMBER('-123.33')
	<b>RAND</b>	Returns a random number.	RAND()
Math functions	<b>ABS</b>	Returns the absolute value of the given numeric expression.	ABS(-1)
	<b>SQRT</b>	$\sqrt{x}$	SQRT(1.1)
	<b>EXP</b>	$e^x$	EXP(-1)
	<b>POWER</b>	$x^y$	POWER(2, 3)
	<b>LN</b>	$\ln(x)$	LN(3)

Function Type	Function	Description	Example
	<b>LOG</b>	$\log_x(y)$	LOG(2, 3)
Array functions	<b>ARRAY_ELEM</b>	Uses the array subscript notation to access an array element.	ARRAY_ELEM(ARRAY[1,2,3], 1)
	<b>ARRAY-prepend</b>	Appends the given element to the beginning of the array.	ARRAY_APPEND(ARRAY[1,2,3], 4)
	<b>ARRAY_CAT</b>	Concatenates the input arrays and returns the result.	ARRAY_CAT(ARRAY[1,2], ARRAY[3,4])
	<b>ARRAY_FILL</b>	Fills an array with values.	ARRAY_FILL(1, 3)
	<b>ARRAY_TO_STRING</b>	Converts the elements of an array to a string and joins them using the specified delimiter.	ARRAY_TO_STRING(ARRAY['a','b','c'], ',')
	<b>ANY</b>	Used on the right-hand side of a comparison expression to test that any array element satisfies the comparison expression against the left-hand side.	10 > ANY(my_array)
	<b>ALL</b>	Used on the right-hand side of a comparison expression to test that all array elements satisfy the comparison expression against the left-hand side.	10 > ALL(my_array)

Function Type	Function	Description	Example
Other functions	<b>MD5</b>	Computes the MD5 hash of the argument.	MD5(my_column)
	<b>ENCODE</b>	Encodes the expression according to the encoding format provided.	ENCODE(myNumber, 'BASE62')
	<b>DECODE</b>	Decodes the expression according to the encoding format provided.	DECODE('000000008512af277fff fff8', 'HEX')

#### 1.10.5.3.4 JDBC APIs

Phoenix implements most **java.sql** interfaces. The SQL syntax follows the ANSI SQL standard.

For details about the functions that are supported, visit:

<http://phoenix.apache.org/language/functions.html>

For details about the syntax that is supported, visit:

<http://phoenix.apache.org/language/index.html>

#### 1.10.5.3.5 Web UI

##### Scenario

The Web UI displays information about the HBase cluster, such as cluster information, RegionServer and Master, snapshot, and running processes. The information helps you understand the status of the entire HBase cluster.

Contact the administrator to obtain a service account that has the permission to access the web UI and its password.

##### Procedure

1. Log in to FusionInsight Manager, choose **Cluster > Services > HBase**, and click **HMaster (Active)** to open the HBase WebUI.
2. On the Home page of the HBase Web UI, the following information about the HBase is displayed:
  - a. The **Region Servers** page displays basic server information.

**Figure 1-139** Basic information

Region Servers			
ServerName	Start time	Requests Per Second	Num. Regions
VM-3,21302,1415117599935	Wed Nov 05 00:13:19 CST 2014	0	1
VM-4,21302,1415117602775	Wed Nov 05 00:13:22 CST 2014	0	3
VM-5,21302,1415117607877	Wed Nov 05 00:13:27 CST 2014	0	0
Total:3		0	4

- b. The **Backup Masters** page displays information about backup master nodes.

**Figure 1-140** Basic information

Backup Masters		
ServerName	Port	Start Time
VM-4	21300	Wed Nov 05 00:13:08 CST 2014
Total:1		

- c. The **Tables** page displays information about tables in HBase, including user tables, catalog tables, and snapshots.

**Figure 1-141** Basic information

Tables		
User Tables	Catalog Tables	Snapshots
1 table(s) in set. [Details]		
Table Name	Online Regions	Description
t	1	't', {NAME => 'd'}

- d. The **Tasks** page displays information about tasks running on HBase, including the start time and status.

## **Figure 1-142 Task basic information**

Tasks				
Show All Monitored Tasks		Show non-RPC Tasks	Show All RPC Handler Tasks	Show Active RPC Calls
View as JSON				
Start Time	Description		State	Status
Wed Nov 05 03:06:35 CST 2014	Closing region availabilityCheck_VM-5_1415127943,1415127994683.1d82d088fbf4ba672ee2235fd98ae695.		COMPLETE (since 44sec ago)	Closed (since 44sec ago)
Wed Nov 05 00:20:13 CST 2014	RpcServer.reader=0,port=21300		WAITING (since 2mins, 36sec ago)	Waiting for a call (since 2mins, 36sec ago)
Wed Nov 05 00:19:49 CST 2014	RpcServer.reader=9,port=21300		WAITING (since 2mins, 53sec ago)	Waiting for a call (since 2mins, 53sec ago)

```

#### 1.10.5.4 Phoenix Command Line

Phoenix supports SQL statements to operate HBase. The following describes how to use SQL statements to create tables, insert data, query data, and delete tables.

#### Prerequisites

The HBase client has been installed. For details, see [Installing a Client](#). For example, the client has been installed in the `/opt/hadoopclient` directory. The client directory in the following operations is only an example. Change it based on the actual installation directory onsite. Before using the client, download and update the client configuration file, and ensure that the active management node of Manager is available.

## Procedure

**Step 1 Optional:** Log in to the node where the client is installed as the client installation user.

Access the HBase client installation directory:

```
cd /opt/hadoopclient
```

**Step 2** Run the following command to configure environment variables:

```
source bigdata_env
```

**Step 3** If Kerberos authentication is enabled for the current cluster, run the following command to authenticate the current user. The current user must have the permission to create HBase tables. If Kerberos authentication is disabled for the current cluster, skip this step:

```
kinit MRS cluster user
```

For example, **kinit hbaseuser**.

**Step 4** Running Commands on the Phoenix Client.

```
sqlline.py
```

**Step 5** Create a table:

```
CREATE TABLE TEST (id VARCHAR PRIMARY KEY, name VARCHAR);
```

**Step 6** Insert data:

```
UPSERT INTO TEST(id,name) VALUES ('1','jamee');
```

**Step 7** Query data:

```
SELECT * FROM TEST;
```

**Step 8** Deleting a table:

```
DROP TABLE TEST;
```

**Step 9** Exit the Phoenix CLI:

```
!quit
```

```
----End
```

### 1.10.5.5 FAQs

#### 1.10.5.5.1 How to Rectify the Fault When an Exception Occurs During the Running of an HBase-developed Application and "org.apache.hadoop.hbase.ipc.controller.ServerRpcControllerFactory" Is Displayed in the Error Information?

**Step 1** Check whether the **hbase.rpc.controllerfactory.class** configuration item is included in the **hbase-site.xml** configuration file.

```
<name>hbase.rpc.controllerfactory.class</name>
<value>org.apache.hadoop.hbase.ipc.controller.ServerRpcControllerFactory</value>
```

**Step 2** If this configuration item is included in the current application development project, you need to import the **phoenix-core-\*jar** package. You can obtain this package from **HBase/hbase/lib** in the HBase client installation directory.

**Step 3** If you do not import this JAR package, you need to delete **hbase.rpc.controllerfactory.class** from the **hbase-site.xml** configuration file.

----End

### 1.10.5.5.2 What Are the Application Scenarios of the Bulkload and put Data-loading Modes?

#### Question

Both the bulkload and put data-loading modes can be used to load data to HBase. Though the bulkload mode loads data faster than the put mode, the bulkload mode has its own disadvantages. The following describes the application scenarios of these two data-loading modes.

#### Answer

The bulkload starts MapReduce tasks to generate HFile files, and then registers HFile files with HBase. Incorrect use of the bulkload mode will consume more cluster memory and CPU resources due to started MapReduce tasks. The large number of HFile files may frequently trigger Compaction, decreasing the query speed drastically.

Incorrect use of the put mode may cause a slow data loading rate. If the memory allocated to RegionServer is not sufficient, the process may exit.

The application scenarios of the bulkload and put modes are as follows:

- bulkload:
  - Load a large amount of data to HBase in the one-off manner.
  - Load data to HBase with low reliability requirements and without generating WAL files.
  - Low loading and query speed if the put mode is used.
  - The size of the HFile generated after data loading is similar to the size of HDFS block.
- put:
  - The size of the data loaded to one Region at a time is smaller than half the size of an HDFS block.
  - Load data to HBase in real time.
  - The query speed does not decrease wildly during data loading.

### 1.10.5.5.3 An Error Occurred When Building a JAR Package

#### Question

When the sample code is compiled using Maven to build a JAR package, the error message "Could not transfer artifact org.apache.commons:commons-crypto:pom:\${commons-crypto.version}" is displayed and the package building fails.

#### Answer

The hbase-common module depends on commons-crypto. In the **pom.xml** file of hbase-common, the **\${commons-crypto.version}** variable is used to introduce

commons-crypto. The parsing logic of this variable is as follows: If the OS is AArch64, the value is **1.0.0-hw-aarch64**. If the OS is x86\_64, the value is **1.0.0**. If Maven fails to parse the variable using the OS due to incorrect configuration in the compilation environment, you can manually modify the **pom.xml** file to prevent correct compilation.

In the **pom.xml** file, manually change the dependency of the hbase-common module to the following to exclude the commons-crypto dependency:

```
<dependency>
    <groupId>org.apache.hbase</groupId>
    <artifactId>hbase-common</artifactId>
    <version>${hbase.version}</version>
    <exclusions>
        <exclusion>
            <groupId>org.apache.commons</groupId>
            <artifactId>commons-crypto</artifactId>
        </exclusion>
    </exclusions>
</dependency>
```

Manually add the commons-crypto dependency of the specified version. Enter a correct version based on the OS architecture (x86\_64 or AArch64).

```
<dependency>
    <groupId>org.apache.commons</groupId>
    <artifactId>commons-crypto</artifactId>
    <version>1.0.0</version>
</dependency>
```

#### 1.10.5.5.4 How to Rectify the Fault When an Exception Occurs During the Running of an HBase-developed Application and "java.lang.OutOfMemoryError: Direct buffer memory" Is Displayed in the Error Information?

**Step 1** Run the **java -version** command to check whether the JDK version is JDK1.8u102 or later.

- If yes, go to [Step 2](#).
- If no, the client for secondary development supports only the built-in OpenJDK 1.8 (jdk-8u181-linux-x64). If the JDK version is not JDK1.8u102 or later, upgrade it to JDK1.8u102 or later, and then go to [Step 2](#).

**Step 2** When running the program, set the JVM parameter **-Djdk.nio.maxCachedBufferSize=262144** to limit the size of the direct memory used by each thread.

----End

#### 1.10.5.5.5 Why Does the Error Information Contain "GSSEException" When an IBM JDK Is Used on a Client to Connect to an HBase Cluster?

##### Question

After an IBM JDK is used on a client to connect to an HBase cluster and the debug log function is enabled, the following error information is displayed:

```
javax.security.sasl.SaslException: Failure to initialize security context [Caused by org.ietf.jgss.GSSEException,
major code: 13, minor code: 0]
```

The error stack is as follows:

```
Caused by: javax.security.sasl.SaslException: Failure to initialize security context [Caused by  
org.ietf.jgss.GSSEException, major code: 13, minor code: 0  
major string: Invalid credentials  
minor string: SubjectCredFinder: no JAAS Subject]  
at com.ibm.security.sasl.gsskerb.GssKrb5Client.<init>(GssKrb5Client.java:161)  
at com.ibm.security.sasl.gsskerb.FactoryImpl.createSaslClient(FactoryImpl.java:79)  
at javax.security.sasl.Sasl.createSaslClient(Sasl.java:400)  
at  
org.apache.hadoop.hbase.security.AbstractHBaseSaslRpcClient.createKerberosSaslClient(AbstractHBaseSaslRp  
cClient.java:125)  
at  
org.apache.hadoop.hbase.security.AbstractHBaseSaslRpcClient.<init>(AbstractHBaseSaslRpcClient.java:106)  
at org.apache.hadoop.hbase.security.NettyHBaseSaslRpcClient.<init>(NettyHBaseSaslRpcClient.java:43)  
at  
org.apache.hadoop.hbase.security.NettyHBaseSaslRpcClientHandler.<init>(NettyHBaseSaslRpcClientHandler.j  
ava:70)  
at org.apache.hadoop.hbase.ipc.NettyRpcConnection.saslNegotiate(NettyRpcConnection.java:194)  
... 20 more
```

## Answer

IBM JDKs and OpenJDK have different SASL implementation methods. When NettyRpcClient is used as the client by default, authentication issues may occur. As a result, the SASL client cannot be created. In this case, you need to modify the client configuration to not to use NettyRpcClient. For details, see [Modifying the Client Configuration](#).

# 1.11 HDFS Development Guide

## 1.11.1 Overview

### 1.11.1.1 Introduction to HDFS

#### Introduction to HDFS

Hadoop distribute file system (HDFS) is a distributed file system with high fault tolerance. HDFS supports data access with high throughput and applies to processing of large data sets.

HDFS applies to the following application scenarios:

- Massive data processing (higher than the TB or PB level).
- Scenarios that require high throughput.
- Scenarios that require high reliability.
- Scenarios that require good scalability.

#### Introduction to HDFS Interface

HDFS can be developed by using Java language. For details of API Reference, see [Java API](#).

### 1.11.1.2 Basic Concepts

#### DataNode

A DataNode is used to store data blocks of each file and periodically report the storage status to the NameNode.

#### NameNode

A NameNode is used to manage the namespace, directory structure, and metadata information of a file system and provide the backup mechanism. NameNodes are classified into the following two types:

- Active NameNode: manages the file system namespace, maintains the directory structure tree and metadata information of a file system, and records the relationship between each data block and the file to which the data block belongs.
- Standby NameNode: Data in a standby NameNode is synchronous with those in an active NameNode. A standby NameNode takes over services from the active NameNode if the active NameNode is exception.

#### JournalNode

A JournalNode synchronizes metadata between the active and standby NameNodes in the High Availability (HA) cluster.

#### ZKFC

ZKFC must be deployed for each NameNode. It is responsible for monitoring NameNode status and writing status information to the ZooKeeper. ZKFC also has permission to select the active NameNode.

#### Colocation

Colocation is used to store associated data or the data to be associated on the same storage node. The HDFS Colocation stores files to be associated on a same data node so that data can be obtained from the same data node during associated operations. This greatly reduces network bandwidth consumption.

#### Federation

Federation is adopted to solve most problems in the HDFS architecture that allows only a single NameNode.

Federation allows multiple NameServices. The NameServices can be configured in the HA mode. In HA mode, a hot standby NameNode is provided for the active NameNode to address the single node failure. The standby NameNode is able to quickly take over services from the active NameNode when the active NameNode breaks down. The administrator can start the failover during maintenance.

This function applies only to MRS physical machine clusters.

## Client

The HDFS can be accessed from the Java application programming interface (API), C API, Shell, HTTP REST API and web user interface (WebUI). For details, see [Common API Introduction](#) and [Shell Command Introduce](#).

- JAVA API  
Provides an application interface for the HDFS. This guide describes how to use the Java API to develop HDFS applications.
- C API  
Provides an application interface for the HDFS. This guide describes how to use the C API to develop HDFS applications.
- Shell  
Provides shell commands to perform operations on the HDFS.
- HTTP REST API  
Additional interfaces except Shell, Java API and C API. You can use the interfaces to monitor HDFS status.
- WEB UI  
Provides a visualized management web page.

## keytab file

The keytab file is a key file that stores user information. Applications use the key file for API authentication on MRS.

### 1.11.1.3 Development Process

All stages of the development process are shown and described in [Figure 1-146](#) and [Table 1-90](#).

Figure 1-146 HDFS development process

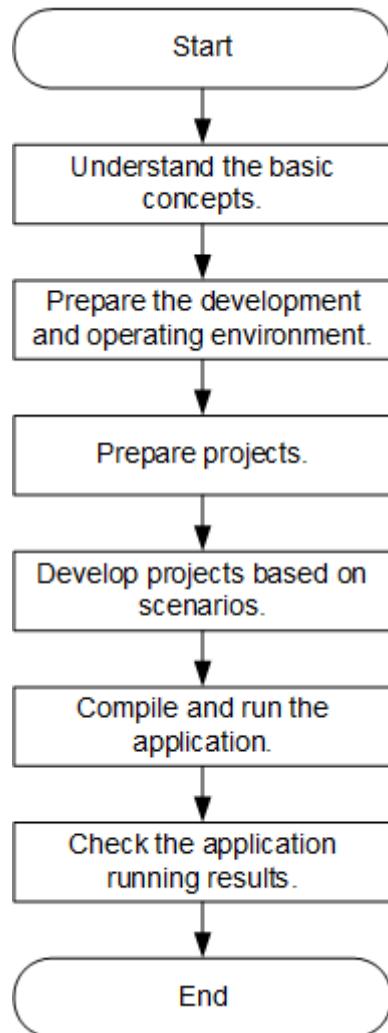

Table 1-90 Description of HDFS development process

Stage	Description	Reference
Understand the basic concepts.	Before the application development, the basic concepts of HDFS are required to be understood.	<a href="#">Basic Concepts</a>
Prepare the development and operating environment.	Use IntelliJ IDEA and configure the development environment based on the reference. The running environment of HDFS is the HDFS client. Install and configure the client based on the reference.	<a href="#">Preparing Development and Operating Environment</a>
Prepare projects.	HDFS provides sample projects in various scenarios. Sample projects can be imported for studying.	<a href="#">Configuring and Importing Sample Projects</a>

Stage	Description	Reference
Prepare for security authentication.	If a safe cluster is used, the safety certification must be performed.	<a href="#">Preparing the Authentication Mechanism</a>
Develop projects based on scenarios.	Provide the sample project. This helps users to learn about the programming interfaces of all HDFS components quickly.	<a href="#">Developing the Project</a>
Compile and run the application.	Users compile the developed application and deliver it for running based on the reference.	<a href="#">Commissioning the Application</a>
Check the application running results.	Application running results are stored in the directory specified by users. Users can also check the running results through the UI.	<a href="#">Commissioning the Application</a>

## 1.11.2 Environment Preparation

### 1.11.2.1 Preparing Development and Operating Environment

#### Preparing Development Environment

[Table 1-91](#) describes the environment required for application development.

**Table 1-91** Development Environment

Preparation	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows OS. Windows 7 or later is supported.</li><li>• Operating environment: Windows OS or Linux OS.</li></ul> <p>If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</p>

Preparation	Description
Installing JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>Oracle JDK 1.8</li><li>IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>For security purposes, the server supports only TLS V1.2 or later.</li><li>By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <code>com.ibm.jsse2.overrideDefaultTLS</code> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstancetls-oracle#matchsslcontext_tls</a>.</li><li>For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>It is the basic configuration for the development environment. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>
Maven installation	Basic configuration of the development environment for project management throughout the lifecycle of software development.
User development preparation	See <a href="#">Preparing a Developer Account</a> for configuration.
7-zip	Used to decompress <b>.zip</b> and <b>.rar</b> packages. The 7-Zip 16.04 is supported.

## Preparing an Operating Environment

During application development, you need to prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. **Accessing FusionInsight Manager of an MRS Cluster.** In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.

- b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\HDFS\config** and manually import the configuration file to the configuration file directory (usually the **conf** folder) of the HDFS sample project.  
The keytab file obtained during the **Preparing a Developer Account** is also stored in this directory.
- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

### NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.  
Ensure that the difference between the client time and the cluster time is less than 5 minutes.  
For details about how to install a cluster client, see **Installing a Client**.
  - b. **Accessing FusionInsight Manager of an MRS Cluster.** Download the cluster client software package to the active management node and

decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/HDFS/config** directory and save them to the **conf** folder of the project code.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp HDFS/config/* root@IP address of the client node:/opt/  
hadoopclient/conf
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. [Table 1-92](#) describes the main configuration files.

**Table 1-92** Configuration files

File	Function
core-site.xml	Configures HDFS parameters.
hdfs-site.xml	Configures HDFS parameters.
user.keytab	Provides HDFS user information for Kerberos security authentication.
krb5.conf	Contains Kerberos server configuration information.

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

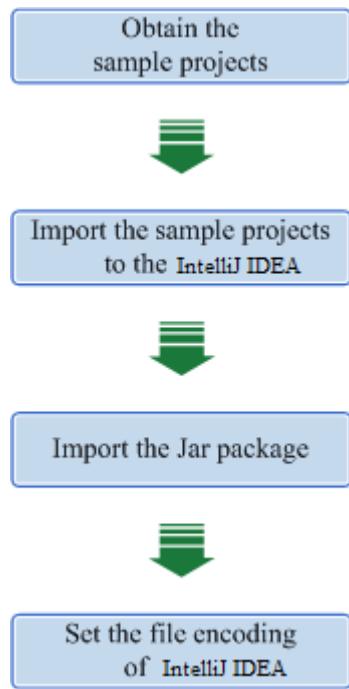

### 1.11.2.2 Configuring and Importing Sample Projects

#### Scenario

HDFS provides sample projects for multiple scenarios to help you quickly learn HDFS projects.

The procedure for importing HDFS example codes is described as follows: [Figure 1-147](#) shows the procedure.

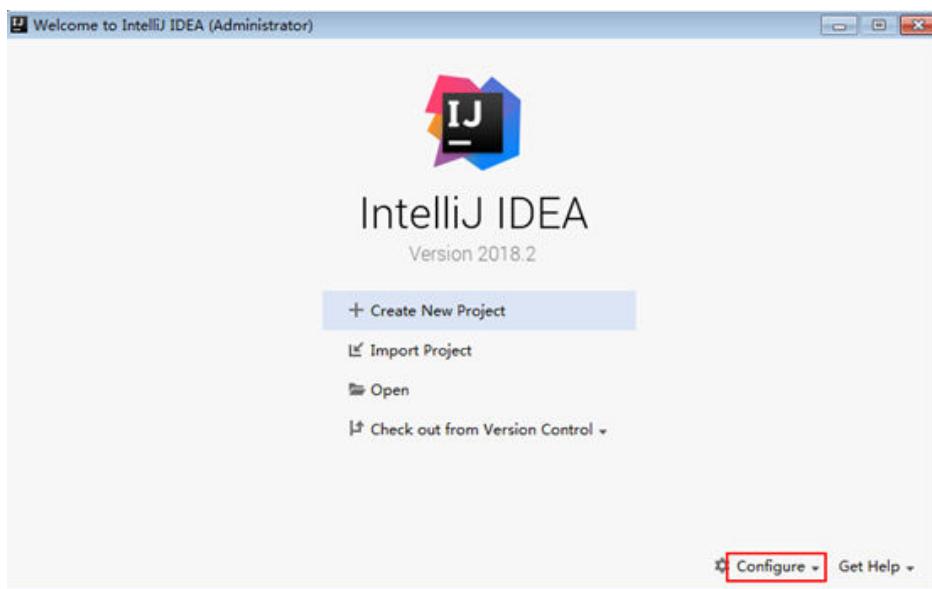

Figure 1-147 Sample project importing procedure

## Procedure

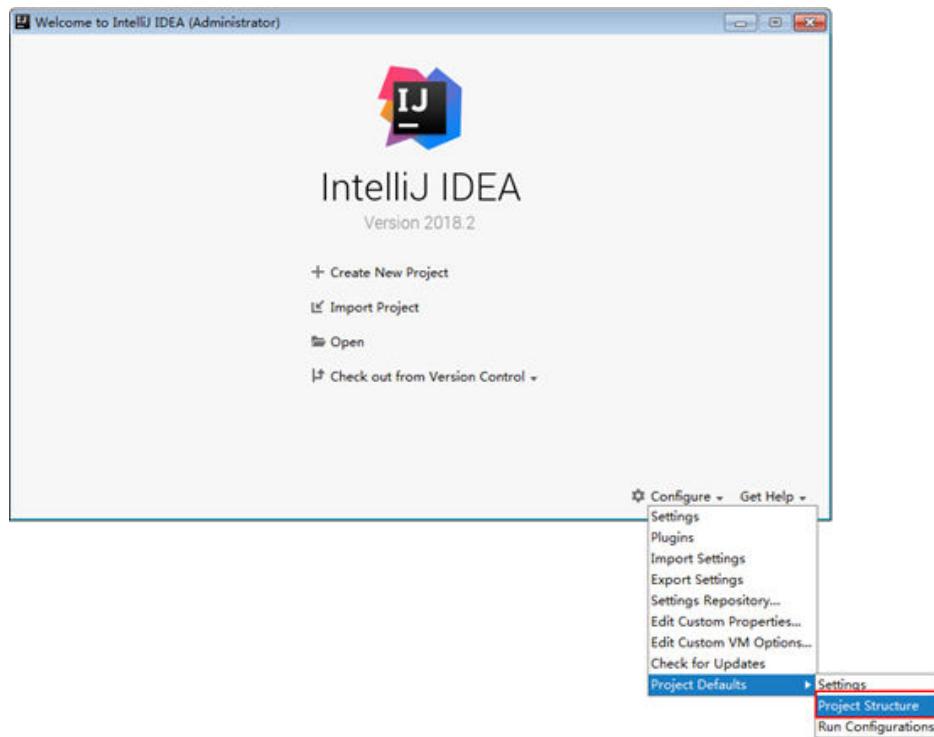

- Step 1** Obtain the sample project folder **hdfs-example-security** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Copy the **user.keytab** and **krb5.conf** files obtained in [Preparing a Developer Account](#) section to the **conf** directory of the sample project.
- Step 3** After installing the IntelliJ IDEA and JDK tools, configure JDK in IntelliJ IDEA.
  1. Open IntelliJ IDEA and click **Configure**.

Figure 1-148 Quick Start

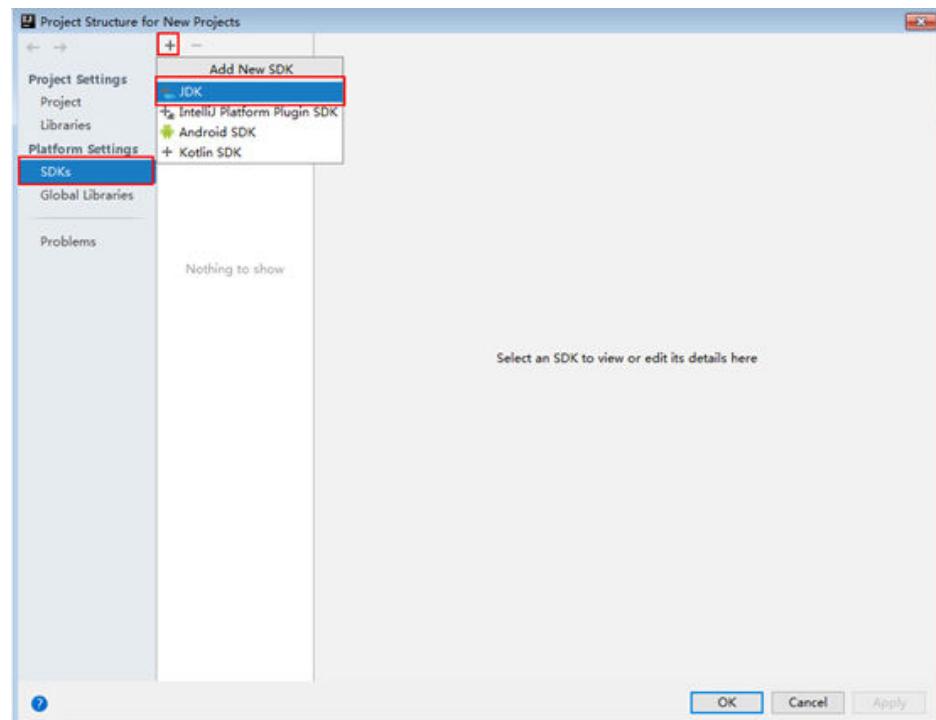

2. Choose **Project Defaults > Project Structure**.

**Figure 1-149** Configure

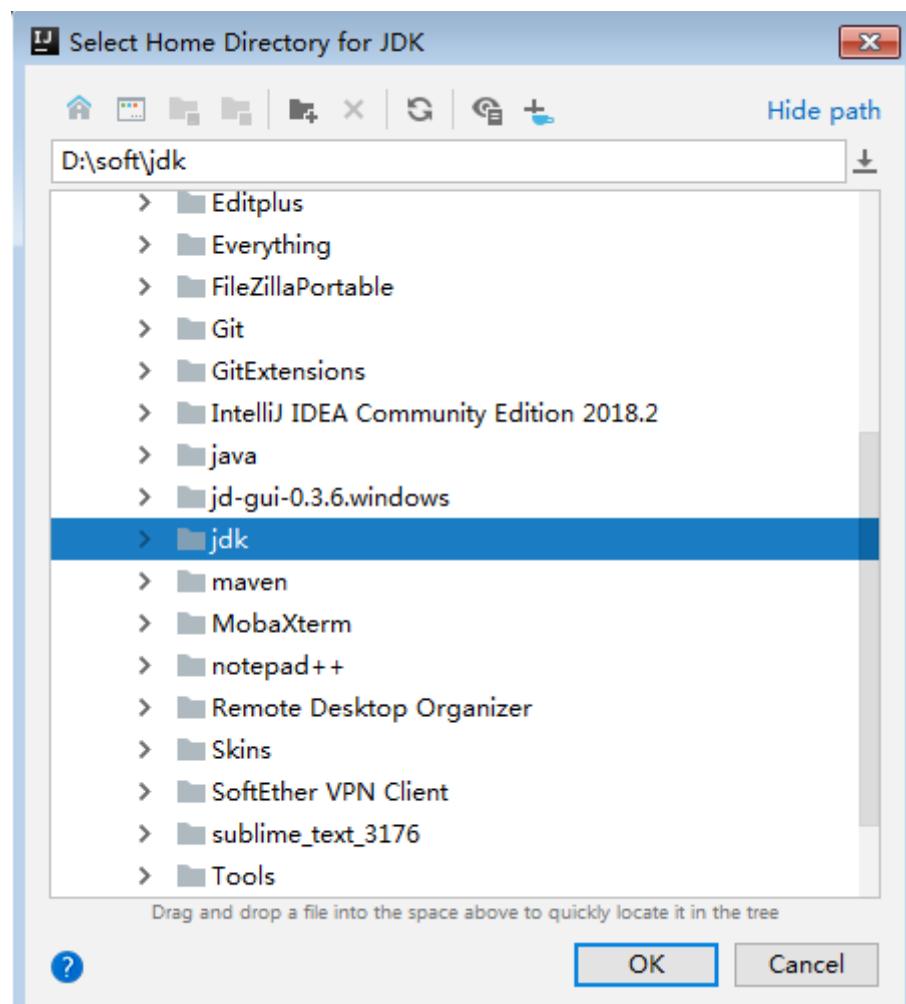

3. In the displayed **Project Structure for New Projects** interface, click **SDKs**. Then click the plus sign (+) and choose **JDK**.

Figure 1-150 Project Structure for New Projects

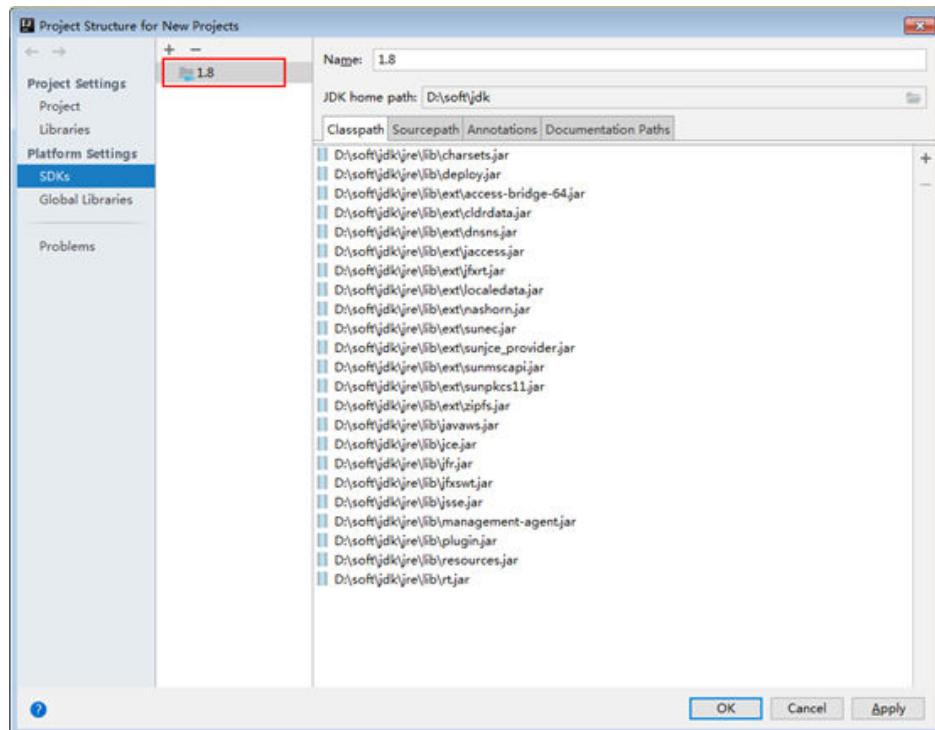

4. In the displayed **Select Home Directory for JDK** interface, select the JDK directory, and click **OK**.

Figure 1-151 Select Home Directory for JDK

5. Click OK.

Figure 1-152 Completing the JDK configuration

**Step 4** Import the example project to the IntelliJ IDEA development environment.

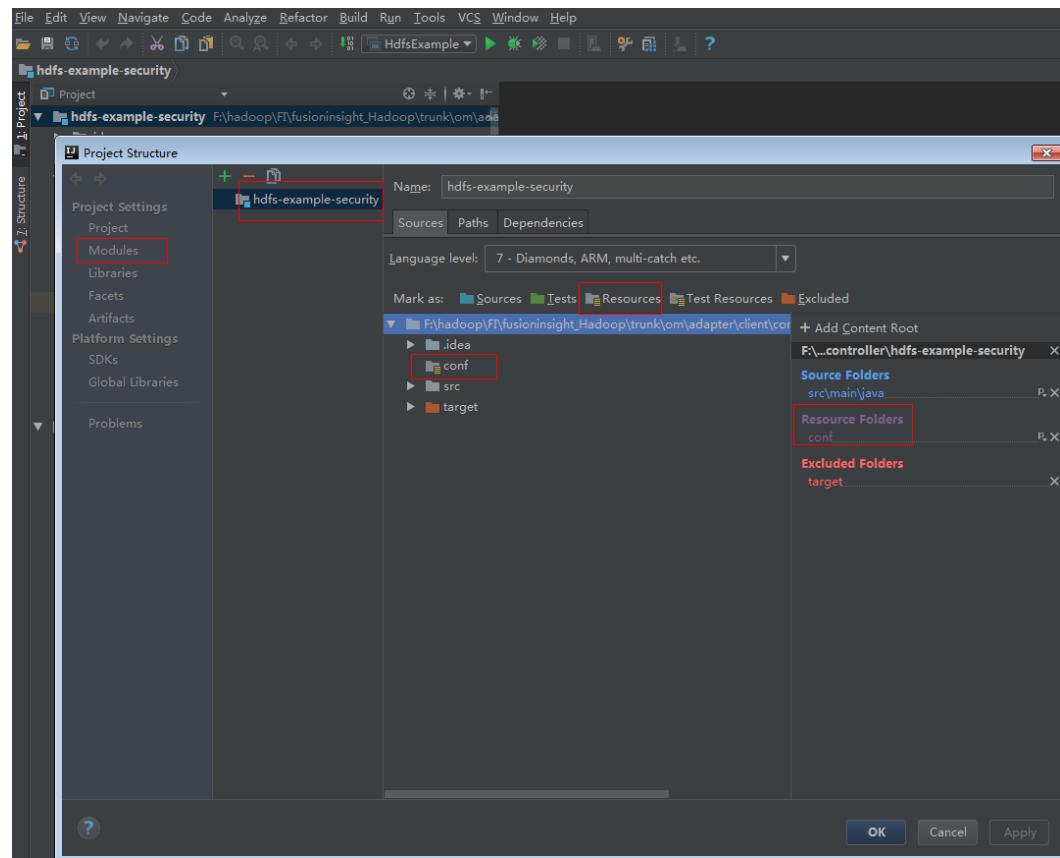

1. Open IntelliJ IDEA and choose **File > Open**.
2. Choose the directory of the example project **hdfs-example-security**. Click **OK**.

**Step 5** Add the related jar files the example project depending on into classpath.

If the sample project code is obtained from an open-source image site, dependency JAR files are automatically downloaded after Maven is configured (for details, see [Configuring Huawei Open-Source Mirrors](#)).

**Step 6** Add the conf directory in the project to the resource path. On the menu bar of the IntelliJ IDEA, choose **File > Project Structure**. In the dialog box that is displayed, click **Modules**, select the current project and click **Resources > conf > OK** to set the resource directory. [Figure 1-153](#) shows the directory for setting the project resource.

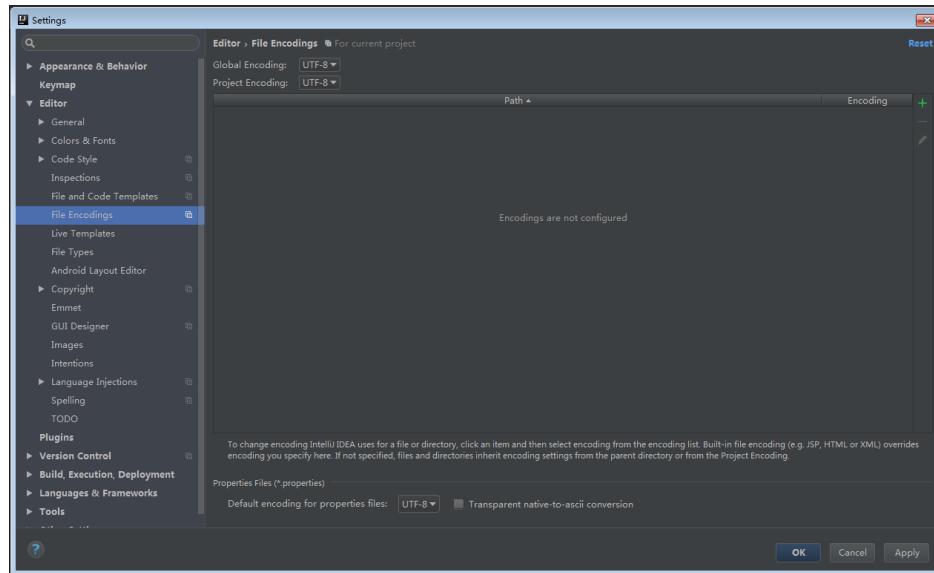

Figure 1-153 Setting the Project Resource Directory

**Step 7** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

1. On the IntelliJ IDEA menu bar, choose **File > Settings**.
2. Choose **Editor > File Encodings** from the navigation tree of the **Settings** window. In the "Global Encoding" and "Project Encodings" area, set the value to **UTF-8**, click **Apply**, and click **OK**, as shown in [Figure 1-154](#)

Figure 1-154 Setting the IntelliJ IDEA coding format

----End

### 1.11.2.3 Preparing the Authentication Mechanism

#### Scenario

Before accessing services in the secure cluster environment, you must be authorized by Kerberos. Codes for security authentication need to be written into the HDFS applications to ensure that the applications can work properly.

Two security authentication methods are described as follows:

- Authentication by running command lines:

Before submitting the HDFS application for running, run the following command in the HDFS client to obtain authentication:

**kinit component service user**

#### NOTE

This method applies only to the Linux OS that is installed with the HDFS client.

- Authentication by adding codes:

Authenticate by obtaining the principal and keytab files of the client.

Change the value of **PRINCIPAL\_NAME** in the code to the actual value.

```
private static final String PRINCIPAL_NAME = "hdfsDeveloper";
```

#### Safety Security Code

The safety authentication of the example codes is completed by invoking the LoginUtil class.

In the HDFS sample project code, different sample projects use different authentication codes which are basic safety authentication and the basic safety authentication with the ZooKeeper authentication.

- Basic safety authentication:

Sample projects of the **HdfsExample** class in the **com.huawei.bigdata.hdfs.examples** package need only the basic safety authentication codes because these sample projects do not need to access the HBase or ZooKeeper. Add the following codes in the program:

```
...
    private static final String PATH_TO_HDFS_SITE_XML =
HdfsExample.class.getClassLoader().getResource("hdfs-site.xml").getPath();
    private static final String PATH_TO_CORE_SITE_XML =
HdfsExample.class.getClassLoader().getResource("core-site.xml").getPath();
    private static final String PRINCIPAL_NAME = "hdfsDeveloper";
    private static final String PATH_TO_KEYTAB =
HdfsExample.class.getClassLoader().getResource("user.keytab").getPath();
    private static final String PATH_TO_KRB5_CONF =
HdfsExample.class.getClassLoader().getResource("krb5.conf").getPath();
    private static Configuration conf = null;
...
    private static void authentication() throws IOException {
        // security mode
        if ("kerberos".equalsIgnoreCase(conf.get("hadoop.security.authentication"))) {
            System.setProperty("java.security.krb5.conf", PATH_TO_KRB5_CONF);
            LoginUtil.login(PRINCIPAL_NAME, PATH_TO_KEYTAB, PATH_TO_KRB5_CONF, conf);
        }
    }
}
```

- Basic safety authentication with ZooKeeper Authentication:

Sample projects of the **ColocationExample** class in the **com.huawei.bigdata.hdfs.examples** package require not only the basic safety authentication, but also the Principal of the server in ZooKeeper to complete the safety authentication. Add the following codes in the program:

```
...
    private static final String ZOOKEEPER_SERVER_PRINCIPAL_KEY = "zookeeper.server.principal";
    private static final String PRINCIPAL = "username.client.kerberos.principal";
    private static final String KEYTAB = "username.client.keytab.file";
    private static final String PRINCIPAL_NAME = "hdfsDeveloper";
    private static final String LOGIN_CONTEXT_NAME = "Client";
    private static final String PATH_TO_KEYTAB = System.getProperty("user.dir") + File.separator +
"conf" + File.separator + "user.keytab";
    private static final String PATH_TO_KRB5_CONF =
ColocationExample.class.getClassLoader().getResource("krb5.conf").getPath();
    private static String zookeeperDefaultServerPrincipal = null;
    private static Configuration conf = new Configuration();
    private static DFSColocationAdmin dfsAdmin;
    private static DFSColocationClient dfs;
    private static void init() throws IOException {
        LoginUtil.login(PRINCIPAL_NAME, PATH_TO_KEYTAB, PATH_TO_KRB5_CONF, conf);
        LoginUtil.setJaasConf(LOGIN_CONTEXT_NAME, PRINCIPAL_NAME, PATH_TO_KEYTAB);
        zookeeperDefaultServerPrincipal = "zookeeper/hadoop." +
KerberosUtil.getKrb5DomainRealm().toLowerCase();
        LoginUtil.setZookeeperServerPrincipal(ZOOKEEPER_SERVER_PRINCIPAL_KEY,
zookeeperDefaultServerPrincipal);
    }
...
}
```

#### NOTE

- The **HdfsDeveloper** user and the user's **user.keytab** and **krb5.conf** in the safety authentication codes are used as an example. In practical operations, contact the administrator to obtain the corresponding account and the keytab and krb5 files related to the account.
- You can log in to FusionInsight Manager, choose **System > Permission > Domain and Mutual Trust**, and check the value of **Local Domain**, which is the current system domain name.
- **zookeeper/hadoop.<system domain name>** is the user name. All letters in the system domain name contained in the user name of the system are lowercase letters. For example, if **Local domain** is set to **9427068F-6EFA-4833-B43E-60CB641E5B6C.COM**, the user name is **zookeeper/hadoop.9427068f-6efa-4833-b43e-60cb641e5b6c.com**.

## 1.11.3 Developing the Project

### 1.11.3.1 Scenario

#### Typical Scenario Description

Based on typical scenarios, users can quickly learn and master the HDFS development process and know important interface functions.

#### Scenario

Service operation objects of HDFS are files. File operations in example codes include creating a folder, writing data into a file, appending data to a file, reading data from a file, and deleting a file or folder. HDFS also supports other services including setting file permission. You can learn how to perform other operations on HDFS after learning the example codes in this chapter.

The example codes are described in the following order:

1. Initializing the HDFS.
2. Creating directories.
3. Writing data into a file.
4. Appending data to a file.
5. Reading data from a file.
6. Deleting a file.
7. Deleting directories.
8. Multi-thread tasks.
9. Setting storage policies.
10. Colocation.

### 1.11.3.2 Development Idea

#### Development Idea

According to the previous scenario description, the following provides the basic operations for HDFS files with read, write, and delete operations on the **/user/hdfs-examples/test.txt** file as an example:

1. Pass the security certification.
2. Create a FileSystem object: fSystem.
3. Call the mkdir interface in fSystem to create a directory.
4. Call the create interface in fSystem to create an FSDataOutputStream object: out. Use the write method to write data into the object out.
5. Call the append interface in fSystem to create an FSDataOutputStream object: out. Use the write method to append data into the object out.
6. Call the open interface in fSystem to create an FSDataInputStream object: in. Use the read method to read files of the object in.
7. Call the delete interface in fSystem to delete the file.
8. Call the delete interface in fSystem to delete the folder.

### 1.11.3.3 Declare the Example Codes

#### 1.11.3.3.1 Initializing the HDFS

##### Function

Hadoop distributed file system (HDFS) initialization is a prerequisite for using application programming interfaces (APIs) provided by the HDFS. The process of initializing the HDFS is

1. Load the HDFS service configuration file.
2. Instantiate a FileSystem.

Obtain the keytab file for Kerberos security authentication in advance.

##### Configuration File Description

**Table 1-93** lists the configuration files to be used during the login to the HDFS. These files already imported to the **conf** directory of the **hdfs-example-security** project.

**Table 1-93** Configuration files

File	Function
core-site.xml	Configures HDFS parameters.
hdfs-site.xml	Configures HDFS parameters.
user.keytab	Provides HDFS user information for Kerberos security authentication.
krb5.conf	Contains Kerberos server configuration information.

 NOTE

- Different clusters cannot share the same **user.keytab** and **krb5.conf** files.
- The **log4j.properties** file under the **conf** directory can be configured based on your needs.

## Example Codes

The following is code snippets. For complete codes, see the HdfsExample class in com.huawei.bigdata.hdfs.examples.

The initialization codes used when applications are run in Linux and the codes used when applications are run in Windows are the same. The example codes are as follows:

```
// Complete initialization and authentication.  
confLoad();  
authentication();  
// Creating a sample project  
HdfsExample hdfs_examples = new HdfsExample("/user/hdfs-examples", "test.txt");  
  
/**  
 *  
 * If the application is running in the Linux OS, the path of core-site.xml, hdfs-site.xml must be modified to  
the absolute path of the client file in the Linux OS.  
 *  
 */  
private static void confLoad() throws IOException {  
    conf = new Configuration();  
    // conf file  
    conf.addResource(new Path(PATH_TO_HDFS_SITE_XML));  
    conf.addResource(new Path(PATH_TO_CORE_SITE_XML));  
}  
  
/**  
 *Safety authentication  
 */  
private static void authentication() throws IOException {  
    // security mode  
    if ("kerberos".equalsIgnoreCase(conf.get("hadoop.security.authentication"))){  
        System.setProperty("java.security.krb5.conf", PATH_TO_KRB5_CONF);  
        LoginUtil.login(PRINCIPAL_NAME, PATH_TO_KEYTAB, PATH_TO_KRB5_CONF, conf);  
    }  
}  
/**  
 *Create a sample project.  
 */  
public HdfsExample(String path, String fileName) throws IOException {  
    this.DEST_PATH = path;  
    this.FILE_NAME = fileName;  
    instanceBuild();  
}  
  
private void instanceBuild() throws IOException {  
    fSystem = FileSystem.get(conf);
```

The login example codes need to be added for the first login when applications are run in both Windows and Linux. For details on the example codes, see the LoginUtil class in com.huawei.hadoop.security.

```
public synchronized static void login(String userPrincipal, String userKeytabPath, String krb5ConfPath,  
Configuration conf)  
throws IOException  
{
```

```
// 1.Check the input parameters.

if ((userPrincipal == null) || (userPrincipal.length() <= 0))
{
    LOG.error("input userPrincipal is invalid.");
    throw new IOException("input userPrincipal is invalid.");
}

if ((userKeytabPath == null) || (userKeytabPath.length() <= 0))
{
    LOG.error("input userKeytabPath is invalid.");
    throw new IOException("input userKeytabPath is invalid.");
}

if ((krb5ConfPath == null) || (krb5ConfPath.length() <= 0))
{
    LOG.error("input krb5ConfPath is invalid.");
    throw new IOException("input krb5ConfPath is invalid.");
}

if ((conf == null))
{
    LOG.error("input conf is invalid.");
    throw new IOException("input conf is invalid.");
}

// 2.Check whether the file exists.

File userKeytabFile = new File(userKeytabPath);
if (!userKeytabFile.exists())
{
    LOG.error("userKeytabFile(" + userKeytabFile.getAbsolutePath() + ") does not exist.");
    throw new IOException("userKeytabFile(" + userKeytabFile.getAbsolutePath() + ") does not exist.");
}
if (!userKeytabFile.isFile())
{
    LOG.error("userKeytabFile(" + userKeytabFile.getAbsolutePath() + ") is not a file.");
    throw new IOException("userKeytabFile(" + userKeytabFile.getAbsolutePath() + ") is not a file.");
}

File krb5ConfFile = new File(krb5ConfPath);
if (!krb5ConfFile.exists())
{
    LOG.error("krb5ConfFile(" + krb5ConfFile.getAbsolutePath() + ") does not exist.");
    throw new IOException("krb5ConfFile(" + krb5ConfFile.getAbsolutePath() + ") does not exist.");
}
if (!krb5ConfFile.isFile())
{
    LOG.error("krb5ConfFile(" + krb5ConfFile.getAbsolutePath() + ") is not a file.");
    throw new IOException("krb5ConfFile(" + krb5ConfFile.getAbsolutePath() + ") is not a file.");
}

// 3.Set and check krb5config.

setKrb5Config(krb5ConfFile.getAbsolutePath());
setConfiguration(conf);

// 4.Log in to Hadoop to check items.

loginHadoop(userPrincipal, userKeytabFile.getAbsolutePath());
LOG.info("Login success!!!!!!!!!!!!!!!");
}
```

### 1.11.3.3.2 Creating Directories

#### Function

Process of creating a directory:

1. Call the exists method of the FileSystem instance to check whether the directory exists.
2. If yes, the method stops.
3. If no, call the mkdirs method in the FileSystem instance to create a directory.

## Example Codes

The following is a code snippet. For complete codes, see the **HdfsExample** class in **com.huawei.bigdata.hdfs.examples**.

```
/**  
 * Create a directory.  
 *  
 * @throws java.io.IOException  
 */  
private void mkdir() throws IOException {  
    Path destPath = new Path(DEST_PATH);  
    if (!createPath(destPath)) {LOG.error("failed to create destPath " + DEST_PATH);  
    return;  
}  
  
    LOG.info("success to create path " + DEST_PATH);  
}  
  
/**  
 * create file path  
 *  
 * @param filePath  
 * @return  
 * @throws java.io.IOException  
 */  
private boolean createPath(final Path filePath) throws IOException {  
    if (!fSystem.exists(filePath)) {  
        fSystem.mkdirs(filePath);  
    }  
    return true;  
}
```

### 1.11.3.3.3 Writing Data into a File

#### Function

The process of writing data into a file is

1. Use the create method in the FileSystem instance to obtain the output stream of writing files.
2. Uses this data stream to write content into a specified file in the HDFS.

Close all requested resources after writing files.

## Example Codes

The following is code snippets. For complete codes, see HdfsExample class in **com.huawei.bigdata.hdfs.examples**.

```
/**  
 * Create a file and write data into the file.  
 *
```

```
* @throws java.io.IOException
* @throws com.huawei.bigdata.hdfs.examples.ParameterException
*/
private void write() throws IOException {
    final String content = "hi, I am bigdata. It is successful if you can see me.";
    FSDataOutputStream out = null;
    try {
        out = fSystem.create(new Path(DEST_PATH + File.separator + FILE_NAME));
        out.write(content.getBytes());
        out.hsync();
        LOG.info("success to write.");
    } finally {
        // make sure the stream is closed finally.
        IOUtils.closeStream(out);
    }
}
```

#### 1.11.3.3.4 Appending Data to a File

### Function

Append data to a specified file in the Hadoop distributed file system (HDFS). The process of appending data to a file is

1. Use the append method in the FileSystem instance to obtain the output stream of the appended data.
2. Use the output stream to add the content to be appended behind the specified file in the HDFS.

Close all requested resources after appending data.

### Example Codes

The following is code snippets. For complete codes, see `HdfsExample` class in `com.huawei.bigdata.hdfs.examples`.

```
/*
 * Append data to a file
 *
 * @throws java.io.IOException
 */
private void append() throws IOException {
    final String content = "I append this content.";
    FSDataOutputStream out = null;
    try {
        out = fSystem.append(new Path(DEST_PATH + File.separator + FILE_NAME));
        out.write(content.getBytes());
        out.hsync();
        LOG.info("success to append.");
    } finally {
        // make sure the stream is closed finally.
        IOUtils.closeStream(out);
    }
}
```

### 1.11.3.3.5 Reading Data from a File

#### Function

Read data from a specified file in the Hadoop distributed file system (HDFS). The process is:

1. Use the open method in the FileSystem instance to obtain the input stream of writing files.
2. Use the input stream to read the content of the specified file in the HDFS.

Close all requested resources after reading files.

#### Example Codes

The following is code snippets. For complete codes, see the `HdfsExample` class in `com.huawei.bigdata.hdfs.examples`.

```
/**  
 * Read s file.  
 *  
 * @throws java.io.IOException  
 */  
private void read() throws IOException {  
    String strPath = DEST_PATH + File.separator + FILE_NAME;  
    Path path = new Path(strPath);  
    FSDataInputStream in = null;  
    BufferedReader reader = null;  
    StringBuffer strBuffer = new StringBuffer();  
    try {  
        in = fSystem.open(path);  
        reader = new BufferedReader(new InputStreamReader(in));  
        String sTempOneLine;  
        // write file  
        while ((sTempOneLine = reader.readLine()) != null) {  
            strBuffer.append(sTempOneLine);  
        }  
        LOG.info("result is : " + strBuffer.toString());  
        LOG.info("success to read.");  
    } finally {  
        // make sure the streams are closed finally.  
        IOUtils.closeStream(reader);  
        IOUtils.closeStream(in);  
    }  
}
```

### 1.11.3.3.6 Deleting a File

#### Function

Delete a file from the Hadoop distributed file system (HDFS).

Exercise caution when you delete files because the deletion is irreversible.

## Example Codes

The following is code snippets. For complete codes, see the `HdfsExample` class in `com.huawei.bigdata.hdfs.examples`.

```
/*
 * Delete a file.
 *
 * @throws java.io.IOException
 */
private void delete() throws IOException {
    Path beDeletedPath = new Path(DEST_PATH + File.separator + FILE_NAME);
    if (fSystem.delete(beDeletedPath, true)) {
        LOG.info("success to delete the file " + DEST_PATH + File.separator + FILE_NAME);
    } else {
        LOG.warn("failed to delete the file " + DEST_PATH + File.separator + FILE_NAME);
    }
}
```

### 1.11.3.3.7 Deleting Directories

## Function

Delete a specified directory from the HDFS.

Files in the deleted directory will be stored in the **Trash/Current** folder of the directory of the current user. In the event of mis-deletion, you can restore the folder from the directory.

## Example Codes

The following is a code snippet of file deletion. For complete codes, see the `HdfsExample` class in `com.huawei.bigdata.hdfs.examples`.

```
/*
 * delete the directory
 *
 * @throws java.io.IOException
 */
private void rmdir() throws IOException {
    Path destPath = new Path(DEST_PATH);
    if (!deletePath(destPath)) {
        LOG.error("failed to delete destPath " + DEST_PATH);
        return;
    }
    LOG.info("success to delete path " + DEST_PATH);
}

/*
 * delete file path
 *
 * @param filePath
 * @return
 * @throws java.io.IOException
 */
private boolean deletePath(final Path filePath) throws IOException {
    if (!fSystem.exists(filePath)) {
        return false;
    }
    // fSystem.delete(filePath, true);
    return fSystem.delete(filePath, true);
}
```

### 1.11.3.3.8 Multi-Thread Tasks

#### Function

Create multi-threaded tasks and initiate multiple instances to perform file operations.

#### Example Codes

The following is a code snippet of file deletion. For complete codes, see the **HdfsExample** class in **com.huawei.bigdata.hdfs.examples**.

```
// Service example 2: multi-thread tasks
final int THREAD_COUNT = 2;
for (int threadNum = 0; threadNum < THREAD_COUNT; threadNum++) {
    HdfsExampleThread example_thread = new HdfsExampleThread("hdfs_example_" + threadNum);
    example_thread.start();
}

class HdfsExampleThread extends Thread {
    private final static Log LOG = LogFactory.getLog(HdfsExampleThread.class.getName());
    /**
     *
     * @param threadName
     */
    public HdfsExampleThread(String threadName) {
        super(threadName);
    }
    public void run() {
        HdfsExample example;
        try {
            example = new HdfsExample("/user/hdfs-examples/" + getName(), "test.txt");
            example.test();
        } catch (IOException e) {
            LOG.error(e);
        }
    }
}
```

The **example.test()** method is the operation on files. The code is as follows:

```
/*
 * HDFS operation instance
 *
 * @throws IOException
 * @throws ParameterException
 *
 * @throws Exception
 */
public void test() throws IOException {
    // Create a directory.
    mkdir();

    // Write data into a file.
    write();

    // Append data to a file.
    append();

    // Read a file.
    read();

    // Delete a file.
    delete();
```

```
// Delete a directory.  
rmdir();  
}
```

### 1.11.3.3.9 Setting Storage Policies

#### Function

Specify storage policies for a file or folder in the HDFS.

#### Example Code

1. [Accessing FusionInsight Manager of an MRS Cluster](#), and choose **Cluster > Name of the desired cluster > Services > HDFS > Configurations > All Configurations**.
2. Check whether the value of **dfs.storage.policy.enabled** is the default value **true**. If not, modify the value to **true**, click **Save**, and restart HDFS.
3. Check the code.

The following code segment is only an example. For details, see the `HdfsExample` class in `com.huawei.bigdata.hdfs.examples`.

```
/**  
 * set storage policy to path  
 * @param policyName  
 * Policy Name can be accepted:  
 * <li>HOT  
 * <li>WARM  
 * <li>COLD  
 * <li>LAZY_PERSIST  
 * <li>ALL_SSD  
 * <li>ONE_SSD  
 * @throws IOException  
 */  
private void setStoragePolicy(String policyName) throws IOException {  
    if (fSystem instanceof DistributedFileSystem) {  
        DistributedFileSystem dfs = (DistributedFileSystem) fSystem;  
        Path destPath = new Path(DEST_PATH);  
        Boolean flag = false;  
        mkdir();  
        BlockStoragePolicySpi[] storage = dfs.getStoragePolicies();  
        for (BlockStoragePolicySpi bs : storage) {  
            if (bs.getName().equals(policyName)) {  
                flag = true;  
            }  
            LOG.info("StoragePolicy:" + bs.getName());  
        }  
        if (!flag) {  
            policyName = storage[0].getName();  
        }  
        dfs.setStoragePolicy(destPath, policyName);  
        LOG.info("success to set Storage Policy path " + DEST_PATH);  
        rmdir();  
    } else {  
        LOG.info("SmallFile not support to set Storage Policy !!!");  
    }  
}
```

### 1.11.3.3.10 Colocation

#### Function Description

Colocation is to store associated data or data on which associated operations are performed on the same storage node. The HDFS Colocation feature stores files on which associated operations are performed on the same data node so that data can be obtained from the same data node during associated operations. This greatly reduces network bandwidth consumption.

Before using the Colocation function, you are advised to be familiar with the internal mechanisms of Colocation, including:

**Colocation node allocation principle**

**Capacity expansion and Colocation allocation**

**Colocation and data node capacity**

- **Colocation node allocation principle**

Colocation allocates data nodes to locators evenly according to the allocation node quantity.

The allocation algorithm principle is as follows: Colocation queries all locators, reads the data nodes allocated to the locators, and records the number of times. Based on the number of times, Colocation sorts the data nodes. The data nodes that are rarely used are placed at the beginning and selected first. The count increase by 1 each time after a node is selected. The nodes are shorted again, and the subsequent node will be selected.

- **Capacity expansion and Colocation allocation**

After cluster capacity expansion, you can select one of the following two policies shown in [Table 1-94](#) to balance the usage of data nodes and ensure that the allocation frequency of the newly added nodes is consistent with that of the old data nodes.

**Table 1-94** Allocation policies

No.	Policy	Description
1	Delete the original locators and create new locators for all data nodes in the cluster.	<ol style="list-style-type: none"><li>1. The original locator before the capacity expansion evenly uses all data nodes. After the capacity expansion, the newly added nodes are not allocated to existing locators, so Colocation stores data only to the old data nodes.</li><li>2. Data nodes are allocated to specific locators. Therefore, after capacity expansion, Colocation needs to reallocated data nodes to locators.</li></ol>

No.	Policy	Description
2	Create new locators and plan the data storage mode again.	The old locators use the old data nodes, while the newly created locators mainly use the new data nodes. Therefore, locators need to be planned again based on the actual service requirements on data.

 NOTE

Generally, you are advised to use the policy to reallocate data nodes to locators after capacity expansion to prevent data from being stored only to the new data nodes.

- **Colocation and data node capacity**

When Colocation is used to store data, the data is stored to the data node of a specified locator. If no locator planning is performed, the data node capacity will be uneven. [Table 1-95](#) summarizes the two usage principles to ensure even data node capacity.

**Table 1-95** Usage Principle

No.	Usage Principle	Description
1	All the data nodes are used in the same frequency in locators.	Assume that there are N data nodes, the number of locators must be an integral multiple of N (N, 2 N, ...).
2	A proper data storage plan must be made for all locators to ensure that data is evenly stored in the locators.	None

During HDFS secondary development, you can obtain the DFSColocatinAdmin and DFSColocatinClient instances to create groups, delete groups, write files, and delete files in or from the location.

 NOTE

- When the Colocation function is enabled and users specify DataNodes, the data volume will be large on some nodes. Serious data skew will result in HDFS data write failures.
- Because of data skew, MapReduce accesses only several nodes. In this case, the load is heavy on these nodes, while other nodes are idle.
- For a single application task, the DFSColocatinAdmin and DFSColocatinClient instances can be used only once. If the instances are used for many time, excessive HDFS links will be created and use up HDFS resources.
- If you need to perform the balance operation for a file uploaded by colocation, you can set the `oi.dfs.colocation.file.pattern` parameter on FusionInsight Manager to the file path to avoid invalid colocation. If there are multiple files, use commas (,) to separate the file paths, for example, `/test1,/test2`.
- Colocation stores associated data or data on which associated operations are performed on the same storage. When Balancer- or Mover-related operations are performed, data blocks will be moved. As a result, the Colocation function becomes unavailable. Therefore, when using the Colocation function, you are advised to set the HDFS configuration item `dfs.datanode.block-pinning.enabled` to `true`. In this case, files written by Colocation will not be moved when Balancer- or Mover-related operations are performed in the cluster, ensuring file colocation.

## Example Codes

For complete example codes, see  
`com.huawei.bigdata.hdfs.examples.ColocationExample`.

 NOTE

- Before using the Colocation function, add HDFS users to the supergroup group.
- When the Colocation project is run, the HDFS parameter `fs.defaultFS` cannot be set to `viewfs://ClusterX`.

### 1. Initialization

Kerberos security authentication is required before using Colocation.

```
private static void init() throws IOException {  
  
    conf.set(KEYTAB, PATH_TO_KEYTAB);  
    conf.set(PRINCIPAL, PRNCIPAL_NAME);  
  
    LoginUtil.setJaasConf(LOGIN_CONTEXT_NAME, PRNCIPAL_NAME, PATH_TO_KEYTAB);  
    LoginUtil.setZookeeperServerPrincipal(ZOOKEEPER_SERVER_PRINCIPAL_KEY,  
    ZOOKEEPER_DEFAULT_SERVER_PRINCIPAL);  
    LoginUtil.login(PRNCIPAL_NAME, PATH_TO_KEYTAB, PATH_TO_KRB5_CONF, conf);  
}
```

### 2. Obtain instances.

Example: Colocation operations require the DFSColocatinAdmin and DFSColocatinClient instances. Therefore, the instances must be obtained before operations, such as creating a group.

```
dfsAdmin = new DFSColocatinAdmin(conf);  
dfs = new DFSColocatinClient();  
dfs.initialize(URI.create(conf.get("fs.defaultFS")), conf);
```

### 3. Create a group.

Example: Create a `gid01` group, which contains three locators.

```
/**  
 * create group  
 *  
 * @throws java.io.IOException
```

```
/*
private static void createGroup() throws IOException {
    dfsAdmin.createColocationGroup(COLOCATION_GROUP_GROUP01,
        Arrays.asList(new String[] { "lid01", "lid02", "lid03" }));
}
```

4. Write data into a file. The related group must be created before writing data into the file.

Example: Write data into the testfile.txt file.

```
/**
 * create and write file
 *
 * @throws java.io.IOException
 */
private static void put() throws IOException {
    FSDatOutputStream out = dfs.create(new Path(TESTFILE_TXT), true,
COLOCATION_GROUP_GROUP01, "lid01");
    // the data to be written to the hdfs.
    byte[] readBuf = "Hello World".getBytes("UTF-8");
    out.write(readBuf, 0, readBuf.length);
    out.close();
}
```

5. Delete a file.

Example: Delete the testfile.txt file.

```
/**
 * delete file
 *
 * @throws java.io.IOException
 */
@SuppressWarnings("deprecation")
private static void delete() throws IOException {
    dfs.delete(new Path(TESTFILE_TXT));
}
```

6. Delete a group.

Example: Delete gid01.

```
/**
 * delete group
 *
 * @throws java.io.IOException
 */
private static void deleteGroup() throws IOException {
    dfsAdmin.deleteColocationGroup(COLOCATION_GROUP_GROUP01);
}
```

## 1.11.4 Commissioning the Application

### 1.11.4.1 Commissioning an Application in the Windows Environment

#### 1.11.4.1.1 Compiling and Running an Application

##### Scenario

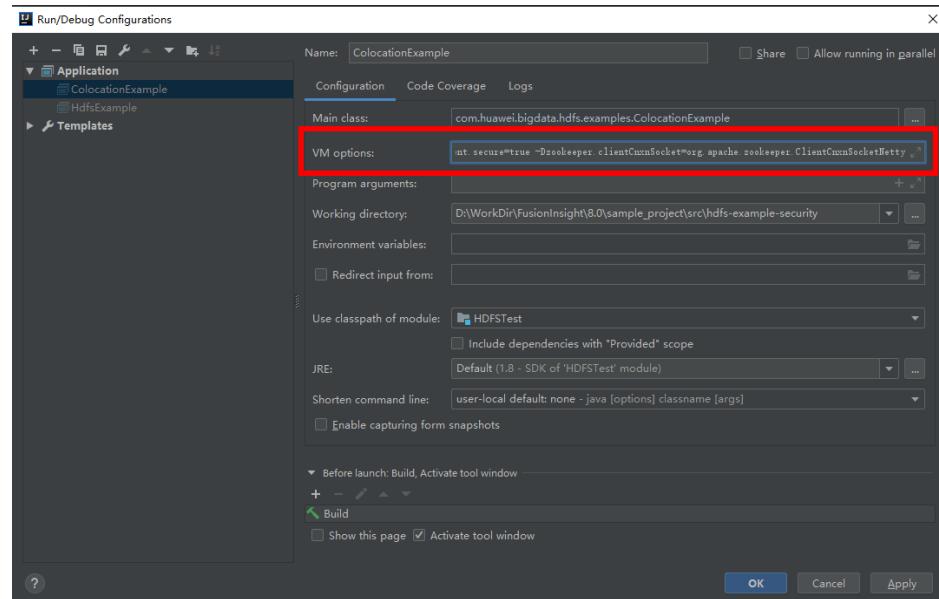

After the code development is complete, you can run an application in the Windows development environment.

If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

## Procedure

**Step 1** If SSL is enabled for the ZooKeeper in the cluster, the **ColocationExample sample** code needs to access the ZooKeeper. Therefore, you need to set the JVM parameter `-Dzookeeper.client.secure=true -Dzookeeper.clientCnxnSocket=org.apache.zookeeper.ClientCnxnSocketNetty` in the **Idea** compilation tool before running `ColocationExample.java`.

As shown in the following figure:

**Step 2** In a development environment (such as IntelliJ IDEA), choose the following two projects separately and run the projects:

- Choose **HdfsExample.java** and right-click the project and choose **Run 'HdfsExample.main()'** from the shortcut menu to run the project.
- Choose **ColocationExample.java** and right-click the project and choose **Run 'ColocationExample.main()'** from the shortcut menu to run the project.

### NOTE

- Do not restart HDFS service while HDFS application is in running status, otherwise the application will fail.
- When the Colocation project is run, the HDFS parameter `fs.defaultFS` cannot be set to `viewfs://ClusterX`.

----End

## Note

During security authentication, Hadoop needs to obtain the domain name of the host where the client is located (**Default Realm**, which is obtained from environment variable **USERDNSDOMAIN**). If the host does not have a domain name, the following error message is displayed when you run the sample program:

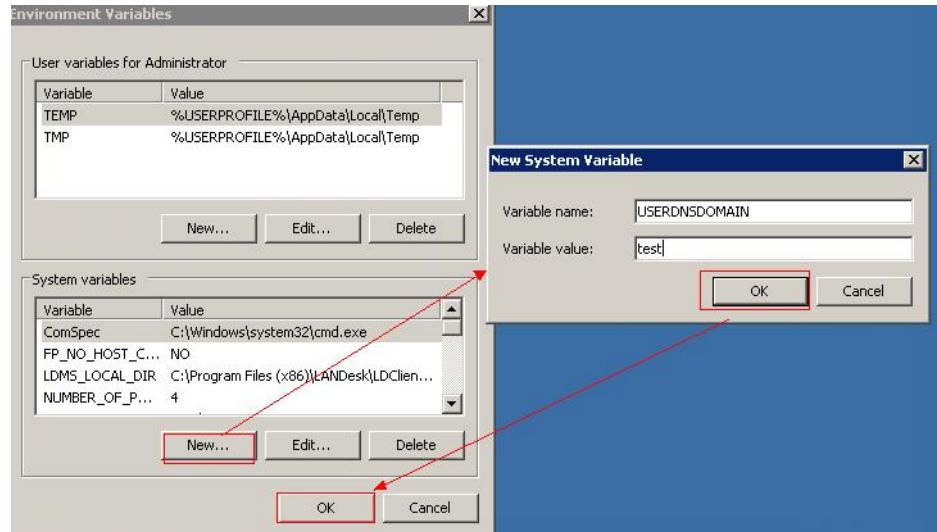

```

Exception in thread "main" java.lang.IllegalArgumentException: Can't get Kerberos realm
at org.apache.hadoop.security.HadoopKerberosName.setConfiguration(HadoopKerberosName.java:65)
at org.apache.hadoop.security.UserGroupInformation.initialize(UserGroupInformation.java:288)
at org.apache.hadoop.security.UserGroupInformation.ensureInitialized(UserGroupInformation.java:273)
at org.apache.hadoop.security.UserGroupInformation.loginUserFromSubject(UserGroupInformation.java:832)
at org.apache.hadoop.security.UserGroupInformation.getLoginUser(UserGroupInformation.java:802)
at org.apache.hadoop.security.UserGroupInformation.getCurrentUser(UserGroupInformation.java:675)
at org.apache.hadoop.conf.Configuration$Resource.getRestrictParserDefault(Configuration.java:243)

at com.huawei.bigdata.hdfs.examples.HdfsExample.confLoad(HdfsExample.java:307)
at com.huawei.bigdata.hdfs.examples.HdfsExample.main(HdfsExample.java:277)
Caused by: java.lang.reflect.InvocationTargetException
at sun.reflect.NativeMethodAccessorImpl.invoke0(Native Method)
at sun.reflect.NativeMethodAccessorImpl.invoke(Unknown Source)
at sun.reflect.DelegatingMethodAccessorImpl.invoke(Unknown Source)
at java.lang.reflect.Method.invoke(Unknown Source)
at org.apache.hadoop.security.authentication.util.KerberosUtil.getDefaultRealm(KerberosUtil.java:88)
at org.apache.hadoop.security.HadoopKerberosName.setConfiguration(HadoopKerberosName.java:63)
... 11 more
Caused by: KrbException: Cannot locate default realm
at sun.security.krb5.Config.getDefaultRealm(Unknown Source)
... 17 more

```

You can set environment variable **USERDNSDOMAIN** of the system to prevent this problem. The details are as follows:

1. Right-click **Computer** and choose **Properties** from the shortcut menu. The dialog box shown in the following figure is displayed. Click **Advanced system settings > Advanced > Environment Variables**.
2. Set the system environment variable and click "New". The New System Variable dialog box is displayed. Enter **USERDNSDOMAIN** in Variable name and set the Variable value to a non-null character string, for example, test. Click OK twice. The system environment variable is set.

3. Close the sample project, open it again, and run it.

#### 1.11.4.1.2 Checking the Commissioning Result

##### Scenario

After an HDFS application is run, you can learn the application running conditions by viewing the running result or HDFS logs.

##### Procedure

- Learn the application running conditions by viewing the running result.

- The running result of the HDFS windows example application is shown as follows:

```
1308 [main] INFO org.apache.hadoop.security.UserGroupInformation - Login successful for user hdfsDeveloper using keytab file
1308 [main] INFO com.huawei.hadoop.security.LoginUtil - Login success!!!!!!!!!!!!!!
2040 [main] WARN org.apache.hadoop.hdfs.shortcircuit.DomainSocketFactory - The short-circuit local reads feature cannot be used because UNIX Domain sockets are not available on Windows.
3006 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to create path /user/hdfs-examples
3131 [main] WARN org.apache.hadoop.util.NativeCodeLoader - Unable to load native-hadoop library for your platform... using builtin-java classes where applicable
3598 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to write.
4408 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to append.
5015 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - result is : hi, I am bigdata. It is successful if you can see me.I append this content.
5015 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to read.
5077 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete the file /user/hdfs-examples\test.txt
5186 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete path /user/hdfs-examples
5311 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to create path /user/hdfs-examples/hdfs_example_0
5311 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to create path /user/hdfs-examples/hdfs_example_1
5669 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to write.
5669 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to write.
7258 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to append.
7741 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to append.
7896 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - result is : hi, I am bigdata. It is successful if you can see me.I append this content.
7896 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to read.
7959 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete the file /user/hdfs-examples/hdfs_example_1\test.txt
8068 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete path /user/hdfs-examples/hdfs_example_1
8364 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - result is : hi, I am bigdata. It is successful if you can see me.I append this content.
8364 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to read.
8426 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete the file /user/hdfs-examples/hdfs_example_0\test.txt
8535 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete path /user/hdfs-examples/hdfs_example_0
```

### NOTE

In the Windows environment, the following exception occurs but does not affect services.

```
java.io.IOException: Could not locate executable null\bin\winutils.exe in the Hadoop binaries.
```

- The running result of the Colocation windows example application is shown as follows:

```
...
945 [main] INFO org.apache.hadoop.security.UserGroupInformation - Login successful for user hdfsDeveloper using keytab file user.keytab
945 [main] INFO com.huawei.hadoop.security.LoginUtil - Login success!!!!!!!!!!!!!!
945 [main] INFO com.huawei.hadoop.security.LoginUtil - JaasConfiguration loginContextName=Client principal=hdfsDeveloper useTicketCache=false keytabFile=XXX \sample_project\src\hdfs-example-security\conf\user.keytab
946 [main] INFO com.huawei.hadoop.security.KerberosUtil - Get default realm successfully, the realm is : HADOOP.COM
```

```
...
Create Group has finished.
Put file is running...

Delete Group is running...
Delete Group has finished.
4946 [main-EventThread] INFO org.apache.zookeeper.ClientCnxn - EventThread shut down for
connection: 0x440751cb41a4d415
4946 [main] INFO org.apache.zookeeper.ZooKeeper - Connection: 0x440751cb41a4d415 closed
...
```

- **Learn the application running conditions by viewing HDFS logs.**  
The NameNode logs of HDFS offer immediate visibility into application running conditions. You can adjust application programs based on the logs.

## 1.11.4.2 Commissioning an Application in the Linux Environment

### 1.11.4.2.1 Compiling and Running an Application With the Client Installed

#### Scenario

The Hadoop distributed file system (HDFS) application can run in the Linux operating system (OS) with the HDFS client installed. After the application code has been developed, you can upload the jar packages to the HDFS client and run the application.

#### Prerequisite

- The HDFS client has been installed.
- When the host where the Linux OS runs is not a node of the cluster, you are required to set the mapping between the host name and IP address in the **hosts** file of the node where the client is installed. The host name must be correctly mapped to the IP address.

#### Procedure

**Step 1** Go to the local root directory of the project, copy the required configuration file to the conf folder of the local project, and run the following command in Windows cmd to compress the package:

**mvn -s "{maven\_setting\_path}" clean package**

##### NOTE

- In the preceding command, {maven\_setting\_path} is the path of the **settings.xml** file of the local Maven.
- After the package is successfully packed, obtain the JAR package, for example, **HDFSTest-XXX.jar**, from the **target** subdirectory in the root directory of the project. The name of the JAR package varies according to the actual package.

**Step 2** Upload the exported jarpackages to any directory in the running environment of the client, for example, **/opt/hadoopclient**.

**Step 3** Configure the environment variables:

**cd /opt/hadoopclient**

**source bigdata\_env**

**Step 4** Run the following commands to execute the jar packages.

**hadoop jar HDFSTest-XXX.jar com.huawei.bigdata.hdfs.examples.HdfsExample**

**hadoop jar HDFSTest-XXX.jar  
com.huawei.bigdata.hdfs.examples.ColocationExample**

When **com.huawei.bigdata.hdfs.examples.ColocationExample** is run, the HDFS parameter **fs.defaultFS** cannot be set to **viewfs://ClusterX**.

----End

#### 1.11.4.2.2 Compiling and Running an Application With the Client Not Installed

##### Scenario

The Hadoop distributed file system (HDFS) application can run in the Linux operating system (OS) with the HDFS client not installed. After the application code has been developed, you can upload the jar packages to the Linux OS and run the application.

##### Prerequisite

- A JDK has been installed in the Linux environment. The version of the JDK must be consistent with that of the JDK used by IDEA to export the JAR package.
- When the host where the Linux OS runs is not a node of the cluster, you are required to set the mapping between the host name and IP address in the **hosts** file of the node where the Linux OS runs. The host name must be correctly mapped to the IP address.

##### Procedure

**Step 1** Go to the local root directory of the project, copy the required configuration file to the conf folder of the local project and run the following command in Windows cmd to compress the package:

**mvn -s "{maven\_setting\_path}" clean package**

- In the preceding command, {maven\_setting\_path} is the path of the **settings.xml** file of the local Maven.
- After the package is successfully packed, obtain the JAR package from the target subdirectory in the root directory of the project.

**Step 2** Upload the exported jar packages to any directory in the running environment of the Linux OS, for example, **/opt/hadoop\_client**.

**Step 3** Upload the **lib** and **conf** folders of the project to the same directory that stores the jar packages (the **lib** Create a **lib** folder in the Linux operating environment directory (for example, **/opt/hadoopclient**) and upload the required **JAR**

packages. The **lib** folder contains all the JAR packages that the project depends on. For details, see section [Preparing an Operating Environment](#).

**Step 4** Run the following commands to execute the jar packages.

```
java -cp HDFSTest-XXX.jar:conf/:lib/*
com.huawei.bigdata.hdfs.examples.HdfsExample
```

```
java -cp HDFSTest-XXX.jar:conf/:lib/*
com.huawei.bigdata.hdfs.examples.ColocationExample
```

#### NOTE

When **com.huawei.bigdata.hdfs.examples.ColocationExample** is run, the HDFS parameter **fs.defaultFS** cannot be set to **viewfs://ClusterX**.

If SSL is enabled for the ZooKeeper in the cluster, the sample code **ColocationExample** needs to access the ZooKeeper. Therefore, you need to add ZooKeeper SSL-related parameters to the command line.

```
java -cp HDFSTest-XXX.jar:conf/:lib/* -Dzookeeper.client.secure=true -
Dzookeeper.clientCnxnSocket=org.apache.zookeeper.ClientCnxnSocketNetty
com.huawei.bigdata.hdfs.examples.ColocationExample
```

----End

### 1.11.4.2.3 Checking the Commissioning Result

#### Scenario

After an HDFS application is run, you can learn the application running conditions by viewing the running result or HDFS logs.

#### Procedure

- **Learn the application running conditions by viewing the running result.**

- The running result of the HDFS example application is shown as follows:  
0 [main] INFO org.apache.hadoop.security.UserGroupInformation - Login successful for user hdfsDevelop using keytab file user:keytab  
1 [main] INFO com.huawei.hadoop.security.LoginUtil - Login success!!!!!!!!!!!!!!  
568 [main] WARN org.apache.hadoop.util.NativeCodeLoader - Unable to load native-hadoop library for your platform... using builtin-java classes where applicable  
582 [main] WARN org.apache.hadoop.hdfs.shortcircuit.DomainSocketFactory - The short-circuit local reads feature cannot be used because libhadoop cannot be loaded.  
793 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to create path / user/hdfs-examples  
969 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to write.  
1068 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to append.  
1191 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - result is : hi, I am bigdata. It is successful if you can see me.I append this content.  
1191 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to read.  
1202 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete the file / user/hdfs-examples/test.txt  
1210 [main] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to delete path / user/hdfs-examples  
1223 [hdfs\_example\_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to create path /user/hdfs-examples/hdfs\_example\_0  
1224 [hdfs\_example\_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to create path /user/hdfs-examples/hdfs\_example\_1  
1261 [hdfs\_example\_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to write.  
1264 [hdfs\_example\_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to write.  
2807 [hdfs\_example\_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to

```
append.  
2810 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
append.  
2861 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - result is : hi, I  
am bigdata. It is successful if you can see me.I append this content.  
2861 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
read.  
2866 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
delete the file /user/hdfs-examples/hdfs_example_0/test.txt  
2874 [hdfs_example_0] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
delete path /user/hdfs-examples/hdfs_example_0  
2874 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - result is : hi, I  
am bigdata. It is successful if you can see me.I append this content.  
2874 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
read.  
2879 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
delete the file /user/hdfs-examples/hdfs_example_1/test.txt  
2885 [hdfs_example_1] INFO com.huawei.bigdata.hdfs.examples.HdfsExample - success to  
delete path /user/hdfs-examples/hdfs_example_1
```

- The running result of the Colocation example application is shown as follows:

```
0 [main] INFO com.huawei.hadoop.security.LoginUtil - JaasConfiguration  
loginContextName=Client principal=hdfsDevelop useTicketCache=false keytabFile=/opt/  
hdfsDemo/conf/user.keytab  
817 [main] INFO org.apache.hadoop.security.UserGroupInformation - Login successful for user  
hdfsDevelop using keytab file user.keytab  
817 [main] INFO com.huawei.hadoop.security.LoginUtil - Login success!!!!!!!!!!!!!!  
1380 [main] WARN org.apache.hadoop.util.NativeCodeLoader - Unable to load native-hadoop  
library for your platform... using builtin-java classes where applicable  
...  
Create Group has finished.  
Put file is running...  
Put file has finished.  
Delete file is running...  
Delete file has finished.  
Delete Group is running...  
Delete Group has finished.  
...
```

- **Learn the application running conditions by viewing HDFS logs.**

The namenode logs of HDFS offer immediate visibility into application running conditions. You can adjust application programs based on the logs.

## 1.11.5 More Information

### 1.11.5.1 Common API Introduction

#### 1.11.5.1.1 Java API

For details about Hadoop distributed file system (HDFS) APIs, see:

<http://hadoop.apache.org/docs/r3.3.1/api/index.html>

#### HDFS Common API

Common HDFS Java classes are as follows:

- **FileSystem:** the core class of client applications. For details about common APIs, see [Table 1-96](#).
- **FileStatus:** record the status of files and directories. For details about common APIs, see [Table 1-97](#).

- DFSColocationAdmin: API used to manage colocation group information. For details about common APIs, see [Table 1-98](#).
- DFSColocationClient: API used to manage colocation files. For details about common APIs, see [Table 1-99](#).

 NOTE

- The system reserves only the mapping between nodes and locator IDs, but does not reserve the mapping between files and locator IDs. When a file is created using a Colocation interface, the file is created on the node that corresponds to a locator ID. File creation and writing must be performed using Colocation interfaces.
- After the file is written, subsequent operations on the file can use other open-source interfaces in addition to Colocation interfaces.
- The DFSColocationClient class inherits from the open-source DistributedFileSystem class and contains common file operation functions. If a user uses the DFSColocationClient class to create a Colocation file, the user is advanced to use the functions of this class in file operations.

**Table 1-96** Common FileSystem APIs

API	Description
public static FileSystem get(Configuration conf)	FileSystem is the API class provided for users in the Hadoop class library. FileSystem is an abstract class. Concrete classes can be obtained only using the get method. The get method has multiple overload versions and is commonly used.
public FSDataOutputStream create(Path f)	This API is used to create files in the HDFS. <i>f</i> indicates a complete file path.
public void copyFromLocalFile(Pat h src, Path dst)	This API is used to upload local files to a specified directory in the HDFS. <i>src</i> and <i>dst</i> indicate complete file paths.
public boolean mkdirs(Path f)	This API is used to create folders in the HDFS. <i>f</i> indicates a complete folder path.
public abstract boolean rename(Path src, Path dst)	This API is used to rename a specified HDFS file. <i>src</i> and <i>dst</i> indicate complete file paths.
public abstract boolean delete(Path f, boolean recursive)	This API is used to delete a specified HDFS file. <i>f</i> indicates the complete path of the file to be deleted, and <b>recursive</b> specifies recursive deletion.
public boolean exists(Path f)	This API is used to query a specified HDFS file. <i>f</i> indicates a complete file path.
public FileStatus getFileStatus(Path f)	This API is used to obtain the FileStatus object of a file or folder. The FsStatus object records status information of the file or folder, including the modification time and file directory.

API	Description
public BlockLocation[] getFileBlockLocations(FileStatus file, long start, long len)	This API is used to query the block location of a specified file in an HDFS cluster. <i>file</i> indicates a complete file path, and <i>start</i> and <i>len</i> specify the block scope.
public FSDataInputStream open(Path f)	This API is used to open the output stream of a specified file in the HDFS and read the file using the API provided by the FSDataInputStream class. <i>f</i> indicates a complete file path.
public FSDataOutputStream create(Path f, boolean overwrite)	This API is used to create the input stream of a specified file in the HDFS and write the file using the API provided by the FSDataOutputStream class. <i>f</i> indicates a complete file path. If <b>overwrite</b> is <b>true</b> , the file is rewritten if it exists; if <b>overwrite</b> is <b>false</b> , an error is reported if the file exists.
public FSDataOutputStream append(Path f)	This API is used to open the input stream of a specified file in the HDFS and write the file using the API provided by the FSDataOutputStream class. <i>f</i> indicates a complete file path.

**Table 1-97** Common FileStatus APIs

API	Description
public long getModificationTime()	This API is used to query the modification time of a specified HDFS file.
public Path getPath()	This API is used to query all files in an HDFS directory.

**Table 1-98** Common DFSColocationAdmin APIs

API	Description
public Map<String, List<DatanodeInfo>> createColocationGroup(String groupId, String file)	This API is used to create a group based on the locatorIds information in the file. <i>file</i> indicates the file path.
public Map<String, List<DatanodeInfo>> createColocationGroup(String groupId, List<String> locators)	This API is used to create a group based on the locatorIds information in the list in the memory.
public void deleteColocationGroup(String groupId)	This API is used to delete a group.

API	Description
public List<String> listColocationGroups()	This API is used to return all group information of Colocation. The returned group ID arrays are sorted by the creation time.
public List<DatanodeInfo> getNodesForLocator(String groupID, String locatorID)	This API is used to obtain the list of all nodes in the locator.

**Table 1-99** Common DFSColocationAdmin APIs

API	Description
public FSDataOutputStream create(Path f, boolean overwrite, String groupID, String locatorID)	This API is used to create a FSDataOutputStream in colocation mode to allow users to write files in f.  f is the HDFS path.  overwrite indicates whether an existing file can be overwritten.  groupID and locatorID of the file specified by a user must exist.
public FSDataOutputStream create(final Path f, final FsPermission permission, final EnumSet<CreateFlag> cflags, final int bufferSize, final short replication, final long blockSize, final Progressable progress, final ChecksumOpt checksumOpt, final String groupID, final String locatorID)	The function of this API is the same as that of FSDataOutputStream create(Path f, boolean overwrite, String groupID, String locatorID), except that users are allowed to customize checksum.
public void close()	This API is used to close the connection.

**Table 1-100** HDFS client WebHdfsFileSystem API

API	Description
public Remotelterator<FileSta- tus> listStatusItera- tor(final Path)	This API will help in fetching the child files and folders information through multiple requests using remote iterator, thus avoiding the user interface from becoming slow when there is a large amount of child information to be fetched.

## Glob path pattern based API to get LocatedFileStatus and Open file from FileStatus

Following APIs are added in DistributedFileSystem to get the FileStatus with block location and open file from FileStatus object. These APIs will reduce the number of RPC calls from client to Namenodes.

**Table 1-101** FileSystem APIs

Interface	Description
public LocatedFileStatus[] globLocatedStatus(Path, PathFilter, boolean) throws IOException	Return an array of LocatedFileStatus objects whose path names match pathPattern and pass the in path filter.
public FSDataInputStream open(FileStatus stat) throws IOException	If the stat is an instance of LocatedFileStatusHdfs that already have the location information, the InputStream is created without contacting NameNode.

### 1.11.5.1.2 C API

#### Function Description

Users can use the C application programming interface (API) to create, read and write, append, and delete files. For details of the C API, see the following official guidelines:

<http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-hdfs/LibHdfs.html>

#### Code Sample

The following code snippets are used as an example. For complete code, see the HDFS C sample code **HDFS/hdfs-c-example/hdfs\_test.c** in the HDFS sample code decompression directory.

1. Configure the HDFS NameNode parameter and create the link connecting to the HDFS files.

```
hdfsFS fs = hdfsConnect("default", 0);
fprintf(stderr, "hdfsConnect- SUCCESS!\n");
```

2. Create the HDFS directory.

```
const char* dir = "/tmp/nativeTest";
int exitCode = hdfsCreateDirectory(fs, dir);
if( exitCode == -1 ){
    fprintf(stderr, "Failed to create directory %s \n", dir );
    exit(-1);
}
fprintf(stderr, "hdfsCreateDirectory- SUCCESS! : %s\n", dir);
```

3. Write files.

```
const char* file = "/tmp/nativeTest/testfile.txt";
hdfsFile writeFile = openFile(fs, (char*)file, O_WRONLY | O_CREAT, 0, 0, 0);
fprintf(stderr, "hdfsOpenFile- SUCCESS! for write : %s\n", file);
```

```

if(!hdfsFileIsOpenForWrite(writeFile)){
    fprintf(stderr, "Failed to open %s for writing.\n", file);
    exit(-1);
}

char* buffer = "Hadoop HDFS Native file write!";

hdfsWrite(fs, writeFile, (void*)buffer, strlen(buffer)+1);
fprintf(stderr, "hdfsWrite- SUCCESS! : %s\n", file);

printf("Flushing file data ....\n");
if (hdfsFlush(fs, writeFile)) {
    fprintf(stderr, "Failed to 'flush' %s\n", file);
    exit(-1);
}
hdfsCloseFile(fs, writeFile);
fprintf(stderr, "hdfsCloseFile- SUCCESS! : %s\n", file);

```

**4. Read files.**

```

hdfsFile readFile = openFile(fs, (char*)file, O_RDONLY, 100, 0, 0);
fprintf(stderr, "hdfsOpenFile- SUCCESS! for read : %s\n", file);

if(!hdfsFileIsOpenForRead(readFile)){
    fprintf(stderr, "Failed to open %s for reading.\n", file);
    exit(-1);
}

buffer = (char *) malloc(100);
tSize num_read = hdfsRead(fs, readFile, (void*)buffer, 100);
fprintf(stderr, "hdfsRead- SUCCESS!, Byte read : %d, File content : %s \n", num_read ,buffer);
hdfsCloseFile(fs, readFile);

```

**5. From the specified location to read the file.**

```

buffer = (char *) malloc(100);
readFile = openFile(fs, file, O_RDONLY, 100, 0, 0);
if (hdfsSeek(fs, readFile, 10)) {
    fprintf(stderr, "Failed to 'seek' %s\n", file);
    exit(-1);
}
num_read = hdfsRead(fs, readFile, (void*)buffer, 100);
fprintf(stderr, "hdfsSeek- SUCCESS!, Byte read : %d, File seek content : %s \n", num_read ,buffer);
hdfsCloseFile(fs, readFile);

```

**6. Copy the file.**

```

const char* destfile = "/tmp/nativeTest/testfile1.txt";
if (hdfsCopy(fs, file, fs, destfile)) {
    fprintf(stderr, "File copy failed, src : %s, des : %s \n", file, destfile);
    exit(-1);
}
fprintf(stderr, "hdfsCopy- SUCCESS!, File copied, src : %s, des : %s \n", file, destfile);

```

**7. Move the file.**

```

const char* mvfile = "/tmp/nativeTest/testfile2.txt";
if (hdfsMove(fs, destfile, fs, mvfile )) {
    fprintf(stderr, "File move failed, src : %s, des : %s \n", destfile , mvfile);
    exit(-1);
}
fprintf(stderr, "hdfsMove- SUCCESS!, File moved, src : %s, des : %s \n", destfile , mvfile);

```

**8. Rename the file.**

```

const char* renamefile = "/tmp/nativeTest/testfile3.txt";
if (hdfsRename(fs, mvfile, renamefile)) {
    fprintf(stderr, "File rename failed, Old name : %s, New name : %s \n", mvfile, renamefile);
    exit(-1);
}
fprintf(stderr, "hdfsRename- SUCCESS!, File renamed, Old name : %s, New name : %s \n", mvfile, renamefile);

```

**9. Delete Files.**

```

if (hdfsDelete(fs, renamefile, 0)) {
    fprintf(stderr, "File delete failed : %s \n", renamefile);
    exit(-1);
}

```

```

    }
    fprintf(stderr, "hdfsDelete- SUCCESS!, File deleted : %s\n", renamefile);
}

10. Set the number of replications.
if (hdfsSetReplication(fs, file, 10)) {
    fprintf(stderr, "Failed to set replication : %s \n", file );
    exit(-1);
}
fprintf(stderr, "hdfsSetReplication- SUCCESS!, Set replication 10 for %s\n",file);

11. Set users, user groups.
if (hdfsChown(fs, file, "root", "root")) {
    fprintf(stderr, "Failed to set chown : %s \n", file );
    exit(-1);
}
fprintf(stderr, "hdfsChown- SUCCESS!, Chown success for %s\n",file);

12. Set permissions.
if (hdfsChmod(fs, file, S_IRWXU | S_IRWXG | S_IROTH)) {
    fprintf(stderr, "Failed to set chmod: %s \n", file );
    exit(-1);
}
fprintf(stderr, "hdfsChmod- SUCCESS!, Chmod success for %s\n",file);

13. Set the file time.
struct timeval now;
gettimeofday(&now, NULL);
if (hdfsUtime(fs, file, now.tv_sec, now.tv_usec)) {
    fprintf(stderr, "Failed to set time: %s \n", file );
    exit(-1);
}
fprintf(stderr, "hdfsUtime- SUCCESS!, Set time success for %s\n",file);

14. Get file information.
hdfsFileInfo *fileInfo = NULL;
if((fileInfo = hdfsGetPathInfo(fs, file)) != NULL) {
    printFileInfo(fileInfo);
    hdfsFreeFileInfo(fileInfo, 1);
    fprintf(stderr, "hdfsGetPathInfo - SUCCESS!\n");
}

15. Variable directory.
hdfsFileInfo *fileList = 0;
int numEntries = 0;
if((fileList = hdfsListDirectory(fs, dir, &numEntries)) != NULL) {
    int i = 0;
    for(i=0; i < numEntries; ++i) {
        printFileInfo(fileList+i);
    }
    hdfsFreeFileInfo(fileList, numEntries);
}
fprintf(stderr, "hdfsListDirectory- SUCCESS!, %s\n", dir);

16. Stream builder interfaces.
buffer = (char *) malloc(100);
struct hdfsStreamBuilder *builder= hdfsStreamBuilderAlloc(fs, (char*)file, O_RDONLY);
hdfsStreamBuilderSetBufferSize(builder,100);
hdfsStreamBuilderSetReplication(builder,20);
hdfsStreamBuilderSetDefaultBlockSize(builder,10485760);
readFile = hdfsStreamBuilderBuild(builder);
num_read = hdfsRead(fs, readFile, (void*)buffer, 100);
fprintf(stderr, "hdfsStreamBuilderBuild- SUCCESS! File read success. Byte read : %d, File content : %s
\n", num_read ,buffer);
free(buffer);

struct hdfsReadStatistics *stats = NULL;
hdfsFileGetReadStatistics(readFile, &stats);
fprintf(stderr, "hdfsFileGetReadStatistics- SUCCESS! totalBytesRead : %" PRId64 ",
totalLocalBytesRead : %" PRId64 ", totalShortCircuitBytesRead : %" PRId64 ",
totalZeroCopyBytesRead : %" PRId64 "\n", stats->totalBytesRead , stats->totalLocalBytesRead, stats-
>totalShortCircuitBytesRead, stats->totalZeroCopyBytesRead);
hdfsFileFreeReadStatistics(stats);

```

17. Disconnect the HDFS links.  
`hdfsDisconnect(fs);`

## Preparing Running Environment

Install a client on the node. For example, install a client in the **/opt/hadoopclient** directory.

## Compiling and Running Applications in Linux

1. Go to the **/opt/hadoopclient** directory and run the following command to import the environment variables of the C client:

```
cd /opt/hadoopclient  
source bigdata_env
```

2. In the directory, run the following command as the hdfs user. For the user password, contact the cluster administrator.

```
kinit hdfs
```

The validity duration of kinit authentication is 24 hours. After 24 hours, you need to re-authenticate the sample with the kinit to restart the sample.

3. Go to the **/opt/hadoopclient/HDFS/hadoop/hdfs-c-example** directory and run the following command to import the environment variables of the C client:

```
cd /opt/hadoopclient/HDFS/hadoop/hdfs-c-example  
source component_env_C_example
```

4. Run the following command to clean the object files and executable files that are generated before:

```
make clean
```

The running result is displayed as follows:

```
[root@10-120-85-2 hdfs-c-example]# make clean  
rm -f hdfs_test.o  
rm -f hdfs_test
```

5. Run the following command to compile the new object files and executable files:

```
make (or make all)
```

The running result is displayed as follows:

```
[root@10-120-85-2 hdfs-c-example]# make  
cc -c -I/opt/hadoopclient/HDFS/hadoop/include -Wall -o hdfs_test.o hdfs_test.c  
cc -o hdfs_test hdfs_test.o -lhdfs
```

6. Run the following command to create, write, read, append, and delete files:

```
make run
```

The running result is displayed as follows:

```
[root@10-120-85-2 hdfs-c-example]# make run  
.hdfs_test  
hdfsConnect- SUCCESS!  
hdfsCreateDirectory- SUCCESS! : /tmp/nativeTest  
hdfsOpenFile- SUCCESS! for write : /tmp/nativeTest/testfile.txt  
hdfsWrite- SUCCESS! : /tmp/nativeTest/testfile.txt  
Flushing file data ....  
hdfsCloseFile- SUCCESS! : /tmp/nativeTest/testfile.txt
```

```
hdfsOpenFile- SUCCESS! for read : /tmp/nativeTest/testfile.txt
hdfsRead- SUCCESS!, Byte read : 31, File content : Hadoop HDFS Native file write!
hdfsSeek- SUCCESS!, Byte read : 21, File seek content : S Native file write!
hdfsPread- SUCCESS!, Byte read : 10, File read content : S Native f
hdfsCopy- SUCCESS!, File copied, src : /tmp/nativeTest/testfile.txt, des : /tmp/nativeTest/testfile1.txt
hdfsMove- SUCCESS!, File moved, src : /tmp/nativeTest/testfile1.txt, des : /tmp/nativeTest/testfile2.txt
hdfsRename- SUCCESS!, File renamed, Old name : /tmp/nativeTest/testfile2.txt, New name : /tmp/
nativeTest/testfile3.txt
hdfsDelete- SUCCESS!, File deleted : /tmp/nativeTest/testfile3.txt
hdfsSetReplication- SUCCESS!, Set replication 10 for /tmp/nativeTest/testfile.txt
hdfsChown- SUCCESS!, Chown success for /tmp/nativeTest/testfile.txt
hdfsChmod- SUCCESS!, Chmod success for /tmp/nativeTest/testfile.txt
hdfsUtime- SUCCESS!, Set time success for /tmp/nativeTest/testfile.txt

Name: hdfs://hacluster/tmp/nativeTest/testfile.txt, Type: F, Replication: 10, BlockSize: 134217728, Size:

totalShortCircuitBytesRead : 0, totalZeroCopyBytesRead : 0
```

## 7. Enter the debug mode (optional)

**make gdb**

The running result is displayed as follows:

```
[root@10-120-85-2 hdfs-c-example]# make gdb
gdb hdfs_test

(gdb)
```

### 1.11.5.1.3 HTTP REST API

#### Function Description

Users can use the application programming interface (API) of Representational State Transfer (REST) to create, read and write, append, and delete files. For details of the REST API, see the following official guidelines:

<http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-hdfs/WebHDFS.html>.

## Preparing Running Environment

**Step 1** Install the client. Install the client on the node. For example, install the client in the `/opt/hadoopclient` directory.

1. Run the following command to for the user authentication. In the command, the hdfs is taken as an example and can be defined by users.

**kinit hdfs**

### NOTE

The validity duration of kinit authentication is 24 hours. After 24 hours, you need to re-authenticate the sample with the kinit to restart the sample.

2. Prepare files **testFile** and **testFileAppend** and write content 'Hello, webhdfs user!' and 'Welcome back to webhdfs!'. Run the following command to prepare **testFile** and **testFileAppend** files:

**touch testFile**

**vi testFile**

```
Hello, webhdfs user!
```

**touch testFileAppend**

**vi testFileAppend**

```
Welcome back to webhdfs!
```

**Step 2** The MRS cluster supports only the HTTPS access by default. If access by using the HTTPS service, perform **Step 3**. If access by using the HTTP service, perform **Step 4**.

**Step 3** HTTPS-based access is different from HTTP-based access. When you access HDFS using HTTPS, you must ensure that the SSL protocol supported by the **curl** command is supported by the cluster because SSL security encryption is used. If the cluster does not support the SSL protocol, change the SSL protocol in the cluster. For example, if the **Curl** command only supports the TLSv1 protocol, modify the protocol configuration performing following measures:

Log in to FusionInsight Manager and choose **Cluster > Name of the desired cluster > Services > HDFS > Configurations > All Configurations**. Type **hadoop.ssl.enabled.protocols** in the research box, check whether the parameter value contains **TLSv1**. If the parameter value does not contain **TLSv1**, add **TLSv1** in the **hadoop.ssl.enabled.protocols** configuration item, and clear the value of **ssl.server.exclude.cipher.list**. Otherwise, HDFS cannot be accessed by using HTTPS. Then click **Save** and click **More > Restart Service** to restart the HDFS service.

TLSv1 has security vulnerabilities. Exercise caution when using it.

**Step 4** [Accessing FusionInsight Manager of an MRS Cluster](#), choose **Cluster > Name of the desired cluster > Services > HDFS > Configurations > All Configurations**. Type **dfs.http.policy** in the research box, select **HTTP\_AND\_HTTPS**, click **Save**, and select **More >Restart Service** to restart the HDFS service.

----End

## Procedure

**Step 1** Accessing FusionInsight Manager of an MRS Cluster, click **Cluster > Name of the desired cluster > Services**, and then select **HDFS**. The HDFS page is displayed.

Because webhdfs is accessed through HTTP/HTTPS, you need to obtain the IP address of the active NameNode and the HTTP/HTTPS port.

1. Click **Instance**, and in HDFS Instances page, view the host name and IP address of the active NameNode.
2. Click **Configurations**, and in HDFS Service Configuration page, find **namenode.https.port** (25002) and **namenode.https.port** (25003).

**Step 2** Create a directory by referring to the following link:

[http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-hdfs/WebHDFS.html#Make\\_a\\_Directory](http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-hdfs/WebHDFS.html#Make_a_Directory).

Click the link, **Figure 1-155** is displayed:

**Figure 1-155** Example code of creating a directory

The client receives a response with a boolean JSON object:

```
HTTP/1.1 200 OK
Content-Type: application/json
Transfer-Encoding: chunked
[{"boolean": true}]
```

Go to the **/opt/hadoopclient** directory, the installation directory of the client, and create the **huawei** directory.

1. Run the following command to check whether the **huawei** directory exists in the current path.

**hdfs dfs -ls /**

The running results are as follows:

```
linux1:/opt/hadoopclient # hdfs dfs -ls /
16/04/22 16:10:02 INFO hdfs.PeerCache: SocketCache disabled.
Found 7 items
-rw-r--r-- 3 hdfs supergroup      0 2016-04-20 18:03 /PRE_CREATE_DIR.SUCCESS
drwxr-x---  - flume hadoop       0 2016-04-20 18:02 /flume
drwx-----  - hbase hadoop      0 2016-04-22 15:19 /hbase
drwxrwxrwx   - mapred hadoop    0 2016-04-20 18:02 /mr-history
drwxrwxrwx   - spark supergroup 0 2016-04-22 15:19 /sparkJobHistory
drwxrwxrwx   - hdfs hadoop     0 2016-04-22 14:51 /tmp
drwxrwxrwx   - hdfs hadoop     0 2016-04-22 14:50 /user
```

The **huawei** directory does not exist in the current path.

2. Run the command in **Figure 1-155** that is named with **huawei**. Replace the <HOST> and <PORT> in the command with the host name or IP address and port number that are obtained in **Step 1**. Type the **huawei** as the directory in the <PATH>.

 NOTE

The <HOST> can be replaced by the host name or IP address. It is noted that the port of HTTP is different from the port of HTTPS.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -i -X PUT --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei?op=MKDIRS"
```

In the command, the <HOST> is replaced by linux 1 and the <PORT> is replaced by 25002.

- The running result is displayed as follows:

```
HTTP/1.1 401 Authentication required
Date: Thu, 05 May 2016 03:10:09 GMT
Pragma: no-cache

drwxrwxrwx - spark supergroup   0 2016-04-22 16:12 /sparkJobHistory
drwxrwxrwx - hdfs hadoop        0 2016-04-22 14:51 /tmp
drwxrwxrwx - hdfs hadoop        0 2016-04-22 16:10 /user
```

**Step 3** Create a command of the upload request to obtain the information about Location where the DataNode IP address is written in.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -i -X PUT --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/
testHdfs?op=CREATE"
```

- The running result is displayed as follows:

```
HTTP/1.1 401 Authentication required

ess=hacluster&overwrite=false"
```

- The running result is displayed as follows:

```
HTTP/1.1 100 Continue
HTTP/1.1 201 Created
Location: hdfs://hacluster/huawei/testHdfs
Content-Length: 0
Connection: close
```

**Step 5** Go to the **/huawei/testHdfs** directory and read the content of **testHdfs** file.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -L --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/testHdfs?
op=OPEN"
```

- The running result is displayed as follows:  
Hello, webhdfs user!
- Run the following command to access HTTPS:  
linux1:/opt/hadoopclient # curl -k -L --negotiate -u: "https://linux1:25003/webhdfs/v1/huawei/testHdfs?op=OPEN"
- The running result is displayed as follows:  
Hello, webhdfs user!

**Step 6** Create a command of the upload request to obtain the information about Location where the DataNode IP address of **testHdfs** file is written in.

- Run the following command to access HTTP:  
linux1:/opt/hadoopclient # curl -i -X POST --negotiate -u: "http://linux1:25002//webhdfs/v1/huawei/testHdfs?op=APPEND"

- The running result is displayed as follows:

ress=hacluster
```

**Step 7** According to the Location information, add the content in the local **testFileAppend** file to the **testHdfs** file that is in the **/huawei/testHdfs** directory of HDFS.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -i -X POST -T testFileAppend --negotiate -u: "http://linux1:250109864/
webhdfs/v1/huawei/testHdfs?
op=APPEND&delegation=HgAFYWRtaW4FYWRtaW4AigFUF2mGHooBVKN2Ch4KCBRzM3jwSMIAowXb
4dhqfKB5rT-8hJXRUIREZTIGRlbGVnYXRpb24UMTAuMTIwLjE3Mi4xMDk6MjUwMDAw&namenoderpcadd
ress=hacluster"
```

- The running result is displayed as follows:

```
HTTP/1.1 100 Continue
HTTP/1.1 200 OK
Content-Length: 0
Connection: close
```

- Run the following command to access HTTPS:

```
linux1:/opt/hadoopclient # curl -i -k -X POST -T testFileAppend --negotiate -u: "https://linux1:25011/
webhdfs/v1/huawei/testHdfs?
op=APPEND&delegation=HgAFYWRtaW4FYWRtaW4AigFUF1xi_4oBVKN0v8HCBS3Fg0f_EwtFKKLODK
QSM2t32CjhNTV0VCSERGUyBkZWxIz2F0aW9uFDEwLjEyMC4xNzluMTA5OjI1MDAw&namenoderpcadd
ress=hacluster"
```

- The running result is displayed as follows:

```
HTTP/1.1 100 Continue
HTTP/1.1 200 OK
Content-Length: 0
Connection: close
```

**Step 8** Go to the **/huawei/testHdfs** directory and read all content in the **testHdfs** file.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -L --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/testHdfs?
op=OPEN"
```

- The running result is displayed as follows:

```
Hello, webhdfs user!
Welcome back to webhdfs!
```

- Run the following command to access HTTPS:

```
linux1:/opt/hadoopclient # curl -k -L --negotiate -u: "https://linux1:25003/webhdfs/v1/huawei/
testHdfs?op=OPEN"
```

- The running result is displayed as follows:

```
Hello, webhdfs user!
Welcome back to webhdfs!
```

**Step 9** List details of all directory and file information in the **huawei** directory of the HDFS.

**LISTSTATUS** will return all child files and folders information in a single request.

- Run the following command to access HTTP.

```
linux1:/opt/hadoopclient # curl --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/testHdfs?op=LISTSTATUS"
```

- The result is displayed as follows:

```
{"FileStatuses":[{"FileStatus": [{"accessTime":1462425245595,"blockSize":134217728,"childrenNum":0,"fileId":17680,"group":"supergr oup","length":70,"modificationTime":1462426678379,"owner":"hdfs","pathSuffix":"","permission":"755","replication":3,"storagePolicy":0,"type":"FILE"}]}]
```

- Run the following command to access HTTPS.

```
linux1:/opt/hadoopclient # curl -k --negotiate -u: "https://linux1:25003/webhdfs/v1/huawei/testHdfs?op=LISTSTATUS"
```

- The result is displayed as follows:

```
{"FileStatuses":[{"FileStatus": [{"accessTime":1462425245595,"blockSize":134217728,"childrenNum":0,"fileId":17680,"group":"supergr oup","length":70,"modificationTime":1462426678379,"owner":"hdfs","pathSuffix":"","permission":"755","replication":3,"storagePolicy":0,"type":"FILE"}]}]
```

**LISTSTATUS** along with **size** and **startafter** param will help in fetching the child files and folders information through multiple requests, thus avoiding the user interface from becoming slow when there is a large amount of child information to be fetched.

- Run the following command to access HTTP.

```
linux1:/opt/hadoopclient # curl --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/?op=LISTSTATUS&startafter=sparkJobHistory&size=1"
```

- The result is displayed as follows:

```
{"FileStatuses":[{"FileStatus": [{"accessTime":1462425245595,"blockSize":134217728,"childrenNum":0,"fileId":17680,"group":"supergr oup","length":70,"modificationTime":1462426678379,"owner":"hdfs","pathSuffix":"testHdfs","permmissio n":"755","replication":3,"storagePolicy":0,"type":"FILE"}]}]
```

- Run the following command to access HTTPS.

```
linux1:/opt/hadoopclient # curl -k --negotiate -u: "https://linux1:25003/webhdfs/v1/huawei/?op=LISTSTATUS&startafter=sparkJobHistory&size=1"
```

- The result is displayed as follows:

```
{"FileStatuses":[{"FileStatus": [{"accessTime":1462425245595,"blockSize":134217728,"childrenNum":0,"fileId":17680,"group":"supergr oup","length":70,"modificationTime":1462426678379,"owner":"hdfs","pathSuffix":"testHdfs","permmissio n":"755","replication":3,"storagePolicy":0,"type":"FILE"}]}]
```

## Step 10 Delete the **testHdfs** file that is in the **/huawei/testHdfs** directory of HDFS.

- Run the following command to access HTTP:

```
linux1:/opt/hadoopclient # curl -i -X DELETE --negotiate -u: "http://linux1:25002/webhdfs/v1/huawei/testHdfs?op=DELETE"
```

- The running result is displayed as follows:

```
HTTP/1.1 401 Authentication required  
Date: Thu, 05 May 2016 05:54:37 GMT

----End

The Key Management Server (KMS) uses the HTTP REST API to provide key management services for external systems. For details about the API, see:

<https://hadoop.apache.org/docs/r3.3.1/hadoop-kms/index.html>.

As REST API reference has done security hardening to prevent script injection attack.  
Through REST API reference, it cannot create directory and file name which contain those key words "<script ", "<iframe", "<frame", "javascript:".

## 1.11.5.2 Shell Command Introduce

### HDFS Shell

You can use the Hadoop Distributed File System (HDFS) Shell command to perform operations on the HDFS, such as reading and writing files.

To run the HDFS Shell:

Go to the directory of HDFS client and enter the command. An example is shown as follows:

```
cd /opt/hadoopclient/HDFS/hadoop/bin
```

```
hdfs dfs -mkdir /tmp/input
```

You can run the following command to seek help about HDFS commands:

```
hdfs --help
```

For details about the shell, see

[http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-common/  
FileSystemShell.html](http://hadoop.apache.org/docs/r3.3.1/hadoop-project-dist/hadoop-common/FileSystemShell.html)

**Table 1-102** Transparent encryption-related commands

Scenario	Operation	Command	Description
hadoop shell command management key	Create keys.	<b><i>hadoop key create &lt;keyname&gt; [-cipher &lt;cipher&gt;] [-size &lt;size&gt;] [-description &lt;description&gt;] [-attr &lt;attribute=value&gt;] [-provider &lt;provider&gt;] [-help]</i></b>	The create subcommand creates a key for the name specified by the <keyname> argument within the provider specified by the -provider argument. You may specify a cipher with the -cipher argument.  The default keysize is 128. You may specify the requested key length using the -size argument. Arbitrary attribute=value style attributes may be specified using the -attr argument. The -attr may be specified for multiple times, once per attribute.
	Rollback	<b><i>hadoop key roll &lt;keyname&gt; [-provider &lt;provider&gt;] [-help]</i></b>	The roll subcommand creates a new version for the specified key within the provider indicated using the -provider argument.
	Delete keys	<b><i>hadoop key delete &lt;keyname&gt; [-provider &lt;provider&gt;] [-f] [-help]</i></b>	The delete subcommand deletes all versions of the key specified by the <keyname> argument within the provider specified by the -provider argument. The command asks for user confirmation unless -f is specified.
	View keys	<b><i>hadoop key list [-provider &lt;provider&gt;] [-metadata] [-help]</i></b>	The list subcommand displays the keynames contained in a particular provider as configured in core-site.xml or specified with the -provider argument. The -metadata argument displays the metadata.

**Table 1-103** Shell commands of Colocation client

Operation	Command	Description
Group creation	hdfs colocationadmin -createGroup -groupID <groupID> -locatorIDs <comma separated locatorIDs> or -file <path of the file contains all of locatorIDs>	Used to create a group. In the command, groupID is the group name and locatorID is the locator name. You can enter comma-separated locator IDs using command lines. You can also write locator IDs into a file so that the system can obtain the locator IDs by reading the file.
Group deletion	hdfs colocationadmin -deleteGroup <groupID>	Used to delete the specified group.
Group query	hdfs colocationadmin -queryGroup <groupID>	Used to query details about a specified group, including locators in the group and information about each locator and its corresponding DataNode.
Viewing all groups	hdfs colocationadmin -listGroups	Used to list all groups and their creation time.
Setting ACL permissions on Colocation directories	hdfs colocationadmin -setAcl	Used to set ACL permissions on Colocation directories in ZooKeeper. The default root directory of Colocation in ZooKeeper is <b>/hadoop/colocationDetails</b> .

## 1.12 HetuEngine Development Guide

### 1.12.1 Overview

### 1.12.1.1 Introduction to HetuEngine

#### Introduction to HetuEngine

HetuEngine is a high-performance interactive SQL analysis and data virtualization engine developed by Huawei. It seamlessly integrates with the big data ecosystem to implement interactive query of massive amounts of data within seconds, and supports cross-source and cross-domain unified data access to enable one-stop SQL convergence analysis in the data lake, between lakes, and between lakehouses.

### 1.12.1.2 Concepts

#### Basic Concepts

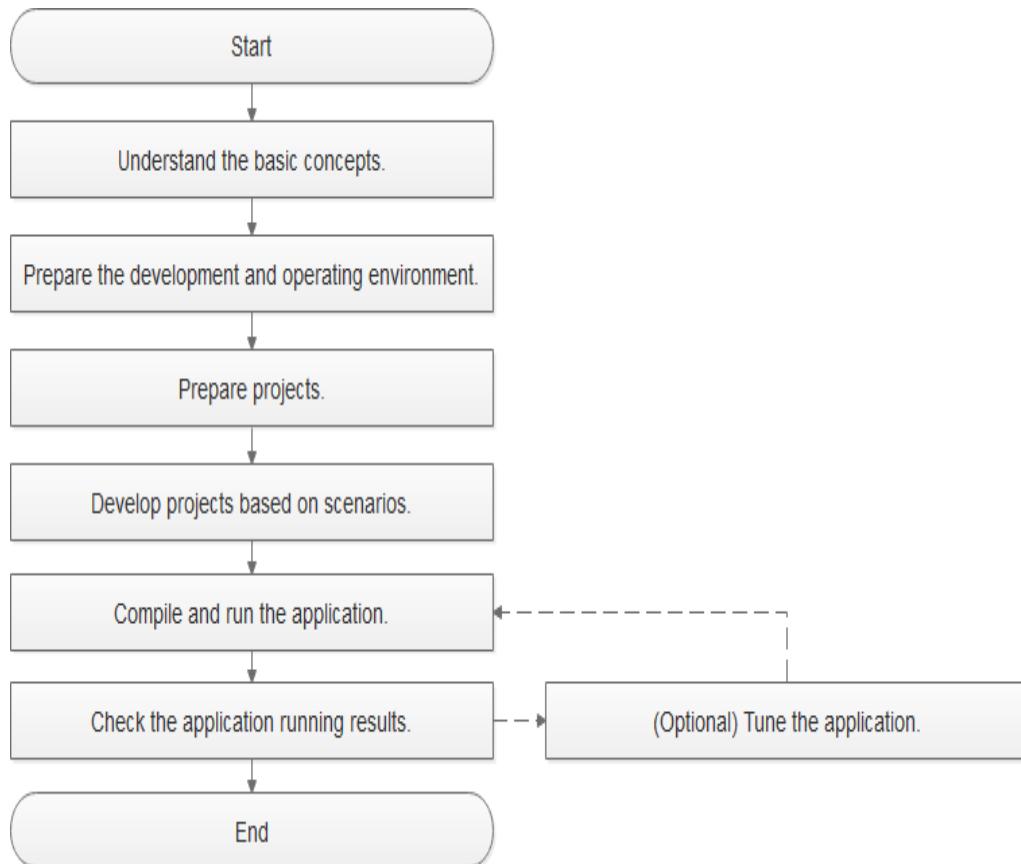

- HSFabric: unified entry for the HetuEngine services. It receives external requests and supports cross-network access to the HetuEngine services.
- HSBroker: service management of the HetuEngine services. It is used for resource management verification, health monitoring, and automatic maintenance of compute instances.
- Coordinator: coordinator of the HetuEngine services. It is responsible for SQL parsing and optimization.
- Worker: compute node of the HetuEngine compute instances. It executes tasks and processes data.
- Connector: an API for HetuEngine to access the database. Through the connector driver, HetuEngine connects to the data sources, reads data source metadata, and operates data (adding, deleting, modification, and query).
- Catalog: the catalog configuration file corresponds to a data source in HetuEngine. A data source can have multiple catalog configurations, which can be configured in the **properties** file of a data source.
- Schema: schema name of the database.
- Table: table name of the database.

### 1.12.1.3 Connection Modes

Connection Mode	Support for Username/Password Authentication	Support for Keytab Authentication	Support for Cross-Network-Segment Client Access	Prerequisite
HSFabric	Supported	Supported	Supported	<ul style="list-style-type: none"><li>The node running user services can communicate with the service nodes where HSFabric resides on the HetuEngine server side.</li><li>Dual-plane network scenarios are supported.</li><li>Only fixed IP addresses and ports need to be opened for HSFabric.</li><li>Supported version: MRS 3.1.3 or later.</li></ul>
HSBroker	Supported	Unsupported	Unsupported	<ul style="list-style-type: none"><li>The node running user services can communicate with the service nodes where HSBroker and Coordinator (randomly distributed in Yarn NodeManager) reside on the HetuEngine server side.</li><li>A large number of IP addresses and ports need to be opened for coordinators.</li><li>Supported version: MRS 3.1.0 or later</li></ul>

### 1.12.1.4 Development Process

This section describes the development process, as shown in [Figure 1-156](#).

**Figure 1-156** HetuEngine application development process**Table 1-104** Description of the HetuEngine application development process

Phase	Description	Reference Documents
Understand basic concepts.	Before application development, learn basic concepts of HetuEngine, and understand the scenario requirements.	<a href="#">Concepts</a>
Prepare the development and running environment.	The HetuEngine application can invoke the JDBC interface in any language for development. The current example uses the Java language. You are advised to use the IDEA tool to configure development environments in different languages according to the guide. The HetuEngine running environment is the client. Install and configure the client according to the guide.	<a href="#">Preparing the Development and Running Environment</a>

Phase	Description	Reference Documents
Prepare a project.	HetuEngine provides sample projects for different scenarios. You can import a sample project to learn the application. You can also create a HetuEngine project according to the guide.	<a href="#">Configuring and Importing Sample Projects</a> <a href="#">Configuring and Importing Sample Projects</a>
Prepare for security authentication.	If a safe cluster is used, the safety certification must be performed.	<a href="#">Preparing for Security Authentication</a>
Develop a project based on the scenario.	A sample project in the Java language is provided, including an example project that connects the HetuEngine, SQL statement execution, result parsing, and disconnection.	<a href="#">Application Development</a>
Compile and run applications .	You can compile the developed application and submit it for running.	<a href="#">Application Commissioning</a>
Check the application running results.	The program running result is displayed in the expected display according to the implementation of the result parsing part.	<a href="#">Application Commissioning</a>

## 1.12.2 Environment Preparation

### 1.12.2.1 Preparing the Development and Running Environment

#### Preparing the Development Environment

This section describes the development and running environment to be prepared for application development, as listed in [Table 1-105](#).

**Table 1-105** Development environment

Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows 7 or later version is recommended.</li><li>• Operating environment: Windows or Linux OS If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane.</li></ul>
JDK installation	<p>Basic configuration of the development and running environment. The version requirements are as follows: The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstanceTLS-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstanceTLS-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>

Item	Description
Installation and configuration of IntelliJ IDEA	<p>Basic configuration of the development environment. The version must be 2019.1 or other compatible versions.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you are using an IBM JDK, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If you are using an Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If you are using an OpenJDK, ensure that the JDK configured in IntelliJ IDEA is the OpenJDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>
Maven installation	Basic configurations of the development environment. Maven is used for project management throughout the lifecycle of software development.
Development user	Cluster user for application development. Create the user and grant permissions to the user by referring to <a href="#">Preparing a Developer Account</a> .
7-zip	Tool used to decompress *.zip and *.rar files. <b>7-Zip 16.04</b> is supported.

**Table 1-106** Python3 environment (required when the Python sample project is used)

Item	Description
Python3	Tool used to develop HetuEngine Python applications. The version must range from 3.6 to 3.9.
Setupools	Basic configuration of the Python3 development environment. Version: 47.3.1
jaydebeapi	Basic configuration of the Python3 development environment. You can use this module to connect to the database using Java JDBC.

## Preparing Operating Environment

During application development, prepare the environment for running and commissioning the program to verify that the application can run properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host;

obtain the cluster configuration file required for commissioning; configure the network connection, and commission the application in Windows.

- a. Log in to FusionInsight Manager. In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Complete Client**, select the correct platform type (**x86\_64** for x86 and **aarch64** for ARM) based on the platform type of the node where the client is to be installed, and click **OK**. After the client file package is generated, download it to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar**. Then, decompress this file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.

- b. Go to the decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\HetuEngine\config** and place the configuration file to the **resources** directory of the sample project.

Save the **keytab** file obtained in [Preparing a Developer Account](#) to the **resources** directory.

Log in to the node where the HSBroker role is deployed as user **omm**, go to the  **\${BIGDATA\_HOME}/FusionInsight\_Hetu\_XXX/XXX\_HSBroker/etc/** directory, download the **hetuserver.jks** file, and save the file to the **resources** directory. [Table 1-107](#) describes the main configuration files.

**Table 1-107** Configuration files

File	Description
hdfs-site.xml	HDFS configuration parameters of the cluster
hetuserver-client.properties	HetuEngine client connection parameters
hetuserver-client-logging.properties	HetuEngine client log parameters
user.keytab	User information for Kerberos security authentication
krb5.conf	Kerberos Server configuration information
hetuserver.jks	Java TrustStore file
jaas-zk.conf	Jaas authentication file

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
  - The local **hosts** file in a Windows environment is stored, for example, in **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
- a. Install the client on the node. For example, install the client in the **/opt/hadoopclient** directory.

The difference between the client time and the cluster time must be less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).
  - b. **Accessing FusionInsight Manager of an MRS Cluster.** Download the cluster client software package to the active management node and decompress it. Then log in to the active management node as user **root**. Go to the decompression directory of the cluster client, and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/HetuEngine/config** directory to the client node to the **conf** directory where the compiled JAR package is stored, for example, **/opt/hadoopclient/conf**, for subsequent commissioning.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active OMS node, run the following commands:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp HetuEngine/config/* root@IP address of the client node:/opt/  
hadoopclient/conf
```

Log in to the node where the HSBroker role is deployed as user **omm**, go to the  **\${BIGDATA\_HOME}/FusionInsight\_Hetu\_xxx/xxx\_HSBroker/etc/** directory, download the **hetuserver.jks** file, and place the file in the directory.

The keytab file obtained in [Preparing a Developer Account](#) is also stored in this directory. **Table 1-108** describes the main configuration files. (Obtain the required files you need.)

**Table 1-108** Configuration files

File	Description
hdfs-site.xml	HDFS parameters
hetuserver-client.properties	HetuEngine client connection parameters

File	Description
hetuserver-client-logging.properties	HetuEngine client log parameters
user.keytab	User information for Kerberos security authentication
krb5.conf	Kerberos Server configuration information
hetuserver.jks	Java TrustStore file
jaas-zk.conf	Jaas authentication file

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If there is no required information, copy the content of the **hosts** file in the decompression directory to the **hosts** file on the node where the client is deployed, to ensure that the local host can communicate with each host in the cluster.

### 1.12.2 Configuring and Importing Sample ProjectsConfiguring and Importing Sample Projects

#### Scenario

The client installation program directory contains a HetuEngine development sample project. You can start the sample project learning by importing the project. This document uses IntelliJ IDEA 2020.1.3 (Community Edition) as an example.

#### Prerequisites

Ensure that the difference between the local PC time and the MRS cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator. You can view the time of the MRS cluster in the upper-right corner on the FusionInsight Manager page.

#### Procedure

- Step 1** Obtain the sample project folder **hetu-examples\hetu-examples-security** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** In the application development environment, import the sample project to the IntelliJ IDEA development environment.
1. Open IntelliJ IDEA and choose **File > New > General > Project from Existing Sources > Select File or Directory to Import** to go to the **Browse Folder** dialog box is displayed.
  2. Select the sample project folder, choose **Import project from external model > Maven** during import, and click **Next** and then **Finish**.

 NOTE

The sample code is a Maven project. You can adjust the project configuration based on the site requirements.

----End

### 1.12.2.3 Setting Up a Python3 Project

#### Scenario

The following content describes the operations you need to do to run the python3 sample code of HetuEngine on FusionInsight MRS.

#### Procedure

**Step 1** Install Python 3.6 or a later version (before 3.9) on the client node.

The Python version can be viewed by running the **python3** command on the CLI of the client. The following information indicates that the Python version is 3.8.2.  
Python 3.8.2 (default, Jun 23 2020, 10:26:03)  
[GCC 4.8.5 20150623 (Red Hat 4.8.5-36)] on linux  
Type "help", "copyright", "credits" or "license" for more information.

**Step 2** Setuptools 47.3.1 must be installed on the client.

Download the software from the official website <https://pypi.org/project/setuptools/#files>.

Copy the downloaded setuptools package to the client, decompress the package, go to the setuptools project directory, and run the **python3 setup.py install** command in the CLI of the client.

The following information indicates that setuptools 47.3.1 is installed successfully.

Finished processing dependencies for setuptools==47.3.1

 NOTE

If the system displays a message indicating that setuptools 47.3.1 fails to be installed, check whether the environment is faulty or Python is faulty.

**Step 3** The JayDeBeApi module must be installed on the client. You can use the Java JDBC to connect to the database through this module.

You can install it either of the following ways:

- pip:  
Run the **pip install JayDeBeApi** command on the client node.
- Script:
  - a. Download the **JayDeBeApi** project file from the official website at <https://pypi.org/project/JayDeBeApi/>
  - b. Go to the **JayDeBeApi** project directory and run the **python3 setup.py install** command. During the installation, if the system displays a message indicating that the python3 module or package is missing, you need to add the module or package.

Take JayDeBeApi-1.2.3 as an example. If **Successfully installed JayDeBeApi-1.2.3** is displayed, the installation is successful.

**Step 4** Install Java on the client. For details about the supported Java versions, see "JDK Installation" in the [Table 1-105](#).

**Step 5** Obtain the Python3 sample code.

1. Obtain the sample project folder **python3-examples** in the **src\hetu-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
2. Go to the **python3-examples** folder.
  - **normal** folder: Python3 sample code for interconnecting with HetuEngine in common mode
  - **security** folder: Python3 sample code for interconnecting with HetuEngine in security mode

**Step 6** Obtain the **hetu-jdbc** JAR package.

- Download the client file to the local PC through Manager.
  - a. Log in to FusionInsight Manager and choose **Cluster > Services > HetuEngine > More > Download Client**.
  - b. Select **Complete Client**, select the correct platform type (**x86\_64** for x86 and **aarch64** for ARM) for the node where the client is to be installed, deselect **Save to Path**, and click **OK**. Wait until the client file package is generated and download it.
  - c. Decompress the downloaded software package to obtain the **hetu-jdbc** package and decompress it to obtain the JDBC package.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress the package to obtain the **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then decompress the package to obtain the **FusionInsight\_Cluster\_1\_Services\_ClientConfig** file. (The path cannot contain spaces.) Decompress **\FusionInsight\_Cluster\_1\_Services\_ClientConfig\HetuEngine\x86\hetu-jdbc.tar.gz** to obtain **hetu-jdbc-XXX.jar** and copy it to the user-defined path on the host where the sample code will run.

- Obtain the cluster client node.

Log in to the node where the HetuEngine client has been installed. For example, if the client installation path is **/opt/hadoopclient**, obtain **hetu-jdbc-XXX.jar** from **/opt/hadoopclient/HetuEngine/hetuserver/jars/**, and copy the file to the user-defined path on the node where the sample code will run.

----End

#### 1.12.2.4 Setting Up a Spring Boot Sample Project

##### Scenario

This topic describes how to run the Spring Boot sample code of the HetuEngine component in MRS.

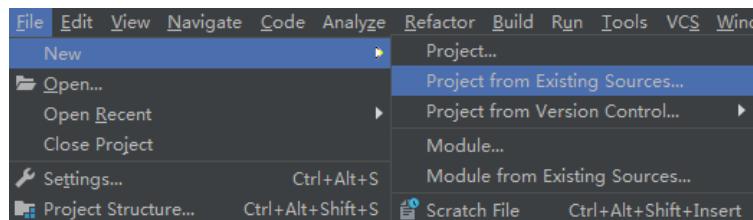

This example develops an application for connecting to the HetuEngine service using Spring Boot in a Windows environment.

## Procedure

**Step 1** Obtain the **src/springboot/hetu-examples** directory in the directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** In the application development environment, import the sample project to IntelliJ IDEA.

1. Choose **File > New > Project from Existing Sources....**

2. In the displayed **Select File or Directory to Import** dialog box, select the **pom.xml** file in the **hetu-examples** folder and click **OK**.
3. Confirm subsequent configurations and click **Next**. If there is no special requirement, use the default values.

Select the recommended JDK version and click **Finish**.

----End

### 1.12.2.5 Preparing for Security Authentication

#### 1.12.2.5.1 KeyTab File Authentication Using HSFabric

The KeyTab file authentication requires the **jaas-zk.conf**, **krb5.conf** and **user.keytab** files.

For details about how to obtain the **krb5.conf** and **user.keytab** files, see [Security Authentication](#).

The **jaas-zk.conf** file is defined as follows:

```
Client {
    com.sun.security.auth.module.Krb5LoginModule required
    useKeyTab=true
    keyTab="/opt/hadoopclient/user.keytab"
    principal="hivetest@System domain name"
    useTicketCache=false
    storeKey=true
    debug=true;
};
```

 NOTE

- **keyTab** is the path of the **user.keytab** file. Change the value of **keyTab** in the **jaas-zk.conf** file based on the site requirements.  
For example:
  - Windows Path: "D:\\hetu-examples\\hetu-examples-security\\src\\main\\resources\\user.keytab".
  - Linux Path: "/opt/hadoopclient/user.keytab".
- **principal** is *the username added for authentication in section **Security Authentication**@domain name*. The domain name is the value of the **default\_realm** field in the **krb5.conf** file (For example, HADOOP.COM).

### 1.12.2.5.2 Username and Password Authentication Using HSFabric

Only the username and password are required to implement this authentication using HSFabric.

### 1.12.2.5.3 Username and Password Authentication Using HSBroker

Only the username and password are required to implement this authentication using HSBroker.

## 1.12.3 Application Development

### 1.12.3.1 Typical Application Scenario

This section describes the application development in a typical scenario, helping you quickly learn and master the HetuEngine development process and know key functions.

#### Scenario

Assume that a user develops an application and needs to perform the join operation on table A of the Hive data source and table B of the MPPDB data source. In this case, HetuEngine can be used to implement data query of the Hive data source, the process is as follows:

1. Connect to the HetuEngine JDBC server.
2. Assemble SQL statements.
3. Execute SQL statements.
4. Parse the returned result.
5. Close the HetuEngine JDBC Server connection.

### 1.12.3.2 Java Sample Code

### 1.12.3.2.1 KeyTab File Authentication Using HSFabric

#### Description

This section describes how to use the KeyTab file and HSFabric to connect to HetuEngine, assemble SQL statements, and send the SQL statements to HetuEngine for execution to add, delete, modify, and query Hive data sources.

```
public class JDBCExampleKeytabByFabric {  
    private static Properties properties = new Properties();  
    private final static String PATH_TO_JAAS_ZK_CONF = JDBCExample.class.getClassLoader()  
        .getResource("jaas-zk.conf")  
        .getPath();  
    private final static String PATH_TO_KRB5_CONF = JDBCExample.class.getClassLoader()  
        .getResource("krb5.conf")  
        .getPath();  
    private final static String PATH_TO_USER_KEYTAB = JDBCExample.class.getClassLoader()  
        .getResource("user.keytab")  
        .getPath();  
  
    private static void init() throws ClassNotFoundException {  
        System.setProperty("user.timezone", "UTC");  
        System.setProperty("java.security.auth.login.config", PATH_TO_JAAS_ZK_CONF);  
        System.setProperty("java.security.krb5.conf", PATH_TO_KRB5_CONF);  
        properties.setProperty("user", "hivetest");  
        properties.setProperty("SSL", "true");  
        properties.setProperty("KerberosConfigPath", PATH_TO_KRB5_CONF);  
        properties.setProperty("KerberosPrincipal", "hivetest");  
        properties.setProperty("KerberosKeytabPath", PATH_TO_USER_KEYTAB);  
        properties.setProperty("KerberosRemoteServiceName", "HTTP");  
        properties.setProperty("tenant", "default");  
        properties.setProperty("deploymentMode", "on_yarn");  
        properties.setProperty("ZooKeeperAuthType", "kerberos");  
        properties.setProperty("ZooKeeperSaslClientConfig", "Client");  
        Class.forName("io.trino.jdbc.TrinoDriver");  
    }  
    /**  
     * Program entry  
     *  
     * @param args no need program parameter  
     */  
    public static void main(String[] args) {  
        Connection connection = null;  
        ResultSet result = null;  
        PreparedStatement statement = null;  
        String url = "jdbc:trino://192.168.1.130:29902,192.168.1.131:29902,192.168.1.132:29902/hive/default?"  
            + "serviceDiscoveryMode=hsfabric";  
        try {  
            init();  
            String sql = "show tables";  
            connection = DriverManager.getConnection(url, properties);  
            statement = connection.prepareStatement(sql.trim());  
            result = statement.executeQuery();  
            ResultSetMetaData metaData = result.getMetaData();  
            Integer colNum = metaData.getColumnCount();  
            for (int j = 1; j <= colNum; j++) {  
                System.out.print(metaData.getColumnName(j) + "\t");  
            }  
            System.out.println();  
            while (result.next()) {  
                for (int j = 1; j <= colNum; j++) {  
                    System.out.print(result.getString(j) + "\t");  
                }  
                System.out.println();  
            }  
        } catch (SQLException | ClassNotFoundException e) {  
            e.printStackTrace();  
        } finally {  
    }
```

```
if (result != null) {
    try {
        result.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
if (statement != null) {
    try {
        statement.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
if (connection != null) {
    try {
        connection.close();
    } catch (SQLException e) {
        e.printStackTrace();
    }
}
}
```

The parameters in the preceding code are described in the following table.

**Table 1-109** Parameter description

Parameter	Description
url	<p>jdbc:trino:// <i>HSFabric1_IP.HSFabric1_Port,HSFabric2_IP.HSFabric2_Port, HSFabric3_IP.HSFabric3_Port/catalog/schema?</i></p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• <b>catalog</b> and <b>schema</b> indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>• <b>HSFabric_IP:HSFabric_Port</b> indicates the HSFabric URL. Use commas (,) to separate multiple URLs, for example, 192.168.1.130:29902,192.168.1.131:29902,192.168.1.132:29902. On FusionInsight Manager, choose <b>Cluster &gt; Services &gt; HetuEngine</b> and click <b>Instance</b> to obtain the service IP addresses of all HSFabric instances. On the <b>Configurations</b> page, search for <b>gateway.port</b> to obtain the port number of HSFabric.</li><li>• (Optional) <b>auditAddition</b>: custom information about the audit log. This field is recorded in the audit log. This parameter is used to supplement information for user audit.<ul style="list-style-type: none"><li>• Name of the image. The name can contain 1 to 255 characters.</li><li>• Only letters, digits, underscores (_), commas (,), and colons (:) are allowed.</li></ul></li></ul>
user	Username for accessing HetuEngine, that is, the username of the human-machine user created in the cluster.
SSL	Whether to use the HTTPS connection. The default value is <b>false</b> .

Parameter	Description
SSLTrustStorePath	Java TrustStore file path
KerberosRemoteServiceName	Kerberos service name, which is fixed to <b>HTTP</b> .
KerberosPrincipal	Username corresponding to <b>keytab</b> specified by <b>KerberosKeytabPath</b>
KerberosConfigPath	The <b>krb5</b> configuration file to access the data source user. For details, see <a href="#">Preparing for Security Authentication</a> .
KerberosKeytabPath	The <b>keytab</b> configuration file of the data source user, which can be obtained by following the instructions in <a href="#">Preparing for Security Authentication</a> .
java.security.auth.login.config	Path of the <b>jaas-zk.conf</b> configuration file, which is used to access ZooKeeper in security mode.
java.security.krb5.conf	The <b>krb5</b> configuration file. For details, see <a href="#">Preparing for Security Authentication</a> .
ZooKeeperAuthType	ZooKeeper authentication mode. The value is <b>kerberos</b> in security mode.
ZooKeeperSaslClientConfig	Item name in the <b>jaas-zk.conf</b> configuration file
tenant	Tenant to which a user belongs
deploymentMode	Only <b>on_yarn</b> is supported.

### 1.12.3.2.2 Username and Password Authentication Using HSFabric

#### Description

An HSFabric connection is used. The username and password are used to connect to HetuEngine, and SQL statements are assembled and sent to HetuEngine for execution.

```
public class JDBCExampleFabric {  
    private static Properties properties = new Properties();  
    private static void init() throws ClassNotFoundException {  
        // Hard-coded password or plaintext password in code poses significant security risks. Encrypt and  
        // store them in configuration files or environment variables and decrypt them when needed.  
        // The password is stored in environment variables for identity authentication. Before running this  
        // example, set the environment variable HETUENGINE_PASSWORD.  
        properties.setProperty("user", "YourUserName");  
        String password = System.getenv("HETUENGINE_PASSWORD");  
        properties.setProperty("password", password);  
        Class.forName("io.trino.jdbc.TrinoDriver");  
    }  
    public static void main(String[] args){  
        Connection connection = null;  
        ResultSet resultSet = null;  
        PreparedStatement statement = null;  
        String url = "jdbc:trino://192.168.1.130:29902,192.168.1.131:29902/hive/default?  
        serviceDiscoveryMode=hsfabric";  
    }  
}
```

```
try {
    init();
    String sql = "show tables";
    connection = DriverManager.getConnection(url, properties);
    statement = connection.prepareStatement(sql.trim());
    resultSet = statement.executeQuery();
    Integer colNum = resultSet.getMetaData().getColumnCount();
    while (resultSet.next()) {
        for (int i = 1; i <= colNum; i++) {
            System.out.println(resultSet.getString(i) + "\t");
        }
    }
} catch (SQLException | ClassNotFoundException e) {
    e.printStackTrace();
} finally {
    if (resultSet != null) {
        try {
            resultSet.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
    if (statement != null) {
        try {
            statement.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
    if (connection != null) {
        try {
            connection.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

**Table 1-110** describes the parameters in the preceding code.

**Table 1-110** Parameter description

Parameter	Description
url	<p>jdbc:trino:// <i>HSFabric1_IP.HSFabric1_Port,HSFabric2_IP.HSFabric2_Port,HSFabric3_IP.HSFabric3_Port/catalog/schema?</i>serviceDiscoveryMode=hsfabric</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>catalog and schema indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>HSFabric_IP:HSFabric_Port indicates the HSFabric URL. On FusionInsight Manager, choose Cluster &gt; Services &gt; HetuEngine and click Instance to obtain the service IP addresses of all HSFabric instances. On the Configurations page, search for gateway.port to obtain the port number of HSFabric.</li><li>(Optional) auditAddition: custom information about the audit log. This field is recorded in the audit log. This parameter is used to supplement information for user audit.<ul style="list-style-type: none"><li>Name of the image. The name can contain 1 to 255 characters.</li><li>Only letters, digits, underscores (_), commas (,), and colons (:) are allowed.</li></ul></li></ul>
user	Username for accessing HetuEngine, that is, the username of the human-machine user created in the cluster.
password	Password of the human-machine user created in the cluster.

### 1.12.3.2.3 Querying SQL Tasks using JDBC

#### Description

A JDBC connection is used. You can use the username and password to connect to HetuEngine, assemble SQL statements, send them to HetuEngine for execution, and query the execution progress and status of the SQL statements.

```
import io.trino.jdbc.TrinoResultSet;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.ResultSetMetaData;
import java.sql.SQLException;
import java.util.Properties;
import java.util.Timer;
import java.util.TimerTask;

public class JDBCExampleStatementProgressPercentage{

    private static Properties properties = new Properties();
    public static Connection connection = null;
    public static ResultSet result = null;
    public static PreparedStatement statement = null;
    private static void init() throws ClassNotFoundException {
        // Hard-coded password or plaintext password in code poses significant security risks. Encrypt and
        // store them in configuration files or environment variables and decrypt them when needed.
        // The password is stored in environment variables for identity authentication. Before running this
```

```
example, set the environment variable HETUENGINE_PASSWORD.
properties.setProperty("user", "YourUserName");
String password = System.getenv("HETUENGINE_PASSWORD");
properties.setProperty("password", password);
Class.forName("io.trino.jdbc.TrinoDriver");
}

/**
 * Program entry
 *
 * @param args no need program parameter
 */
public static void main(String[] args) {
    String url = "jdbc:trino://192.168.81.37:29860,192.168.195.232:29860,192.168.169.84:29860/hive/
default?serviceDiscoveryMode=hsbroker";
    try {
        init();
        String sql = "show tables";
        connection = DriverManager.getConnection(url, properties);
        statement = connection.prepareStatement(sql.trim());
        result = statement.executeQuery();

        TrinoResultSet rs = (TrinoResultSet) result;
        new Thread() {
            public void run() {
                Timer timer = new Timer();
                // Indicates that the task will be executed three seconds later and will be executed every two
seconds.
                timer.schedule(new TimerTask() {
                    @Override
                    public void run() {
                        double statementProgressPercentage = rs.getProgressPercentage().orElse(0.0);
                        System.out.println("The Current Query Progress Percentage is " +
statementProgressPercentage*100 + "%");
                        if("FINISHED".equals(rs.getStatementStatus().orElse(""))) {
                            System.out.println("The Current Query Progress Percentage is 100%");
                            timer.cancel();
                            Thread.currentThread().interrupt();
                        }
                    }
                }, 3000, 2000);
            }
        }.start();

        ResultSetMetaData resultMetaData = result.getMetaData();
        int colNum = resultMetaData.getColumnCount();
        for (int j = 1; j <= colNum; j++) {
            try {
                System.out.print(resultMetaData.getColumnLabel(j) + "\t");
            } catch (SQLException throwables) {
                throwables.printStackTrace();
            }
        }

        while (result.next()) {
            for (int j = 1; j <= colNum; j++) {
                System.out.print(result.getString(j) + "\t");
            }
            System.out.println();
        }
    } catch (SQLException | ClassNotFoundException e) {
        e.printStackTrace();
    } finally {
        if (result != null) {
            try {
                result.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
    }
}
```

```
        }
        if (statement != null) {
            try {
                statement.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
        if (connection != null) {
            try {
                connection.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
    }
}
```

**Table 1-111** describes the parameters in the preceding code.

**Table 1-111** Parameter description

Parameter	Description
url	<p>jdbc:trino:// <i>HSBroker1_IP.HSBroker1_Port,HSBroker2_IP.HSBroker2_Port,HSBroker3_IP.HSBroker3_Port/catalog/schema?serviceDiscovery-Mode=hsbroker</i></p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• <b>catalog</b> and <b>schema</b> indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>• <i>HSBroker_IP:HSBroker_Port</i> indicates the HSBroker URL. user	Username for accessing HetuEngine, that is, the username of the human-machine user created in the cluster.
password	Password of the human-machine user created in the cluster.
getStatementStatus()	Execution status of the SQL statement. There are 11 states: {'RUNNING', 'FAILED', 'FINISHED', 'QUEUED', 'WAITING_FOR_RESOURCES', 'DISPATCHING', 'PLANNING', 'STARTING', 'RESCHEDULING', 'RESUMING', 'FINISHING' }
getProgressPercentage()	Execution progress of the SQL statement. Value range: [0,1].

### 1.12.3.2.4 Username and Password Authentication Using HSBroker

#### Description

This section describes how to use HSBroker to connect to HetuEngine with the username and password, and assemble and send the SQL statements to HetuEngine for execution.

```
public class JDBCExampleBroker {  
    private static Properties properties = new Properties();  
    private static void init() throws ClassNotFoundException {  
        // Hard-coded password or plaintext password in code poses significant security risks. Encrypt and  
        // store them in configuration files or environment variables and decrypt them when needed.  
        // The password is stored in environment variables for identity authentication. Before running this  
        // example, set the environment variable HETUENGINE_PASSWORD.  
        properties.setProperty("user", "YourUserName");  
        String password = System.getenv("HETUENGINE_PASSWORD");  
        properties.setProperty("password", password);  
        Class.forName("io.trino.jdbc.TrinoDriver");  
    }  
    public static void main(String[] args){  
        Connection connection = null;  
        ResultSet resultSet = null;  
        PreparedStatement statement = null;  
        String url = "jdbc:trino://192.168.1.130:29860,192.168.1.131:29860/hive/default?  
serviceDiscoveryMode=hsbroker";  
        try {  
            init();  
            String sql = "show tables";  
            connection = DriverManager.getConnection(url, properties);  
            statement = connection.prepareStatement(sql.trim());  
            resultSet = statement.executeQuery();  
            Integer colNum = resultSet.getMetaData().getColumnCount();  
            while (resultSet.next()) {  
                for (int i = 1; i <= colNum; i++) {  
                    System.out.println(resultSet.getString(i) + "\t");  
                }  
            }  
        } catch (SQLException | ClassNotFoundException e) {  
            e.printStackTrace();  
        } finally {

password	Password of the human-machine user created in the cluster.

### 1.12.3.3 Python3 Sample Code

#### 1.12.3.3.1 Username and Password Authentication Using HSBroker

This section describes how to use HSBroker to connect to HetuEngine with the username and password, and assemble and send the SQL statements to HetuEngine for execution.

```
import jaydebeapi
import os

driver = "io.trino.jdbc.TrinoDriver"

# need to change the value based on the cluster information
url = "jdbc:trino://192.168.43.223:29860,192.168.43.244:29860/hive/default?serviceDiscoveryMode=hsbroker"
user = "YourUserName"
# Hard-coded or plaintext password is risky. For security, encrypt your passwords and store them in the configuration file or environment variables.
# The password is stored in environment variables for identity authentication. Before running this example, set the environment variable HETUENGINE_PASSWORD.
password = os.getenv('HETUENGINE_PASSWORD')
tenant = "YourTenant"
jdbc_location = "Your file path of the jdbc jar"

sql = "show tables"

if __name__ == '__main__':
    conn = jaydebeapi.connect(driver, url, {"user": user,
   "password": password,
   "tenant": tenant},
                             [jdbc_location])
    curs = conn.cursor()
```

```
curs.execute(sql)
result = curs.fetchall()
print(result)
curs.close()
conn.close()
```

The following table describes the parameters in the preceding code.

**Table 1-113** Parameter description

Parameter	Description
url	<p>jdbc:trino:// <i>HSBroker1_IP.HSBroker1_Port,HSBroker2_IP.HSBroker2_Port,HSB roker3_IP.HSBroker3_Port/catalog/schema?serviceDiscovery- Mode=hsbroker</i></p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• <i>catalog</i> and <i>schema</i> indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>• <i>HSBroker_IP:HSBroker_Port</i> indicates the HSBroker URL. Use commas (,) to separate multiple URLs, for example, 192.168.81.37:29860,192.168.195.232:29860,192.168.169.84:29860.</li><li>• (Optional) <b>auditAddition</b>: custom information about the audit log. This field is recorded in the audit log. This parameter is used to supplement information for user audit.<ul style="list-style-type: none"><li>• Name of the image. user	Username for accessing HetuEngine, that is, the username of the human-machine user created in the cluster.
password	Password of the human-machine user created in the cluster.
tenant	Tenant resource queue for accessing HetuEngine compute instances
jdbc_location	<p>Full path of the <b>hetu-jdbc-XXX.jar</b> package obtained in <a href="#">Setting Up a Python3 Project</a>.</p> <ul style="list-style-type: none"><li>• Example path in Windows: D:\\hetu-examples-python3\\ \\hetu-jdbc-XXX.jar</li><li>• Example path in Linux: /opt/hetu-examples-python3/hetu- jdbc-XXX.jar</li></ul>

### 1.12.3.3.2 Username and Password Authentication Using HSFabric

This section describes how to use HSFabric to connect to HetuEngine with the username and password, and assemble and send the SQL statements to HetuEngine for execution.

```
import jaydebeapi
driver = "io.trino.jdbc.TrinoDriver"
# need to change the value based on the cluster information
```

```
url = "jdbc:trino://192.168.43.244:29902/hive/default?serviceDiscoveryMode=hsfabric"
user = "YourUserName"
# Hard-coded or plaintext password is risky. For security, encrypt your passwords and store them in the
configuration file or environment variables.
# The password is stored in environment variables for identity authentication. Before running this example,
set the environment variable HETUENGINE_PASSWORD.
password = os.getenv('HETUENGINE_PASSWORD')
tenant = "YourTenant"
jdbc_location = "Your file path of the jdbc jar"

sql = "show tables"

if __name__ == '__main__':
    conn = jaydebeapi.connect(driver, url, {"user": user,
   "SSL": "true",
   "password": password,
   "tenant": tenant},
                               [jdbc_location])
    curs = conn.cursor()
    curs.execute(sql)
    result = curs.fetchall()
    print(result)
    curs.close()
    conn.close()
```

The following table describes the parameters in the preceding code.

**Table 1-114** Parameter description

Parameter	Description
url	<p>jdbc:trino:// <i>HSFabric1_IP:HSFabric1_Port,HSFabric2_IP:HSFabric2_Port,HSFabric3_IP:HSFabric3_Port/catalog/schema?serviceDiscoveryMode=hsfabric</i></p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• <b>catalog</b> and <b>schema</b> indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>• <b>HSFabric_IP:HSFabric_Port</b> indicates the HSFabric URL. user	Username for accessing HetuEngine, that is, the username of the human-machine user created in the cluster.
password	Password of the human-machine user created in the cluster.
tenant	Tenant resource queue for accessing HetuEngine compute instances

Parameter	Description
jdbc_location	Full path of the <b>hetu-jdbc-XXX.jar</b> package obtained in <a href="#">Setting Up a Python3 Project</a> . <ul style="list-style-type: none"><li>• Example path in Windows: <b>D:\\hetu-examples-python3\\hetu-jdbc-XXX.jar</b></li><li>• Example path in Linux: <b>/opt/hetu-examples-python3/hetu-jdbc-XXX.jar</b></li></ul>

### 1.12.3.3.3 KeyTab File Authentication Using HSFabric

This section describes how to use the KeyTab file and HSFabric to connect to HetuEngine, assemble SQL statements, and send the SQL statements to HetuEngine for execution to add, delete, modify, and query Hive data sources.

```
import jaydebeapi

driver = "io.trino.jdbc.TrinoDriver"

# need to change the value based on the cluster information
url = "jdbc:trino://192.168.43.244:29902/hive/default?serviceDiscoveryMode=hsfabric"
user = "YourUserName"
KerberosPrincipal = "YourUserName"
tenant = "YourTenant"
KerberosConfigPath = "Your file path of krb5.conf"
KerberosKeytabPath = "Your file path of user.keytab"
jdbc_location = "Your file path of the jdbc jar"

sql = "show tables"

if __name__ == '__main__':
    conn = jaydebeapi.connect(driver, url, {'user': user,
   'SSL': "true",
   'KerberosPrincipal': KerberosPrincipal,
   'KerberosConfigPath': KerberosConfigPath,
   'KerberosRemoteServiceName': "HTTP",
   'KerberosKeytabPath': KerberosKeytabPath,
   'tenant': tenant,
   'deploymentMode': "on_yarn",
   "ZooKeeperSaslClientConfig": "Client"},
                               [jdbc_location])
    curs = conn.cursor()
    curs.execute(sql)
    result = curs.fetchall()
    print(result)
    curs.close()
    conn.close()
```

The following table describes the parameters in the preceding code.

**Table 1-115** Parameter description

Parameter	Description
url	<p>jdbc:trino:// <i>HSFabric1_IP.HSFabric1_Port,HSFabric2_IP.HSFabric2_Port,HSFabric3_IP.HSFabric3_Port/catalog/schema?serviceDiscoveryMode=hsfabric</i></p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>catalog and schema indicate the names of the catalog and schema to be connected to the JDBC client, respectively.</li><li>HSFabric_IP:HSFabric_Port indicates the HSFabric URL. Use commas (,) to separate multiple URLs, for example, 192.168.1.130:29902,192.168.1.131:29902,192.168.1.132:29902. On FusionInsight Manager, choose <b>Cluster &gt; Services &gt; HetuEngine</b> and click <b>Instance</b> to obtain the service IP addresses of all HSFabric instances. On the <b>Configurations</b> page, search for <b>gateway.port</b> to obtain the port number of HSFabric.</li><li>(Optional) <b>auditAddition</b>: custom information about the audit log. This field is recorded in the audit log. This parameter is used to supplement information for user audit.</li><li>Name of the image. The name can contain 1 to 255 characters.</li><li>Only letters, digits, underscores (_), commas (,), and colons (:) are allowed.</li></ul>
user	Username for accessing HetuEngine, that is, the username of the human-machine user created in the cluster.
KerberosPrincipal	Username corresponding to <b>keytab</b> specified by <b>KerberosKeytabPath</b>
tenant	Tenant resource queue for accessing HetuEngine compute instances
KerberosConfigPath	The <b>krb5</b> configuration file to access the data source user. For details, see <a href="#">Preparing for Security Authentication</a> .
KerberosKeytabPath	The <b>keytab</b> configuration file of the data source user, which can be obtained by following the instructions in <a href="#">Preparing for Security Authentication</a> .
jdbc_location	<p>Full path of the <b>hetu-jdbc-XXX.jar</b> package obtained in <a href="#">Setting Up a Python3 Project</a>.</p> <ul style="list-style-type: none"><li>Example path in Windows: <b>D:\\hetu-examples-python3\\hetu-jdbc-XXX.jar</b></li><li>Example path in Linux: <b>/opt/hetu-examples-python3/hetu-jdbc-XXX.jar</b></li></ul>

## 1.12.4 Application Commissioning

### 1.12.4.1 Commissioning Applications on Windows

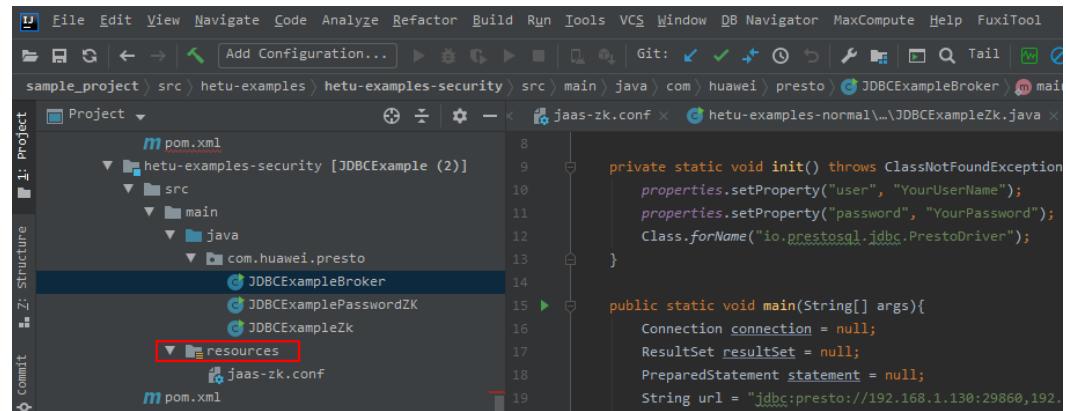

#### Scenario

After the program code is developed, you can compile the program in the Windows environment. If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

#### Procedure

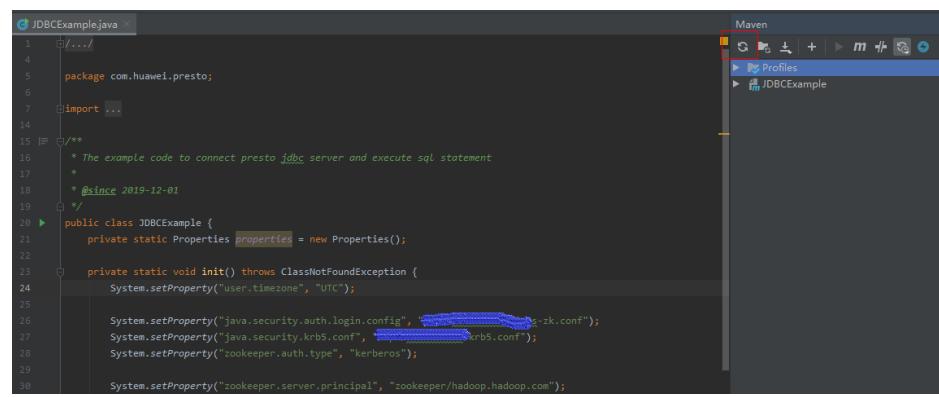

- Step 1** In the IntelliJ IDEA development environment on Windows, check that the **user.keytab** and **krb5.conf** files obtained in [Preparing for Security Authentication](#) are saved to the **resources** directory, and modify the parameters in the **jaas-zk.conf** file based on the actual path and username.

**Figure 1-157** Saving the authentication file to the resources directory

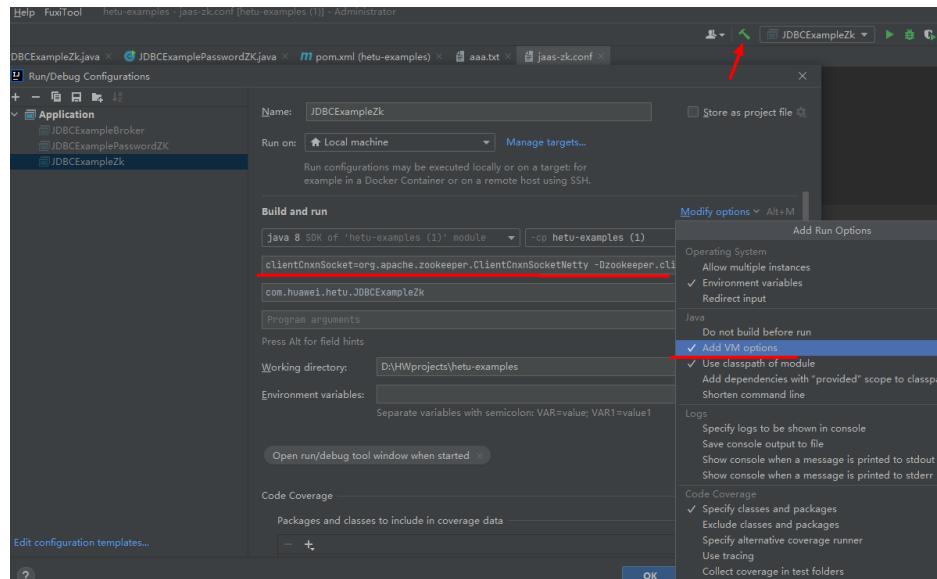

- Step 2** Click **Maven** on the right of IDEA to import the dependency.

**Figure 1-158** Importing the dependency

- Step 3** (Optional) If the SSL authentication communication function of ZooKeeper is enabled for the interconnected cluster, add the JVM configuration

**-Dzookeeper.clientCnxnSocket=org.apache.zookeeper.ClientCnxnSocketNetty -Dzookeeper.client.secure=true** when you run JDBCExampleZk and JDBCExamplePasswordZK.

**Step 4** Right-click the **\*.java** file of the sample project and choose **Run'\*.main()'** from the shortcut menu. Wait until the execution is successful. (The default sample is to query a Hive table.)

- The running result of the JDBCExampleZk example application is shown as follows:

```
...
principal is hivetest@HADOOP.COM
Will use keytab
Commit Succeeded
...
The final connection url is: trino://192.168.1.189:29896/hive/default
Table
user_info
user_info2
```

- The running result of the JDBCExamplePasswordZK example application is as follows:

```
...
The final connection url is: trino://192.168.1.189:29896/hive/default
Table
user_info
user_info2
```

- The running result of the JDBCExampleBroker example application is as follows:

```
...
The final connection url is: trino://192.168.1.189:29896/hive/default
coordinator uri is trino://192.168.1.189:29896/hive/default
user_info
user_info2
```

----End

### 1.12.4.2 Commissioning Applications on Linux

#### Scenario

After the code is developed, you can compile the code into a JAR file and upload it to a Linux environment for application function commissioning.

 NOTE

Before commissioning applications on Linux, you need to pre-install a client on the Linux node.

## Procedure

- Step 1** Change the path for storing the KeyTab file in the **jaas-zk.conf** file in the Linux environment as required. for example, **/opt/hadoopclient/conf/user.keytab**.
- Step 2** Modify the configuration file path of the sample code, as shown in the following example:

```
private final static String PATH_TO_KRB5_CONF = "/opt/hadoopclient/krb5.conf"
```
- Step 3** In the Windows development environment IntelliJ IDEA, choose **Maven Projects > Example project name > Lifecycle** and perform the clean and package operations. After the compilation is complete, the **hetu-examples-XXX.jar** file is generated in the **target** directory.
- Step 4** Upload the **hetu-examples-XXX.jar** file to the **/opt/hadoopclient** directory in the Linux environment.
- Step 5** Download and decompress the client file **FusionInsight\_Cluster\_Cluster\_ID\_HetuEngine\_Client.tar** by referring to [Preparing Operating Environment](#), obtain the JDBC drive package, and upload it to the **/opt/hadoopclient** directory in the Linux environment.

 NOTE

The JDBC driver package **hetu-jdbc-\*jar** can be obtained from the **FusionInsight\_Cluster\_1\_Services\_ClientConfig\HetuEngine\XXX\** directory where the cluster client software package is decompressed. In the directory, **XXX** indicates ARM or x86.

- Step 6** Upload the **jaas-zk.conf**, **user.keytab**, and **krb5.conf** files obtained in [Preparing for Security Authentication](#) to the **/opt/hadoopclient** directory in the Linux environment.
- Step 7** Run the following command to go to the client installation directory:  
**cd /opt/hadoopclient**
- Step 8** Run the following command to configure environment variables:  
**source bigdata\_env**
- Step 9** Run the following command to debug the development program:  
**java -classpath hetu-examples-\*jar:hetu-jdbc-\*jar com.huawei.hetu.className**

 NOTE

- Replace the JDBC driver package name and class name with the actual ones, for example, `java -classpath hetu-examples-*.jar:hetu-jdbc-*.jar com.huawei.hetu.JDBCExampleBroker`.
- If SSL authentication of ZooKeeper is enabled for the interconnected cluster, you need to add the following JVM configuration

-  
`Dzookeeper.clientCnxnSocket=io.trino.jdbc.$internal.org.apache.zookeeper.ClientCnxnSocketNetty -Dzookeeper.client.secure=true.`

Using JDBCExampleZK as an example, the corresponding debugging command is as follows:

`java -cp hetu-examples-*.jar:hetu-jdbc-*.jar -Dzookeeper.clientCnxnSocket=io.trino.jdbc.$internal.org.apache.zookeeper.ClientCnxnSocketNetty -Dzookeeper.client.secure=true com.huawei.hetu.JDBCExampleZK.`

**Step 10** Check whether the command output is normal.

```
Jul 01, 2021 8:41:23 PM io.trino.jdbc.$internal.airlift.log.Logger info  
INFO: hsbroker finalUri is https://192.168.1.150:29860  
Jul 01, 2021 8:41:24 PM io.trino.jdbc.$internal.airlift.log.Logger info  
INFO: The final connection url is: trino://192.168.1.189:29896/hive/default  
Jul 01, 2021 8:41:24 PM io.trino.jdbc.$internal.airlift.log.Logger info  
INFO: coordinator uri is trino://192.168.1.189:29896/hive/default  
user_info  
user_info2
```

----End

### 1.12.4.3 Commissioning a Python3 Application

#### Scenario

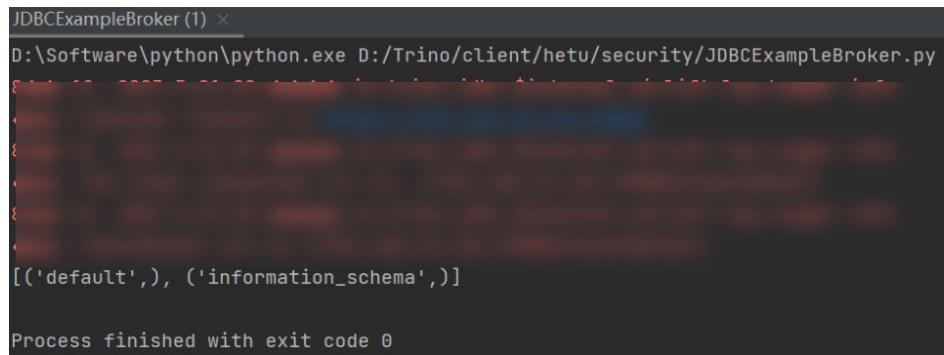

After the program code is written, you can commission the code in the Windows environment or upload the code to the Linux environment. If the local environment can communicate with the cluster service plane network, you can commission the program locally.

#### Procedure

1. Refer to [Setting Up a Python3 Project](#) to obtain the sample code, obtain the **hetu-jdbc-XXX.jar** file, and copy it to the user-defined directory.
2. Refer to [KeyTab File Authentication Using HSFabric](#) to obtain the **user.keytab** and **krb5.conf** files and save them to the customized directory.
3. Edit the sample code, modify URLs, user information, and passwords based on the cluster requirements, and modify **jdbc\_location** based on the actual path.
  - Example path in Windows: **D:\\hetu-examples-python3\\hetu-jdbc-XXX.jar**
  - Example path in Linux: **/opt/hetu-examples-python3/hetu-jdbc-XXX.jar**
4. Run the python3 sample code.
  - In Windows, run the **py** script through pycharm or Python IDLE.
  - To run the sample code on Linux, install Java first.  
Go to the sample code path and run the **py** script. An example of the sample code path is **/opt/hetu-examples-python3**.  
**cd /opt/hetu-examples-python3**

**python3 JDBCExampleBroker.py**

5. View the command output.
  - In Windows, view the running result on the console.

**Figure 1-159** Running result

```
JDBCExampleBroker (1) >
D:\Software\python\python.exe D:/Trino/client/hetu/security/JDBCExampleBroker.py
[('default',), ('information_schema',)]
Process finished with exit code 0
```

- The following is an example of the running result in Linux:

```
Aug 12, 2023 5:19:53 PM io.trino.jdbc.$internal.airlift.log.Logger info
INFO: hsbroker finalUri is https://192.168.43.223:29860
Aug 12, 2023 5:19:53 PM io.trino.jdbc.$internal.airlift.log.Logger info
INFO: The final connection url is: //192.168.43.161:29888/hive/default
Aug 12, 2023 5:19:53 PM io.trino.jdbc.$internal.airlift.log.Logger info
INFO: coordinator uri is //192.168.43.161:29888/hive/default
[('default',), ('information_schema',)]
```

#### 1.12.4.4 Commissioning a Spring Boot Application

**Step 1** Configure the properties required for connecting the Spring Boot sample program to HetuEngine. Set the following parameters in the **springboot\hetu-examples\src\main\resources\application.yml** configuration file:

**Table 1-116** Configuring HetuEngine

Parameter	Mandatory	Description
host	Yes	HS Fabric address list of the HetuEngine service. The format is <i>HSFabric_IP1:HSFabric_Port,HSFabric_IP2:HSFabric_Port,HSFabric_IP3:HSFabric_Port</i> . Log in to FusionInsight Manager, choose <b>Cluster &gt; Services &gt; HetuEngine &gt; Instances</b> , and obtain the service IP addresses of all HSFabric instances. In the <b>Configurations</b> tab, search for <b>gateway.port</b> to obtain the HSFabric port.
catalog	Yes	Catalog name of the HetuEngine compute instance
schema	Yes	Schema name of the HetuEngine compute instance
user	Yes	Username for connecting to the HetuEngine compute instance

Parameter	Mandatory	Description
password	No	Password of the user for connecting to the HetuEngine compute instance in a cluster in security mode
ssl	Yes	Whether to use SSL to connect to the HetuEngine compute instance <ul style="list-style-type: none"> <li>For a cluster in security mode, set this parameter to <b>true</b>.</li> <li>For a cluster in normal mode, set this parameter to <b>false</b>.</li> </ul>

**Step 2** Click **Terminal** on the lower left part of the IDEA page to access the terminal. Run the following command to compile the file:

**mvn clean package**

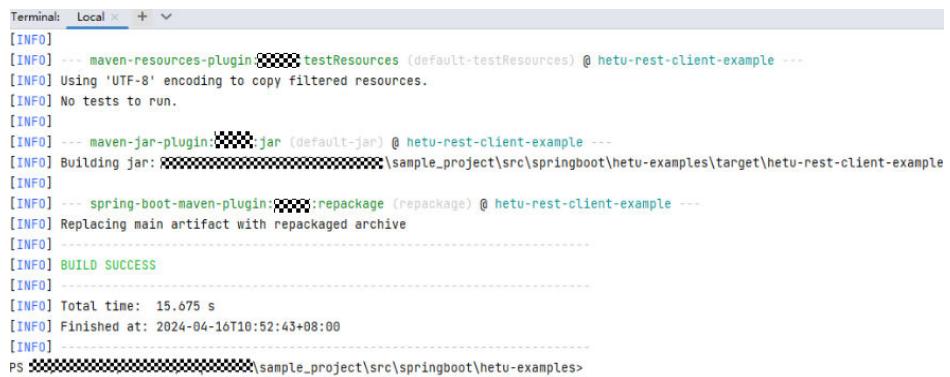

**Figure 1-160** Compile command

```
Terminal: Local + 
PowerShell
PS C:\sample_project\src\springboot\hetu-examples> mvn clean package
```

If "BUILD SUCCESS" is displayed, the compilation is successful. A JAR package containing the **hetu-rest-client-example** field is generated in the target directory of the sample project.

**Figure 1-161** Successful compilation

```
[INFO]
[INFO] --- maven-resources-plugin:2.6:testResources (default-testResources) @ hetu-rest-client-example ---
[INFO] Using 'UTF-8' encoding to copy filtered resources.
[INFO] No tests to run.
[INFO]
[INFO] --- maven-jar-plugin:3.1.0:jar (default-jar) @ hetu-rest-client-example ---
[INFO] Building jar: C:\sample_project\src\springboot\hetu-examples\target\hetu-rest-client-example.jar
[INFO]
[INFO] --- spring-boot-maven-plugin:2.7.1:repackage (repackage) @ hetu-rest-client-example ---
[INFO] Replacing main artifact with repackaged archive
[INFO]
[INFO] BUILD SUCCESS
[INFO]
[INFO] Total time: 15.075 s
[INFO] Finished at: 2024-04-16T10:52:43+08:00
[INFO]
```

**Step 3** Create a directory in the system as the run directory to save the JAR package that contains the **hetu-rest-client-example** field generated in **Step 2**.

- Create a directory on Windows, for example, **D:\hetu-rest-client-example**.
- Create a directory on Linux, for example, **/opt/hetu-rest-client-example**.

**Step 4** Run the following command to start the SpringBoot service:

- Commands for Windows:

**cd /d D:\hetu-rest-client-example**

```
java -jar hetu-rest-client-example-*-SNAPSHOT.jar
```

- Commands for Linux:

```
chmod +x /opt/hetu-rest-client-example -R
```

```
cd /opt/hetu-rest-client-example
```

```
java -jar hetu-rest-client-example-*-SNAPSHOT.jar
```

The preceding JAR package names are for reference only. Use the actual names.

**Step 5** Call a Spring Boot sample API of HetuEngine to run the sample code.

- For the Windows environment:

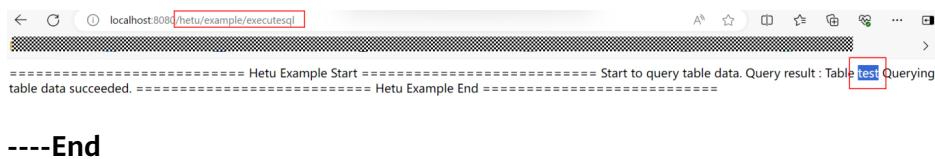

Open a browser and enter **http://localhost:8080/hetu/example/executesql** in the address box.

- For the Linux environment:

Run the **curl http://localhost:8080/hetu/example/executesql** command on the node where the JAR package is stored in **Step 3**.

**Step 6** View the query result of the SQL statement used in the sample code.

**Figure 1-162** Query results

## 1.13 Hive Development Guide

### 1.13.1 Overview

#### 1.13.1.1 Application Development Overview

##### Hive Introduction

Hive is an open-source data warehouse built on Hadoop. It stores structured data and provides basic data analysis services using the Hive query language (HQL), a language like the SQL. Hive converts HQL statements to Mapreduce or Spark jobs for querying and analyzing massive data stored in Hadoop clusters.

Hive provides the following features:

- Extracts, transforms, and loads (ETL) data using HQL.
- Analyzes massive structured data using HQL.
- Supports flexible data storage formats, including JavaScript object notation (JSON), comma separated values (CSV), TextFile, RCFile, ORCFILE, and SequenceFile, and supports custom extensions.
- Multiple client connection modes. Interfaces, such as JDBC and Thrift interfaces are supported.

Hive applies to offline massive data analysis (such as log and cluster status analysis), large-scale data mining (such as user behavior analysis, interest region analysis, and region display), and other scenarios.

To ensure Hive high availability (HA), user data security, and service access security, MRS incorporates the following features based on Hive 3.1.0:

- Kerberos security authentication
- Data file encryption
- Complete rights management

For Hive features in the Open Source Community, see <https://cwiki.apache.org/confluence/display/hive/designdocs>.

### 1.13.1.2 Common Concepts

- **keytab file**

The keytab file is a key file that stores user information. Applications use the key file for API authentication on MRS.

- **Client**

Users can access the server from the client through the Java API and Thrift API to perform Hive-related operations.

- **HQL**

Similar to SQL

- **HCatalog**

HCatalog is a table information management layer created based on Hive metadata and absorbs DDL commands of Hive. HCatalog provides read/write interfaces for Mapreduce and provides Hive command line interfaces (CLIs) for defining data and querying metadata. Hive and Mapreduce development personnel can share metadata based on the HCatalog component of MRS, preventing intermediate conversion and adjustment and improving the data processing efficiency.

- **WebHCat**

WebHCat running users use Rest APIs to perform operations, such as running Hive DDL commands, submitting Mapreduce tasks, and querying Mapreduce task execution results.

### 1.13.1.3 Required Permissions

Before developing an application based on this guide, ensure that the basic permissions of the users belong to a Hive group and obtain additional operation permissions from the system administrator. **Table 1-117** describes the permission required for each operation. To run example programs, you must have the create permission for the default database.

**Table 1-117** Required permissions

Operation Type/ Functional Object	Operation	Required Permission
DATABASE	CREATE DATABASE <i>dbname</i> [LOCATION "hdfs_path"]	If the HDFS path <b>hdfs_path</b> is specified, the ownership and RWX permission of <b>hdfs_path</b> are required.
	DROP DATABASE <i>dbname</i>	The database <b>dbname</b> ownership is required.
	ALTER DATABASE <i>dbname</i> SET OWNER <i>user_or_role</i>	The admin permission is required.
TABLE	CREATE TABLE <i>table_a</i>	The create permission for the database is required.
	CREATE TABLE <i>table_a</i> AS SELECT <i>table_b</i>	The create permission for the database and the select permission for <b>table_b</b> are required.
	CREATE TABLE <i>table_a</i> LIKE <i>table_b</i>	The create permission for the database is required.
	CREATE [EXTERNAL] TABLE <i>table_a</i> LOCATION "hdfs_path"	The create permission for the database, and the ownership and RWX permission of <b>hdfs_path</b> on HDFS are required.
	DROP TABLE <i>table_a</i>	The ownership of <b>table_a</b> is required.
	ALTER TABLE <i>table_a</i> SET LOCATION "hdfs_path"	The ownership of <b>table_a</b> , and the ownership and RWX permission of <b>hdfs_path</b> on HDFS are required.
	ALTER TABLE <i>table_a</i> SET FILEFORMAT	The ownership of <b>table_a</b> is required.
	TRUNCATE TABLE <i>table_a</i>	The ownership of <b>table_a</b> is required.
	ANALYZE TABLE <i>table_a</i> COMPUTE STATISTICS	The select and insert permission for <b>table_a</b> is required.
	SHOW TBLPROPERTIES <i>table_a</i>	The select permission for <b>table_a</b> is required.

Operation Type/ Functional Object	Operation	Required Permission
	SHOW CREATE TABLE <i>table_a</i>	The select permission with grant option for <b>table_a</b> is required.
Alter	ALTER TABLE <i>table_a</i> ADD COLUMN	The ownership of <b>table_a</b> is required.
	ALTER TABLE <i>table_a</i> REPLACE COLUMN	The ownership of <b>table_a</b> is required.
	ALTER TABLE <i>table_a</i> RENAME	The ownership of <b>table_a</b> is required.
	ALTER TABLE <i>table_a</i> SET SERDE	The ownership of <b>table_a</b> is required.
	ALTER TABLE <i>table_a</i> CLUSTER BY	The ownership of <b>table_a</b> is required.
PARTITION	ALTER TABLE <i>table_a</i> ADD PARTITION <i>partition_spec</i> LOCATION "hdfs_path"	The insert permission for <b>table_a</b> , and the ownership and RWX permission of <b>hdfs_path</b> on HDFS are required.
	ALTER TABLE <i>table_a</i> DROP PARTITION <i>partition_spec</i>	The delete permission for <b>table_a</b> is required.
	ALTER TABLE <i>table_a</i> PARTITION <i>partition_spec</i> SET LOCATION "hdfs_path"	The ownership of <b>table_a</b> , and the ownership and RWX permission of <b>hdfs_path</b> on HDFS are required.
	ALTER TABLE <i>table_a</i> PARTITION <i>partition_spec</i> SET FILEFORMAT	The ownership of <b>table_a</b> is required.
LOAD	LOAD INPATH 'hdfs_path' INTO TABLE <i>table_a</i>	The insert permission for <b>table_a</b> , and the ownership and RWX permission of <b>hdfs_path</b> on HDFS are required.
INSERT	INSERT TABLE <i>table_a</i> SELECT FROM <i>table_b</i>	The update permission for <b>table_a</b> and select permission for <b>table_b</b> are required.
SELECT	SELECT * FROM <i>table_a</i>	The select permission for <b>table_a</b> is required.

Operation Type/ Functional Object	Operation	Required Permission
	SELECT FROM <i>table_a</i> JOIN <i>table_b</i>	The select permission for <b>table_a</b> and <b>table_b</b> , the Submit permission of the default Yarn queue is required.
	SELECT FROM (SELECT FROM <i>table_a</i> UNION ALL SELECT FROM <i>table_b</i> )	The select permission for <b>table_a</b> and <b>table_b</b> , the Submit permission of the default Yarn queue is required.
EXPLAIN	EXPLAIN [EXTENDED] DEPENDENCY] <i>query</i>	The RX permissions for related table directory is required.
VIEW	CREATE VIEW <i>view_name</i> AS SELECT ...	The select permission with grant option for related tables is required.
	ALTER VIEW <i>view_name</i> RENAME TO <i>new_view_name</i>	The ownership of <b>view_name</b> is required.
	DROP VIEW <i>view_name</i>	The ownership of <b>view_name</b> is required.
INDEX	CREATE INDEX <i>index_name</i> ON TABLE <i>base_table_name</i> ( <i>col_name</i> , ...) AS <i>index_type</i>	The ownership of <b>table_a</b> is required.
	DROP INDEX <i>index_name</i> ON <i>table_name</i>	The ownership of <b>index_name</b> is required.
	ALTER INDEX <i>index_name</i> ON <i>table_name</i> REBUILD	The ownership of <b>index_name</b> is required.
FUNCTION	CREATE [TEMPORARY] FUNCTION <i>function_name</i> AS ' <i>class_name</i> '	The admin permission is required.
	DROP [TEMPORARY] <i>function_name</i>	The admin permission is required.
MACRO	CREATE TEMPORARY MACRO <i>macro_name</i> ...	The admin permission is required.

Operation Type/ Functional Object	Operation	Required Permission
	DROP TEMPORARY MACRO <i>macro_name</i>	The admin permission is required.

 NOTE

- You can perform all the previous operations when owning the **admin** permission of Hive and the corresponding directory permission of HDFS.
- If the current component uses Ranger for permission control, you need to configure permission management policies based on Ranger. For details, see "Component Operation Guide > Using Ranger > Adding a Ranger Access Permission Policy for Hive" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

#### 1.13.1.4 Development Process

[Figure 1-163](#) and [Table 1-118](#) illustrates each phase of the development process.

**Figure 1-163** Hive application development process

**Table 1-118** Description of the Hive application development process

Phase	Description	Reference Document
Understand the basic concepts.	Before application development, understand common concepts about Hive.	<a href="#">Common Concepts</a>
Prepare the development and operating environment.	Hive applications support Java and Python development languages. You are advised to use the IntelliJ IDEA tool to configure the development environment based on the language.	<a href="#">Preparing the Environment</a>
Develop projects based on scenarios.	Provides example projects of the Java and Python languages as well as example projects covering table creation, data load, and data query.	<a href="#">Developing an Application</a>
Run the application and view results.	Describes how to submit a developed application for compiling and view the result.	<a href="#">Commissioning Applications</a>

## 1.13.2 Preparing the Environment

### 1.13.2.1 Preparing Development and Operating Environment

#### Preparing Development Environment

Hive applications can be developed by using the JDBC/Metastore/Python/Python3 API. The following table describes the development and operating environment to be prepared.

**Table 1-119** JDBC/Metastore development environment

Item	Description
OS	<ul style="list-style-type: none"><li>Development environment: Windows OS. Windows 7 or later is supported.</li><li>Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul>
Installing JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>Oracle JDK 1.8</li><li>IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>For security purposes, the server supports only TLS V1.2 or later.</li><li>By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>Tool used for developing Hive applications. Requirements are as follows:</p> <p>JDK 1.8 is used. IntelliJ IDEA 2019.1 or other compatible versions are used.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li></ul>

Item	Description
Installation of Maven	Basic configurations of the development environment. It can be used for project management throughout the lifecycle of software development.
Developer account preparation	See <a href="#">Preparing a Developer Account</a> for configuration.
7-zip	Used to decompress .zip and .rar packages. The 7-Zip 16.04 is supported.

**Table 1-120** Python development environment

Item	Description
OS	Development and operating environment: Linux OS
Python installation	Python is a tool used to develop Hive applications. Its version must be 2.6.6 or later but should not be later than 2.7.13.
setuptools installation	Basic configuration for the Python development environment. The version must be 5.0 or later.
Developer account preparation	See <a href="#">Preparing a Developer Account</a> for configuration.

 NOTE

For details about how to install and configure the Python development tool, see the [Configuring the Python Sample Project](#).

**Table 1-121** Python3 development environment

Item	Description
OS	Development and operating environment: Linux OS
Python3 installation	Python3 is a tool used to develop Hive applications. Its version must be 3.6 or later but should not be later than 3.9.
setuptools installation	Basic configuration for the Python3 development environment. The version must be 47.3.1.
Developer account preparation	See <a href="#">Preparing a Developer Account</a> for configuration.

 NOTE

For details about how to install and configure the Python3 development tool, see the [Configuring the Python3 Sample Project](#).

## Preparing an Operating Environment

During application development, you need to prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. Log in to the FusionInsight Manager, click **Download Client** in the upper right corner of the Homepage, set **Select Client Type** to **Configuration Files Only** and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles** directory on the local PC. The directory name cannot contain spaces.

- b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles\Hive\config** and manually import the configuration file to the configuration file directory (usually the **resources** folder) of the Hive sample project.

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. **Table 1-122** describes the main configuration files.

**Table 1-122** Configuration file

Document Name	Function
hive metastore-site.xml	Configures Hive parameters.
hiveclient.properties	Configures Hive parameters.
user.keytab	Provides Hive user information for Kerberos security authentication.
krb5.conf	Contains Kerberos server configuration information.
core-site.xml	Configures Hive parameters.

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where

the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.
- When configuring IPv6 hosts on the local PC running Windows, add % and InterfaceIndex of the network interface card (NIC) to the end of the IPv6 address. The InterfaceIndex can be obtained by running the **ipconfig** command.

Example:

fec1:0:0:e505:8:99:5:1%10

- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.

Ensure that the difference between the client time and the cluster time is less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).

- b. **Accessing FusionInsight Manager of an MRS Cluster**. Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/Hive/config** directory to the **src/main/resources** directory where the compiled JAR package is stored for subsequent commissioning, for example, **/opt/hadoopclient/src/main/resources**.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Hive/config/* root@IP address of the client node:/opt/  
hadoopclient/src/main/resources
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. [Table 1-123](#) describes the main configuration files.

**Table 1-123 Configuration files**

File	Function
hive metastore-site.xml	Configures Hive parameters.
hiveclient.properties	Configures Hive parameters.
user.keytab	Provides Hive user information for Kerberos security authentication.
krb5.conf	Contains Kerberos server configuration information.
core-site.xml	Configures Hive parameters.

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

### 1.13.2.2 Configuring the JDBC Sample Project

#### Scenario

To run the JDBC API example codes of the Hive component of MRS, perform the following operations.

#### NOTE

- The following uses the development of an application for connecting the Hive service in JDBC mode on Windows as an example.
- After importing the jdbc-example sample project, you need to change xxx of `USER_NAME = "xxx"` in the code to the development user created in [Preparing a Developer Account](#).

#### Procedure

**Step 1** Obtain the sample project folder **hive-jdbc-example** in the **src\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** Copy the **user.keytab** and **krb5.conf** files obtained in [Preparing a Developer Account](#) to the **hive-jdbc-example\src\main\resources** directory of the sample project.

**Step 3** Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles\Hive\config** and manually import the **core-site.xml** and **hiveclient.properties** files to the **hive-jdbc-example\src\main\resources** directory of the sample project.

### NOTE

Hive allows you to add extension identifiers to JDBC connection strings. These extension identifiers are printed in HiveServer audit logs to distinguish SQL sources. If you need to configure an identifier, add the following content to the **hive-jdbc-example\src\main\resources\hiveclient.properties** file:

```
auditAddition=xxx
```

*xxx* is the custom identifier. The identifier can contain a maximum of 256 bytes and only letters, digits, underscores (\_), commas (,), and colons (:) are allowed.

After the SQL statement is executed, the configured extension identifier is printed in the HiveServer audit log **/var/log/Bigdata/audit/hive/hiveserver/hive-audit.log**. The following is an example.

```
2024-02-27 11:55:56,501 | INFO | HiveServer2-Handler-Pool: Thread-402 | UserName=test UserID=192.168.64.239 Time=2024/02/27 11:55:56 Operation=OpenSession Result= Data
1=Addition=xxx | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:512)
2024-02-27 11:55:56,501 | INFO | HiveServer2-Handler-Pool: Thread-402 | UserName=test UserID=192.168.64.239 Time=2024/02/27 11:55:56 Operation=OpenSession Result=SUCCE
2=Addition=xxx | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:512)
2024-02-27 11:55:59,312 | INFO | HiveServer2-Handler-Pool: Thread-402 | UserName=test UserID=192.168.64.239 Time=2024/02/27 11:55:59 Operation=ExecuteStatement Stmt
=(show tables) Result= Details=Addition=xxx | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:512)
2024-02-27 11:55:59,316 | INFO | HiveServer2-Handler-Pool: Thread-402 | OperationId=718760c-bb8d-42f0-80d3-760baef5282ef UserName=test UserID=192.168.64.239 Time=2024/02/27 11:55:59 Operation=ExecuteStatement Stmt=[show tables] Result=SUCCESS Detail=Addition=xxx | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:512)
```

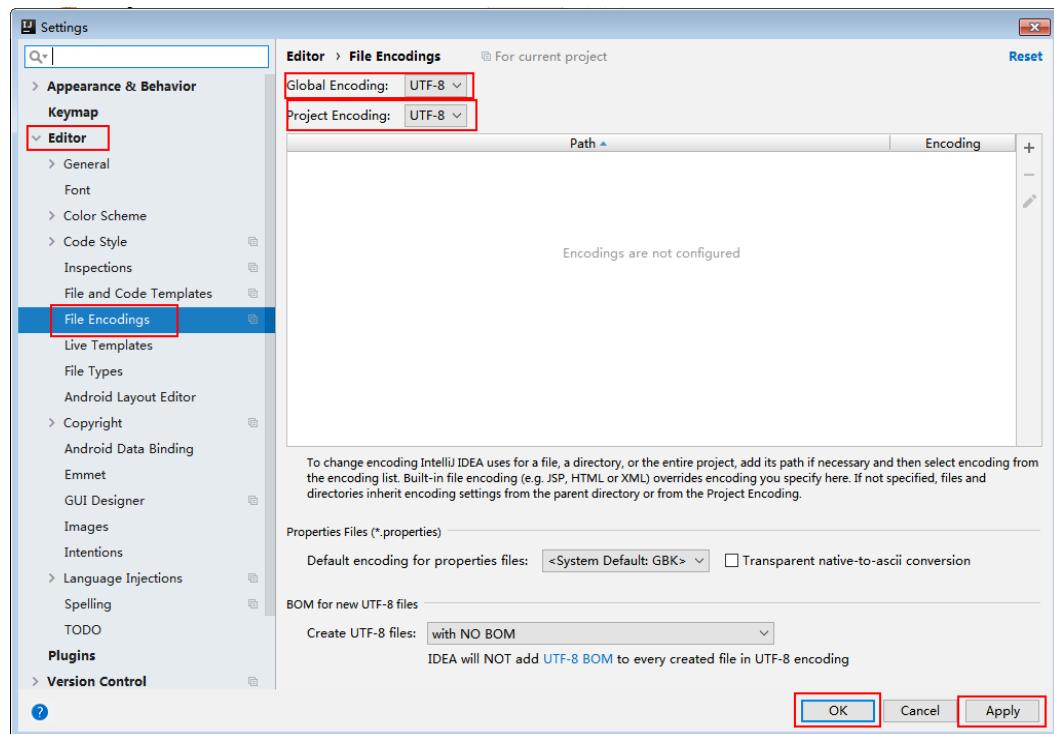

### Step 4 Import the example project to the IntelliJ IDEA development environment.

- On the IntelliJ IDEA menu bar, choose **File > Open....** The **Open File or Project** window is displayed.
- In the displayed window, select the folder **hive-jdbc-example**, and click **OK**. On Windows, the path cannot contain any space.

### Step 5 Set the IntelliJ IDEA text file coding format to prevent garbled characters.

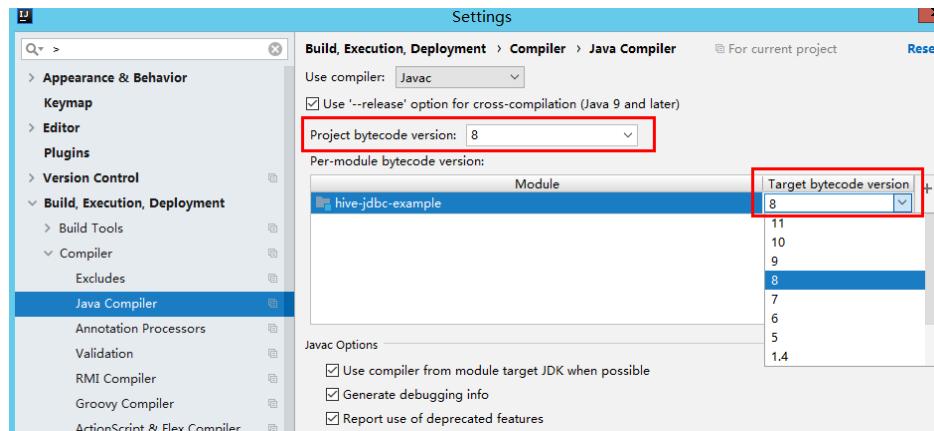

- On the IntelliJ IDEA menu bar, choose **File > Settings**. The **Settings** window is displayed.
- In the navigating tree on the left, choose **Editor > File Encodings**. In the **Project Encoding** area and **Global Encoding** area, set the value to **UTF-8**, and click **Apply** and **OK**, as shown in [Figure 1-164](#).

**Figure 1-164** Setting the IntelliJ IDEA coding format

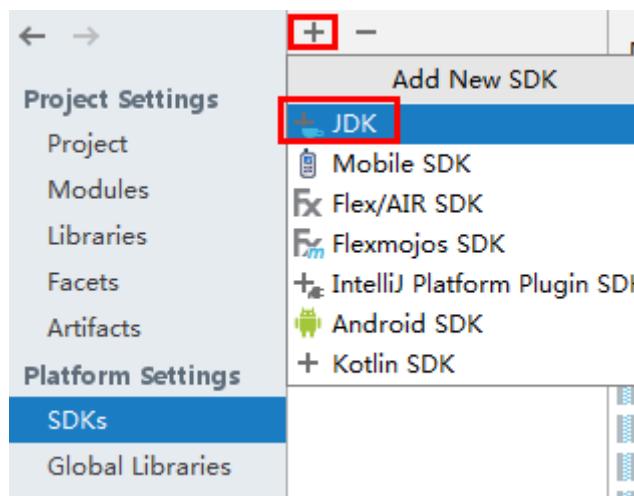

**Step 6** Set the JDK of the project.

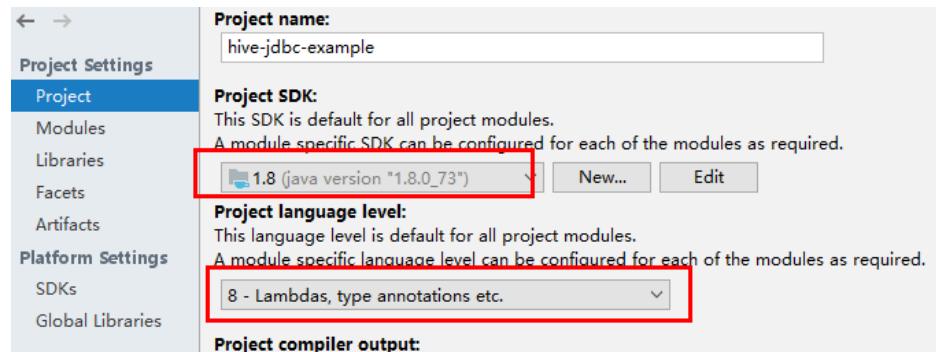

1. On the IntelliJ IDEA menu bar, choose **File > Settings....** The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler**, select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** to **8** for **hive-jdbc-example**.

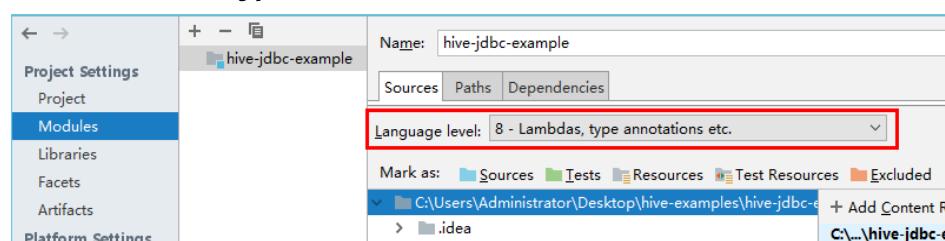

3. Click **Apply** and **OK**.
4. On the IntelliJ IDEA menu bar, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Select **SDKs**, click the plus sign (+), and select **JDK**.

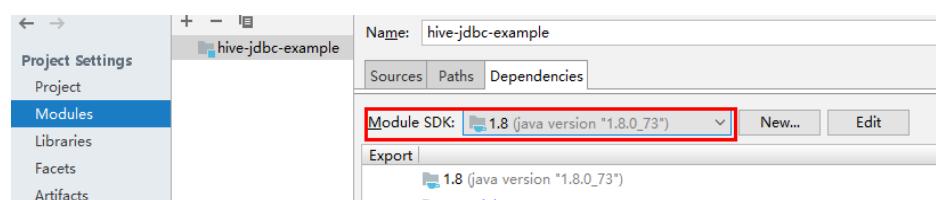

6. On the **Select Home Directory for JDK** page that is displayed, select the **JDK** directory and click **OK**.
7. After selecting the JDK, click **Apply**.
8. Select **Project**, select the JDK added in **SDKs** from the **Project SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Project language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Source** page, change the value of **Language level** to **8 - Lambdas, type annotations etc.**

On the **Dependencies** page, change the value of **Module SDK** to the JDK added in **SDKs**.

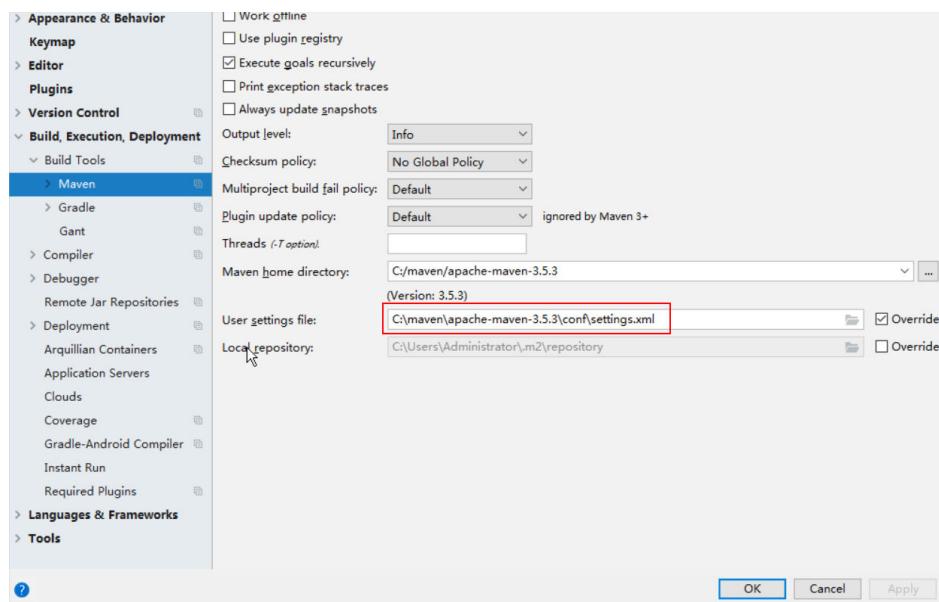

11. Click **Apply** and **OK**.

#### Step 7 Configure Maven.

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, select **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is **<Local Maven installation directory>\conf\settings.xml**.

Figure 1-165 Directory for storing the **settings.xml** file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply**, and then click **OK**.

----End

### 1.13.2.3 Configuring the Hcatalog Sample Project

#### Scenario

To run the HCatalog interface example codes of the Hive component of MRS, perform the following operations.

##### NOTE

The following uses the development of an application for connecting the Hive service in HCatalog mode on Windows as an example.

#### Procedure

**Step 1** Obtain the sample project folder **hcatalog-example** in the **src\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

**Step 2** Import the example project to the IntelliJ IDEA development environment.

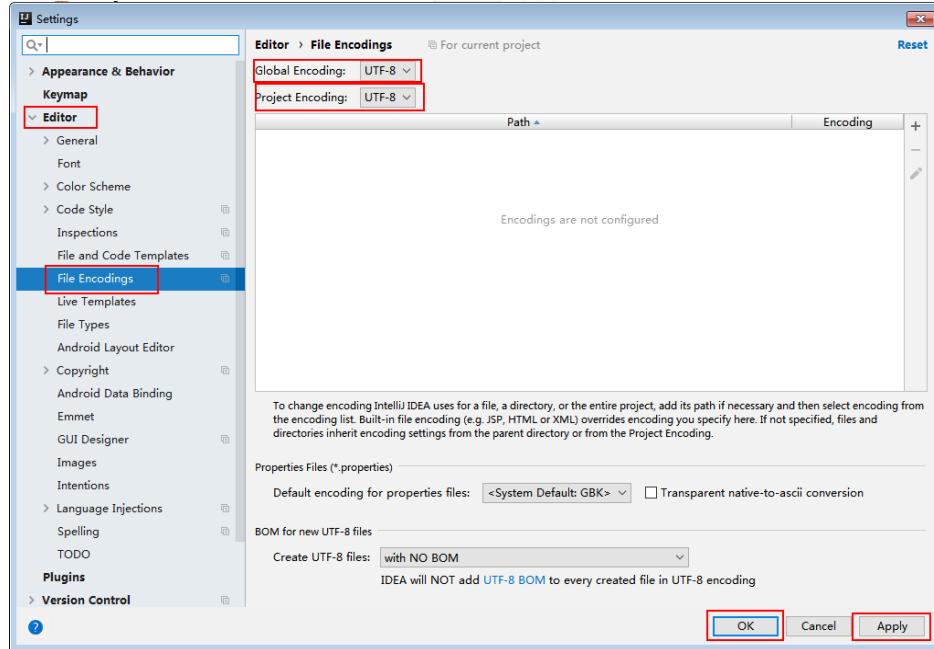

1. On the IntelliJ IDEA menu bar, choose **File > Open....** The **Open File or Project** window is displayed.
2. In the displayed window, select the folder **hcatalog-example**, and click **OK**. On Windows, the path cannot contain any space.

**Step 3** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

1. On the IntelliJ IDEA menu bar, choose **File > Settings**. The **Settings** window is displayed.

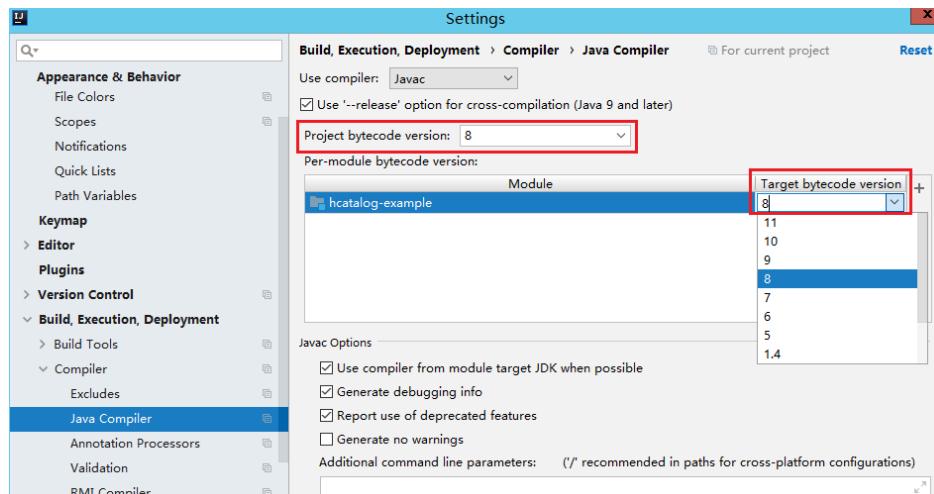

2. Choose **Editor > File Encodings** from the navigation tree. In the **Project Encoding** area and **Global Encoding** area, set the value to **UTF-8**, click **Apply**, and click **OK**, as shown in [Figure 1-166](#).

**Figure 1-166** Setting the IntelliJ IDEA coding format

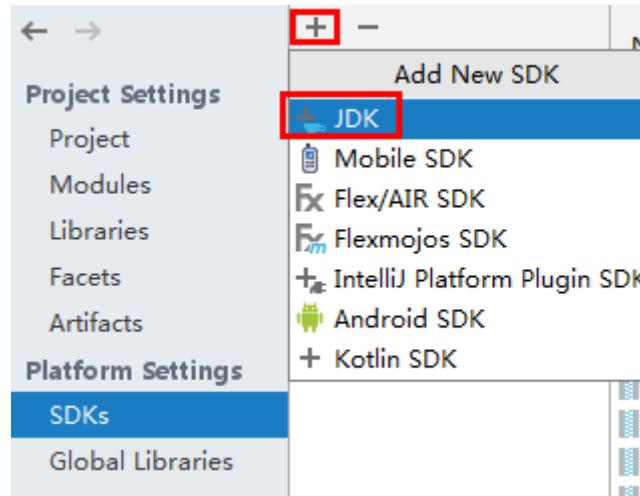

#### Step 4 Set the JDK of the project.

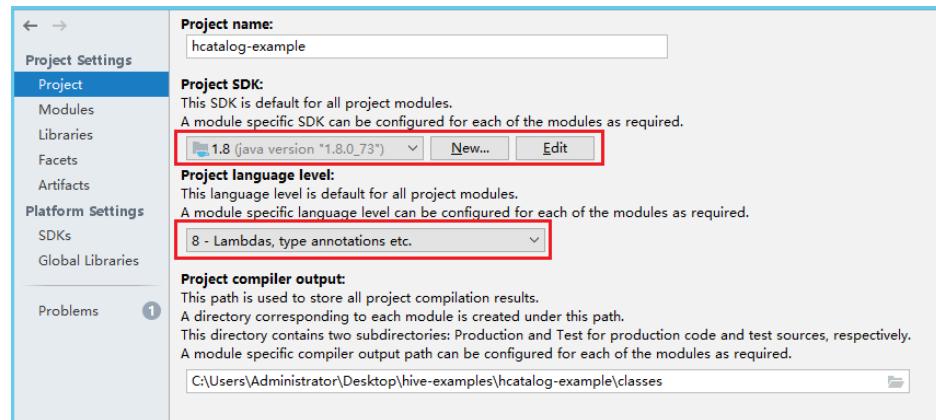

1. On the IntelliJ IDEA menu bar, choose **File > Settings....** The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler**, select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** to **8** for **hive-jdbc-example**.

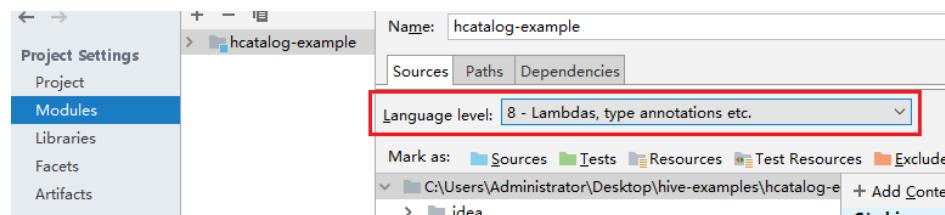

3. Click **Apply** and **OK**.
4. On the IntelliJ IDEA menu bar, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Select **SDKs**, click the plus sign (+), and select **JDK**.

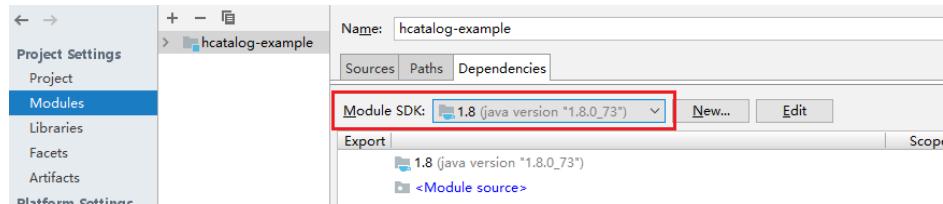

6. On the **Select Home Directory for JDK** page that is displayed, select the **JDK** directory and click **OK**.
7. After selecting the JDK, click **Apply**.
8. Select **Project**, select the JDK added in SDKs from the **Project SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Project language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Source** page, change the value of **Language level** to **8 - Lambdas, type annotations etc.**

11. On the **Dependencies** page, change the value of **Module SDK** to the JDK added in SDKs.

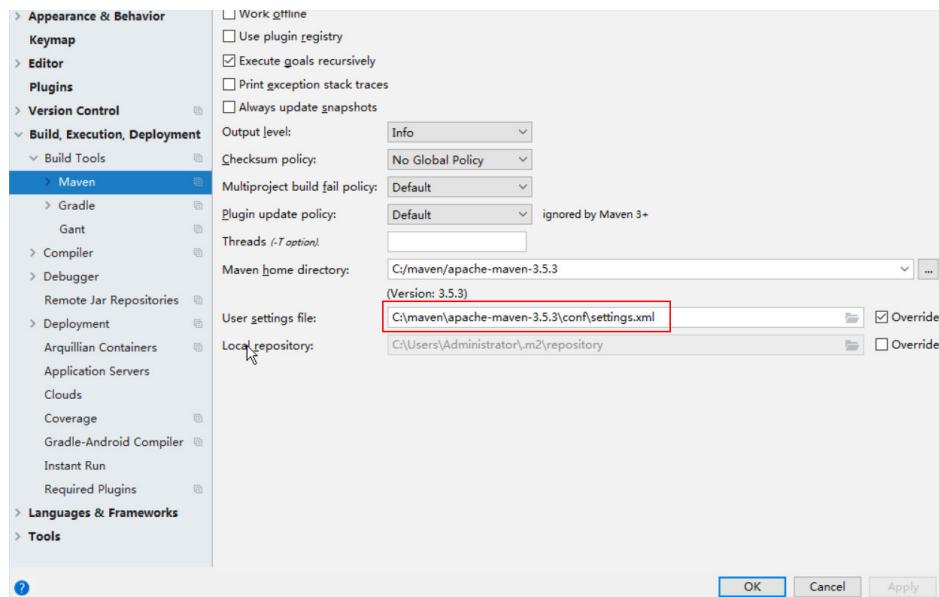

12. Click **Apply** and **OK**.

#### Step 5 Configure Maven.

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, select **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is **<Local Maven installation directory>\conf\settings.xml**.

Figure 1-167 Directory for storing the **settings.xml** file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply**, and then click **OK**.

----End

#### 1.13.2.4 Configuring the Python Sample Project

##### Scenario

To run the Python interface example codes of the Hive component of MRS, perform the following operations.

## Procedure

- Step 1** Python of 2.6.6 or a higher version has been installed on a client. The Python version cannot be higher than 2.7.13.

The Python version can be viewed by running the **python** command on the command-line interface (CLI) of the client. The following information indicates that the Python version is 2.6.6.

```
Python 2.6.6 (r266:84292, Oct 12 2012, 14:23:48)
[GCC 4.4.6 20120305 (Red Hat 4.4.6-4)] on linux2
Type "help", "copyright", "credits" or "license" for more information.
```

- Step 2** Setuptools of 5.0 or a higher version has been installed on a client. The setuptools version cannot be higher than 36.8.0.

To obtain the software, visit the official website.

<https://pypi.org/project/setuptools/#files>

Copy the downloaded setuptools package to the client, decompress the package, go to the decompressed directory, and run the **python setup.py install** command in the CLI of the client.

The following information indicates that setuptools 5.7 is installed successfully.

```
Finished processing dependencies for setuptools==5.7
```

- Step 3** Install Python on the client.

1. Obtain the sample project folder **python-examples** in the **src\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
2. Go to the **python-examples** folder.
3. Go to the **python-examples** folder.
4. Run the **python setup.py install** command in the CLI.

The following information indicates that Python is installed successfully.

```
Finished processing dependencies for pyhs2==0.5.0
```

- Step 4** After the installation is successful, the following files are generated. **python-examples/pyCLI\_sec.py** is the Python client example codes. **python-examples/pyhs2/haconnection.py** is the Python client API. Run **hive\_python\_client** scripts to execute the SQL functions, for example, **sh hive\_python\_client 'show tables'**.

### NOTE

This function applies to only simple SQL statements and depends on the ZooKeeper client.

----End

## 1.13.2.5 Configuring the Python3 Sample Project

### Scenario

To run the Python3 interface example codes of the Hive component of MRS, perform the following operations.

## Procedure

- Step 1** Python3 of 3.6 or a higher version has been installed on a client. The Python3 version cannot be higher than 3.9.

The Python version can be viewed by running the **python3** command on the command-line interface (CLI) of the client. The following information indicates that the Python version is 3.8.2.

```
Python 3.8.2 (default, Jun 23 2020, 10:26:03)
[GCC 4.8.5 20150623 (Red Hat 4.8.5-36)] on linux
Type "help", "copyright", "credits" or "license" for more information.
```

- Step 2** Setuptools of 47.3.1 version has been installed on a client.

To obtain the software, visit the official website.

<https://pypi.org/project/setuptools/#files>

Copy the downloaded setuptools package to the client, decompress the package, go to the decompressed directory, and run the **python3 setup.py install** command in the CLI of the client.

The following information indicates that setuptools 47.3.1 is installed successfully.

```
Finished processing dependencies for setuptools==47.3.1
```

If the system displays a message indicating that the installation of setuptools of 47.3.1 fails, check whether the environment is faulty or whether the problem is caused by Python.

- Step 3** Install Python on the client.

1. Obtain the sample project folder **python3-examples** in the **src\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
2. Go to the **python3-examples** folder.
3. Go to the **dependency\_python3.6**, **dependency\_python3.7**, or **dependency\_python3.8**, or **dependency\_python3.9** folder based on the Python3 version.
4. Run the **whereis easy\_install** command to find the path of the **easy\_install** program. If there are multiple paths, run the **easy\_install --version** command to select the **easy\_install** path corresponding to the **setuptools** version, for example, **/usr/local/bin/easy\_install**.
5. Run the **easy\_install** command to install the egg files in the **dependency\_python3.x** folder. If the egg file has dependencies, you can use wildcards to install the egg file. For example:
  - **dependency\_python3.6** directory:  
**/usr/local/bin/easy\_install future\*egg six\*egg python\*egg sasl-\*linux-\$(uname -p).egg thrift-\*egg thrift\_sasl\*egg**
  - **dependency\_python3.7** directory:  
**/usr/local/bin/easy\_install future\*egg six\*egg sasl-\*linux-\$(uname -p).egg thrift-\*egg thrift\_sasl\*egg**
  - **dependency\_python3.8** directory:  
**/usr/local/bin/easy\_install future\*egg six\*egg python\*egg sasl-\*linux-\$(uname -p).egg thrift-\*linux-\$(uname -p).egg thrift\_sasl\*egg**

- dependency\_python3.9 directory:

```
/usr/local/bin/easy_install future*egg six*egg sasl-*linux-$(uname -p).egg six-*.egg thrift-*linux-$(uname -p).egg thrift_sasl*egg
```

If the following information is displayed for each egg file, the installation is successful:

```
Finished processing dependencies for ***
```

**Step 4** After the installation is successful, the following files are generated. **python3-examples/pyCLI\_sec.py** is the Python client example codes. **python3-examples/pyhive/hive.py** is the Python client API.

----End

### 1.13.2.6 Configuring a Spring Boot Sample Project

#### Scenario

Run the Spring Boot interface sample code of MRS Hive.

The following example develops an application that uses SpringBoot to connect to Hive in the Windows environment.

#### Procedure

- Step 1** Obtain the sample project folder **hive-rest-client-example** in the **src\springboot\hive-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Save the keytab files **user.keytab** and **krb5.conf** obtained when a developer account is prepared by referring to [Preparing a Developer Account](#) to the **hive-rest-client-example\src\main\resources** directory of the sample project.
- Step 3** Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Hive\config** and copy the **core-site.xml** and **hiveclient.properties** files to the **hive-jdbc-example\src\main\resources** directory of the sample project.

#### NOTE

Hive allows you to add extension identifiers to JDBC connection strings. These extension identifiers are printed in HiveServer audit logs to distinguish SQL sources. If you need to configure an identifier, add the following content to the **hive-jdbc-example\src\main\resources\hiveclient.properties** file:

```
auditAddition=xxx
```

**xxx** is the custom identifier. The identifier can contain a maximum of 256 bytes and only letters, digits, underscores (\_), commas (,), and colons (:) are allowed.

After the SQL statement is executed, the configured extension identifier is printed in the HiveServer audit log **/var/log/Bigdata/audit/hive/hiveserver/hive-audit.log**. The following is an example.

```
2024-02-27 11:55:56,501 | INFO  | HiveServer2-Handler-Pool: Thread-402 | UserName=test UserId=192.168.64.230 Time=2024/02/27 11:55:56      Operation=OpenSession Result= Data
11=Addition=xx | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:512)
2024-02-27 11:55:56,501 | INFO  | HiveServer2-Handler-Pool: Thread-402 | UserName=test UserId=192.168.64.230 Time=2024/02/27 11:55:56      Operation=OpenSession Result=SUCCE
SS Detail= Addition=xx | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:512)
2024-02-27 11:55:59,212 | INFO  | HiveServer2-Handler-Pool: Thread-402 | UserName=test UserId=192.168.64.230 Time=2024/02/27 11:55:59      Operation=ExecuteStatement  stmt
=(show tables)  Result= Detail= Addition=xx | org.apache.hive.service.cli.thrift.ThriftCLIService.logAuditEvent(ThriftCLIService.java:512)
2024-02-27 11:55:59,336 | INFO  | HiveServer2-Handler-Pool: Thread-402 | OperationId=7187e0c-b8d3-42f0-80d3-760babf5202ef  UserName=test UserId=192.168.64.230 Time=2024/02/27 11:55:59      Operation=ExecuteStatement  stmt
=(ThriftCLIService.java:512)
```

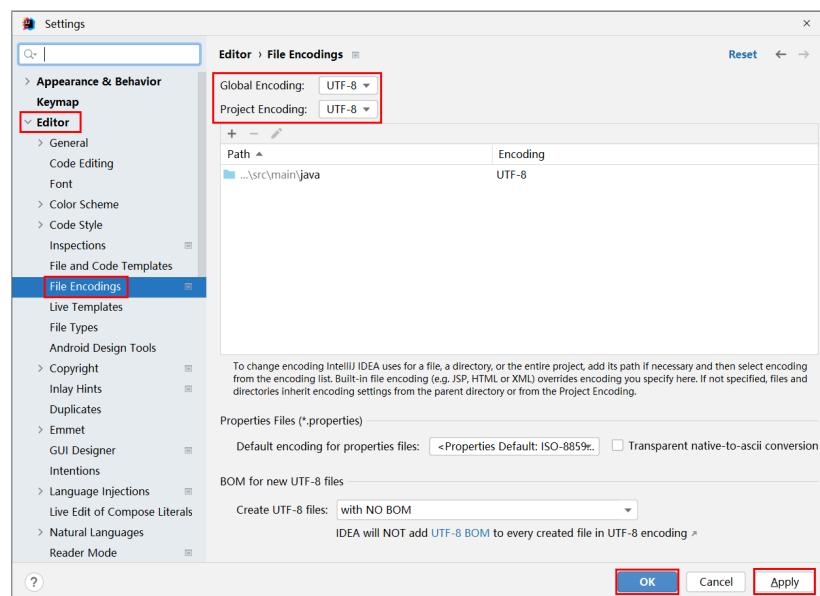

**Step 4** Import the sample project to the IntelliJ IDEA development environment.

1. On the menu bar of IntelliJ IDEA, choose **File > Open....**
2. In the **Open File or Project** dialog box that is displayed, select the **hive-rest-client-example** folder and click **OK**. In Windows, the folder path cannot contain any space.

**Step 5** Set the IntelliJ IDEA text file coding format to prevent garbled characters.

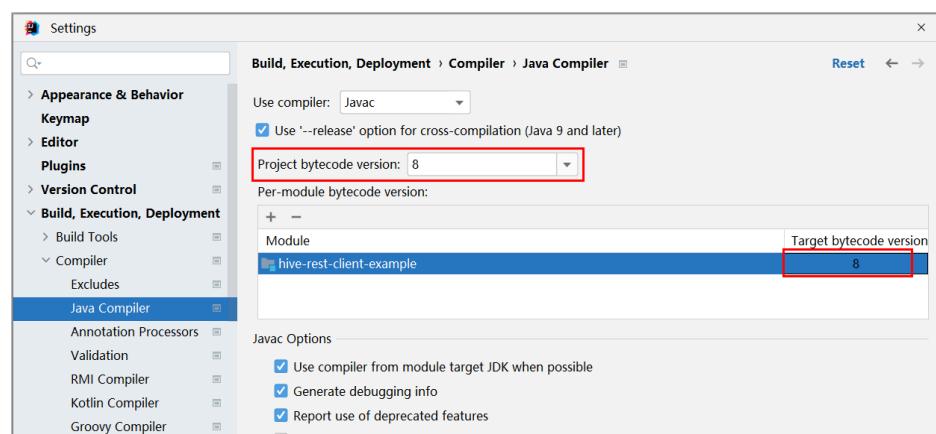

1. On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
2. In the left navigation pane, choose **Editor > File Encodings**. In the **Project Encoding** and **Global Encoding** areas, set the parameter to **UTF-8**. Click **Apply** and **OK**.

**Figure 1-168** Setting the IntelliJ IDEA coding format

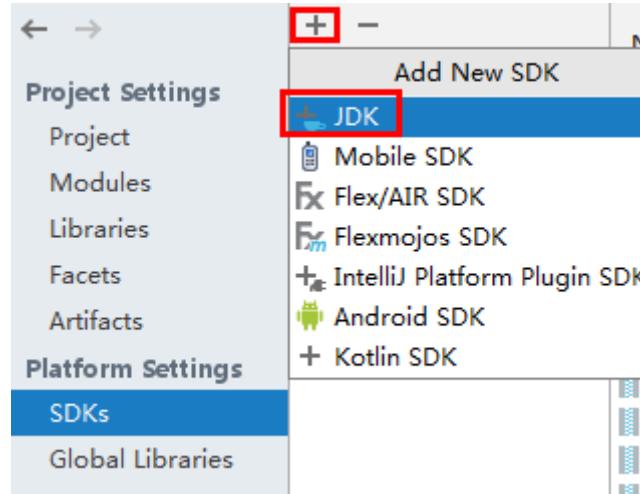

**Step 6** Set the JDK of the project.

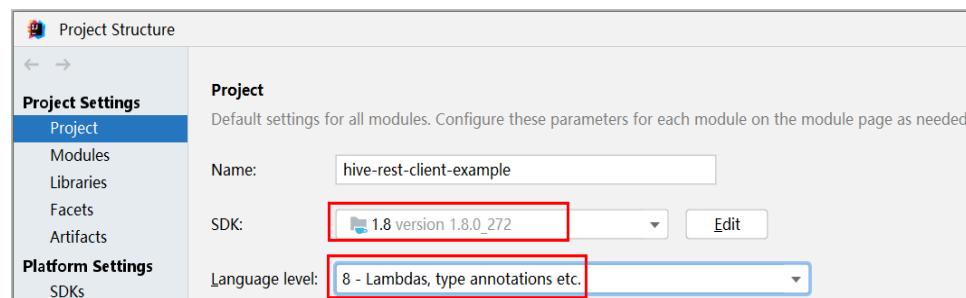

1. On the menu bar of IntelliJ IDEA, choose **File > Settings**. The **Settings** window is displayed.
2. Choose **Build, Execution, Deployment > Compiler > Java Compiler** and select **8** from the **Project bytecode version** drop-down list box. Change the value of **Target bytecode version** in **hive-rest-client-example** to **8**.

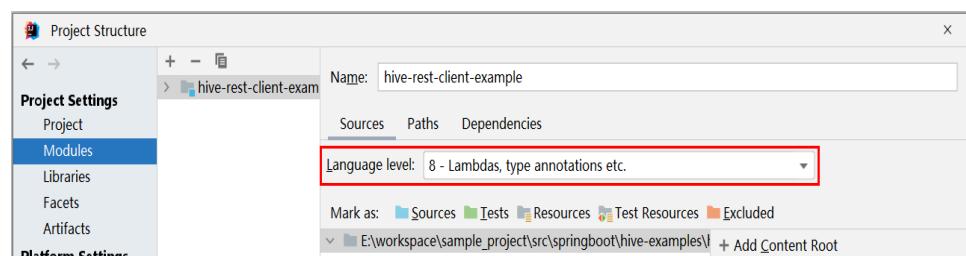

3. Click **Apply** then **OK**.
4. On the menu bar of IntelliJ IDEA, choose **File > Project Structure....** The **Project Structure** window is displayed.
5. Choose **SDKs**, click the plus sign (+), and select **JDK**.

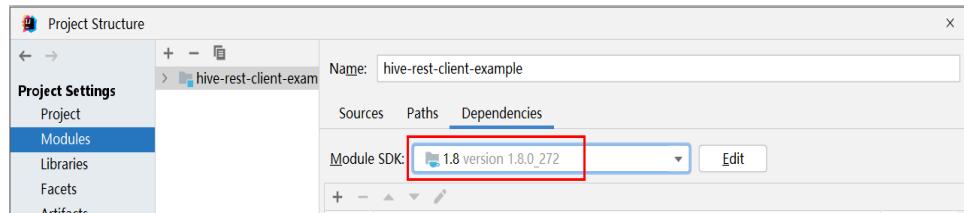

6. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.
7. Click **Apply**.
8. Select **Project**, select the JDK added in **SDKs** from the **SDK** drop-down list box, and select **8 - Lambdas, type annotations etc.** from the **Language level** drop-down list box.

9. Click **Apply**.
10. Choose **Modules**. On the **Sources** tab page, change the value of **Language level** to **8 - Lambdas, type annotations etc..**

On the **Dependencies** tab page, change the value of **Module SDK** to the JDK added in **SDKs**.

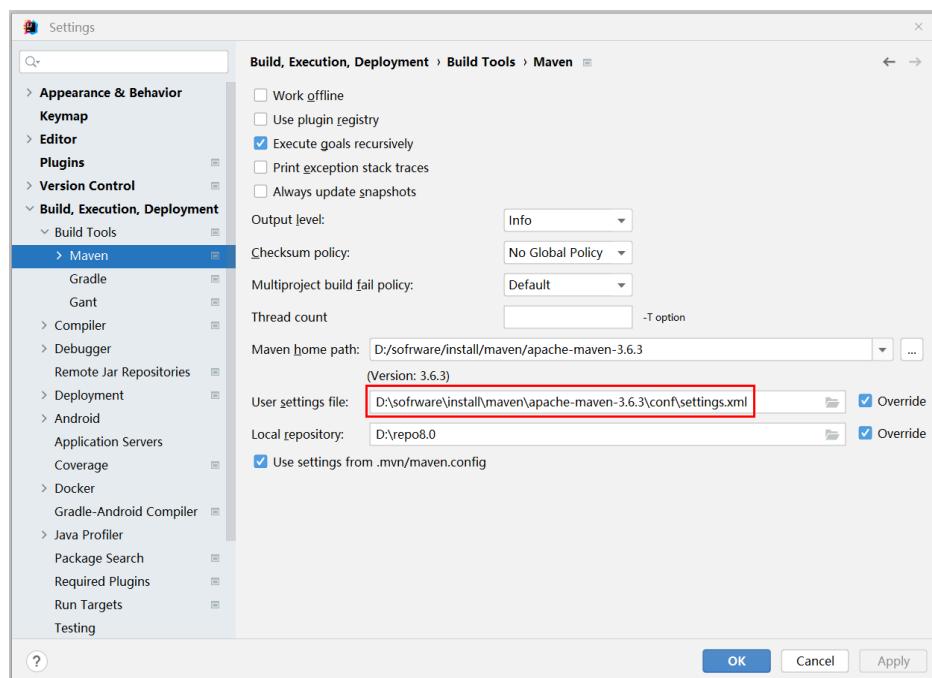

11. Click **Apply** then **OK**.

**Step 7** Configure Maven.

1. Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).
2. On the IntelliJ IDEA page, choose **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is **<Local Maven installation directory>\conf\settings.xml**.

**Figure 1-169** Directory for storing the **settings.xml** file

3. Click the drop-down list next to **Maven home directory** and select the Maven installation directory.
4. Click **Apply** then **OK**.

**Step 8** Find the **hiveclient.properties** configuration file in **src\main\resources** and add the following content to the file. Replace **xxx** with the development user created during development account preparation.

```
user.name=xxx
```

----End

## 1.13.3 Developing an Application

### 1.13.3.1 Typical Scenario Description

#### Scenarios

Assume that you need to develop a Hive data analysis application to manage the employee information described in [Table 1-124](#) and [Table 1-125](#).

#### Development Guidelines

##### Step 1 Prepare data.

1. Create three tables: employee information table **employees\_info**, employee contact table **employees\_contact**, and extended employee information table **employees\_info\_extended**.
  - Employee information table **employees\_info** contains fields such as employee ID, name, salary currency, salary, tax category, work place, and hire date. In salary currency, **R** indicates RMB and **D** indicates USD.
  - Fields in the **employees\_contact** table include the employee ID, phone number, and email address.
  - Fields in the **employees\_info\_extended** table include the employee ID, name, mobile phone number, e-mail address, salary currency, salary, tax category, and work place. The partition field is the hire date.
2. Load employee information to **employees\_info**.  
For data loading codes, see [Loading Data](#).

[Table 1-124](#) describes employee information.

**Table 1-124** Employee information

ID	Name	Salary Currency	Salary	Tax Category	Work Place	Hiring Date
1	Wang	R	8000.01	personal income tax&0.05	Country 1:City1	2014
3	Tom	D	12000.02	personal income tax&0.09	Country 2:City2	2014
4	Jack	D	24000.03	personal income tax&0.09	Country 3:City3	2014
6	Linda	D	36000.04	personal income tax&0.09	Country 4:City4	2014

ID	Name	Salary Currency	Salary	Tax Category	Work Place	Hiring Date
8	Zhang	R	9000.05	personal income tax&0.05	Country5:City5	2014

3. Load employee contact information to **employees\_contact**.

**Table 1-125** describes employee contact information.

**Table 1-125** Employee contact information

ID	Mobile Phone Number	E-mail Address
1	135 XXXX XXXX	xxxx@xx.com
3	159 XXXX XXXX	xxxxx@xx.com.cn
4	186 XXXX XXXX	xxxx@xx.org
6	189 XXXX XXXX	xxxx@xxx.cn
8	134 XXXX XXXX	xxxx@xxxx.cn

4. Load extended employee information to **employees\_info\_extended**.

**Table 1-126** describes the extended employee information.

**Table 1-126** Extended employee information

ID	Name	Mobile Phone Number	E-mail Address	Salary Currency	Salary	Tax Category	Work Place	Hiring Date
1	Wa ng	135 XXXX XXXX	xxxx@x x.com	R	8000 .01	personal income tax&0.0 5	Country1 :City1	201 4
3	To m	159 XXXX XXXX	xxxxx@ xx.com. cn	D	1200 0.02	personal income tax&0.0 9	Country2 :City2	201 4
4	Jack	186 XXXX XXXX	xxxx@x x.org	D	2400 0.03	personal income tax&0.0 9	Country3 :City3	201 4

ID	Name	Mobile Phone Number	E-mail Address	Salary Currency	Salary	Tax Category	Work Place	Hiring Date
6	Linda	189 XXXX XXXX	xxxx@xx.cn	D	3600 0.04	personal income tax&0.09	Country4 :City4	2014
8	Zhang	134 XXXX XXXX	xxxx@xxx.cn	R	9000 .05	personal income tax&0.05	Country5 :City5	2014

## Step 2 Analyze data.

For data analysis codes, see [Querying Data](#).

- Query contact information of employees whose salaries are paid in USD.
- Query the IDs and names of employees who were hired in 2014, and load the query results to the partition with the hiring date of 2014 in **employees\_info\_extended**.
- Collect the number of records in the **employees\_info** table.
- Query information about employees whose email addresses end with "cn".

## Step 3 Submit a data analysis task to collect the number of records in the **employees\_info** table. For details about the implementation, see [Example Program Guide](#).

----End

### 1.13.3.2 Example Codes

#### 1.13.3.2.1 Creating a Table

##### Function

This section describes how to use Hive Query Language (HQL) to create internal and external tables. You can create a table in three modes:

- Customize the table structure, and use the key word **EXTERNAL** to differentiate between internal and external tables.
  - If data is to be processed by Hive, create an internal table. When an internal table is deleted, the metadata and data in the table are deleted together.
  - If data is to be processed by multiple tools, create an external table. When an external table is deleted, only metadata is deleted.
- Create a table based on existing tables. Use **CREATE LIKE** to fully copy the original table structure, including the storage format.

- Create a table based on query results using CREATE AS SELECT.

In this mode, you can specify fields (except for the storage format) that you want to copy to the new table when copying the structure of the existing table.

#### NOTE

- To perform the following operations on a cluster enabled with the security service, you must have the CREATE permission for databases. To create a table using the CREATE AS SELECT statement, you must have the SELECT permission for tables. For details about the permission requirements, see [Overview](#).
- Both the table name and field name can contain a maximum of 128 bytes. Both the field comment and value can contain a maximum of 4,000 bytes. The key in **WITH SERDEPROPERTIES** can contain a maximum of 256 bytes.

## Sample Codes

```
-- Create an external table employees_info.  
CREATE EXTERNAL TABLE IF NOT EXISTS employees_info  
(  
    id INT,  
    name STRING,  
    usd_flag STRING,  
    salary DOUBLE,  
    deductions MAP<STRING, DOUBLE>,  
    address STRING,  
    entrytime STRING  
)  
-- Specify the field delimiter.  
-- "delimited fields terminated by" indicates that the column delimiter is ',' and "MAP KEYS TERMINATED BY" indicates that the delimiter of key values in the MAP is '&'.  
ROW FORMAT delimited fields terminated by ',' MAP KEYS TERMINATED BY '&'  
-- Set the storage format to TEXTFILE.  
STORED AS TEXTFILE;  
  
-- Create an external table employees_contact.  
CREATE EXTERNAL TABLE IF NOT EXISTS employees_contact  
(  
    id INT,  
    tel_phone STRING,  
    email STRING  
)  
ROW FORMAT delimited fields terminated by ','  
STORED AS TEXTFILE;  
  
-- Create an external table employees_info_extended.  
CREATE EXTERNAL TABLE IF NOT EXISTS employees_info_extended(id INT, name STRING, usd_flag STRING,  
salary DOUBLE, deductions MAP<STRING, DOUBLE>, address STRING)  
-- A table may have one or multiple partitions. Each partition is saved as an independent folder in the table directory. Partitions help minimize the query scope, accelerate data query, and allow users to manage data based on certain criteria.  
-- Use PARTITIONED BY to specify the column name and data type of the partition.  
PARTITIONED BY(entrytime STRING)  
ROW FORMAT delimited fields terminated by ',' MAP KEYS TERMINATED BY '&'  
STORED AS TEXTFILE;  
-- After a table is created, you can use ALTER TABLE to add or delete fields to or from the table, modify table attributes, and add partitions.  
-- Add the tel_phone and email fields to the employees_info_extended table.  
ALTER TABLE employees_info_extended ADD COLUMNS (tel_phone STRING, email STRING);
```

### 1.13.3.2.2 Loading Data

#### Function

This section describes how to use HQL to load data to the existing **employees\_info** table. You can learn how to load data from a local file system and MRS cluster. LOCAL is used to differentiate between local and non-local data sources.

##### NOTE

To perform the following operations on a cluster enabled with the security service, you must have the UPDATE permission for databases, and owner permission and read/write permission for files to be loaded. For details about permission requirements, see [Overview](#).

If LOCAL is used in data loading statements, data is loaded from a local directory. In addition to the UPDATE permission for tables, you must have the read permission for the data path. It is also required that the data can be accessed by user **omm** on the active HiveServer.

If OVERWRITE is used in data loading statements, the existing data in a table will be overwritten by new data. If OVERWRITE does not exist, data will be added to the table.

#### Example Codes

```
-- Load the employee_info.txt file from the /opt/hive_examples_data/ directory of the local file system to the employees_info table.  
---- Overwrite the original data using the new data.  
LOAD DATA LOCAL INPATH '/opt/hive_examples_data/employee_info.txt' OVERWRITE INTO TABLE employees_info;  
---- Retain the original data and add the new data to the table.  
LOAD DATA LOCAL INPATH '/opt/hive_examples_data/employee_info.txt' INTO TABLE employees_info;  
  
-- Load /user/hive_examples_data/employee_info.txt from HDFS to the employees_info table.  
---- Overwrite the original data using the new data.  
LOAD DATA INPATH '/user/hive_examples_data/employee_info.txt' OVERWRITE INTO TABLE employees_info;  
---- Retain the original data and add the new data to the table.  
LOAD DATA INPATH '/user/hive_examples_data/employee_info.txt' INTO TABLE employees_info;
```

##### NOTE

The essence of loading data is to copy the data to the specified table directory in HDFS.

#### Sample Data

Data in **employees\_info** is as follows:

```
1,Wang,R,8000.01,person&personal^Btype&income^Btax&0.05,Country1:City1,2014  
3,Tom,D,12000.02,person&personal^Btype&income^Btax&0.09,Country2:City2,2014  
4,Jack,D,24000.03,person&personal^Btype&income^Btax&0.05,Country3:City3,2014  
6,Linda,D,36000.04,person&personal^Btype&income^Btax&0.05,Country4:City4,2014  
8,Zhang,R,9000.05,person&personal^Btype&income^Btax&0.05,Country5:City5,2014
```

Data in **employees\_contact** is as follows:

```
1,135 XXXX XXXX,xxxx@xx.com  
3,159 XXXX XXXX,xxxx@xx.com.cn  
4,186 XXXX XXXX,xxxx@xx.org  
6,189 XXXX XXXX,xxxx@xxx.cn  
8,134 XXXX XXXX,xxxx@xxxx.cn
```

Data in **employees\_info\_extended** is as follows:

```
1,Wang,135 XXXX  
XXXX,xxxx@xx.com,R,8000.01,person&personal^Btype&income^Btax&0.05,Country1:City1,2014
```

```
3,Tom,159 XXXX  
XXXX,xxxx@xx.com.cn,D,12000.02,person&personal^Btype&income^Btax&0.09,Country2:City2,2014  
4,Jack,186 XXXX  
XXXX,xxx@xx.org,D,24000.03,person&personal^Btype&income^Btax&0.05,Country3:City3,2014  
6,Linda,189 XXXX  
XXXX,xxx@xxx.cn,D,36000.04,person&personal^Btype&income^Btax&0.05,Country4:City4,2014  
8,Zhang,134 XXXX  
XXXX,xxx@xxx.cn,R,9000.05,person&personal^Btype&income^Btax&0.05,Country5:City5,2014
```

### 1.13.3.2.3 Querying Data

#### Function

This topic describes how to use Hive Query Language (HQL) to query and analyze data. You can query and analyze data using the following methods:

- Use common features for SELECT query, such as JOIN.
- Load data to a specified partition.
- Use Hive-provided functions.
- Query and analyze data using user-defined functions (UDFs). For details about how to create and define UDFs, see [UDF](#).

#### NOTE

To perform the following operations on a cluster enabled with the security service, you must have related permissions for tables. For details about permission requirements, see [Overview](#).

#### Example Codes

```
-- Query the contact information of employees whose salaries are paid in USD.  
SELECT  
a.name,  
b.tel_phone,  
b.email  
FROM employees_info a JOIN employees_contact b ON(a.id = b.id) WHERE usd_flag='D';  
  
-- Query the IDs and names of employees who were hired in 2014, and load query results to the partition  
with the hiring time of 2014 in the employees_info_extended table.  
INSERT OVERWRITE TABLE employees_info_extended PARTITION (entrytime = '2014')  
SELECT  
a.id,  
a.name,  
a.usd_flag,  
a.salary,  
a.deductions,  
a.address,  
b.tel_phone,  
b.email  
FROM employees_info a JOIN employees_contact b ON (a.id = b.id) WHERE a.entrytime = '2014';  
  
-- Use the existing Hive function COUNT() to count the number of records in the employees_info table.  
SELECT COUNT(*) FROM employees_info;  
  
-- Query information about employees whose email addresses end with "cn".  
SELECT a.name, b.tel_phone FROM employees_info a JOIN employees_contact b ON (a.id = b.id) WHERE  
b.email like '%cn';
```

#### Extensions

- Configure intermediate Hive data encryption.  
Set the table format to RCFile (recommended) or SequenceFile, and the encryption algorithm to ARC4Codec. SequenceFile is a unique Hadoop file

format, and RCFile is a Hive file format with optimized column storage. When a big table is queried, RCFile provides higher performance than SequenceFile.

```
set hive.exec.compress.output=true;
set hive.exec.compress.intermediate=true;
set hive.intermediate.compression.codec=org.apache.hadoop.io.encryption.arc4.ARC4Codec;
```

- For details about UDFs, see [UDF](#).

#### 1.13.3.2.4 UDF

When internal functions of Hive cannot meet requirements, you can compile user-defined functions (UDFs) and use them for query.

According to implementation methods, UDFs are classified as follows:

- Common UDFs: used to perform operations on a single data row and export a single data row.
- User-defined aggregating functions (UDAFs): used to input multiple data rows and export a single data row.
- User-defined table-generating functions (UDTFs): used to perform operations on a single data row and export multiple data rows.

According to usage methods, UDFs are classified as follows:

- Temporary functions: used only in the current session and must be recreated after a session restarts.
- Permanent function: used in multiple sessions and do not have to be created every time a session restarts.

The following uses AddDoublesUDF as an example to describe how to compile and use UDFs.

## Function

AddDoublesUDF is used to add two or multiple floating point values. The following example describes how to compile and use UDFs.

### NOTE

- The normal UDF must be originated from [org.apache.hadoop.hive.ql.exec.UDF](#).
- The normal UDF must implement at least one evaluate(). The evaluate function supports overloading.
- To develop a customized function, you need to add the hive-exec-3.1.0.jar dependency package to the project. The package can be obtained from the Hive installation directory.

## Example Codes

The following is a UDF example:

```
package com.huawei.bigdata.hive.example.udf;
import org.apache.hadoop.hive.ql.exec.UDF;

public class AddDoublesUDF extends UDF {
    public Double evaluate(Double... a) {
        Double total = 0.0;
        // Processing logic
        for (int i = 0; i < a.length; i++)
```

```
    if (a[i] != null)
        total += a[i];
    return total;
}
```

## How to Use

- Step 1** Package the preceding program into **AddDoublesUDF.jar**, and upload it to a directory on the HDFS (such as `/user/hive_examples_jars/`). The user who creates the UDF and the user who uses the UDF function must have read right on this JAR file. Example statements:

```
hdfs dfs -put ./hive_examples_jars /user/hive_examples_jars
```

```
hdfs dfs -chmod 777 /user/hive_examples_jars
```

- Step 2** Use a user with admin rights to log in to the Beeline client and run the following command:

```
kinit Hive service user
```

```
beeline
```

```
set role admin;
```

- Step 3** Define the function in Hive Server. Run the following SQL statement to create a permanent function:

```
CREATE FUNCTION addDoubles AS
'com.huawei.bigdata.hive.example.udf.AddDoublesUDF' using jar 'hdfs://
hacluster/user/hive_examples_jars/AddDoublesUDF.jar';
```

*addDoubles* indicates the function alias that is used for SELECT query.

Run the following statement to create a temporary function:

```
CREATE TEMPORARY FUNCTION addDoubles AS
'com.huawei.bigdata.hive.example.udf.AddDoublesUDF' using jar 'hdfs://
hacluster/user/hive_examples_jars/AddDoublesUDF.jar';
```

- *addDoubles* indicates the function alias that is used for SELECT query.
- TEMPORARY indicates that the function is used only in the current session with the Hive server.

- Step 4** Run the following SQL statement to use the function in the Hive server:

```
SELECT addDoubles(1,2,3);
```

If an **[Error 10011]** error is displayed when you log in to the client again, run the **reload function**; command and then use this function.

- Step 5** Run the following SQL statement to delete the function from the Hive server:

```
DROP FUNCTION addDoubles;
```

----End

## Extensions

None

### 1.13.3.2.5 Example Program Guide

## Function

This section describes how to use an example program to complete an analysis task. An example program can submit a task by using the following methods:

- Submitting a data analysis task by using JDBC interfaces
- Submitting a data analysis task by using Python

## Example Codes

- Submit a data analysis task using the Hive Java database connectivity (JDBC) interface, that is, JDBCExample.java.
  - Read the **property** file of the HiveServer client. The **hiveclient.properties** file is saved in the **resources** directory of the JDBC example program provided by Hive.

```
Properties clientInfo = null;
String userdir = System.getProperty("user.dir") + File.separator
+ "conf" + File.separator;
InputStream fileInputStream = null;
try{
    clientInfo = new Properties();
    //hiveclient.properties indicates the client configuration file. If the multiple-service feature is
    used, the file must be replaced with the hiveclient.properties file on the instance client.
    //hiveclient.properties is located under the config directory of the directory where the instance
    client installation package is decompressed.
    String hiveclientProp = userdir + "hiveclient.properties";
    File propertiesFile = new File(hiveclientProp);
    fileInputStream = new FileInputStream(propertiesFile);
    clientInfo.load(fileInputStream);
} catch (Exception e) {
    throw new IOException(e);
} finally{
    if(fileInputStream != null){
        fileInputStream.close();
        fileInputStream = null;
    }
}
```

- Obtain the IP address and port list of ZooKeeper, the cluster authentication mode, the SASL configuration of HiveServers, node names of HiveServers in ZooKeeper, the discovery mode from the client to the server, and the principal server process for user authentication. You can read all these configurations from the **hiveclient.properties** file.

```
//The format of zkQuorum is
xxx.xxx.xxx.xxx:24002,xxx.xxx.xxx.xxx:24002,xxx.xxx.xxx.xxx:24002";
//xxx.xxx.xxx.xxx is the IP address of the node where ZooKeeper resides. The default port is
24002.
```

```
zkQuorum = clientInfo.getProperty("zk.quorum");
auth = clientInfo.getProperty("auth");
sasl_qop = clientInfo.getProperty("sasl.qop");
zooKeeperNamespace = clientInfo.getProperty("zooKeeperNamespace");
serviceDiscoveryMode = clientInfo.getProperty("serviceDiscoveryMode");
principal = clientInfo.getProperty("principal");
auditAddition = clientInfo.getProperty("auditAddition");
```

- c. In security mode, the kerberos user and keytab file path are required for login authentication. For details about how to obtain **USER\_NAME**, **USER\_KEYTAB\_FILE**, and **KRB5\_FILE**, see [Running JDBC and Viewing Results](#).

```
// Set the userName of new user.
USER_NAME = "xxx";
// Set the keytab and krb5 files location of client.
String userdir = System.getProperty("user.dir") + File.separator
+ "conf" + File.separator;
USER_KEYTAB_FILE = userdir + "user.keytab";
KRB5_FILE = userdir + "krb5.conf";
```

- d. Define HQL. HQL must be a single statement and cannot contain ";".

```
// Define HQL. HQL cannot contain ";"
String[] sqls = {"CREATE TABLE IF NOT EXISTS employees_info(id INT,name STRING)",
"SELECT COUNT(*) FROM employees_info", "DROP TABLE employees_info"};
```

- e. Build JDBC URL.

#### NOTE

You can also implement pre-authentication without the need of providing the account and keytab file path. For details, see JDBC code example 2 in [Examples](#). If IBM JDK is used to run Hive applications, pre-authentication in JDBC sample code 2 must be implemented.

The following is an example of the JDBC URL composed of code snippets:

```
jdbc:hive2://
xxx.xxx.xxx.xxx:24002,xxx.xxx.xxx:24002,xxx.xxx.xxx:24002;/serviceDiscoveryMode=zooKeeper;zooKeeperNamespace=hiveserver2;sasl.qop=auth-conf;auth=KERBEROS;principal=hive/hadoop.<system domain name>@<system domain name>

// Concat JDBC URL
StringBuilder sBuilder = new StringBuilder(
    "jdbc:hive2://"").append(zkQuorum).append("/");

if ("KERBEROS".equalsIgnoreCase(auth)) {
    sBuilder.append(";serviceDiscoveryMode=")
        .append(serviceDiscoveryMode)
        .append(";zooKeeperNamespace=")
        .append(zooKeeperNamespace)
        .append(";sasl.qop=")
        .append(sasl_qop)
        .append(";auth=")
        .append(auth)
        .append(";principal=")
        .append(principal)
        .append(";user.principal=")
        .append(USER_NAME)
        .append(";user.keytab=")
        .append(USER_KEYTAB_FILE);
}

} else {
    // Normal mode
    sBuilder.append(";serviceDiscoveryMode=")
        .append(serviceDiscoveryMode)
        .append(";zooKeeperNamespace=")
        .append(zooKeeperNamespace)
        .append(";auth=none;");
}
if (auditAddition != null && !auditAddition.isEmpty()) {
    strBuilder.append(";auditAddition=").append(auditAddition);
}
String url = sBuilder.toString();
```

- f. Load the Hive JDBC driver.

```
// Load the Hive JDBC driver.  
Class.forName(HIVE_DRIVER);
```

- g. Obtain the JDBC connection, confirm the HQL type (DDL/DML), call ports to run the HQL statement, return the queried column name and results to the console, and close the JDBC connection.

```
Connection connection = null;  
try {  
    // Obtain the JDBC connection.  
    // If the normal mode is used, the second parameter needs to be set to a correct username.  
    // Otherwise, the anonymous user will be used for login.  
    connection = DriverManager.getConnection(url, "", "");  
  
    // Create a table  
    // To import data to a table after the table is created, you can use the LOAD statement. For  
    // example, import data from the HDFS to the table.  
    //load data inpath '/tmp/employees.txt' overwrite into table employees_info;  
    execDDL(connection,sqls[0]);  
    System.out.println("Create table success!");  
  
    // Query  
    execDML(connection,sqls[1]);  
  
    // Delete the table  
    execDDL(connection,sqls[2]);  
    System.out.println("Delete table success!");  
}  
finally {  
    // Close the JDBC connection.  
    if (null != connection) {  
        connection.close();  
    }  
  
public static void execDDL(Connection connection, String sql)  
throws SQLException {  
    PreparedStatement statement = null;  
    try {  
        statement = connection.prepareStatement(sql);  
        statement.execute();  
    }  
    finally {  
        if (null != statement) {  
            statement.close();  
        }  
    }  
}  
  
public static void execDML(Connection connection, String sql) throws SQLException {  
    PreparedStatement statement = null;  
    ResultSet resultSet = null;  
    ResultSetMetaData metaData = null;  
  
    try {  
        // Run the HQL statement.  
        statement = connection.prepareStatement(sql);  
        resultSet = statement.executeQuery();  
  
        // Return the queried column name to the console.  
        metaData = resultSet.getMetaData();  
        int columnCount = metaData.getColumnCount();  
        for (int i = 1; i <= columnCount; i++) {  
            System.out.print(metaData.getColumnName(i) + '\t');  
        }  
        System.out.println();  
  
        // Return the results to the console.  
    }
```

```
        while (resultSet.next()) {
            for (int i = 1; i <= columnCount; i++) {
                System.out.print(resultSet.getString(i) + '\t');
            }
            System.out.println();
        }
    } finally {
    if (null != resultSet) {
        resultSet.close();
    }

    if (null != statement) {
        statement.close();
    }
}
```

- Submit a data analysis task using the Python interface, that is, **python-examples/pyCLI\_sec.py**. The authentication mode of the cluster to which the example program connects is the secure mode. Before running the example program, run the kinit command to authenticate the kerberos user with related rights.

- Import the HAConnection class.

```
from pyhs2.haconnection import HAConnection
```

- Declare the HiveServer IP address list. In this example, **hosts** indicate the nodes of HiveServer, and **xxx.xxx.xxx.xxx** indicates the service IP address.

```
hosts = ["xxx.xxx.xxx.xxx", "xxx.xxx.xxx.xxx"]
```

#### NOTE

- If the HiveServer instance is migrated, the original sample program is invalid. You need to update the IP address of the HiveServer after the migration of the HiveServer instance used in the sample program.
- If multiple Hive instances are used, update the IP address based on the address of the instance that is actually connected.
- Configure the kerberos host name and service name. In this example, the kerberos host name is hadoop and service name is hive.

```
conf = {"krb_host": "hadoop.<system domain name>", "krb_service": "hive"}
```

#### NOTE

If multiple Hive instances are used, change the service name based on the cluster that is actually connected. For example, if the Hive1 instance is connected, change the service name to hive1.

- Create a connection, run the HQL statement, and return the queried column name and results to the console.

```
try:
    with HAConnection(hosts = hosts,
                      port = 21066,
                      authMechanism = "KERBEROS",
                      configuration = conf) as haConn:
        with haConn.getConnection() as conn:
            with conn.cursor() as cur:
                # show databases
                print cur.getdatabases()

                # execute query
```

```
cur.execute("show tables")

# return column info from query
print cur.getschema()

# fetch table results
for i in cur.fetch():
    print i

except exception, e:
    print e
```

#### NOTE

If multiple Hive instances are used, you need to modify hosts according to the description in **b** and change the port number based on to the actual port number. The default ports of Hive to Hive4 are 21066 to 21070, respectively.

### 1.13.3.2.6 Accessing Multiple ZooKeepers

#### Description

This section describes how to access both FusionInsight ZooKeeper and the third-party ZooKeeper in the same client process using the `testConnectHive` and `testConnectApacheZK` methods respectively.

In the `JDBCExample` class of the `hive-jdbc-example-multizk` package, the code structure of the `main` method is as follows:

```
public static void main(String[] args) throws InstantiationException, IllegalAccessException,
ClassNotFoundException, SQLException, IOException{
    testConnectHive(); // Method of accessing FusionInsight ZooKeeper
    testConnectApacheZk(); // Method of accessing the open-source ZooKeeper
}
```

#### Accessing FusionInsight ZooKeeper

If only the method of accessing FusionInsight ZooKeeper needs to be executed, comment out the `testConnectApacheZk` method in the `main` function.

Before using the `testConnectHive` method to access FusionInsight ZooKeeper, perform the following operations:

- Step 1** Change the value of `USER_NAME` in the `init` method in `JDBCExample`.  
`USER_NAME` indicates the user that is used to access FusionInsight ZooKeeper and has permissions of the FusionInsight Hive and Hadoop common user groups.
- Step 2** Go to the client decompression path  
`FusionInsight_Cluster_1_Services_ClientConfig_ConfigFiles\Hive\config` and manually import the `core-site.xml` and `hiveclient.properties` files to the `hive-jdbc-example-multizk\src\main\resources` directory of the sample project.
- Step 3** Download the `krb5.conf` and `user.keytab` files of the user to the `resources` directory in the `hive-jdbc-example-multizk` package.
- Step 4** Check and change the values of `zk.port` and `zk.quorum` in the `hiveclient.properties` file in the `resources` directory.
  - `zk.port`: indicates the port for accessing FusionInsight ZooKeeper. Generally, the default value is used. Change the value as required.

- **zk.quorum:** indicates the IP address for accessing ZooKeeper quorumpeer. Set it to the IP address of the cluster deployed with the FusionInsight ZooKeeper service.

----End

## Accessing Open-Source ZooKeeper

To use **testConnectApacheZk** to connect to the open-source ZooKeeper code, change xxx.xxx.xxx.xxx in the following code to the IP address of the open-source ZooKeeper to be connected. Change the port number as required. After the connection is used, run the try statement in try-with-resources mode to automatically close the ZooKeeper connection. If only the sample for accessing the third-party ZooKeeper needs to be executed, comment out the **testConnectHive** method in the **main** function.

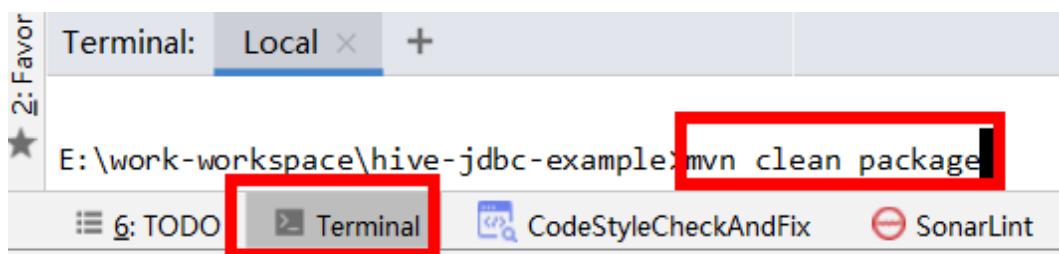

```
private static void testConnectApacheZk() {  
    //After the try statement is executed, the ZooKeeper connection is automatically disabled to prevent  
    //connection leakage.  
    try (org.apache.zookeeper.ZooKeeper digestZk =  
        new org.apache.zookeeper.ZooKeeper("xxx.xxx.xxx.xxx:port", 600000, null)) {  
        while (true) {  
            if (digestZk.getState().isConnected()) {  
                List<String> nodes = digestZk.getChildren("/", null);  
                logger.info("digest root path:{}", nodes);  
                for (String node : nodes) {  
                    List<String> subNodes = digestZk.getChildren "/" + node, null);  
                    logger.info("{} child path:{}", node, subNodes);  
                    for (String subNode : subNodes) {  
                        logger.info(  
                            "child patch:{}", subNode, digestZk.getChildren "/" + node + "/" + subNode, null));  
                    }  
                }  
                break;  
            }  
            Thread.sleep(1000);  
        }  
    } catch (IOException | KeeperException | InterruptedException e) {  
        logger.error("failed to connect zookeeper", e);  
    }  
}
```

## 1.13.4 Commissioning Applications

### 1.13.4.1 Running JDBC and Viewing Results

#### Running JDBC in CLI Mode

**Step 1** In the lower left corner of the IDEA page, click **Terminal** to access the terminal. Run the **mvn clean package** command to compile the package.

If **BUILD SUCCESS** is displayed, the compilation is successful, as shown in the following figure. A JAR file containing the **-with-dependencies** field is generated in the **target** directory of the sample project.

```
Terminal: Local +  
[INFO] com/ already added, skipping  
[INFO] com/huawei/ already added, skipping  
[INFO] com/huawei/bigdata/ already added, skipping  
[INFO] META-INF/maven/ already added, skipping  
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 32.933 s  
[INFO] Finished at: 2020-11-23T16:18:08+08:00  
[INFO] -----
```

**Step 2** Create a directory on Windows or Linux as the running directory, for example, **D:\jdbc\_example** (Windows) or **/opt/jdbc\_example** (Linux). Place the JAR file whose name contains **-with-dependencies** in the **target** directory generated in **Step 1** to this directory. Create the **src/main/resources** subdirectory in the directory. Copy all files in the **resources** directory of the **jdbc-examples** project to the **resources** directory.

**Step 3** In Windows, run the following command:

```
cd /d d:\jdbc_example  
java -jar hive-jdbc-example-1.0-SNAPSHOT-jar-with-dependencies.jar
```

In Linux, run the following command:

```
chmod +x /opt/jdbc_example -R  
cd /opt/jdbc_example  
java -jar hive-jdbc-example-1.0-SNAPSHOT-jar-with-dependencies.jar
```

#### NOTE

The preceding JAR file names are for reference only. The actual names may vary.

**Step 4** In the CLI, view the HQL query results in the example codes.

The following information is displayed if the sample project is successful in Windows:

```
Create table success!  
_c0  
0  
Delete table success!
```

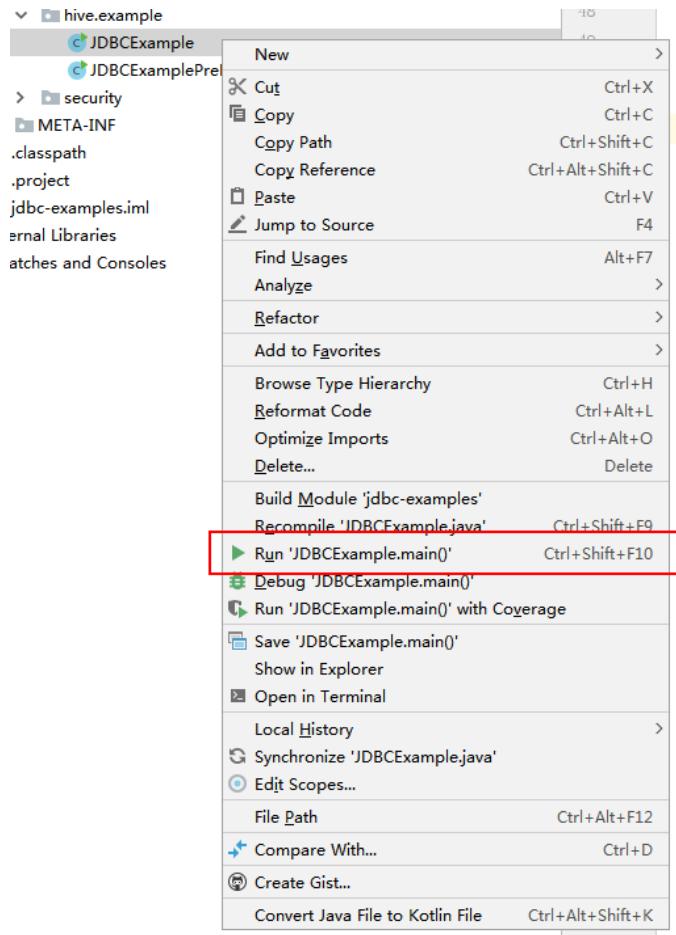

The following information is displayed if the sample project is successful in Linux:

```
Create table success!  
_c0  
0  
Delete table success!
```

----End

## Running JDBC in IntelliJ IDEA Mode

**Step 1** Right-click the JDBCExample class in the IntelliJ IDEA jdbc-examples project, and choose **Run JDBCExample.main()** from the shortcut menu. As shown in the following figure.

**Step 2** In the IntelliJ IDEA output window, view the HQL query results in the example codes.

```
Create table success!
```

```
_c0
```

```
0
```

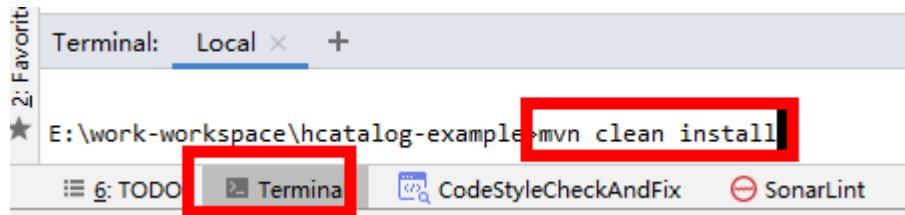

```
Delete table success!
```

----End

### 1.13.4.2 Running HCatalog and Viewing Results

#### Running HCatalog Example Projects

**Step 1** In the lower left corner of the IDEA page, click **Terminal** to access the terminal. Run the **mvn clean install** command to compile the package.

If **BUILD SUCCESS** is displayed, the compilation is successful, as shown in the following figure. The **hcatalog-example-\*.jar** package is generated in the **target** directory of the sample project.

```
Terminal: Local +  
[INFO] --- maven-jar-plugin:2.4:jar (default-jar) @ hcatalog-example ---  
[INFO] Building jar: E:\other-workspase\sample_project\src\hive-examples\hcata...  
[INFO]  
[INFO] --- maven-install-plugin:2.4:install (default-install) @ hcatalog-exa...  
[INFO] Installing E:\other-workspase\sample_project\src\hive-examples\hcata...  
[INFO] Installing E:\other-workspase\sample_project\src\hive-examples\hcata...  
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 4.916 s  
[INFO] Finished at: 2020-11-23T16:25:57+08:00  
[INFO] -----
```

#### NOTE

The preceding JAR file names are for reference only. The actual names may vary.

- Step 2** Upload the **hcatalog-example-\*jar** file generated in the **target** directory in the previous step to the specified directory on Linux, for example, **/opt/hive\_client**, marked as **\$HCAT\_CLIENT**, and ensure that the Hive and YARN clients have been installed. Execute environment variables for the HCAT\_CLIENT to take effect.
- ```
export HCAT_CLIENT=/opt/hive_client
```

- Step 3** Run the following command to configure environment parameters (client installation path **/opt/hadoopclient** is used as an example):

```
export HADOOP_HOME=/opt/hadoopclient/HDFS/hadoop  
export HIVE_HOME=/opt/hadoopclient/Hive/Beeline  
export HCAT_HOME=$HIVE_HOME/..../HCatalog  
export LIB_JARS=$HCAT_HOME/lib/hive-hcatalog-core-xxx.jar,$HCAT_HOME/lib/hive-metastore-xxx.jar,$HCAT_HOME/lib/hive-standalone-metastore-xxx.jar,$HIVE_HOME/lib/hive-exec-xxx.jar,$HCAT_HOME/lib/libfb303-xxx.jar,$HCAT_HOME/lib/slf4j-api-xxx.jar,$HCAT_HOME/lib/jdo-api-xxx.jar,$HCAT_HOME/lib/antlr-runtime-xxx.jar,$HCAT_HOME/lib/datanucleus-api-jdo-xxx.jar,$HCAT_HOME/lib/datanucleus-core-xxx.jar,$HCAT_HOME/lib/datanucleus-rdbms-fi-xxx.jar,$HCAT_HOME/lib/log4j-api-xxx.jar,$HCAT_HOME/lib/log4j-core-xxx.jar,$HIVE_HOME/lib/commons-lang-xxx.jar,$HIVE_HOME/lib/hive-exec-xxx.jar  
export HADOOP_CLASSPATH=$HCAT_HOME/lib/hive-hcatalog-core-xxx.jar:$HCAT_HOME/lib/hive-metastore-xxx.jar:$HCAT_HOME/lib/hive-standalone-metastore-xxx.jar:$HIVE_HOME/lib/hive-exec-xxx.jar:$HCAT_HOME/lib/libfb303-xxx.jar:$HADOOP_HOME/etc/hadoop:$HCAT_HOME/conf:$HCAT_HOME/lib/slf4j-api-xxx.jar:$HCAT_HOME/lib/jdo-api-xxx.jar:$HCAT_HOME/lib/antlr-runtime-xxx.jar:$HCAT_HOME/lib/datanucleus-api-jdo-xxx.jar:$HCAT_HOME/lib/datanucleus-core-xxx.jar:$HCAT_HOME/lib/datanucleus-rdbms-fi-xxx.jar:$HCAT_HOME/lib/log4j-api-xxx.jar:$HCAT_HOME/lib/log4j-core-xxx.jar:$HIVE_HOME/lib/commons-lang-xxx.jar:$HIVE_HOME/lib/hive-exec-xxx.jar
```

 NOTE

- xxx: Indicates the version number of the JAR package. **Change the version numbers of the JAR files specified in LIB\_JARS and HADOOP\_CLASSPATH based on the actual environment.**
- If the multi-instance function is enabled for Hive, perform the configuration in **export HIVE\_HOME=/opt/hadoopclient/Hive/Beeline**. For example, if Hive 1 is used, ensure that the Hive 1 client has been installed before using it. Change the value of **export HIVE\_HOME** to **/opt/hadoopclient/Hive1/Beeline**.

**Step 4** Prepare for the running:

1. Use the Hive client to create source table t1 in beeline: **create table t1(col1 int);**

Insert the following data into t1:

```
+-----+  
| t1.col1 |  
+-----+  
| 1      |  
| 1      |  
| 1      |  
| 2      |  
| 2      |  
| 3      |
```

2. Create destination table t2: **create table t2(col1 int,col2 int);**

**Step 5** Use the Yarn client to submit tasks:

```
yarn --config $HADOOP_HOME/etc/hadoop jar $HCAT_CLIENT/hcatalog-example-1.0-SNAPSHOT.jar com.huawei.bigdata.HCatalogExample -libjars $LIB_JARS t1 t2
```

**Step 6** View the running result. The data in t2 is as follows:

```
0: jdbc:hive2://192.168.1.18:24002,192.168.1.> select * from t2;  
+-----+-----+  
| t2.col1 | t2.col2 |  
+-----+-----+  
1	3
2	2
3	1
+-----+-----+
```

----End

### 1.13.4.3 Running Python and Viewing Results

#### Running Python in CLI Mode

**Step 1** Grant the execution permission for the script of **python-examples** folder. Run the following command in the CLI:

```
chmod +x python-examples -R.
```

**Step 2** Enter the service plane IP address of the node where HiveServer is installed in the hosts array of **python-examples/pyCLI\_sec.py**.

 NOTE

When the multi-instance is enabled: In **python-examples/pyCLI\_sec.py**, the hosts array must be modified. In addition, the port must be set according to the used instance. The port (**hive.server2.thrift.port**) is used for Hive to provide the Thrift service. For example, if the Hive 1 instance is used, port must be set to 21067. (The default ports of Hive to Hive 4 is 21066 to 21070, respectively).

**Step 3** Change `hadoop.hadoop.com` in the `conf` array of `python-examples/pyCLI_sec.py` and `python-examples/pyline.py` to `hadoop.the actual domain name`. To view the actual domain name, log in to FusionInsight Manager and choose **System > Permission > Domain and Mutual Trust > Local Domain**.

**Step 4** Run the `kinit` command to obtain the cache for Kerberos authentication.

Use the developer account created in [Preparing a Developer Account](#) to run the following commands to run the client program:

`kinit -kt keytabstorage path username`

`cd python-examples`

`python pyCLI_sec.py`

**Step 5** In the CLI, view the HQL query results in the example codes. For example:

```
[[{'default': ''}]]  
[{'comment': 'from deserializer', 'columnName': 'tab_name', 'type': 'STRING_TYPE'}]  
['xx']
```

 NOTE

If the following exception occurs:

```
importError: libsasl2.so.2: cannot open shared object file: No such file or directory
```

You can handle the problem as follows:

1. Run the following command to check the LibSASL version in the installed operating system.

```
ldconfig -p|grep sasl
```

If the following is displayed, the current operating system only has the 3.x version.

```
libsasl2.so.3 (libc6,x86-64) => /usr/lib64/libsasl2.so.3  
libsasl2.so.3 (libc6) => /usr/lib/libsasl2.so.3
```

2. If only the 3.x version exists, run the following command to create a soft link.

```
ln -s /usr/lib64/libsasl2.so.3.0.0 /usr/lib64/libsasl2.so.2
```

----End

#### 1.13.4.4 Running Python3 and Viewing Results

##### Running Python in CLI Mode

**Step 1** Grant the execution permission for the script of `python3-examples` folder. Run the following command in the CLI:

`chmod +x python3-examples -R.`

**Step 2** In `python3-examples/pyCLI_nosec.py`, change the value of host to the service plane IP address of the node where HiveServer is installed, and change the value of port to the port (**hive.server2.thrift.port**) used by Hive to provide the Thrift service. The default value is 21066.

 NOTE

When the multi-instance is enabled: In **python3-examples/pyCLI\_sec.py**, the hosts must be modified. In addition, the port must be set according to the used instance. The port (`hive.server2.thrift.port`) is used for Hive to provide the Thrift service. For example, if the Hive 1 instance is used, port must be set to 21067. (The default ports of Hive to Hive 4 is 21066 to 21070, respectively).

**Step 3** Change `hadoop.hadoop.com` in the conf of `python-examples/pyCLI_sec.py` to `hadoop.the actual domain name`. To view the actual domain name, log in to FusionInsight Manager and choose **System > Permission > Domain and Mutual Trust > Local Domain**.

**Step 4** Run the **kinit** command to obtain the cache for Kerberos authentication.

Use the developer account created in [Preparing a Developer Account](#) to run the following commands to run the client program:

```
kinit -kt keytabstorage path username
```

```
cd python3-examples
```

```
python3 pyCLI_sec.py
```

**Step 5** In the CLI, view the HQL query results in the example codes. For example:

```
('table_name1',)  
(‘table_name2’,)  
(‘table_name3’,)  
(‘table_name4’,)  
(‘table_name5’,)
```

In the preceding command, `table_nameX` indicates the actual table name.

----End

#### 1.13.4.5 Running a Spring Boot Sample Project and Viewing Results

##### Running the Spring Boot Sample Project in CLI

**Step 1** Click **Terminal** in the lower left corner of the IDEA page to access the terminal. Run the **mvn clean package** command to perform compilation.

```
PS E:\workspace\sample_project\src\springboot\hive-examples\hive-rest-client-example> mvn clean package
```

If "BUILD SUCCESS" is displayed, the compilation is successful. A JAR file containing the **-with-dependencies** field is generated in the **target** directory of the sample project.

```
Terminal: Local × +  
[INFO] com/ already added, skipping  
[INFO] com/huawei/ already added, skipping  
[INFO] com/huawei/bigdata/ already added, skipping  
[INFO] META-INF/maven/ already added, skipping  
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 32.933 s  
[INFO] Finished at: 2020-11-23T16:18:08+08:00  
[INFO] -----
```

**Step 2** Create a directory on Windows or Linux as the running directory, for example, **D:\hive-rest-client-example** (Windows) or **/opt/hive-rest-client-example** (Linux). Place the JAR file in **Step 1** to this directory, and create the **src/main/resources** subdirectory in the directory. Copy all files in the **resources** directory of the **hive-rest-client-example** project to **resources**.

**Step 3** Run the following commands to start the Spring Boot service:

- Commands for Windows:  
`cd /d D:\hive-rest-client-example  
java -jar hive-rest-client-example-8.3.1-3.3.1-SNAPSHOT-jar-with-dependencies.jar`
- Commands for Linux:  
`chmod +x /opt/hive-rest-client-example -R  
cd /opt/hive-rest-client-example  
java -jar hive-rest-client-example-8.3.1-3.3.1-SNAPSHOT-jar-with-dependencies.jar`

#### BOOK NOTE

The preceding JAR file name is for reference only. Replace it with the actual one.

**Step 4** Call the Spring Boot sample API of Hive to trigger running the sample code.

- Running method in Windows:  
Open the browser and enter **http://localhost:8080/hive/example/executesql** in the address box.
- Running method in Linux:  
Run the **curl http://localhost:8080/hive/example/executesql** command on the node where the JAR file is stored in **Step 2**.

#### BOOK NOTE

The following information may be printed in the log when the sample code is executed. Although the log level is ERROR, the execution result is not affected.

```
ERROR 51320 --- [c-8-EventThread] o.a.c.framework.ims.EnsembleTracker : Invalid config event  
received: {version=100000000, server48=IP address of the ZooKeeper node:ZooKeeper port  
number.ZooKeeper port number:participant...}
```

**Step 5** View the HQL query results in the sample code.

- The following information is displayed if the sample project is successful in Windows:

```
===== Hive Example Start =====
Start create table.
Table created successfully.
Start to insert data into the table.
Inserting data to the table succeeded.
Start to query table data.
Query result :
employees_infoa.id    employees_infoa.age    employees_infoa.name
1      31     SJK
2      25     HS
3      28     HT

Querying table data succeeded.
Start to delete the table.
Table deleted successfully.
===== Hive Example End =====
```

- The following information is displayed if the sample project is successful in Linux:

```
===== Hive Example Start =====
Start create table.
Table created successfully.
Start to insert data into the table.
Inserting data to the table succeeded.
Start to query table data.
Query result :
employees_infoa.id    employees_infoa.age    employees_infoa.name
1      31     SJK
2      25     HS
3      28     HT

Querying table data succeeded.
Start to delete the table.
Table deleted successfully.
===== Hive Example End =====
```

----End

## 1.13.5 More Information

### 1.13.5.1 Interface Reference

#### 1.13.5.1.1 JDBC

The Hive Java database connectivity (JDBC) interface complies with the Java JDBC driver standard.

As a data warehouse, Hive does not support all JDBC APIs. For example, if transactional operations, such as rollback and setAutoCommit, are performed, SQL exceptions like **Method not supported** will occur.

#### 1.13.5.1.2 Hive SQL

Hive SQL supports all features in Hive-3.1.0. For details, visit <https://cwiki.apache.org/confluence/display/hive/languagemanual>.

**Table 1-127** describes the extended Hive statements provided by MRS.

**Table 1-127** Extended Hive statements

| Extended Syntax   | Syntax Description  | Syntax Example   | Example Description   |
|---|---|--|---|
| <pre>CREATE [TEMPORARY] [EXTERNAL] TABLE [IF NOT EXISTS] [db_name.]table_ name (col_name data_type [COMMENT col_comment], ...) [ROW FORMAT row_format] [STORED AS file_format]   STORED BY 'storage.handler.cl ass.name' [WITH SERDEPROPERTIE S (...) ] ..... [TBLPROPERTIES ("groupId"= group1 ,"locatorId"="loc ator1")] ...;</pre> | <p>The statement is used to create a Hive table and specify locators on which table data files locate. For details, see "Component Operation Guide" &gt; "Using Hive" &gt; "Using HDFS Colocation to Store Hive Tables" in <i>MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)</i> in the <i>MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)</i>.</p> | <pre>CREATE TABLE tab1 (id INT, name STRING) row format delimited fields terminated by '\t' stored as RCFILE TBLPROPERTIES( "groupId"= group1 ,"locatorId"="loc ator1");</pre> | <p>The statement is used to create table <b>tab1</b> and specify locator1 on which the table data of <b>tab1</b> locates.</p> |

| Extended Syntax  | Syntax Description  | Syntax Example  | Example Description  |
|--|---|---|--|
| <pre>CREATE [TEMPORARY] [EXTERNAL] TABLE [IF NOT EXISTS] [db_name.]table_ name (col_name data_type [COMMENT col_comment], ...) [ROW FORMAT row_format] [STORED AS file_format]   STORED BY 'storage.handler.cl ass.name' [WITH SERDEPROPERTIE S (...) ] ... [TBLPROPERTIES ('column.encode. columns'=col_na me1,col_name2')  'column.encode.i ndices'=col_id1,c ol_id2', 'column.encode.c lassname'=encod e_classname')]...;</pre> | <p>The statement is used to create a hive table and specify the table encryption column and encryption algorithm. For details, see "Component Operation Guide" &gt; "Using Hive" &gt; "Using the Hive Column Encryption Function" in <i>MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)</i> in the <i>MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)</i>.</p> | <pre>create table encode_test(id INT, name STRING, phone STRING, address STRING) ROW FORMAT SERDE 'org.apache.hadoo p.hive.serde2.lazy. LazySimpleSerDe' WITH SERDEPROPERTIE S ('column.encode.i ndices'=2,3', 'column.encode.cl assname='org.apa che.hadoop.hive.s erde2.SMS4Rewrit er') STORED AS TEXTFILE;</pre> | <p>The statement is used to create table <b>encode_test</b> and specify that column 2 and column 3 will be encrypted using the <b>org.apache.hadoop.hive.serde2.SMS4Rewriter</b> encryption algorithm class during data insertion.</p> |

| Extended Syntax  | Syntax Description  | Syntax Example   | Example Description  |
|--|---|--|--|
| <code>REMOVE TABLE<br/>hbase_tablename<br/>[WHERE<br/>where_condition];</code>   | The statement is used to delete data that meets criteria from the Hive on HBase table. For details, see "Component Operation Guide" > "Using Hive" > "Deleting Single-Row Records from Hive on HBase" in <i>MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)</i> in the <i>MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)</i> .  | <code>remove table<br/>hbase_table1<br/>where id = 1;</code>   | The statement is used to delete data that meets the criterion of "id = 1" from the table.  |
| <code>CREATE<br/>[TEMPORARY]<br/>[EXTERNAL]<br/>TABLE [IF NOT<br/>EXISTS]<br/>[db_name.]table_<br/>name (col_name<br/>data_type<br/>[COMMENT<br/>col_comment], ...)<br/>[ROW FORMAT<br/>row_format]<br/>STORED AS<br/>inputformat<br/>'org.apache.hadoop.hive.contrib.format.SpecifiedDelimiterInputFormat'<br/>outputformat<br/>'org.apache.hadoop.hive.io.HiveIgnoreKeyTextOutputFormat';</code> | The statement is used to create a hive table and specify that the table supports customized row delimiters. For details, see "Component Operation Guide" > "Using Hive" > "Customizing Row Separators" in <i>MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)</i> in the <i>MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)</i> . | <code>create table<br/>blu(time string,<br/>num string, msg<br/>string) row<br/>format delimited<br/>fields terminated<br/>by ',' stored as<br/>inputformat<br/>'org.apache.hadoop.hive.contrib.format.SpecifiedDelimiterInputFormat'<br/>outputformat<br/>'org.apache.hadoop.hive.io.HiveIgnoreKeyTextOutputFormat';</code> | The statement is used to create table <b>blu</b> and set <b>inputformat</b> to <b>SpecifiedDelimiterInputFormat</b> so that the query row delimiter can be specified during the query. |

### 1.13.5.1.3 WebHCat

#### NOTE

- The following uses the service IP address of WebHCat and the WebHCat HTTP port configured during the installation as an example.
- You can perform the example operations only after **kinit** authentication is implemented on the installed client.
- The examples of the HTTPS protocol are as follows. To use the HTTP protocol, you need to perform the following operations:
  1. Switch the RESTful API to the HTTP protocol. For details, see "Component Operation Guide" > "Using Hive" > "Configuring HTTPS/HTTP-based REST APIs" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.
  2. Delete **--insecure** from the example and replace HTTPS with HTTP, for example:  
`curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1/status'`  
is changed to  
`curl -i -u : --negotiate 'http://10.64.35.144:21055/templeton/v1/status'`
- Before performing the operation, ensure that the curl in use is later than 7.34.0. You can run the following command to view the curl version:  
`curl -V`

#### 1. :version(GET)

##### - Description

Queries a list of response types supported by WebHCat.

##### - URL

`https://www.myserver.com/templeton/:version`

##### - Parameter

| Parameter             | Description   |
|-----------------------|---|
| <code>:version</code> | WebHCat version number. Currently, the version number must be v1. |

##### - Returned result

| Parameter                  | Description                                  |
|----------------------------|--|
| <code>responseTypes</code> | List of response types supported by WebHCat. |

##### - Example

```
curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1'
```

#### 2. status (GET)

##### - Description

Obtains the status of the current server.

- URL  
`https://www.myserver.com/templeton/v1/status`
- Parameter  
None
- Returned result

| Parameter | Description  |
|-----------|--|
| status    | If the WebHCat connection is normal, <b>OK</b> is returned.      |
| version   | Character string, including the version number, for example, v1. |

- Example  
`curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1/status'`

### 3. version (GET)

- Description  
Obtains the WebHCat version of the server.
- URL  
`https://www.myserver.com/templeton/v1/version`
- Parameter  
None
- Returned result

| Parameter         | Description                    |
|-------------------|--------------------------------|
| supportedVersions | All supported versions.        |
| version           | WebHCat version of the server. |

- Example  
`curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1/version'`

### 4. version/hive (GET)

- Description  
Obtains the Hive version of the server.
- URL  
`https://www.myserver.com/templeton/v1/version/hive`
- Parameter  
None
- Returned result

| Parameter | Description   |
|-----------|---------------|
| module    | Hive.         |
| version   | Hive version. |

- Example  

```
curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1/version/hive'
```

## 5. version/hadoop (GET)

- Description  

Obtains the Hadoop version of the server.
- URL  

<https://www.myserver.com/templeton/v1/version/hadoop>
- Parameter  

None
- Returned result

| Parameter | Description     |
|-----------|-----------------|
| module    | Hadoop.         |
| version   | Hadoop version. |

- Example  

```
curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1/version/hadoop'
```

## 6. ddl (POST)

- Description  

Executes a DDL statement.
- URL  

<https://www.myserver.com/templeton/v1/ddl>
- Parameter

| Parameter   | Description  |
|-------------|--|
| exec        | HCatalog DDL statement to be executed.   |
| group       | User group used when DDL is used to create a table.                                  |
| permissions | Permission used when DDL is used to create a table. The format is <b>rwxr-xr-x</b> . |

- Returned result

| Parameter | Description  |
|-----------|--|
| stdout    | Standard output value during HCatalog execution. The value may be empty. |
| stderr    | Error output during HCatalog execution. The value may be empty.          |

| Parameter | Description               |
|-----------|---------------------------|
| exitcode  | Return value of HCatalog. |

- Example

```
curl -i -u : --insecure --negotiate -d exec="show tables" 'https://10.64.35.144:21055/templeton/v1/ddl'
```

#### 7. ddl/database (GET)

- Description  
Lists all databases.
- URL  
<https://www.myserver.com/templeton/v1/ddl/database>
- Parameter

| Parameter | Description   |
|-----------|---|
| like      | Regular expression used to match the database name. |

- Returned result

| Parameter | Description    |
|-----------|----------------|
| databases | Database name. |

- Example

```
curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1/ddl/database'
```

#### 8. ddl/database/:db (GET)

- Description  
Obtains details about a specified database.
- URL  
<https://www.myserver.com/templeton/v1/ddl/database/:db>
- Parameter

| Parameter | Description    |
|-----------|----------------|
| :db       | Database name. |

- Returned result

| Parameter | Description  |
|-----------|--|
| location  | Database location.   |
| comment   | Database remarks. If there are no database remarks, the value is null. |
| database  | Database name.   |

| Parameter | Description                 |
|-----------|-----------------------------|
| owner     | Database owner.             |
| owertype  | Type of the database owner. |

- Example  

```
curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1/ddl/database/default'
```
9. **ddl/database/:db (PUT)**
- Description  

Creates a database.
  - URL  

<https://www.myserver.com/templeton/v1/ddl/database/:db>
  - Parameter
- | Parameter  | Description                                 |
|------------|---|
| :db        | Database name.                              |
| group      | User group used for creating the database.  |
| permission | Permission used for creating the database.  |
| location   | Database location.                          |
| comment    | Database remarks, for example, description. |
| properties | Database properties.                        |
- Returned result
- | Parameter | Description                         |
|-----------|-------------------------------------|
| database  | Name of the newly created database. |
- Example  

```
curl -i -u : --insecure --negotiate -X PUT -HContent-type:application/json -d '{"location": "/tmp/a", "comment": "my db", "properties": {"a": "b"}}' 'https://10.64.35.144:21055/templeton/v1/ddl/database/db2'
```
10. **ddl/database/:db (DELETE)**
- Description  

Deletes a database.
  - URL  

<https://www.myserver.com/templeton/v1/ddl/database/:db>
  - Parameter

| Parameter | Description   |
|-----------|---|
| :db       | Database name.  |
| IfExists  | If the specified database does not exist, Hive returns an error unless <b>IfExists</b> is set to <b>true</b> .  |
| option    | Set the parameter to <b>cascade</b> or <b>restrict</b> . If you set it to <b>cascade</b> , all data and definitions are cleared. If you set it to <b>restrict</b> , the table content is empty and the mode does not exist. |

- Returned result

| Parameter | Description                   |
|-----------|-------------------------------|
| database  | Name of the deleted database. |

- Example

```
curl -i -u : --insecure --negotiate -X DELETE 'https://10.64.35.144:21055/templeton/v1/ddl/database/db3?IfExists=true'
```

## 11. ddl/database/:db/table (GET)

- Description

Lists all tables in the database.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table>

- Parameter

| Parameter | Description                                    |
|-----------|--|
| :db       | Database name.                                 |
| like      | Regular expression used to match a table name. |

- Returned result

| Parameter | Description                     |
|-----------|---------------------------------|
| database  | Database name.                  |
| tables    | List of tables in the database. |

- Example

```
curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1/ddl/database/default/table'
```

## 12. ddl/database/:db/table/:table (GET)

- Description  
Obtains details about a table.
- URL  
<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table>
- Parameter

| Parameter | Description  |
|-----------|--|
| :db       | Database name.   |
| :table    | Table name.  |
| format    | The format is "format=extended". If you want to see additional information, use "table extended like". |

- Returned result

| Parameter        | Description   |
|------------------|---|
| columns          | Column name and type.   |
| database         | Database name.  |
| table            | Table name.   |
| partitioned      | Whether a table is a partition table. This parameter is available only when the table format is <b>extended</b> . |
| location         | Table location. This parameter is available only when the table format is <b>extended</b> .                       |
| outputformat     | Output format. This parameter is available only when the table format is <b>extended</b> .                        |
| inputformat      | Input format. This parameter is available only when the table format is <b>extended</b> .                         |
| owner            | Table owner. This parameter is available only when the table format is <b>extended</b> .                          |
| partitionColumns | Partition column. This parameter is available only when the table format is <b>extended</b> .                     |

- Example

```
curl -i -u : --insecure --negotiate 'https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/t1?format=extended'
```

13. `ddl/database/:db/table/:table (PUT)`

- Description  
Creates a table.
- URL  
`https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table`
- Parameter

| Parameter     | Description   |
|---------------|---|
| :db           | Database name.  |
| :table        | New table name.   |
| group         | User group used for creating the table.   |
| permissions   | Permission used for creating the table.   |
| external      | Allows you to specify a location so that Hive does not use the default location for this table.   |
| ifNotExists   | If this parameter is set to <b>true</b> , no error is reported if a table exists.   |
| comment       | Remarks.  |
| columns       | Column description, including the column name, type, and optional remarks.  |
| partitionedBy | Partition column description, which is used to partition tables. The <b>columns</b> parameter is used to list the column name, type, and optional remarks.  |
| clusteredBy   | Bucket column description, including the <b>columnNames</b> , <b>sortedBy</b> , and <b>numberOfBuckets</b> parameters. The <b>columnNames</b> parameter includes <b>columnName</b> and sorting sequence ( <b>ASC</b> indicates an ascending order, and <b>DESC</b> indicates a descending order). |
| format        | Storage format. The parameters include <b>rowFormat</b> , <b>storedAs</b> , and <b>storedBy</b> .   |
| location      | HDFS path.  |

| Parameter       | Description   |
|-----------------|---|
| tableProperties | Table property names and values (name-value pairs). |

- Returned result

| Parameter | Description    |
|-----------|----------------|
| database  | Database name. |
| table     | Table name.    |

- Example

```
curl -i -u : --insecure --negotiate -X PUT -HContent-type:application/json -d '{"columns": [{"name": "id", "type": "int"}, {"name": "name", "type": "string"}], "comment": "hello", "format": {"storedAs": "orc"} }' 'https://10.64.35.144:21055/templeton/v1/ddl/database/db3/table/tbl1'
```

#### 14. ddl/database/:db/table/:table (POST)

- Description  
Renames a table.
- URL  
<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table>
- Parameter

| Parameter | Description          |
|-----------|----------------------|
| :db       | Database name.       |
| :table    | Existing table name. |
| rename    | New table name.      |

- Returned result

| Parameter | Description     |
|-----------|-----------------|
| database  | Database name.  |
| table     | New table name. |

- Example

```
curl -i -u : --insecure --negotiate -d rename=table1 'https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/tbl1'
```

#### 15. ddl/database/:db/table/:table (DELETE)

- Description  
Deletes a table.
- URL  
<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table>
- Parameter

| Parameter | Description   |
|-----------|---|
| :db       | Database name.  |
| :table    | Table name.   |
| IfExists  | If this parameter is set to <b>true</b> , no error is reported. |

- Returned result

| Parameter | Description    |
|-----------|----------------|
| database  | Database name. |
| table     | Table name.    |

- Example

```
curl -i -u : --insecure --negotiate -X DELETE 'https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/table2?IfExists=true'
```

## 16. ddl/database/:db/table/:existingtable/like/:newtable (PUT)

- Description

Creates a table that is the same as an existing table.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:existingtable/like/:newtable>

- Parameter

| Parameter      | Description  |
|----------------|--|
| :db            | Database name.   |
| :existingtable | Existing table name.   |
| :newtable      | New table name.  |
| group          | User group used for creating the table.  |
| permissions    | Permission used for creating the table.  |
| external       | Allows you to specify a location so that Hive does not use the default location for this table.        |
| ifNotExists    | If this parameter is set to <b>true</b> , the Hive does not report an error if a table already exists. |
| location       | HDFS path.   |

- Returned result

| Parameter | Description    |
|-----------|----------------|
| database  | Database name. |
| table     | Table name.    |

- Example

```
curl -i -u : --insecure --negotiate -X PUT -HContent-type:application/json -d '{"ifNotExists": "true"}' 'https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/t1/like/tt1'
```

17. `ddl/database/:db/table/:table/partition(GET)`

- Description

Lists information about all partitions of a table.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/partition>

- Parameter

| Parameter | Description    |
|-----------|----------------|
| :db       | Database name. |
| :table    | Table name.    |

- Returned result

| Parameter  | Description   |
|------------|---|
| database   | Database name.  |
| table      | Table name.   |
| partitions | List of partition attribute values and partition names. |

- Example

```
curl -i -u : --insecure --negotiate https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/x1/partition
```

18. `ddl/database/:db/table/:table/partition/:partition(GET)`

- Description

Lists information about a specific partition of a table.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/partition/:partition>

- Parameter

| Parameter | Description    |
|-----------|----------------|
| :db       | Database name. |
| :table    | Table name.    |

| Parameter  | Description  |
|------------|--|
| :partition | Partition name. Exercise caution when decoding HTTP quote, for example, <b>country=%27algeria%27</b> . |

- Returned result

| Parameter        | Description   |
|------------------|---|
| database         | Database name.  |
| table            | Table name.   |
| partition        | Partition name.   |
| partitioned      | If this parameter is set to <b>true</b> , the table is a partitioned table. |
| location         | Storage path of the table.  |
| outputFormat     | Output format.  |
| columns          | Column name, type, and remarks.   |
| owner            | Owner.  |
| partitionColumns | Partition column.   |
| inputFormat      | Input format.   |
| totalNumberFiles | Number of files in a partition.   |
| totalFileSize    | Total size of files in a partition.   |
| maxFileSize      | Maximum file size.  |
| minFileSize      | Minimum file size.  |
| lastAccessTime   | Last access time.   |
| lastUpdateTime   | Last update time.   |

- Example

```
curl -i -u : --insecure --negotiate https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/x1/partition/dt=1
```

## 19. ddl/database/:db/table/:table/partition/:partition(PUT)

- Description  
Adds a table partition.
- URL  
<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/partition/:partition>
- Parameter

| Parameter   | Description  |
|-------------|--|
| :db         | Database name.   |
| :table      | Table name.  |
| group       | User group used for creating a partition.  |
| permissions | User permission used for creating a partition.   |
| location    | Storage location of the new partition.   |
| ifNotExists | If this parameter is set to <b>true</b> , the system reports an error when the partition already exists. |

- Returned result

| Parameter  | Description     |
|------------|-----------------|
| database   | Database name.  |
| table      | Table name.     |
| partitions | Partition name. |

- Example

```
curl -i -u : --insecure --negotiate -X PUT -HContent-type:application/json -d '{}' https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/x1/partition/dt=10
```

## 20. ddl/database/:db/table/:table/partition/:partition(DELETE)

- Description

Deletes a table partition.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/partition/:partition>

- Parameter

| Parameter   | Description   |
|-------------|---|
| :db         | Database name.  |
| :table      | Table name.   |
| group       | User group used for deleting a new partition.                                       |
| permissions | User permission used for deleting a new partition. The format is <b>rwxrw-r-x</b> . |

| Parameter | Description   |
|-----------|---|
| IfExists  | If the specified partition does not exist, the Hive reports an error, unless this parameter is set to <b>true</b> . |

- Returned result

| Parameter  | Description     |
|------------|-----------------|
| database   | Database name.  |
| table      | Table name.     |
| partitions | Partition name. |

- Example

```
curl -i -u : --insecure --negotiate -X DELETE -HContent-type:application/json -d '{}' https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/x1/partition/dt=10
```

## 21. `ddl/database/:db/table/:table/column(GET)`

- Description

Obtains a column list of a table.

- URL

`https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/column`

- Parameter

| Parameter | Description    |
|-----------|----------------|
| :db       | Database name. |
| :table    | Table name.    |

- Returned result

| Parameter | Description           |
|-----------|-----------------------|
| database  | Database name.        |
| table     | Table name.           |
| columns   | Column name and type. |

- Example

```
curl -i -u : --insecure --negotiate https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/t1/column
```

## 22. `ddl/database/:db/table/:table/column/:column(GET)`

- Description

Obtains details about a column in a table.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/column/:column>

- Parameter

| Parameter | Description    |
|-----------|----------------|
| :db       | Database name. |
| :table    | Table name.    |
| :column   | Column name.   |

- Returned result

| Parameter | Description           |
|-----------|-----------------------|
| database  | Database name.        |
| table     | Table name.           |
| column    | Column name and type. |

- Example

```
curl -i -u : --insecure --negotiate https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/t1/column/id
```

### 23. `ddl/database/:db/table/:table/column/:column(PUT)`

- Description

Adds a column to a table.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/column/:column>

- Parameter

| Parameter | Description                               |
|-----------|---|
| :db       | Database name.                            |
| :table    | Table name.                               |
| :column   | Column name.                              |
| type      | Column type, for example, string and int. |
| comment   | Column remarks, for example, description. |

- Returned result

| Parameter | Description    |
|-----------|----------------|
| database  | Database name. |
| table     | Table name.    |
| column    | Column name.   |

- Example

```
curl -i -u : --insecure --negotiate -X PUT -HContent-type:application/json -d '{"type": "string", "comment": "new column"}' https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/t1/column/name
```

#### 24. ddl/database/:db/table/:table/property(GET)

- Description

Obtains properties of a table.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/property>

- Parameter

| Parameter | Description    |
|-----------|----------------|
| :db       | Database name. |
| :table    | Table name.    |

- Returned result

| Parameter  | Description    |
|------------|----------------|
| database   | Database name. |
| table      | Table name.    |
| properties | Property.      |

- Example

```
curl -i -u : --insecure --negotiate https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/t1/property
```

#### 25. ddl/database/:db/table/:table/property/:property(GET)

- Description

Obtains a specific property value of a table.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/property/:property>

- Parameter

| Parameter | Description    |
|-----------|----------------|
| :db       | Database name. |

| Parameter | Description    |
|-----------|----------------|
| :table    | Table name.    |
| :property | Property name. |

- Returned result

| Parameter | Description    |
|-----------|----------------|
| database  | Database name. |
| table     | Table name.    |
| property  | Property list. |

- Example

```
curl -i -u : --insecure --negotiate https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/t1/property/last_modified_by
```

## 26. ddl/database/:db/table/:table/property/:property(PUT)

- Description

Adds a property value to a table.

- URL

<https://www.myserver.com/templeton/v1/ddl/database/:db/table/:table/property/:property>

- Parameter

| Parameter | Description     |
|-----------|-----------------|
| :db       | Database name.  |
| :table    | Table name.     |
| :property | Property name.  |
| value     | Property value. |

- Returned result

| Parameter | Description    |
|-----------|----------------|
| database  | Database name. |
| table     | Table name.    |
| property  | Property name. |

- Example

```
curl -i -u : --insecure --negotiate -X PUT -HContent-type:application/json -d '{"value": "my value"}' https://10.64.35.144:21055/templeton/v1/ddl/database/default/table/t1/property/mykey
```

## 27. mapreduce/jar(POST)

- Description

Executes a MapReduce job. Before executing a MapReduce job, upload the JAR file of the MapReduce job to HDFS.

- URL

<https://www.myserver.com/templeton/v1/mapreduce/jar>

- Parameter

| Parameter | Description   |
|-----------|---|
| jar       | JAR file of the MapReduce job to be executed.   |
| class     | Class of the MapReduce job to be executed.  |
| libjars   | JAR file names of <b>classpath</b> to be added, separated by commas (,).  |
| files     | Names of files to be copied to the MapReduce cluster, separated by commas (,).  |
| arg       | Input parameter received by the Main class.   |
| define    | This parameter is used to configure Hadoop in the <b>define=NAME=VALUE</b> format.  |
| statusdir | WebHCat writes the status of the MapReduce task to <b>statusdir</b> . If this parameter is set, you need to manually delete it.   |
| enablelog | If <b>statusdir</b> is set and <b>enablelog</b> is set to <b>true</b> , Hadoop task configurations and logs are collected to <b>\$statusdir/logs</b> . Then, successful and failed attempts are recorded in the logs. The layout of the subdirectories in <b>\$statusdir/logs</b> is as follows:<br><br>logs/\$job_id (directory for \$job_id)<br>logs/\$job_id/job.xml.html<br>logs/\$job_id/\$attempt_id (directory for \$attempt_id)<br>logs/\$job_id/\$attempt_id/stderr<br>logs/\$job_id/\$attempt_id/stdout<br>logs/\$job_id/\$attempt_id/syslog<br>Only Hadoop 1.X is supported. |

| Parameter | Description  |
|-----------|--|
| callback  | Callback address after MapReduce job execution. Use <b>\$jobId</b> to embed the job ID in the callback address. In the callback address, replace the <b>\$jobId</b> with the job ID. |

- Returned result

| Parameter | Description                                       |
|-----------|---|
| id        | Job ID, similar to <b>job_201110132141_0001</b> . |

- Example

```
curl -i -u : --insecure --negotiate -d jar="/tmp/word.count-0.0.1-SNAPSHOT.jar" -d class=com.huawei.word.count.WD -d statusdir="/output" -d enablelog=true "https://10.64.35.144:21055/templeton/v1/mapreduce/jar"
```

## 28. mapreduce/streaming(POST)

- Description

Submits a MapReduce job in Streaming mode.

- URL

<https://www.myserver.com/templeton/v1/mapreduce/streaming>

- Parameter

| Parameter | Description   |
|-----------|---|
| input     | Input path of Hadoop.   |
| output    | Output save path. If this parameter is not specified, WebHCat will store the output in a path that can be found by using queue resources. |
| mapper    | Location of the mapper program.   |
| reducer   | Location of the reducer program.  |
| files     | Add HDFS files to the distributed cache.  |
| arg       | Set an argument.  |
| define    | Set Hadoop configuration variables in the <b>define=NAME=VALUE</b> format.  |
| cmdenv    | Set environment variables in the <b>cmdenv=NAME=VALUE</b> format.   |

| Parameter | Description   |
|-----------|---|
| statusdir | WebHCat writes the status of the MapReduce task to <b>statusdir</b> . If this parameter is set, you need to manually delete it.   |
| enablelog | If <b>statusdir</b> is set and <b>enablelog</b> is set to <b>true</b> , Hadoop task configurations and logs are collected to <b>\$statusdir/logs</b> . Then, successful and failed attempts are recorded in the logs. The layout of the subdirectories in <b>\$statusdir/logs</b> is as follows:<br><br>logs/\$job_id (directory for \$job_id)<br>logs/\$job_id/job.xml.html<br>logs/\$job_id/\$attempt_id (directory for \$attempt_id)<br>logs/\$job_id/\$attempt_id/stderr<br>logs/\$job_id/\$attempt_id/stdout<br>logs/\$job_id/\$attempt_id/syslog<br>Only Hadoop 1.X is supported. |
| callback  | Callback address after MapReduce job execution. Use <b>\$jobId</b> to embed the job ID in the callback address. In the callback address, replace the <b>\$jobId</b> with the job ID.  |

- Returned result

| Parameter | Description                                       |
|-----------|---|
| id        | Job ID, similar to <b>job_201110132141_0001</b> . |

- Example

```
curl -i -u : --insecure --negotiate -d input=/input -d output=/oooo -d mapper=/bin/cat -d reducer="/usr/bin/wc -w" -d statusdir="/output" 'https://10.64.35.144:21055/templeton/v1/mapreduce/streaming'
```

#### NOTE

Before using this API, ensure that the prerequisites are met. For details, see [Rules](#).

### 29. /hive(POST)

- Description  
Runs Hive commands.
- URL  
<https://www.myserver.com/templeton/v1/hive>

## - Parameter

| Parameter | Description  |
|-----------|--|
| execute   | Hive commands, including entire and short Hive commands.   |
| file      | HDFS file containing Hive commands.  |
| files     | Names of files to be copied to the MapReduce cluster, separated by commas (,).   |
| arg       | Set an argument.   |
| define    | Hive configuration. The format is <b>define=key=value</b> . When using the post statement, you need to configure the scratch dir of the instance. The WebHCat instance uses <b>define=hive.exec.scratchdir=/tmp/hive-scratch</b> , and the WebHCat1 instance uses <b>define=hive.exec.scratchdir=/tmp/hive1-scratch</b> . The same rule applies to other instances.  |
| statusdir | WebHCat writes the status of the MapReduce task to <b>statusdir</b> . If this parameter is set, you need to manually delete it.  |
| enablelog | If <b>statusdir</b> is set and <b>enablelog</b> is set to <b>true</b> , Hadoop task configurations and logs are collected to <b>\$statusdir/logs</b> . Then, successful and failed attempts are recorded in the logs. The layout of the subdirectories in <b>\$statusdir/logs</b> is as follows:<br><b>logs/\$job_id</b> (directory for \$job_id)<br><b>logs/\$job_id/job.xml.html</b><br><b>logs/\$job_id/\$attempt_id</b> (directory for \$attempt_id)<br><b>logs/\$job_id/\$attempt_id/stderr</b><br><b>logs/\$job_id/\$attempt_id/stdout</b><br><b>logs/\$job_id/\$attempt_id/syslog</b> |

| Parameter | Description  |
|-----------|--|
| callback  | Callback address after MapReduce job execution. Use <b>\$jobId</b> to embed the job ID in the callback address. In the callback address, replace the <b>\$jobId</b> with the job ID. |

- Returned result

| Parameter | Description                                       |
|-----------|---|
| id        | Job ID, similar to <b>job_201110132141_0001</b> . |

- Example

```
curl -i -u : --insecure --negotiate -d execute="select count(*) from t1" -d
define=hive.exec.scratchdir=/tmp/hive-scratch -d statusdir="/output" "https://10.64.35.144:21055/
templeton/v1/hive"
```

### 30. jobs(GET)

- Description  
Obtains all job IDs.
- URL  
<https://www.myserver.com/templeton/v1/jobs>
- Parameter

| Parameter | Description  |
|-----------|--|
| fields    | If this parameter is set to *, details about each job are returned. If this parameter is not set, only a job ID is returned. The parameter can only be set to *. If the parameter is set to another value, an exception occurs.  |
| jobid     | If <b>jobid</b> is set, only jobs whose lexicographic order is greater than <b>jobid</b> are returned. For example, if the value of <b>jobid</b> is <b>job_201312091733_0001</b> , only the job whose value is greater than the value can be returned. The number of returned jobs depends on the value of <b>numrecords</b> . |

| Parameter  | Description  |
|------------|--|
| numrecords | If <b>numrecords</b> and <b>jobid</b> are set, the <b>jobid</b> list is sorted lexicographically. After <b>jobid</b> is returned, the maximum value of <b>numrecords</b> can be obtained. If <b>jobid</b> is not set but <b>numrecords</b> is set, the maximum value of <b>numrecords</b> can be obtained after the <b>jobid</b> list is sorted lexicographically. In contrast, if <b>numrecords</b> is not set but <b>jobid</b> is set, all jobs whose lexicographic orders are greater than <b>jobid</b> will be returned. |
| showall    | If <b>showall</b> is set to <b>true</b> , the request will return all jobs the user has permission to view, not only the jobs belonging to the user.   |

- Returned result

| Parameter | Description  |
|-----------|--|
| id        | Job id   |
| detail    | If the value of <b>showall</b> is <b>true</b> , details are displayed. Otherwise, the value is null. |

- Example

```
curl -i -u : --insecure --negotiate "https://10.64.35.144:21055/templeton/v1/jobs"
```

### 31. jobs/:jobid(GET)

- Description

Obtains information about a specified job.

- URL

<https://www.myserver.com/templeton/v1/jobs/:jobid>

- Parameter

| Parameter | Description                              |
|-----------|--|
| jobid     | Job ID, received after a job is created. |

- Returned result

| Parameter       | Description  |
|-----------------|--|
| status          | JSON object containing job status information.   |
| profile         | JSON object containing job information. WebHCat parses information in the <b>JobProfile</b> object. The object varies according to the Hadoop version. |
| id              | Job ID.  |
| percentComplete | Job completion percentage, for example, 75%. If the job is complete, the value is null.  |
| user            | User who created the job.  |
| callback        | Callback URL (if any).   |
| userargs        | Parameter <b>argument</b> and parameter value when a user submits a job.   |
| exitValue       | Exit value of the job.   |

- Example

```
curl -i -u : --insecure --negotiate "https://10.64.35.144:21055/templeton/v1/jobs/  
job_1440386556001_0255"
```

### 32. jobs/:jobid(DELETE)

- Description

Kills a job.

- URL

<https://www.myserver.com/templeton/v1/jobs/:jobid>

- Parameter

| Parameter | Description                  |
|-----------|------------------------------|
| :jobid    | ID of the job to be deleted. |

- Returned result

| Parameter | Description                                    |
|-----------|--|
| user      | User who submits a job.                        |
| status    | JSON object containing job status information. |

| Parameter | Description  |
|-----------|--|
| profile   | JSON object containing job information. WebHCat parses information in the <b>JobProfile</b> object. The object varies according to the Hadoop version. |
| id        | Job ID.  |
| callback  | Callback URL (if any).   |

- Example

```
curl -i -u : --insecure --negotiate -X DELETE "https://10.64.35.143:21055/templeton/v1/jobs/job_1440386556001_0265"
```

## 1.13.5.2 FAQ

### 1.13.5.2.1 A Message Is Displayed Stating "Unable to read HiveServer2 configs from ZooKeeper" During the Use of the Secondary Development Program

#### Question

A Message Is Displayed Stating "Unable to read HiveServer2 configs from ZooKeeper" During the Use of the Secondary Development Program.

#### Answer

- Possible Causes
  - The used **krb5.conf** and **user.keytab** may not be the latest ones, or the user names in the files do not match with those in example codes.
  - The difference between the time of the client and that of the connected cluster is greater than 5 minutes.
- Possible Causes
  - Check the code and download the latest credential file for user authentication.
  - Check whether the difference between the time of the client and that of the connected cluster is greater than 5 minutes. If yes, adjust the time of the client.

### 1.13.5.2.2 Problem performing GSS wrap Message Is Displayed Due to IBM JDK Exceptions

#### Question

IBM JDK is abnormal, and the **Problem performing GSS wrap** message is displayed.

#### Answer

##### Possible Causes

The Hive connection duration exceeds the user authentication timeout duration (one day by default), causing authentication failure.

 **NOTE**

The IBM JDK mechanism is different from the Oracle JDK mechanism. IBM JDK executes time check after authentication and login, but does not check external time update. This results in refreshing failure even Hive relogin is invoked explicitly.

**Solution**

When one Hive connection fails, disable this connection, and create a connection to continue performing previous operations.

### 1.13.5.2.3 Hive SQL Is Incompatible with SQL2003 Standards

This document describes the incompatibility issues between Hive SQL and SQL2003.

- **The view cannot be written in having.**

For example:

```
select c_last_name
      ,c_first_name
      ,s_store_name
      ,sum(netpaid) paid
  from ssales
 where i_color = 'chiffon'
 group by c_last_name
      ,c_first_name
      ,s_store_name
 having sum(netpaid) > (select 0.05*avg(netpaid) from ssales);
```

**Error message:**

Error: Error while compiling statement: FAILED:ParseException line 46:23 cannot recognize input near 'select' '0.05' '\*' in expression specification (state=42000,code=40000)

- **The Having does not support sub-query.**

For example:

```
select
      ps_partkey,
      sum(ps_supplycost * ps_availqty) as value
  from
      partsupp,
      supplier,
      nation
 where
      ps_suppkey = s_suppkey
      and s_nationkey = n_nationkey
      and n_name = 'SAUDI ARABIA'
 group by
      ps_partkey having
      sum(ps_supplycost * ps_availqty) > (
          select
              sum(ps_supplycost * ps_availqty) * 0.000100000
          from
              partsupp,
              supplier,
              nation
          where
              ps_suppkey = s_suppkey
              and s_nationkey = n_nationkey
              and n_name = 'SAUDI ARABIA'
      )
 order by
      value desc;
```

### Error message:

Error: Error while compiling statement: FAILED: SemanticException Line 0:-1 Unsupported SubQuery Expression "SAUDI ARABIA": Only SubQuery expressions that are top level conjuncts are allowed (state=42000,code=40000)

- **Multiple query results cannot be displayed as multiple fields.**

For example:

```
select
    c_count,
    count(*) as custdist
from
(
    select
        c_custkey,
        count(o_orderkey)
    from
        customer left outer join orders on
            c_custkey = o_custkey
            and o_comment not like '%pending%requests%'
    group by
        c_custkey
) as c_orders (c_custkey, c_count)
group by
    c_count
order by
    custdist desc,
    c_count desc;
```

### Error message:

Error: Error while compiling statement: FAILED: ParseException line 1:213 missing EOF at '(' near 'c\_orders' (state=42000,code=40000)

- **The query results cannot be compared as fields.**

For example:

```
select
    sum(l_extendedprice) / 7.0 as avg_yearly
from
    lineitem,
    part
where
    p_partkey = l_partkey
    and p_brand = 'Brand#25'
    and p_container = 'MED JAR'
    and l_quantity < (
        select
            0.2 * avg(l_quantity)
        from
            lineitem
        where
            l_partkey = p_partkey
    );
```

### Error message:

Error: Error while compiling statement: FAILED: SemanticException [Error 10249]: Line 14:4 Unsupported SubQuery Expression 'ps\_suppkey': Correlating expression contains ambiguous column references. (state=42000,code=10249)

- **The multi-table association query does not support the sub-query filter by not in or in.**

For example:

```
select
    p_brand,
    p_type,
    p_size,
    count(distinct ps_suppkey) as supplier_cnt
from
```

```
partsupp,  
part  
where  
p_partkey = ps_partkey  
and p_brand <> 'Brand#12'  
and p_type not like 'PROMO PLATED%'  
and p_size in (25, 2, 43, 9, 35, 36, 48, 24)  
and ps_suppkey in (  
select  
s_suppkey as ps_suppkey  
from  
supplier  
where  
s_comment like '%Customer%Complaints%'  
)  
group by  
p_brand,  
p_type,  
p_size  
order by  
supplier_cnt desc,  
p_brand,  
p_type,  
p_size;
```

**Error message:**

Error: Error while compiling statement: FAILED: SemanticException [Error 10249]: Line 14:4  
Unsupported SubQuery Expression 'ps\_suppkey': Correlating expression contains ambiguous column  
references. (state=42000,code=10249)

- **The multi-table association does not support filtering of not in and in sub-queries.**

For example:

```
select  
c_name,  
c_custkey,  
o_orderkey,  
o_orderdate,  
o_totalprice,  
sum(l_quantity)  
from  
customer,  
orders,  
lineitem  
where  
o_orderkey in (  
select  
l_orderkey  
from  
lineitem  
group by  
l_orderkey having  
sum(l_quantity) > 315  
)  
and c_custkey = o_custkey  
and o_orderkey = l_orderkey  
group by  
c_name,  
c_custkey,  
o_orderkey,  
o_orderdate,  
o_totalprice  
order by  
o_totalprice desc,  
o_orderdate  
limit 100;
```

**Error message:**

Error: Error while compiling statement: FAILED: SemanticException [Error 10249]: Line 13:0  
Unsupported SubQuery Expression 'o\_orderkey': Correlating expression contains ambiguous column references. (state=42000,code=10249)

- **The association conditions do not support multiple exists query entities.**

For example:

```
select
    s_name,
    count(*) as numwait
from
    supplier,
    lineitem l1,
    orders,
    nation
where
    s_suppkey = l1.l_suppkey
    and o_orderkey = l1.l_orderkey
    and o_orderstatus = 'F'
    and l1.l_receiptdate > l1.l_commitdate
    and exists (
        select
            *
        from
            lineitem l2
        where
            l2.l_orderkey = l1.l_orderkey
            and l2.l_suppkey <> l1.l_suppkey
    )
    and not exists (
        select
            *
        from
            lineitem l3
        where
            l3.l_orderkey = l1.l_orderkey
            and l3.l_suppkey <> l1.l_suppkey
            and l3.l_receiptdate > l3.l_commitdate
    )
    and s_nationkey = n_nationkey
    and n_name = 'VIETNAM'
group by
    s_name
order by
    numwait desc,
    s_name
limit 100;
```

**Error message:**

Error: Error while compiling statement: FAILED: SemanticException [Error 10249]: Line 23:8  
Unsupported SubQuery Expression 'l\_commitdate': Only 1 SubQuery expression is supported.  
(state=42000,code=10249)

- **The multi-level in-nested sub-query is not supported.**

For example:

```
select i_item_id item_id,
       sum(sr_return_quantity) sr_item_qty
  from store_returns,
       item,
       date_dim
 where sr_item_sk = i_item_sk
   and d_date in
       (select d_date
          from date_dim
         where d_week_seq in
              (select d_week_seq
                 from date_dim
                where d_date in ('1998-01-02','1998-10-15','1998-11-10'))
   and sr_returned_date_sk = d_date_sk
```

```
group by i_item_id),
cr_items as
(select i_item_id item_id,
       sum(cr_return_quantity) cr_item_qty
  from catalog_returns,
       item,
       date_dim
 where cr_item_sk = i_item_sk);
```

**Error message:**

Unsupported SubQuery Expression 'd\_week\_seq': SubQuery cannot use the table alias: date\_dim; this is also an alias in the Outer Query and SubQuery contains a unqualified column reference  
(state=42000,code=10249)

### 1.13.5.2.4 "version 'GLIBCXX\_3.4.21' not found" Exception Occurs When the Python 3 Secondary Development Program Is Used to Access Hive

#### Question

"version 'GLIBCXX\_3.4.21' not found" exception occurs when the Python 3 secondary development program is used to access Hive.

#### Answer

- **Possible Causes**

The default GCC version of the OS used by the client is too early, and the dynamic link library (DLL) does not contain **GLIBCXX\_3.4.21**.

- **Solution**

Upgrade the GCC version of the client OS to 5.4.0.

## 1.14 IoTDB Development Guide

### 1.14.1 Overview

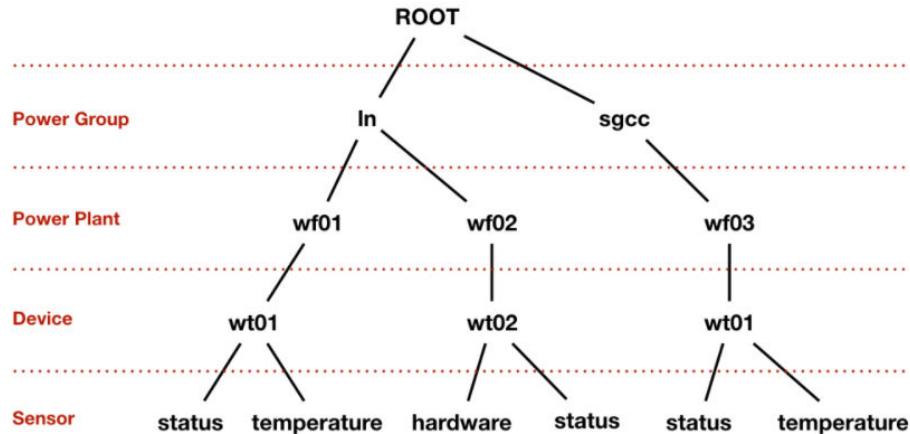

#### 1.14.1.1 Application Development Overview

##### Introduction to IoTDB

IoTDB is a data management engine that integrates collection, storage, and analysis of time series data. It features lightweight, high performance, and ease of use. It perfectly interconnects with the Hadoop and Spark ecosystems and meets the requirements of high-speed write and complex analysis and query on massive time series data in industrial IoT applications.

##### 1.14.1.2 Basic Concepts

The following uses an electric power scenario as an example to describe how to create a correct data model in IoTDB.

**Figure 1-170** Hierarchical structure of attributes in an electric power scenario

**Figure 1-170** shows the power group layer, power plant layer, device layer, and sensor layer. **ROOT** is a root node, and each node at the sensor layer is a leaf node. According to the IoTDB syntax, the path from **ROOT** to a leaf node is separated by a dot (.). The complete path is used to name a time series in the IoTDB. For example, the time series name corresponding to the path on the left in **Figure 1-170** is **ROOT.In.wf01.wt01.status**.

## Basic Concepts

- **Device**  
A device is a machine equipped with sensors in actual scenarios. In IoTDB, all sensors must have their corresponding devices.
- **Sensor**  
A sensor is a detection machine in actual scenarios. It can sense the information to be measured, and can transform the sensed information into an electrical signal or other desired form of information output and send it to IoTDB. In IoTDB, all data and paths stored are organized in units of sensors.
- **Database**  
A database is also called a storage group. You can set any prefixed path as a database. If there are four time series, for example, **root.vehicle.d1.s1**, **root.vehicle.d1.s2**, **root.vehicle.d2.s1**, and **root.vehicle.d2.s2**, two devices **d1** and **d2** in the path **root.vehicle** may belong to the same owner or manufacturer, so **d1** and **d2** are closely related. In this case, the prefixed path **root.vehicle** can be designated as a database, which will enable IoTDB to store the data of all devices under it in the same folder. Newly added devices in **root.vehicle** will also belong to this storage group.

### NOTE

- A proper number of databases can improve performance. There is neither the slowdown of the system due to frequent I/O switching (which will also take up excessive memory and result in frequent memory-file switching) caused by too many storage files or folders, nor the block of write commands caused by too few storage files or folders (which reduces concurrency).
- You need to balance the storage group settings of storage files according to their own data size and usage scenarios to achieve better system performance.

- **Time series**

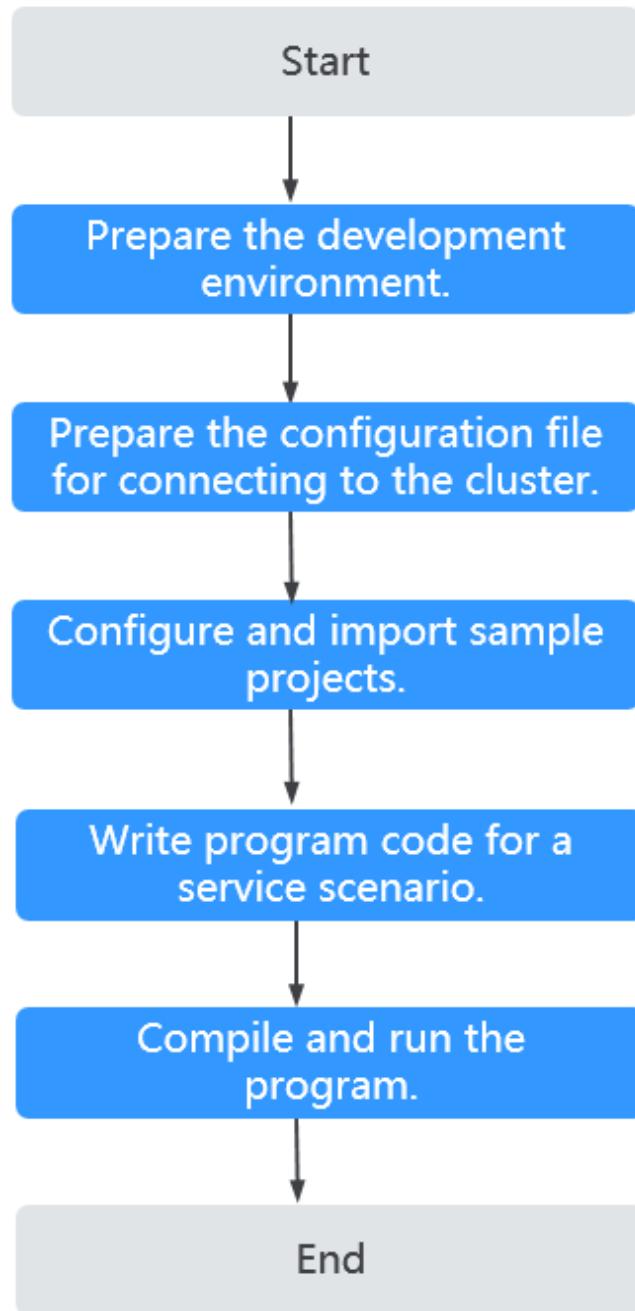

Time series is a core concept in IoTDB. The time series can be considered as the complete path of the sensor that generates the time series data. In IoTDB, all time series must start with root and end with the sensor.

### 1.14.1.3 Development Process

This section describes how to use Java APIs to develop IoTDB applications.

[Figure 1-171](#) and [Table 1-128](#) describe the phases in the development process.

[Figure 1-171](#) IoTDB application development process

**Table 1-128** Description of the IoTDB application development process

| Phase   | Description   | Reference   |
|---|---|---|
| Prepare the development environment.                          | Before developing an application, you need to prepare the development environment. You are advised to use the Java language and IntelliJ IDEA tool for development. In addition, you need to complete the initial configuration of the JDK and Maven.   | <a href="#">Preparing the Environment</a>                                       |
| Prepare the Configuration File for Connecting to the Cluster. | During application development or running, you need to connect to the MRS cluster through cluster configuration files. Configuration files include cluster component information files and user files used for security authentication. You can obtain related content from the created MRS cluster.<br><br>Nodes used for program commissioning or running must be able to communicate with nodes in the MRS cluster and the hosts domain name must be configured. | <a href="#">Preparing the Configuration Files for Connecting to the Cluster</a> |
| Configure and import the sample project.                      | IoTDB provides multiple sample programs in different scenarios. You can obtain sample projects and import them to the local development environment for program learning.   | <a href="#">Configuring and Importing a Sample Project</a>                      |
| Develop programs based on business scenarios.                 | Sample projects of the Java language are provided, including JDBC and Session connection modes. A sample project covers the entire process from creating a storage group, creating a time sequence, inserting data, to deleting a storage group.  | <a href="#">Application Development</a>   |
| Compile and run the application.                              | Compile the developed application and submit it for running.  | <a href="#">Application Commissioning</a>                                       |

#### 1.14.1.4 IoTDB Sample Project

To obtain an MRS sample project, visit <https://github.com/huaweicloud/huaweicloud-mrs-example> and switch to the branch that matches the MRS cluster version. Download the package to the local PC and decompress it to obtain the sample project of each component.

MRS provides the following IoTDB sample projects.

**Table 1-129** IoTDB sample projects

| Sample Project Location              | Description  |
|--------------------------------------|--|
| iotdb-examples/iotdb-flink-example   | Program for using Flink to access IoTDB data, including FlinkIoTDBSink and FlinkIoTDBSource data.<br>FlinkIoTDBSink can use Flink jobs to write time series data to IoTDB. FlinkIoTDBSource reads time series data from IoTDB through Flink jobs and prints the data. For details, see <a href="#">IoTDB Flink</a> . |
| iotdb-examples/iotdb-jdbc-example    | Java sample program for IoTDB JDBC to process data<br>This example demonstrates how to use JDBC APIs to connect to IoTDB and run IoTDB SQL statements. For details, see <a href="#">IoTDB JDBC</a> .   |
| iotdb-examples/iotdb-kafka-example   | Sample program for accessing IoTDB data through Kafka<br>This program demonstrates how to send time series data to Kafka and then use multiple threads to write the data to IoTDB. For details, see <a href="#">IoTDB Kafka</a> .  |
| iotdb-examples/iotdb-session-example | Java sample program for IoTDB Session to process data<br>This example demonstrates how to use Session to connect to IoTDB and run IoTDB SQL statements. For details, see <a href="#">IoTDB Session</a> .   |
| iotdb-examples/iotdb-udf-exmaple     | This sample program describes how to implement a simple IoTDB user-defined function (UDF). For details, see <a href="#">IoTDB UDF Program</a> .  |

## 1.14.2 Environment Preparations

### 1.14.2.1 Preparing the Environment

[Table 1-130](#) describes the environment required for application development.

**Table 1-130** Development environment

| Item | Description  |
|------|--|
| OS   | <ul style="list-style-type: none"><li>Development environment: Windows 7 or later versions</li><li>Operating environment: Windows or Linux<br/>If the program needs to be commissioned locally, the operating environment must be able to communicate with network on the cluster service plane.</li></ul> |

| Item          | Description   |
|---------------|---|
| JDK           | <p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>● For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>● For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>● For security purposes, the server supports only TLS V1.2 or later.</li><li>● By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetin-stancetls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetin-stancetls-oracle#matchsslcontext_tls</a>.</li><li>● For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul> |
| IntelliJ IDEA | <p>Tool used for developing IoTDB applications. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>● If you use IBM JDK, ensure that the JDK configured in IntelliJ IDEA is IBM JDK.</li><li>● If you use Oracle JDK, ensure that the JDK configured in IntelliJ IDEA is Oracle JDK.</li><li>● If you use OpenJDK, ensure that the JDK configured in IntelliJ IDEA is OpenJDK.</li><li>● Do not use the same workspace or the sample project in the same path for different IntelliJ IDEA programs.</li></ul>   |
| Maven         | <p>Basic configurations of the development environment. Maven is used for project management throughout the lifecycle of software development.</p> <p>Huawei provides an open-source mirror site, Huawei Mirrors. You can download the dependent JAR packages of the sample projects from this site. You can download the rest open-source JAR packages from the Maven central repository or other user-defined repositories. For details, see <a href="#">Configuring Huawei Open-Source Mirrors</a>.</p>  |

| Item  | Description   |
|-------|---|
| 7-zip | This tool is used to decompress *.zip and *.rar files. <b>7-zip 16.04</b> is supported. |

### 1.14.2.2 Preparing the Configuration Files for Connecting to the Cluster

#### Preparing for User Authentication

For an MRS cluster with Kerberos authentication enabled, you need to prepare a user who has the operation permission on related components for program authentication.

The following IoTDB permission configuration example is for reference only. You can modify the configuration as you need.

**Step 1** Log in to FusionInsight Manager.

**Step 2** Choose **System > Permission > Role**. On the displayed page, click **Create Role**.

1. Enter the role name, for example, **developrole**.
2. In the **Configure Resource Permission** table, choose *Name of the desired cluster > IoTDB > Common User Permission*, and select **Set Database** for the **root** directory.
3. Click **root**, select the desired storage group, select **Create, Modify, Write, Read, and Delete**, and click **OK**.

**Step 3** Choose **User** in the navigation pane and click **Create** on the displayed page. Create a machine-machine user, for example, **developuser**.

- Add the **iotdbgroup** user group to **User Group**.
- Add the new role created in **Step 2** to **Role**.

**Step 4** Log in to FusionInsight Manager as user **admin** and choose **System > Permission > User**. In the **Operation** column of **developuser**, choose **More > Download Authentication Credential**. Save the file and decompress it to obtain the **user.keytab** and **krb5.conf** files of the user.

----End

#### Generating an SSL Certificate for the IoTDB Client

If SSL encrypted transmission is enabled for the cluster and this is your first time running IoTDB sample code in the local Windows or Linux environment, perform the following operations to generate a client SSL certificate:

**Step 1** Log in to the node where the client is installed as the client installation user.

**Step 2** Switch to the IoTDB client installation directory, for example, **/opt/hadoopclient**.

```
cd /opt/hadoopclient
```

**Step 3** Configure environment variables.

```
source bigdata_env
```

**Step 4** Generate the client SSL certificate **truststore.jks**.

```
keytool -noprompt -import -alias myservercert -file ca.crt -keystore  
truststore.jks
```

You are required to set a password.

**Step 5** To run the sample code in the Linux environment, copy the generated **truststore.jks** file to the *Client installation directory/iotDB/iotdb/conf* directory.

```
cp truststore.jks Client installation directory/iotDB/iotdb/conf
```

----End

## Preparing the Configuration Files of the Running Environment

During the development or a test run of the program, you need to use cluster configuration files to connect to an MRS cluster. The configuration files usually contain the cluster component information file and user files used for security authentication. You can obtain the required information from the created MRS cluster.

Nodes used for program debugging or running must be able to communicate with nodes within the MRS cluster, and the hosts domain name must be configured.

- Scenario 1: Preparing the configuration files required for debugging in the local Windows development environment
  - a. Log in to FusionInsight Manager. In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Configuration Files Only**, and click **OK**. After the client file package is generated, download it to the local PC as prompted and decompress it.  
For example, if the client configuration file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar**. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles.tar**. Decompress the package to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig\_ConfigFiles** directory on the local PC.
  - b. Copy all items from the **hosts** file in the decompression directory to the **hosts** file on the node where the client is installed. Ensure that the network communication between the local PC and hosts listed in the **hosts** file is normal.

### NOTE

- If the client host is outside the cluster, configure network connections to the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored, for example, in **C:\WINDOWS\system32\drivers\etc\hosts**.
- Scenario 2: Preparing the configuration files required for running the program in a Linux environment
  - a. Install the client. For example, install the client in the **/opt/hadoopclient** directory.

- Ensure that the difference between the client time and the cluster time is less than 5 minutes.
- b. Log in to FusionInsight Manager, click **Download Client** in the upper right corner of **Homepage**. Set **Select Client Type** to **Configuration Files Only**, select **Save to Path**, and click **OK** to download the client configuration file to the active OMS node of the cluster.
  - c. Log in to the active OMS node as user **root**, go to the directory where the client configuration files are stored (**/tmp/FusionInsight-Client** by default), decompress the software package, and obtain all configuration files in the **IoTDB/config** directory. Place the files in the **conf** directory where the compiled JAR package is stored on the client node, for example, **/opt/hadoopclient/conf**.  
For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and it is downloaded to the **/tmp/FusionInsight-Client** directory on the active management node, run the following commands:  

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp IoTDB/config/* root@IP address of the client node:/opt/  
hadoopclient/conf
```
  - d. Check the network connection of the client node.  
During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If there is no required information, copy the content of the **hosts** file in the decompression directory to the **hosts** file on the node where the client is deployed, to ensure that the local host can communicate with each host in the cluster.

### 1.14.2.3 Configuring and Importing a Sample Project

#### Scenario

Obtain the IoTDB development sample project and import the project to IntelliJ IDEA to learn the sample project.

#### Procedure

- Step 1** Obtain the sample project from the **src/iotdb-examples** directory in the directory where the sample code is decompressed by referring to [Obtaining Sample Projects from Huawei Mirrors](#). You can select a sample based on the actual service scenario. For details about the samples, see [IoTDB Sample Project](#).
- Step 2** To debug **iotdb-flink-example**, **iotdb-jdbc-example**, **iotdb-kafka-example**, or **iotdb-session-example** sample code on the local Windows environment, perform the following operations:

- Store the authentication files **user.keytab** and **krb5.conf** obtained in [Preparing for User Authentication](#) and SSL certificate file **truststore.jks** to the ..\src\main\resources directory of each sample project.
- Configure the **com.huawei.bigdata.iotdb.IoTDBProperties** class in the ..\src\main\resources directory of each sample project, change the value of **proPath** in the **IoTDBProperties()** method to the absolute path of the **iotdb-example.properties** file.

**Figure 1-172** Configuring the proPath parameter

```
private IoTDBProperties() {
    // If Windows environment, proPath is "iotdb-example.properties" absolute file path.
    // eg:D:\\sample_project\\sample_project\\src\\iotdb-examples\\iotdb-session-example\\src\\main\\resources\\iotdb-example.properties
    String proPath = "D:\\code\\CodeHub\\sample_project\\sample_project\\src\\iotdb-examples\\iotdb-session-example\\src\\main\\resources\\iotdb-example.properties";
    // String proPath = System.getProperty("user.dir") + File.separator + "src" + File.separator + "main"
    //           + File.separator + "resources" + File.separator + "iotdb-example.properties";
    try {
        iotdbProps.load(new FileInputStream(new File(proPath)));
    } catch (IOException e) {
        LOG.info(s:"The Exception occurred.", e);
    }
}
```

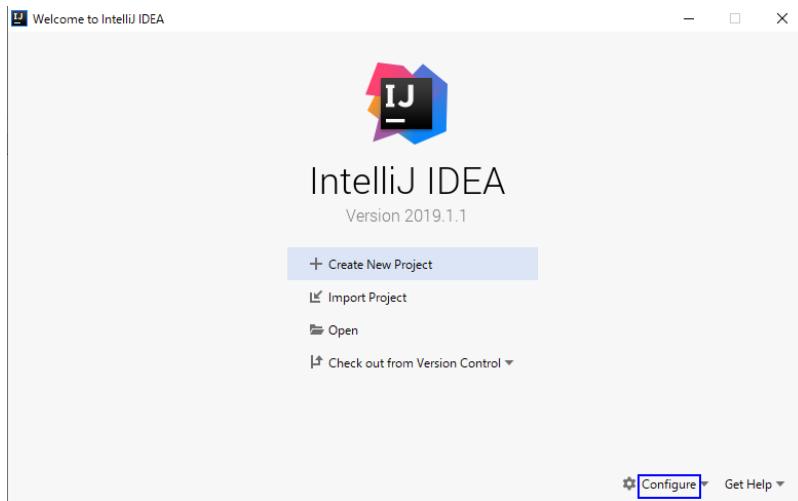

**Step 3** Modify the **iotdb-example.properties** file in the ..\src\main\resources directory of each sample project.

```
iotdb_ssl_enable=true
jdbc_url=jdbc:iotdb://IP address of the IoTDBServer instance:IoTDBServer RPC port
# Username for authentication
username=developuser
# User password for authentication. It is recommended that the password be stored in ciphertext and decrypted when being used.
password=xxx
# Location of the krb5.conf file in the downloaded authentication credential. In Linux, you are advised to use the krb5.conf file that has been uploaded to the IoTDB client installation directory/IoTDB/iotdb/conf directory. In Windows, use \\ to specify the absolute path of the file.
krb5_conf_dest=/opt/hadoopclient/IoTDB/iotdb/conf/krb5.conf
# Location of the user.keytab file in the downloaded authentication credential. In Linux, you are advised to use the user.keytab file that has been uploaded to the IoTDB client installation directory/IoTDB/iotdb/conf directory. In Windows, use \\ to specify the absolute path of the file.
key_tab_dest=/opt/hadoopclient/IoTDB/iotdb/conf/user.keytab
# Username corresponding to user.keytab followed by @HADOOP.COM
client_principal=developuser@HADOOP.COM
# Location of the truststore file. In Linux, you are advised to use the truststore.jks file that has been uploaded to the IoTDB client installation directory/IoTDB/iotdb/conf directory. In Windows, use \\ to specify the absolute path of the file.
iotdb_ssl_truststore=/opt/hadoopclient/IoTDB/iotdb/conf/truststore.jks
```

**Step 4** After the IntelliJ IDEA and JDK tools are installed, configure the JDK in IntelliJ IDEA.

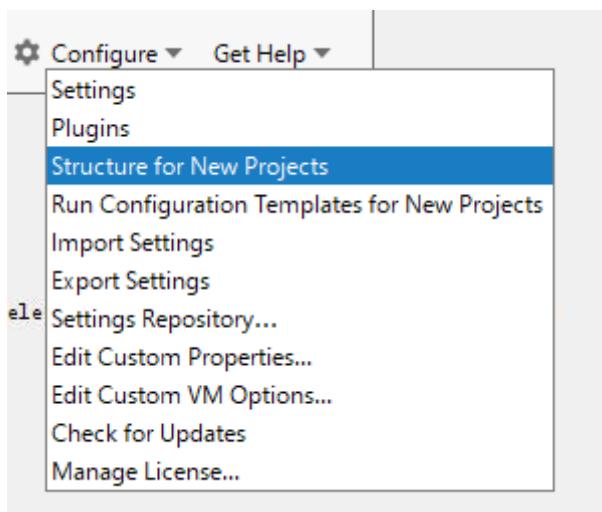

1. Start IntelliJ IDEA and choose **Configure**.

Figure 1-173 Quick Start

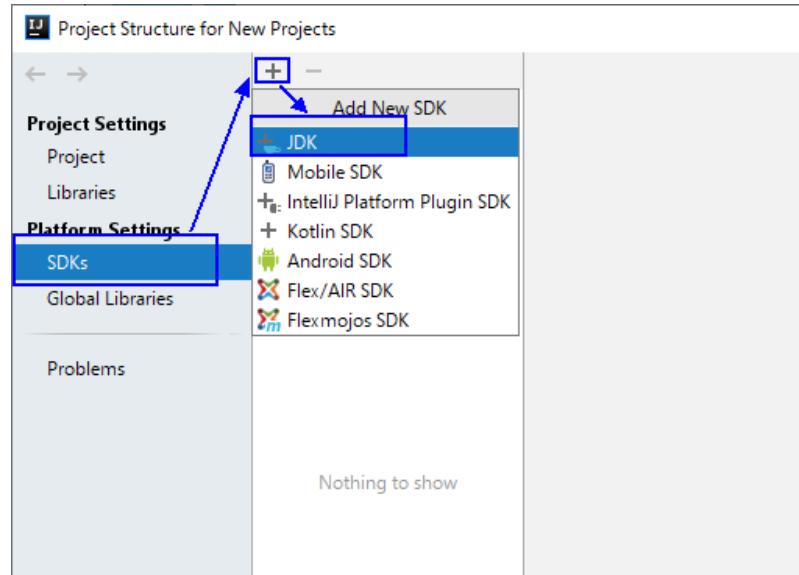

2. Select **Structure for New Projects** from the drop-down list.

Figure 1-174 Configure

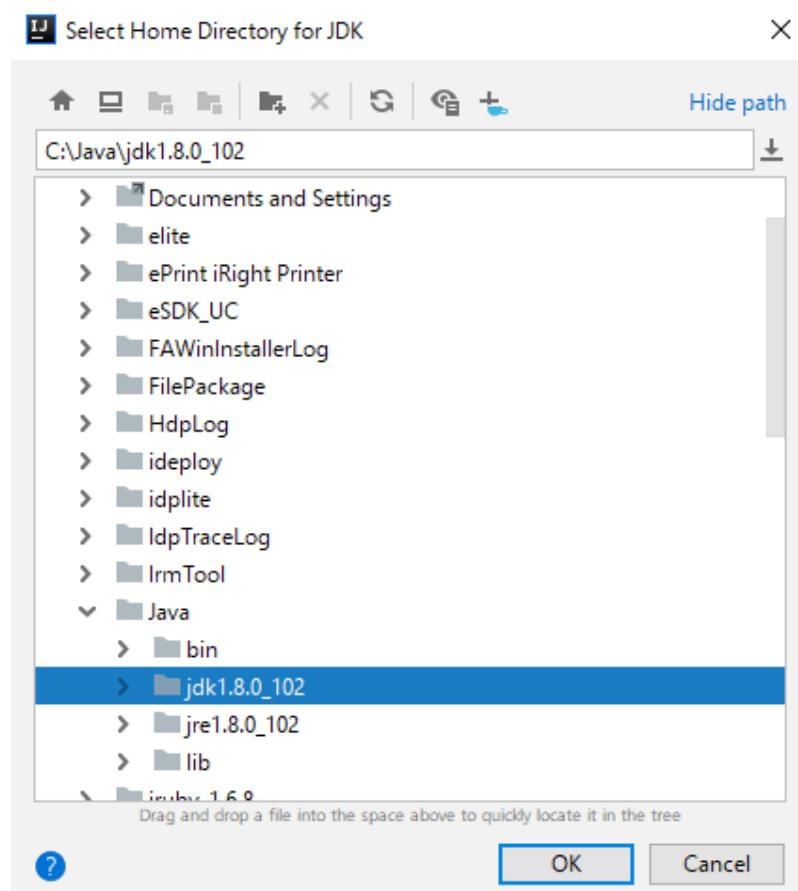

3. On the displayed **Project Structure for New Projects** page, select **SDKs**, click the plus sign (+), and click **JDK**.

Figure 1-175 Project Structure for New Projects

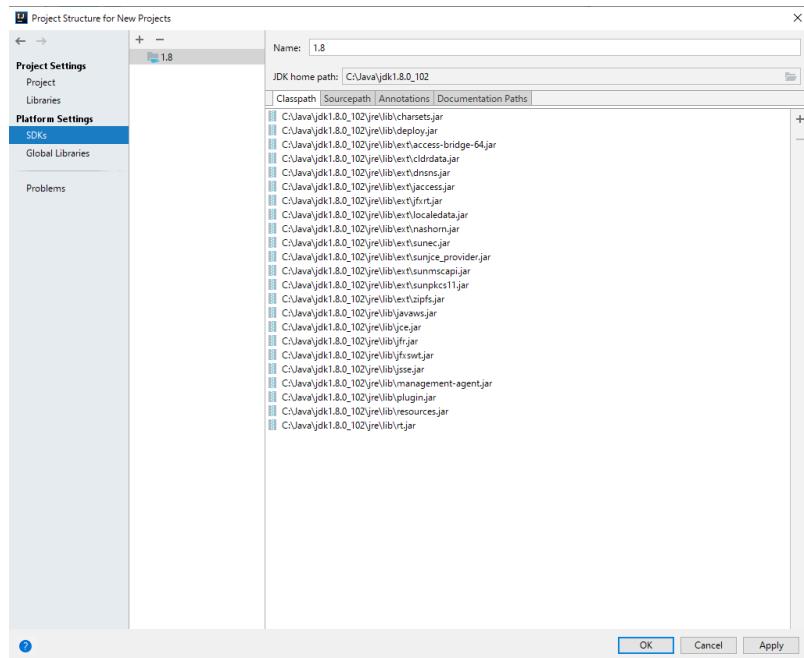

4. On the **Select Home Directory for JDK** page that is displayed, select the JDK directory and click **OK**.

Figure 1-176 Select Home Directory for JDK

5. After selecting the JDK, click **OK** to complete the configuration.

Figure 1-177 Completing the JDK configuration

**NOTE**

The operation procedure may vary according to the IDEA version.

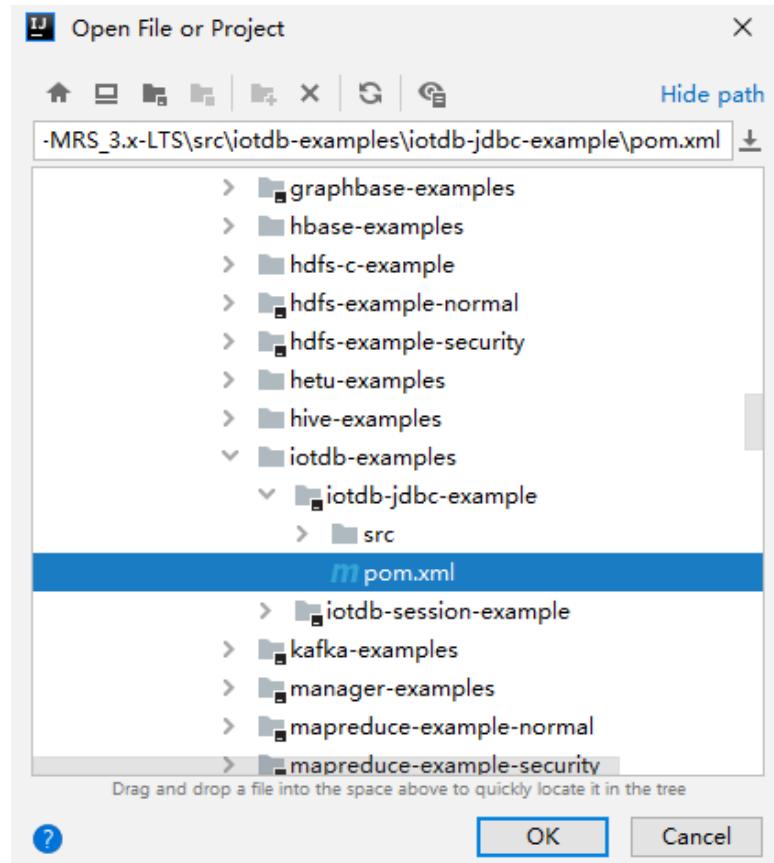

**Step 5** Import the sample project to the IntelliJ IDEA development environment.

1. Start the IntelliJ IDEA, and click **Open or Import** on the quick start page.  
For the IDEA tool that has been used, you can choose **File > Import project...** on the main interface to import the sample project.

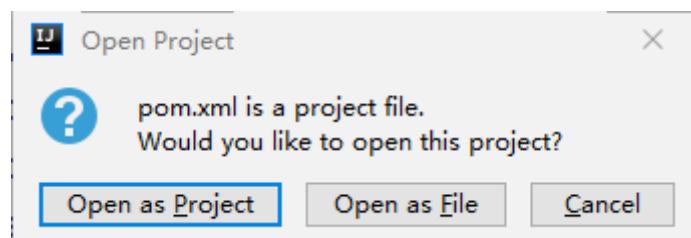

Figure 1-178 Open or Import (quick start page)

2. Select the **pom.xml** file of **iotdb-jdbc-example** in the sample project folder **iotdb-examples**, and click **OK**.

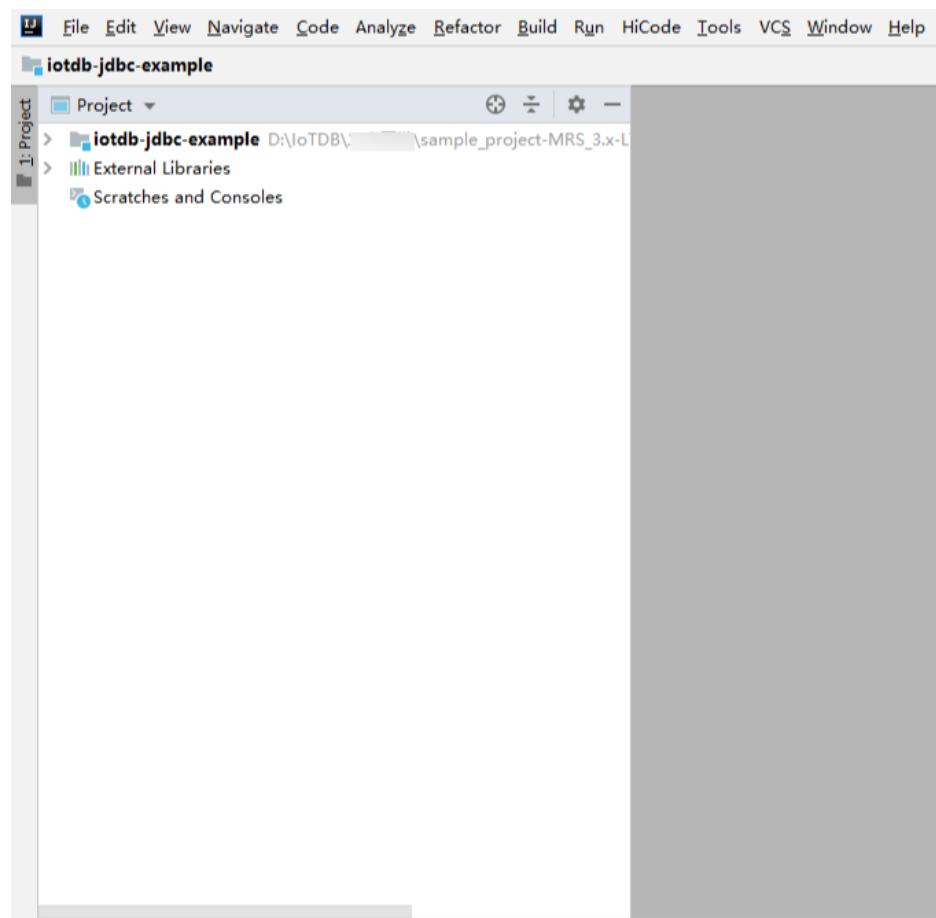

Select Open as Project.

3. After the import is complete, check that the imported sample projects are displayed on the IDEA home page.

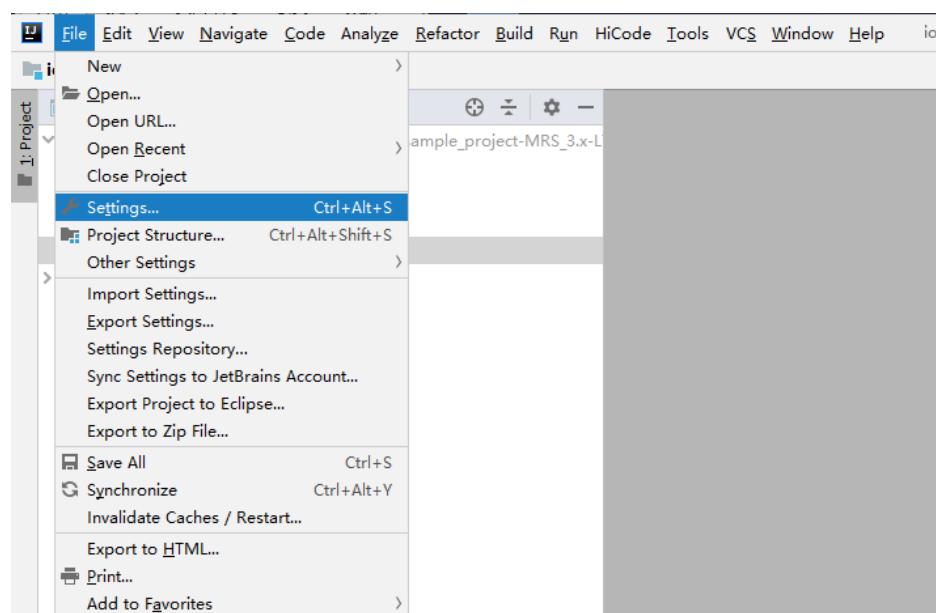

Figure 1-179 Successfully importing sample projects

**Step 6** Set the Maven version used by the project.

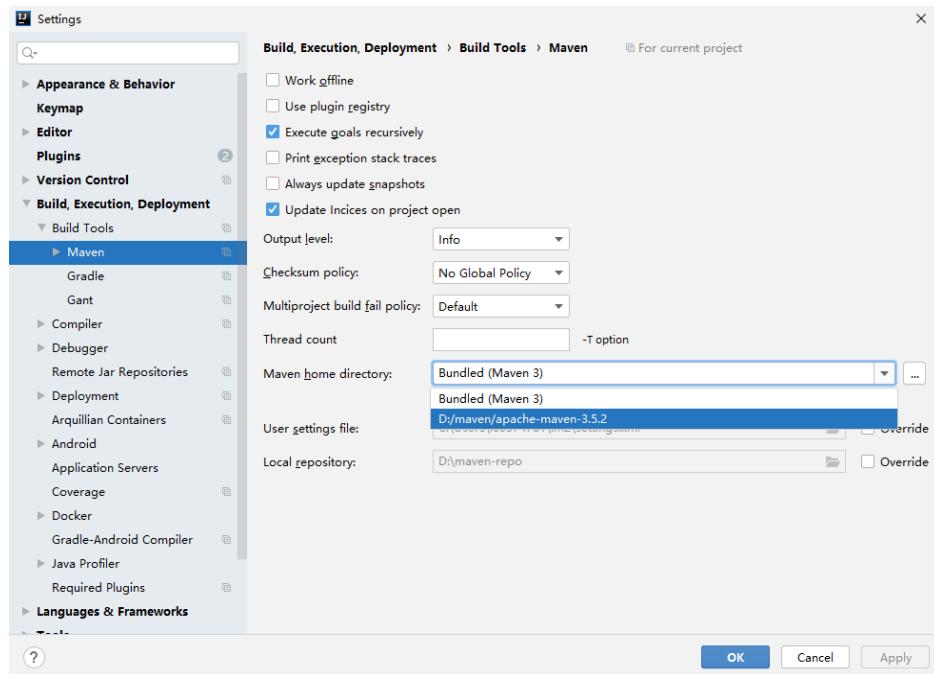

1. Choose **File > Settings...** from the main menu of IntelliJ IDEA.

Figure 1-180 Settings

2. Choose **Build, Execution, Deployment > Maven** and set **Maven home directory** to the Maven version installed on the local host.  
Configure **User settings file** and **Local repository** based on the site requirements.

**Figure 1-181** Selecting the local Maven installation directory

3. Click **Apply** and **OK** to complete the configuration.

----End

## 1.14.3 Application Development

### 1.14.3.1 IoTDB JDBC

#### 1.14.3.1.1 Java Example Code

##### Description

Run the IoTDB SQL statement in JDBC connection mode.

##### Sample Code

The following code snippet is used as an example. For complete code, see the **com.huawei.bigdata.iotdb.JDBCExample** class.

**jdbc url** includes the IP address, RPC port number, username, and password of the node where the IoTDBServer to be connected is located.

### NOTE

- On FusionInsight Manager, choose **Cluster > Services > IoTDB > Instance** to view the IP address of the node where the IoTDBServer to be connected is located.
- The default RPC port is **22260**. To obtain the port number, choose **Cluster > Services > IoTDB**, click **Configurations** then **All Configurations**, and search for **IOTDB\_SERVER\_RPC\_PORT**.
- In security mode, the username and password for logging in to the node where IoTDBServer resides are controlled by FusionInsight Manager. Ensure that the user has the permission to operate the IoTDB service. For details, see [Preparing for User Authentication](#).
- You need to set the username and password for authentication in the local environment variables. You are advised to store the username and password in ciphertext and decrypt them upon using.
  - Authentication username* is the username for accessing IoTDB.
  - Password* is the password for accessing IoTDB.

```
/**  
 * In security mode, the default value of SSL_ENABLE is true. You need to import the truststore.jks file.  
 * In security mode, you can also log in to FusionInsight Manager, choose Cluster > Services > IoTDB > Configuration, search for SSL in the search box, and change the value of SSL_ENABLE to false. After saving the configuration, restart the IoTDB service for the configuration to take effect. Modify the following configuration in the iotdb-client.env file in the Client installation directory/iotDB/iotdb/conf directory on the client: iotdb_ssl_enable="false"  
*/  
private static final String IOTDB_SSL_ENABLE = "true"; // Set it to the SSL_ENABLE value.  
public static void main(String[] args) throws ClassNotFoundException, SQLException {  
    Class.forName("org.apache.iotdb.jdbc.IoTDBDriver");  
    // set iotdb_ssl_enable  
    System.setProperty("iotdb_ssl_enable", IOTDB_SSL_ENABLE);  
    if ("true".equals(IOTDB_SSL_ENABLE)) {  
        // set truststore.jks path  
        System.setProperty("iotdb_ssl_truststore", "truststore file path");  
    }  
    try (Connection connection =  
        DriverManager.getConnection("jdbc:iotdb://IP address of the IoTDBServer instance node:Port",  
        "authentication username", "authentication user password")) {  
        Statement statement = connection.createStatement()  
  
        // set JDBC fetchSize  
        statement.setFetchSize(10000);  
        for (int i = 0; i <= 100; i++) {  
            statement.addBatch(prepareInsertStatement(i));  
        }  
        statement.executeBatch();  
        statement.clearBatch();  
  
        ResultSet resultSet = statement.executeQuery("select ** from root where time <= 10");  
        outputResult(resultSet);  
        resultSet = statement.executeQuery("select count(**) from root");  
        outputResult(resultSet);  
        resultSet =  
            statement.executeQuery(  
                "select count(**) from root where time >= 1 and time <= 100 group by ([0, 100), 20ms, 20ms]");  
        outputResult(resultSet);  
    } catch (IoTDBSQLException e) {  
        System.out.println(e.getMessage());  
    }  
}
```

#### 1.14.3.1.2 Using the keytab File for JDBC Authentication

##### Description

Use the keytab file for JDBC authentication.

## Preparations

Log in to FusionInsight Manager, choose **System > Permission > User**, and download the user credential prepared in [Preparing for User Authentication](#).

## Sample Code

The following code snippet is used as an example. For complete code, see the **com.huawei.bigdata.iotdb.JDBCbyKerberosExample** class.

### NOTE

- On FusionInsight Manager, choose **Cluster > Services > IoTDB > Instance** to view the IP address of the node where the IoTDBServer to be connected is located.
- The default RPC port is **22260**. To obtain the port number, choose **Cluster > Services > IoTDB**, click **Configurations** then **All Configurations**, and search for **IOTDB\_SERVER\_RPC\_PORT**.
- In security mode, the username and password for logging in to the node where IoTDBServer resides are controlled by FusionInsight Manager. Ensure that the user has the permission to operate the IoTDB service. For details, see [Preparing for User Authentication](#).
- Log in to FusionInsight Manager and choose **System > Permission > Domain and Mutual Trust**. On the page that is displayed, the value of **Local Domain** is the domain name.

```
package com.huawei.bigdata.iotdb;

import com.huawei.iotdb.client.security.IoTDBClientKerberosFactory;
import org.apache.iotdb.jdbc.IoTDBSQLException;
import org.ietf.jgss.GSException;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.sql.Statement;
import java.util.Base64;
import javax.security.auth.login.LoginException;

public class JDBCbyKerberosExample {

    /**
     * In security mode, the default value of SSL_ENABLE is true. You need to import the truststore.jks file.
     * In security mode, you can also log in to FusionInsight Manager, choose Cluster > Services > IoTDB > Configuration, search for SSL in the search box, and change the value of SSL_ENABLE to false. After saving the configuration, restart the IoTDB service for the configuration to take effect. Modify the following configuration in the iotdb-client.env file in the Client installation directory/iotdb/conf directory on the client: iotdb_ssl_enable="false"
     */

 */
private static final String SERVER_PRINCIPAL = "iotdb/hadoop.hadoop.com@HADOOP.COM";// You can
obtain this parameter value by searching for iotdb_server_kerberos_principal in ${BIGDATA_HOME}/
FusionInsight_IoTDB_/*_*_IoTDBServer/etc/iotdb-datanode.properties on any node with the IoTDB service
installed.

/**
 * Get kerberos token as password
 * @return kerberos token
 * @throws IOException loginException
 * @throws GSSEException GSSEException
 */
public static String getAuthToken() throws IOException, GSSEException {
    IoTDBClientKerberosFactory kerberosHandler = IoTDBClientKerberosFactory.getInstance();
    System.setProperty(JAVA_KRB5_CONF, KRB5_CONF_DEST);
    kerberosHandler.loginSubjectFromKeytab(PRINCIPAL, KEY_TAB_DEST);
    byte[] tokens = kerberosHandler.generateServiceToken(PRINCIPAL);
    return Base64.getEncoder().encodeToString(tokens);
}

public static void main(String[] args) throws SQLException {
    // set iotdb_ssl_enable
    System.setProperty("iotdb_ssl_enable", IOTDB_SSL_ENABLE);
    if ("true".equals(IOTDB_SSL_ENABLE)) {
        // set truststore.jks path
        System.setProperty("iotdb_ssl_truststore", "truststore file path");
    }

    try (Connection connection =
        DriverManager.getConnection("jdbc:iotdb://IP address of the IoTDBServer instance
node:port number/", "Authentication username", getAuthToken());
        Statement statement = connection.createStatement()) {
        // set JDBC fetchSize
        statement.setFetchSize(10000);

        try {
            statement.execute("SET STORAGE GROUP TO root.sg1");
            statement.execute(
                "CREATE TIMESERIES root.sg1.d1.s1 WITH DATATYPE=INT64, ENCODING=RLE,
COMPRESSOR=SNAPPY");
            statement.execute(
                "CREATE TIMESERIES root.sg1.d1.s2 WITH DATATYPE=INT64, ENCODING=RLE,
COMPRESSOR=SNAPPY");
            statement.execute(
                "CREATE TIMESERIES root.sg1.d1.s3 WITH DATATYPE=INT64, ENCODING=RLE,
COMPRESSOR=SNAPPY");
        } catch (IoTDBSQLException e) {
            System.out.println(e.getMessage());
        }
    } catch (GSSEException | IOException e) {
        System.out.println(e.getMessage());
    }
}
}
```

### 1.14.3.2 IoTDB Session

#### 1.14.3.2.1 Java Example Code

##### Description

Run the IoTDB SQL statement in Session connection mode.

## Sample Code

The following code snippet is used as an example. For complete code, see [com.huawei.bigdata.SessionExample](#).

Change **HOST\_1**, **HOST\_2**, and **HOST\_3** to the service IP addresses of the nodes accommodating IoTDBServer. Set the username and password in the **Session** object.

### NOTE

- On Manager, choose **Cluster > Services > IoTDB > Instance** to view the IP addresses of the nodes where the IoTDBServer to be connected is located.
- The default RPC port is **22260**. To obtain the port number, choose **Cluster > Services > IoTDB**, click **Configurations** then **All Configurations**, and search for **IOTDB\_SERVER\_RPC\_PORT**.
- In security mode, the username and password for logging in to the node where IoTDBServer resides are controlled by FusionInsight Manager. Ensure that the user has the permission to operate the IoTDB service. For details, see [Preparing for User Authentication](#).
- You need to set the username and password for authentication in the local environment variables. You are advised to store the username and password in ciphertext and decrypt them upon using.
  - *Authentication.username* is the username for accessing IoTDB.
  - *Password* is the password for accessing IoTDB.

```
/**  
 * In security mode, the default value of SSL_ENABLE is true. You need to import the truststore.jks file.  
 * In security mode, you can also log in to FusionInsight Manager, choose Cluster > Services > IoTDB > Configuration, search for SSL in the search box, and change the value of SSL_ENABLE to false. After saving the configuration, restart the IoTDB service for the configuration to take effect. Modify the following configuration in the iotdb-client.env file in the Client installation directory/IoTDB/iotdb/conf directory on the client: iotdb_ssl_enable="false"  
 */  
private static final String IOTDB_SSL_ENABLE = "true"; // Set it to the SSL_ENABLE value.  
public static void main(String[] args)  
    throws IoTDBConnectionException, StatementExecutionException {  
    // set iotdb_ssl_enable  
    System.setProperty("iotdb_ssl_enable", IOTDB_SSL_ENABLE);  
    if ("true".equals(IOTDB_SSL_ENABLE)) {  
        // set truststore.jks path  
        System.setProperty("iotdb_ssl_truststore", "truststore file path");  
    }  
  
    session = new Session(nodeUrls, Port, Authentication.username, Authentication.user.password);  
    session.open(false);  
  
    // set session fetchSize  
    session.setFetchSize(10000);  
  
    try {  
        session.setStorageGroup("root.sg1");  
    } catch (StatementExecutionException e) {  
        if (e.getStatusCode() != TSStatusCode.PATH_ALREADY_EXIST_ERROR.getStatusCode()) {  
            throw e;  
        }  
    }  
  
    createTimeseries();  
    createMultiTimeseries();  
    insertRecord();  
    insertTablet();  
    insertTablets();  
    insertRecords();  
}
```

```
nonQuery();
query();
queryWithTimeout();
rawDataQuery();
queryByIterator();
deleteData();
deleteTimeseries();
setTimeout();

sessionEnableRedirect = new Session(nodeUrls, Authentication.username, Authentication.user.password);
sessionEnableRedirect.setEnableQueryRedirection(true);
sessionEnableRedirect.open(false);

// set session fetchSize
sessionEnableRedirect.setFetchSize(10000);

insertRecord4Redirect();
query4Redirect();
sessionEnableRedirect.close();
session.close();
}
```

### 1.14.3.2.2 Using the Keytab File for Session Authentication

#### Description

Use the Keytab file for session authentication.

#### Preparations

Log in to FusionInsight Manager, choose **System > Permission > User**, and download the user credential prepared in [Preparing for User Authentication](#).

#### Sample Code

The following code snippet is used as an example. For complete code, see the **com.huawei.bigdata.iotdb.SessionbyKerberosExample** class.

##### NOTE

- On FusionInsight Manager, choose **Cluster > Services > IoTDB > Instance** to view the IP address of the node where the IoTDBServer to be connected is located.
- The default RPC port is **22260**. To obtain the port number, choose **Cluster > Services > IoTDB**, click **Configurations** then **All Configurations**, and search for **IOTDB\_SERVER\_RPC\_PORT**.
- In security mode, the username and password for logging in to the node where IoTDBServer resides are controlled by FusionInsight Manager. Ensure that the user has the permission to operate the IoTDB service. For details, see [Preparing for User Authentication](#).
- Log in to FusionInsight Manager and choose **System > Permission > Domain and Mutual Trust**. On the page that is displayed, the value of **Local Domain** is the domain name.

```

}  
}
```

### 1.14.3.3 IoTDB Flink

#### 1.14.3.3.1 FlinkIoTDBSink

##### Description

It is an integration of IoTDB and Flink. This module contains IoTDBSink and writes time series data into IoTDB using a Flink job.

##### Sample Code

This example shows how to send data from a Flink job to an IoTDB server.

- A simulated source SensorSource generates a data point every second.
- Flink uses IoTDBSink to consume produced data and write the data into IoTDB.

Session object parameters include the IP address, port number, username, and password of the node where the IoTDBServer is located.

## NOTE

- On FusionInsight Manager, choose **Cluster > Services > IoTDB > Instance** to view the IP address of the node where the IoTDBServer to be connected is located.
- The default RPC port is **22260**. To obtain the port number, choose **Cluster > Services > IoTDB**, click **Configurations** then **All Configurations**, and search for **IOTDB\_SERVER\_RPC\_PORT**.
- In security mode, the username and password for logging in to the node where IoTDBServer resides are controlled by FusionInsight Manager. Ensure that the user has the permissions to operate the IoTDB and Flink services. For details, see [Preparing for User Authentication](#).
- You need to set the username and password for authentication in the local environment variables. You are advised to store the username and password in ciphertext and decrypt them upon using.
  - *Authentication username* is the username for accessing IoTDB.
  - *Password* is the password for accessing IoTDB.

```
public class FlinkIoTDBSink {  
    public static void main(String[] args) throws Exception {  
        // run the flink job on local mini cluster  
        StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();  
  
        IoTDBSinkOptions options = new IoTDBSinkOptions();  
        options.setHost("127.0.0.1");  
        options.setPort(22260);  
        options.setUser ("Authentication username");  
        options.setPassword ("Password");  
  
        // If the server enables auto_create_schema, then we do not need to register all timeseries  
        // here.  
        options.setTimeseriesOptionList(  
            Lists.newArrayList(  
                new IoTDBSinkOptions.TimeseriesOption(  
                    "root.sg.d1.s1", TSDDataType.DOUBLE, TSEncoding.GORILLA, CompressionType.SNAPPY)));  
  
        IoTSerializationSchema serializationSchema = new DefaultIoTSerializationSchema();  
        IoTDBSink ioTDBSink =  
            new IoTDBSink(options, serializationSchema)  
                // enable batching  
                .withBatchSize(10)  
                // how many connections to the server will be created for each parallelism  
                .withSessionPoolSize(3);  
  
        env.addSource(new SensorSource())  
            .name("sensor-source")  
            .setParallelism(1)  
            .addSink(ioTDBSink)  
            .name("iotdb-sink");  
  
        env.execute("iotdb-flink-example");  
    }  
  
    private static class SensorSource implements SourceFunction<Map<String, String>> {  
        boolean running = true;  
        Random random = new SecureRandom();  
  
        @Override  
        public void run(SourceContext context) throws Exception {  
            while (running) {  
                Map<String, String> tuple = new HashMap();  
                tuple.put("device", "root.sg.d1");  
                tuple.put("timestamp", String.valueOf(System.currentTimeMillis()));  
                tuple.put("measurements", "s1");  
                tuple.put("types", "DOUBLE");  
                tuple.put("values", String.valueOf(random.nextDouble()));  
            }  
        }  
    }  
}
```

```
        context.collect(tuple);
        Thread.sleep(1000);
    }
}

@Override
public void cancel() {
    running = false;
}
}
```

### 1.14.3.3.2 FlinkIoTDBSource

#### Description

It is an integration of IoTDB and Flink. This module contains IoTDBSource and reads time series data from IoTDB and prints the data using a Flink job.

#### Sample Code

This example shows how a Flink job reads time series data from a IoTDB server.

- Flink uses IoTDBSource to read data from a IoTDB server.
- To use IoTDBSource, you need to construct an IoTDBSource instance by specifying **IoTDBSourceOptions** and implementing the abstract method **convert()** in IoTDBSource. The **convert()** method defines how you want to convert row data.

Session object parameters include the IP address, port number, username, and password of the node where the IoTDBServer is located.

#### NOTE

- On FusionInsight Manager, choose **Cluster > Services > IoTDB > Instance** to view the IP address of the node where the IoTDBServer to be connected is located.
- The default RPC port is **22260**. To obtain the port number, choose **Cluster > Services > IoTDB**, click **Configurations** then **All Configurations**, and search for **IOTDB\_SERVER\_RPC\_PORT**.
- In security mode, the username and password for logging in to the node where IoTDBServer resides are controlled by FusionInsight Manager. Ensure that the user has the permissions to operate the IoTDB and Flink services. For details, see [Preparing for User Authentication](#).
- If SSL is enabled for a cluster in security mode, copy the **truststore.jks** file to all nodes where NodeManager instances of Yarn reside in the current cluster. The copy path must be the same as **truststore file path** in the following code, for example, **/opt/truststore.jks**.
- You need to set the username and password for authentication in the local environment variables. You are advised to store the username and password in ciphertext and decrypt them upon using.
  - *Authentication username* is the username for accessing IoTDB.
  - *Password* is the password for accessing IoTDB.

```
public class FlinkIoTDBSource {
    /**
     * In security mode, the default value of SSL_ENABLE is true. You need to import the truststore.jks file.
     * In security mode, you can also log in to FusionInsight Manager, choose Cluster > Services > IoTDB > Configuration, search for SSL in the search box, and change the value of SSL_ENABLE to false. After saving the configuration, restart the IoTDB service for the configuration to take effect. Modify the following
```

```
configuration in the iotdb-client.env file in the Client installation directory/loTDB/iotdb/conf directory  
on the client: iotdb_ssl_enable="false"  
*/  
private static final String IOTDB_SSL_ENABLE = "true"; // Set it to the SSL_ENABLE value.  
static final String LOCAL_HOST = "127.0.0.1";  
static final String ROOT_SG1_D1_S1 = "root.sg1.d1.s1";  
static final String ROOT_SG1_D1 = "root.sg1.d1";  
  
public static void main(String[] args) throws Exception {  
    // use session api to create data in loTDB  
    prepareData();  
  
    // run the flink job on local mini cluster  
    StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();  
  
    IoTDBSourceOptions ioTDBSourceOptions =  
        new IoTDBSourceOptions()  
            .setHost(LOCAL_HOST, 22260, "Authentication username", "Password", "select s1 from "+ ROOT_SG1_D1 +"  
align by device");  
  
    IoTDBSource<RowRecord> source =  
        new IoTDBSource<RowRecord>(ioTDBSourceOptions) {  
            @Override  
            public RowRecord convert(RowRecord rowRecord) {  
                return rowRecord;  
            }  
        };  
    env.addSource(source).name("sensor-source").print().setParallelism(2);  
    env.execute();  
}  
  
private static void prepareData()  
    throws IoTDBConnectionException, StatementExecutionException, TTransportException {  
    // set iotdb_ssl_enable  
    System.setProperty("iotdb_ssl_enable", IOTDB_SSL_ENABLE);  
    if ("true".equals(IOTDB_SSL_ENABLE)) {  
        // set truststore.jks path  
        System.setProperty("iotdb_ssl_truststore", "truststore file path");  
    }  
    Session session = new Session(LOCAL_HOST, 22260, "Authentication username", "Password");  
    session.open(false);  
    try {  
        session.setStorageGroup("root.sg1");  
        if (!session.checkTimeseriesExists(ROOT_SG1_D1_S1)) {  
            session.createTimeseries(  
                ROOT_SG1_D1_S1, TSDataType.INT64, TSEncoding.RLE, CompressionType.SNAPPY);  
            List<String> measurements = new ArrayList<>();  
            measurements.add("s1");  
            measurements.add("s2");  
            measurements.add("s3");  
            List<TSDataType> types = new ArrayList<>();  
            types.add(TSDataType.INT64);  
            types.add(TSDataType.INT64);  
            types.add(TSDataType.INT64);  
  
            for (long time = 0; time < 1000; time++) {  
                List<Object> values = new ArrayList<>();  
                values.add(1L);  
                values.add(2L);  
                values.add(3L);  
                session.insertRecord(ROOT_SG1_D1, time, measurements, types, values);  
            }  
        }  
    } catch (StatementExecutionException e) {  
        if (e.getStatusCode() != TSStatusCode.PATH_ALREADY_EXIST_ERROR.getStatusCode()) {  
            throw e;  
        }  
    }  
}
```

```
}
```

### 1.14.3.4 IoTDB Kafka

#### 1.14.3.4.1 Java Example Code

##### Description

This section describes how to use Kafka to send data to IoTDB.

##### Sample Code

- Producer.java:

This example shows how to send time series data to a Kafka cluster.

- Change the value of the **public final static String TOPIC** variable in the **KafkaProperties.java** file based on the site requirements, for example, **kafka-topic**.
- The default time series data format of this sample is *Device name, Timestamp, Value*, for example, **sensor\_1,1642215835758,1.0**. You can change the value of **IOTDB\_DATA\_SAMPLE\_TEMPLATE** in the **Constant.java** file based on the site requirements.

```
public static void main(String[] args) {  
    // whether use security mode  
    final boolean isSecurityModel = true;  
  
    if (isSecurityModel) {  
        try {  
            LOG.info("Security mode start.");  
  
            // Note: During security authentication, you need to manually change the account to a  
            // machine-machine one that you have applied for.  
            LoginUtil.securityPrepare(Constant.USER_PRINCIPAL, Constant.USER_KEYTAB_FILE);  
        } catch (IOException e) {  
            LOG.error("Security prepare failure.", e);  
            return;  
        }  
        LOG.info("Security prepare success.");  
    }  
  
    // whether to use the asynchronous sending mode  
    final boolean asyncEnable = false;  
    Producer producerThread = new Producer(KafkaProperties.TOPIC, asyncEnable);  
}
```

##### NOTE

For details about the Kafka producer code, see [Producer API Usage Sample](#).

- KafkaConsumerMultThread.java:

This example shows how to write data from a Kafka cluster to IoTDB using multiple threads. Kafka cluster data is generated by **Producer.java**.

- Change the value of the **public final static String TOPIC** variable in the **KafkaProperties.java** file based on the site requirements, for example, **kafka-topic**.

- b. Change the value of **CONCURRENCY\_THREAD\_NUM** in the **KafkaConsumerMultThread.java** file to adjust the number of consumer threads.

#### NOTICE

- If multiple threads are used to consume Kafka cluster data, ensure that the number of consumed topic partitions is greater than 1.
- The Kafka client configuration files **client.properties** and **log4j.properties** must be stored in the configuration file directory of the program.

- c. Set the IP address, port number, username, and password of the node where the IoTDBServer is located in the IoTDBSessionPool object parameters.

#### NOTE

- On FusionInsight Manager, choose **Cluster > Services > IoTDB** and click the **Instance** tab to view the IP address of the node where the IoTDBServer to be connected is located.
- The default RPC port number is **22260**. To obtain the port number, choose **Cluster > Services > IoTDB**, choose **Configurations > All Configurations**, and search for **rpc\_port**.
- In security mode, the username and password for logging in to the node where IoTDBServer resides are controlled by FusionInsight Manager. Ensure that the user has the permission to operate the IoTDB service. For details, see [Preparing for User Authentication](#).
- You need to set the username and password for authentication in the local environment variables. You are advised to store the username and password in ciphertext and decrypt them upon using.
  - *Authentication username* is the username for accessing IoTDB.
  - *Password* is the password for accessing IoTDB.

```
/*
 * In security mode, the default value of SSL_ENABLE is true. You need to import the truststore.jks file.
 * In security mode, you can also log in to FusionInsight Manager, choose Cluster > Services > IoTDB > Configuration, search for SSL in the search box, and change the value of SSL_ENABLE to false. After saving the configuration, restart the IoTDB service for the configuration to take effect. Modify the following configuration in the iotdb-client.env file in the Client installation directory/IoTDB/iotdb/conf directory on the client: iotdb_ssl_enable="false"
 */
private static final String IOTDB_SSL_ENABLE = "true"; // Set it to the SSL_ENABLE value.
public static void main(String[] args) {
    // whether use security mode
    final boolean isSecurityModel = true;

    if (isSecurityModel) {
        try {
            LOG.info("Securitymode start.");

            // Note: During security authentication, you need to manually change the account to a machine-machine one.
            LoginUtil.securityPrepare(Constant.USER_PRINCIPAL, Constant.USER_KEYTAB_FILE);
        } catch (IOException e) {
            LOG.error("Security prepare failure.", e);
            return;
        }
        LOG.info("Security prepare success.");
    }
}
```

```
        }
        // set iotdb_ssl_enable
        System.setProperty("iotdb_ssl_enable", IOTDB_SSL_ENABLE);
        if ("true".equals(IOTDB_SSL_ENABLE)) {
            // set truststore.jks path
            System.setProperty("iotdb_ssl_truststore", "truststore file path");
        }

        // create IoTDB session connection pool
        IoTDBSessionPool sessionPool = new IoTDBSessionPool("127.0.0.1", 22260, "Authentication
username", "Password", 3);

        // start consumer thread
        KafkaConsumerMultThread consumerThread = new
        KafkaConsumerMultThread(KafkaProperties.TOPIC, sessionPool);
        consumerThread.start();
    }

    /**
     * consumer thread
     */
    private class ConsumerThread extends ShutdownableThread {
        private int threadNum;
        private String topic;
        private KafkaConsumer<String, String> consumer;
        private IoTDBSessionPool sessionPool;

        public ConsumerThread(int threadNum, String topic, Properties props, IoTDBSessionPool
sessionPool) {
            super("ConsumerThread" + threadNum, true);
            this.threadNum = threadNum;
            this.topic = topic;
            this.sessionPool = sessionPool;
            this.consumer = new KafkaConsumer<>(props);
            consumer.subscribe(Collections.singleton(this.topic));
        }

        public void doWork() {
            ConsumerRecords<String, String> records = consumer.poll(Duration.ofMillis(waitTime));
            for (ConsumerRecord<String, String> record : records) {
                LOG.info("Consumer Thread-" + this.threadNum + " partitions:" + record.partition() + "
record: "
+ record.value() + " offsets: " + record.offset());

                // insert kafka consumer data to iotdb
                sessionPool.insertRecord(record.value());
            }
        }
    }
}
```

#### NOTE

For details about the Kafka consumer code, see [Multi-thread Producer Sample](#).

### 1.14.3.5 IoTDB UDF Program

#### 1.14.3.5.1 IoTDB UDF Sample Code

#### Description

This section describes how to implement a simple IoTDB user-defined function (UDF). For details, see "UDFs" in the *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

## Sample Code

```
package com.huawei.bigdata.iotdb;
import org.apache.iotdb.udf.api.UDTF;
import org.apache.iotdb.udf.api.access.Row;
import org.apache.iotdb.udf.api.collector.PointCollector;
import org.apache.iotdb.udf.api.customizer.config.UDTFConfigurations;
import org.apache.iotdb.udf.api.customizer.parameter.UDFParameters;
import org.apache.iotdb.udf.api.customizer.strategy.RowByRowAccessStrategy;
import org.apache.iotdb.udf.api.type.Type;
import java.io.IOException;

public class UDTFExample implements UDTF {
    @Override
    public void beforeStart(UDFParameters parameters, UDTFConfigurations configurations) {
        configurations.setAccessStrategy(new RowByRowAccessStrategy()).setOutputDataType(Type.INT32);
    }

    @Override
    public void transform(Row row, PointCollector collector) throws IOException {
        collector.putInt(row.getTime(), -row.getInt(0));
    }
}
```

## 1.14.4 Application Commissioning

### 1.14.4.1 Commissioning Applications on Windows

#### 1.14.4.1.1 Compiling and Running Applications

##### Scenario

Run applications in a Windows development environment after application code is developed. If the local and cluster service planes can communicate with each other, you can perform the commissioning on the local host.

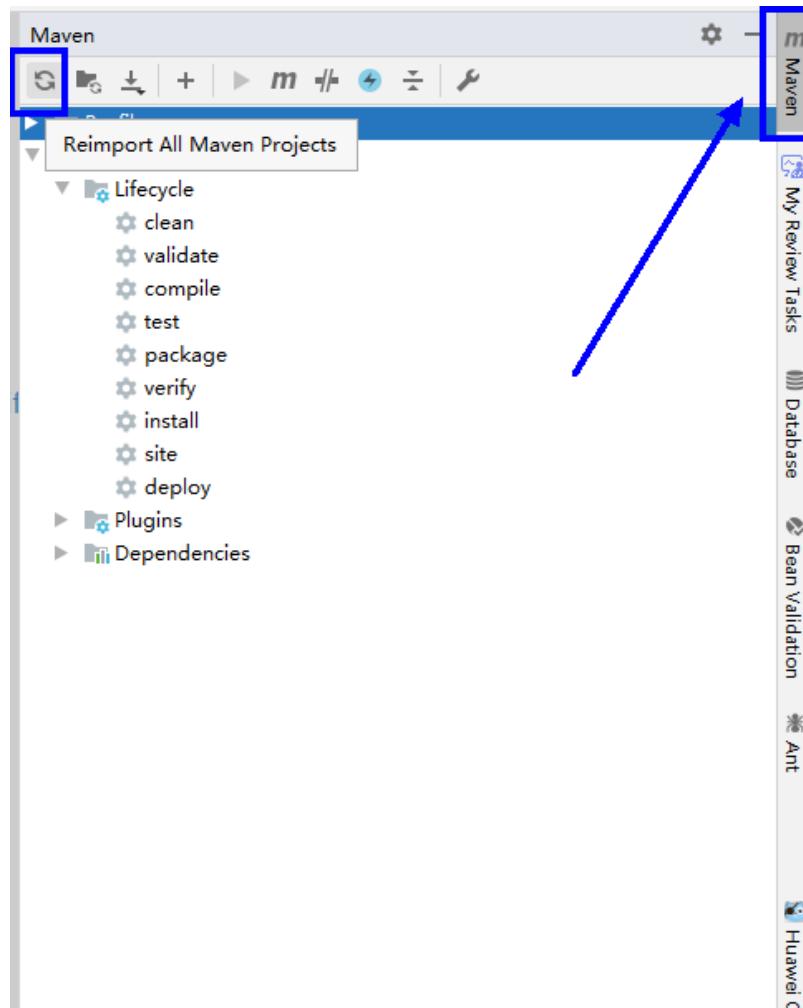

##### NOTE

- If the IBM JDK is used in the Windows environment, applications cannot be directly run in the Windows environment.
- You need to set the mapping between the host names and IP addresses of the access nodes in the **hosts** file on the local host where the sample code is run. The host names and IP addresses must be mapped one by one.

##### Procedure

**Step 1** Click **Reimport All Maven Projects** in the Maven window on the right of the IDEA to import the Maven project dependency.

Figure 1-182 reimport projects

**Step 2** Compile and run the application.

Modify the IP address, port number, login username, and password of the IoTDBServer node that matches the code.

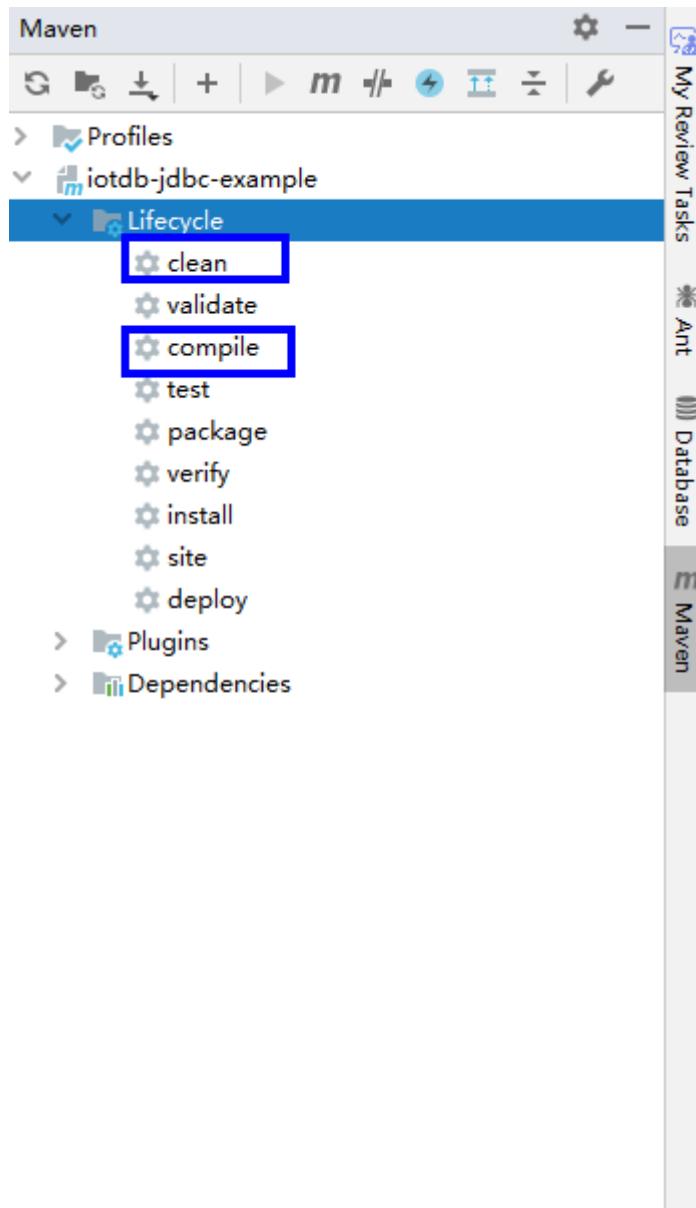

1. Use either of the following two methods:

- Method 1

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean** and double-click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **compile** and double-click **compile** to run the **compile** command of Maven.

Figure 1-183 Maven tools clean and compile

- Method 2

Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean compile** command to compile the **pom.xml** file.

Figure 1-184 Enter **mvn clean compile** in the IDEA **Terminal** text box.

```
Terminal: Local +  
Microsoft Windows [Version 10.0.18362.592]  
(c) 2019 Microsoft Corporation. All rights reserved.  
D:\IoTDB\develop\sample_project-MRS_3.x-LTS\src\iotdb-examples\iotdb-jdbc-example>mvn clean compile
```

After the compilation is complete, the message "BUILD SUCCESS" is displayed.

**Figure 1-185** Compilation completed

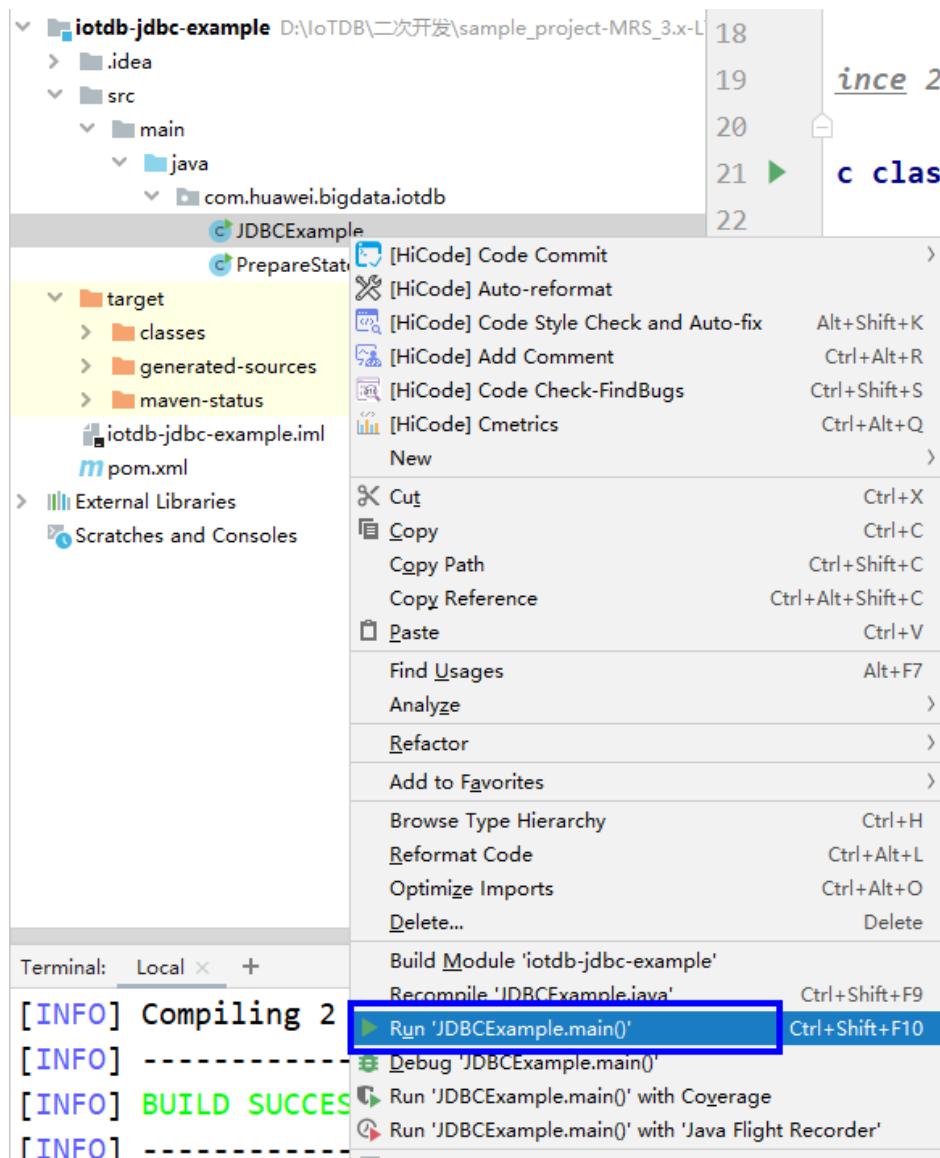

```
Terminal: Local +  
[INFO] Compiling 2 source files to D:\IoTDB\develop\sample_project-MRS_3.x-LTS\src\io  
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 1.156 s  
[INFO] Finished at: 2021-06-16T14:29:36+08:00  
[INFO] -----  
D:\IoTDB\develop\sample_project-MRS_3.x-LTS\src\iotdb-examples\iotdb-jdbc-example>[]
```

The screenshot shows a terminal window titled "Local". The output of the compilation process is displayed, including the message "BUILD SUCCESS". The terminal window has a tab bar with several icons and labels: Cmetrics, CodeCheck-FindBugs, CodeReview, CodeStyleCheckAndFix, Terminal, Build, Messages, Run, and TODO. The "Terminal" tab is currently selected.

2. Run the application. A JDBC application is used as an example. The operations for running other applications are the same.

Right-click the **JDBCExample.java** file and choose **Run 'JDBCExample.main()'** from the shortcut menu.

Figure 1-186 Running the application

----End

#### 1.14.4.1.2 Viewing Commissioning Results

After the IoTDB application is run, you can view the running results in IntelliJ IDEA.

- The running result of the JDBCExample example application is as follows:

```

## 1.14.4.2 Commissioning JDBC and Session Applications on Linux

### 1.14.4.2.1 Compiling and Running Applications

#### Scenario

IoTDB applications can run in a Linux environment where an IoTDB client is installed. After the application code is developed, you can upload the JAR file to the prepared Linux environment. A Session application is used as an example. Operations for JDBC applications are the same as those for Session applications.

#### Prerequisites

- You have installed the IoTDB client.
- If the host where the client is installed is not a node in the cluster, the mapping between the host name and the IP address must be set in the **hosts** file on the node where the client is located. The host names and IP addresses must be mapped one by one.

#### Procedure

##### Step 1 Export a JAR file.

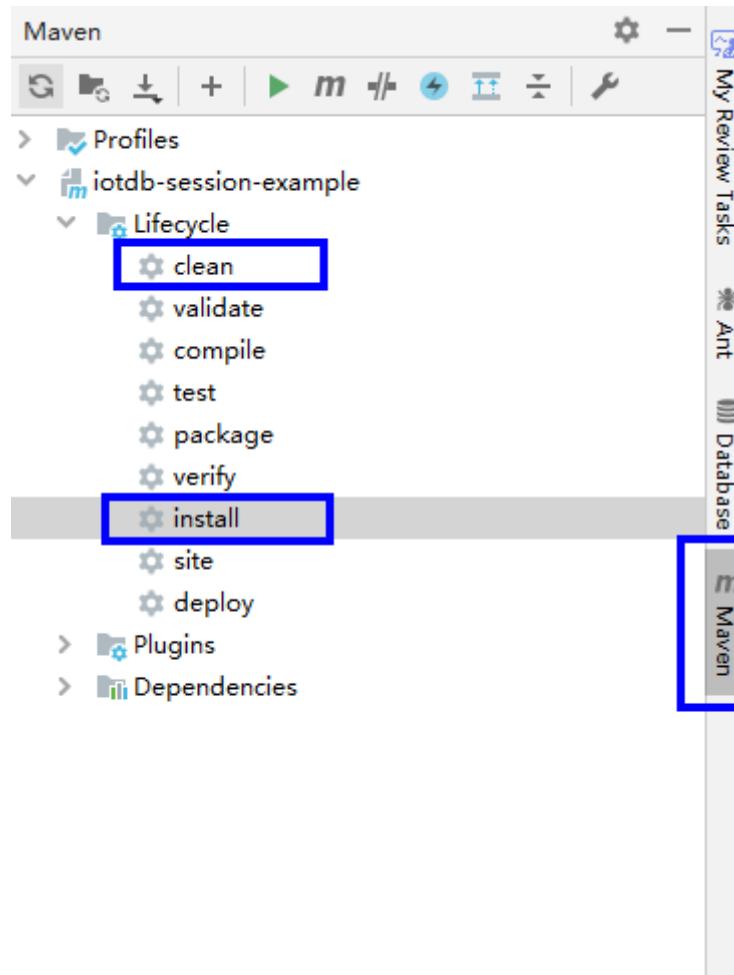

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean** and double-click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **install** and double-click **install** to run the **install** command of Maven.

**Figure 1-187** Maven tools clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean install** command to compile the file.

**Figure 1-188** Entering mvn clean install in the IDEA Terminal text box

```
Terminal: Local +  
1006\iotdb-session-example-0.12.0-hw-ei-311006.pom  
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 1.401 s  
[INFO] Finished at: 2021-07-31T11:22:12+08:00  
[INFO] -----  
D:\IoTDB\1006\sample_project\src\iotdb-examples\iotdb-session-example>mvn clean install
```

After the compilation is completed, the message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

**Step 2** Prepare the dependent JAR file.

1. Log in to the IoTDB client and import the JAR file generated in [Step 1](#) to the **lib** directory of the IoTDB client, for example, **/opt/hadoopclient/IoTDB/iotdb/lib**.
2. Upload the user authentication files **user.keytab** and **krb5.conf** obtained in [Preparing for User Authentication](#) to *Client installation directory/IoTDB/iotdb/conf*.
3. In the root directory of the IoTDB client, for example, **/opt/hadoopclient/IoTDB/iotdb**, create the **run.sh** script, modify the content as follows, and save the modification.

```
#!/bin/sh
BASEDIR=`cd $(dirname $0);pwd`
cd ${BASEDIR}
for file in ${BASEDIR}/lib/*.jar
do
i_cp=$i_cp:$file
echo "$file"
done
for file in ${BASEDIR}/conf/*
do
i_cp=$i_cp:$file
done

java -cp ${i_cp} com.huawei.bigdata.iotdb.JDBCExample
```

*com.huawei.bigdata.iotdb.JDBCExample* is an example. Use the actual code instead.

4. Run the **run.sh** script to run the JAR file.

```
sh /opt/hadoopclient/IoTDB/iotdb/run.sh
```

----End

#### 1.14.4.2.2 Viewing Commissioning Results

If the application running is successful, the following information is displayed.

```
11:53:47.586 [main] INFO org.apache.iotdb.session.Session - EndPoint(ip:8.5.248.2, port:22260) execute sql select * from root.redirect2.d1 where time >= 1 and time < 10 and root.redirect2.d1.s1 > 1

#### 1.14.4.3 Commissioning Flink Applications on Flink Web UI and Linux

##### 1.14.4.3.1 Compiling and Running Applications

###### Scenario

IoTDB applications can run in a Linux environment where the Flink client is installed and in an environment where the Flink web UI is installed. After the application code is developed, you can upload the JAR file to the prepared environment.

## Prerequisites

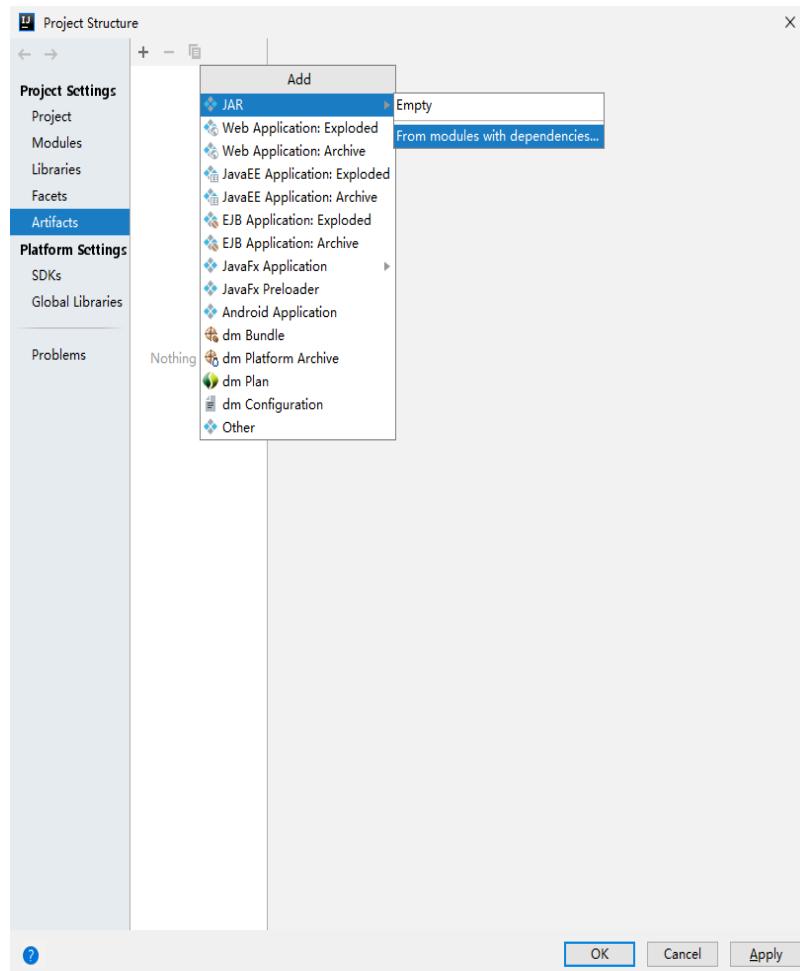

- The Flink component has been installed in the cluster and the FlinkServer instance has been added.
- The cluster client that contains the Flink service has been installed, for example, in the **/opt/hadoopclient** directory.
- If the host where the client is installed is not a node in the cluster, the mapping between the host name and the IP address must be set in the **hosts** file on the node where the client is located. The host names and IP addresses must be mapped one by one.

## Procedure

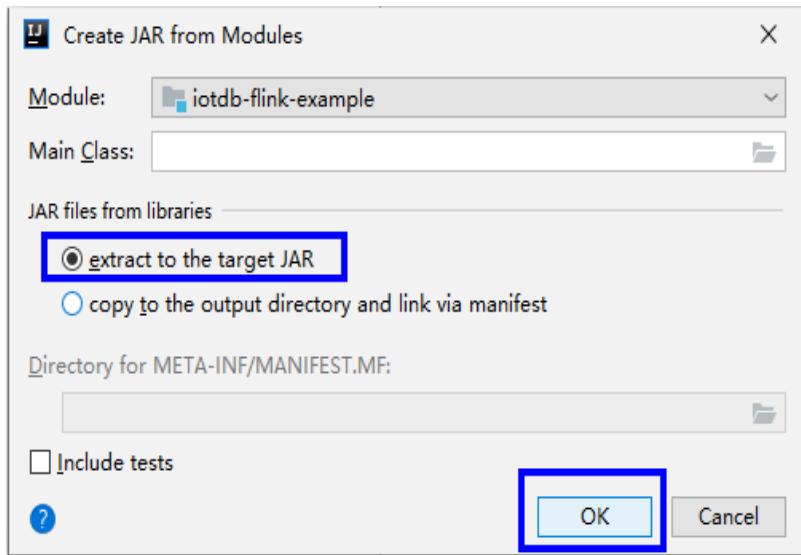

### Step 1 Build a JAR file.

- In IntelliJ IDEA, configure **Artifacts** of the project before generating a JAR file.
  - a. On the IDEA homepage, choose **File > Project Structures...** to go to the **Project Structure** page.
  - b. On the **Project Structure** page, select **Artifacts**, click **+**, and select **From modules with dependencies....**

Figure 1-189 Adding Artifacts

- c. Select **extract to the target JAR** and click **OK**.

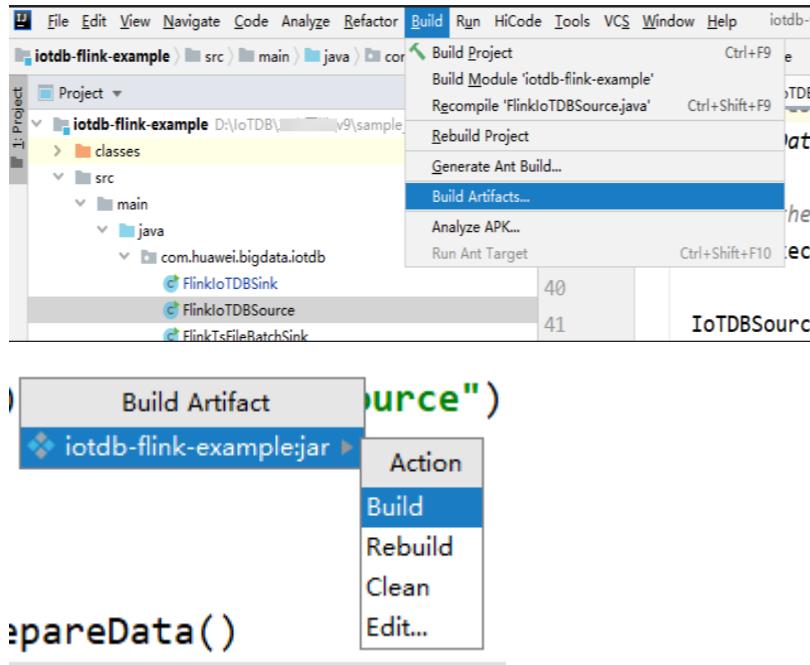

- d. Set the name, type, and output path of the JAR file based on the site requirements.

To avoid JAR file conflicts caused by unnecessary JAR files, you only need to load the following basic JAR files related to IoTDB:

- flink-iotdb-connector-\*
- flink-tsfile-connector-\*
- hdoop-tsfile-\*
- influxdb-thrift-\*
- iotdb-antlr-
- iotdb-session-\*
- iotdb-thrift-\*
- iotdb-thrift-commons-\*
- isession-\*
- libthrift-\*
- service-rpc-\*
- tsfile-\*

Click **OK**.

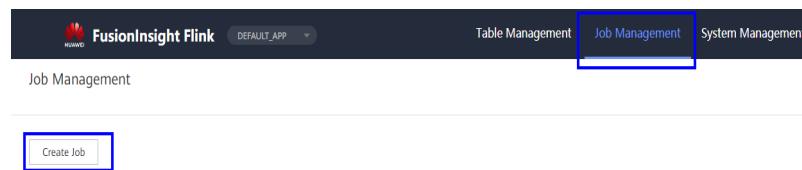

- e. On the IDEA home page, choose **Build > Build Artifacts....** On the **Build Artifact** page that is displayed, choose **Action > Build**.

- f. After the build is successful, the message "Build completed successfully" is displayed in the lower right corner, and the corresponding JAR file is generated in the **Output Directory** directory.

**Step 2** (Scenario 1) Run a Flink job on the Flink web UI.

1. Log in to FusionInsight Manager of the cluster as a user who has the FlinkServer web UI management permission, choose **Cluster > Services > Flink**, and click the hyperlink next to **Flink WebUI** on the dashboard page to go to the FlinkServer web UI.
2. On the FusionInsight Flink web UI, choose **Job Management > Create Job** to create a job.

3. Set **Type** to **Flink Jar**, enter the name of the job to be created, select a task type, and click **OK**.

Create Job

\*Type Flink SQL Flink Jar

\*Name iotdb\_flink

\*Task Type Stream job Batch Job

Description Enter the description.

OK Cancel

- Upload the JAR file generated in **Step 1**, set **Main Class** to **Specify**, enter the class to be executed in **Class Parameter**, and click **Submit**.

For example, set **Type** to **com.huawei.bigdata.iotdb.FlinkIoTDBSink** (development program that executes [FlinkIoTDBSink](#)) or **com.huawei.bigdata.iotdb.FlinkIoTDBSource** (development program that executes [FlinkIoTDBSource](#)).

Configure Parameters Parallelism EnterParallelism JobManager Memory(MB) Enter the memory

Save Submit

### Step 3 (Scenario 2) Submit a Flink job on the Flink client in the Linux environment.

- Log in to the MRS client as a client installation user.
- Run the following command to initialize environment variables:  
`source /opt/hadoopclient/bigdata_env`
- If Kerberos authentication is enabled for the cluster, perform [Step 3.4](#) to [Step 3.11](#). If Kerberos authentication is disabled for the cluster, skip these steps.
- Prepare a user for submitting Flink jobs.  
For details, see [Preparing a Developer Account](#).

5. Log in to Manager using the created user, choose **System > Permission > User**. Locate the row that contains the new user and choose **More > Download Authentication Credential** in the **Operation** column.
6. Decompress the downloaded authentication credential package and copy the **user.keytab** file to the client node, for example, to the **/opt/hadoopclient/Flink/flink/conf** directory on the client node. If the client is installed on a node outside the cluster, copy the **krb5.conf** file to the **/etc/** directory on this node.
7. In security mode, append the service IP address of the node where the client is installed and floating IP address of Manager to the **jobmanager.web.allow-access-address** configuration item in the **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** file. Use commas (,) to separate IP addresses.
8. Run the following commands to configure security authentication by adding the **keytab** path and username to the **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** configuration file.  
**security.kerberos.login.keytab: <user.keytab file path>**  
**security.kerberos.login.principal: <Username>**

Example:

```
security.kerberos.login.keytab: /opt/hadoopclient/Flink/flink/conf/user.keytab  
security.kerberos.login.principal: test
```

9. In the **bin** directory of the Flink client, run the following command to perform security hardening. For details, see "Component Operation Guide" > "Using Flink" > "Security Hardening" > "Authentication and Encryption" in the *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

**sh generate\_keystore.sh**

After the script is executed, enter a password for submitting jobs. Then, the value of SSL in **/opt/hadoopclient/Flink/flink/conf/flink-conf.yaml** is automatically replaced.

#### NOTE

- After the operations in "Component Operation Guide" > "Using Flink" > "Security Hardening" > "Authentication and Encryption" in the *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)* are performed, the generated **flink.keystore**, **flink.truststore**, and **security.cookie** are automatically filled in the corresponding configuration items in the **flink-conf.yaml** file.
- The values of **security.ssl.key-password**, **security.ssl.keystore-password**, and **security.ssl.truststore-password** must be obtained using the Manager plaintext encryption API by running the following command:  
**curl -k -i -u <user name>:<password> -X POST -HContent-type:application/json -d '{"plainText":"<password>"}' 'https://x.x.x.x:28443/web/api/v2/tools/encrypt'**; in the preceding command, **<password>** must be the same as the password used for issuing the certificate, and **x.x.x.x** indicates the floating IP address of Manager in the cluster.

10. Configure paths for the **flink.keystore** and **flink.truststore** files.
  - Absolute path: After the script is executed, the **flink.keystore** and **flink.truststore** file paths are automatically set to absolute paths in the **flink-conf.yaml** file. In this case, you need to place the **flink.keystore** and **flink.truststore** files in the **conf** directory to the absolute paths of the Flink client and each Yarn node in the cluster, respectively.

- Relative path: Perform the following operations to set the **flink.keystore** and **flink.truststore** files to relative paths:
  - i. In the **/opt/hadoopclient/Flink/flink/conf/** directory, create a directory, for example, **ssl**.  
**cd /opt/hadoopclient/Flink/flink/conf**  
**mkdir ssl**
  - ii. Move the **flink.keystore** and **flink.truststore** files to the new folder.  
**mv flink.keystore flink.truststore ssl/**
  - iii. Change the values of the following parameters to relative paths in the **flink-conf.yaml** file:  
security.ssl.keystore: **ssl/flink.keystore**  
security.ssl.truststore: **ssl/flink.truststore**

11. Add the IP addresses of the nodes where the clients are located to the following configuration items in the **flink-conf.yaml** file. Use commas (,) to separate IP addresses.  
web.access-control-allow-origin: **xx.xx.xxx.xxx**  
jobmanager.web.allow-access-address: **xx.xx.xxx.xxx**
12. Upload the JAR file generated in **Step 1** to the Flink client node, for example, **/opt/hadoopclient/Flink/flink**, and submit the job.

---

#### NOTICE

To submit or run jobs on Flink, the user must have the following permissions:

- If Ranger authentication is enabled, the current user must belong to the **hadoop** group or the user has been granted the **/flink** read and write permissions in Ranger.
- If Ranger authentication is disabled, the current user must belong to the **hadoop** group.
- If the **flink.keystore** and **flink.truststore** files are stored in the absolute path:  
Run the following commands to start a session and submit a job in the session: **com.huawei.bigdata.iotdb.FlinkIoTDBSink** is the application in **FlinkIoTDBSink**.  
**yarn-session.sh -nm "session-name"**  
**flink run --class com.huawei.bigdata.iotdb.FlinkIoTDBSink /opt/hadoopclient/Flink/flink/flink-example.jar**
- If the **flink.keystore** and **flink.truststore** files are stored in the relative path:  
In the same directory of SSL, run the following commands to start a session and submit a job in the session. The SSL directory is a relative path. For example, if the SSL directory is **/opt/hadoopclient/Flink/flink/conf/**, then run the following commands in this directory.  
**com.huawei.bigdata.iotdb.FlinkIoTDBSink** is the application in **FlinkIoTDBSink**.  
**yarn-session.sh -t ssl/ -nm "session-name"**

```
flink run --class com.huawei.bigdata.iotdb.FlinkIoTDBSink /opt/
hadoopclient/Flink/flink-example.jar
```

---End

### 1.14.4.3.2 Viewing Commissioning Results

- Check whether the job is executed.

- Using the Flink web UI

If a success message is returned on the Flink web UI, the execution is successful. You can choose **More > Job Monitoring** in the **Operation** column to view detailed logs.

- Using the Flink client

Log in to FusionInsight Manager as a running user, go to the native page of the Yarn service, find the application of the corresponding job, and click the application name to go to the job details page.

- If the job is not complete, click **Tracking URL** to go to the native Flink service page and view the job running information.
- If the job submitted in a session has been completed, you can click **Tracking URL** to log in to the native Flink service page to view job information.

The screenshot shows the Yarn service native page with the following details:

- Application Overview:**
  - User: administ
  - Name: session-name
  - Application Type: Apache Flink
  - Application ID: application\_1627029644621\_0039
  - Yarn Application State: RUNNING (AM has registered with RM and started running)
  - Queue: default
  - Final Status Reported by AM: Application has not completed yet.
  - Started: Sat Jul 31 10:28:43 +0800 2021
  - Elapsed: 48m, 57m, 29s
  - Tracking URL: ApplicationMaster
  - Log Aggregate Status: NOT START
  - Application Timeout (Remaining Time): Unlimited
  - Diagnostics:
  - Unmanaged Application: false
  - Application Node Label expression: <Not set>
  - AM container Node Label expression: <DEFAULT\_PARTITION>
- Application Metrics:**
  - Total Resource Preempted: <memory0, vCores0>
  - Total Number of Non-AM Containers Preempted: 0
  - Total Number of AM Containers Preempted: 0
  - Resource Preempted from Current Attempt: <memory0, vCores0>
  - Number of Non-AM Containers Preempted from Current Attempt: 0
  - Aggregate Resource Allocation: 362854138 MB-seconds, 354346 vcore-seconds, 0 yarn.io/gpu-seconds
  - Aggregate Preempted Resource Allocation: 0 MB-seconds, 0 vcore-seconds

- Verify the job execution result.

- FlinkIoTDBSink execution result:

- Run the following command on the IoTDB client and check whether the data has been written from Flink to IoTDB:

```
select * from root.sg.d1
```

```
IoTDB@...:22260> select * from root.sg.d1
+-----+
| Time |      root.sg.d1.s1 |
+-----+

```

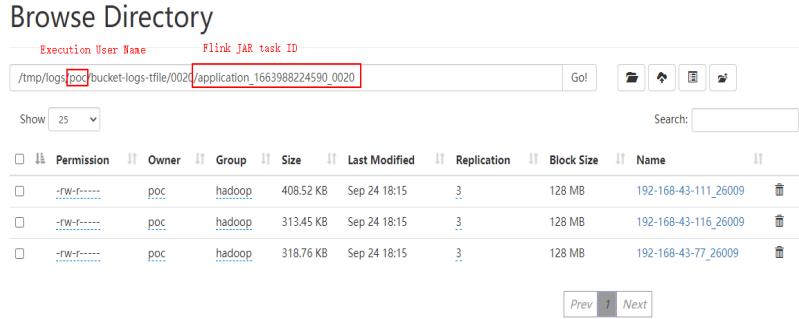

- FlinkIoTDBSource execution result:

- 1) Log in to FusionInsight Manager as a running user and choose **Cluster > Services > HDFS**. Click the hyperlink next to **NameNode WebUI** to access the HDFS web UI.
- 2) Choose **Utilities > Browse the file system**.

The screenshot shows the 'Startup Progress' section of the HDFS Utilities page. At the top, there's a green navigation bar with 'Utilities' and a dropdown menu. The dropdown menu has an option 'Browse the file system' highlighted with a red box and a red arrow pointing to it. Below the dropdown, the 'Startup Progress' section displays the progress of various startup phases. The first phase listed is 'Loading fsimage /srv/BigData/namenode/current/fsimage\_00000000000000000000 399 B', which is at 100% completion and took 1 sec.

| Phase  | Completion | Elapsed Time |
|--|------------|--------------|
| Loading fsimage /srv/BigData/namenode/current/fsimage_00000000000000000000 399 B | 100%       | 1 sec        |
| erasure coding policies (0/0)  | 100%       |              |
| inodes (1/1)   | 100%       |              |
| delegation tokens (0/0)  | 100%       |              |
| cache pools (0/0)  | 100%       |              |
| Loading edits  | 100%       | 0 sec        |
| Saving checkpoint  | 100%       | 0 sec        |
| Safe mode  | 100%       | 0 sec        |

- 3) Go to the **/tmp/logs/Execution username/bucket-logs-tfile/Task ID/Flink task ID** directory and download all files in the directory to the local PC.

- 4) Search for **root.sg.d1** in the files downloaded in [2.3](#)). If the following information is displayed, data is successfully read from IoTDB.

#### 1.14.4.4 Commissioning Kafka Applications on Linux

#### **1.14.4.4.1 Compiling and Running Applications**

# Scenario

After code development is complete, you can run an IoTDB-Kafka sample application in the Linux environment.

## Prerequisites

- You have installed the IoTDB and Kafka clients.
  - If the host where the client is installed is not a node in the cluster, the mapping between the host name and the IP address must be set in the **hosts** file on the node where the client is located. The host names and IP addresses must be mapped one by one.

## Procedure

## **Step 1 Export a JAR file.**

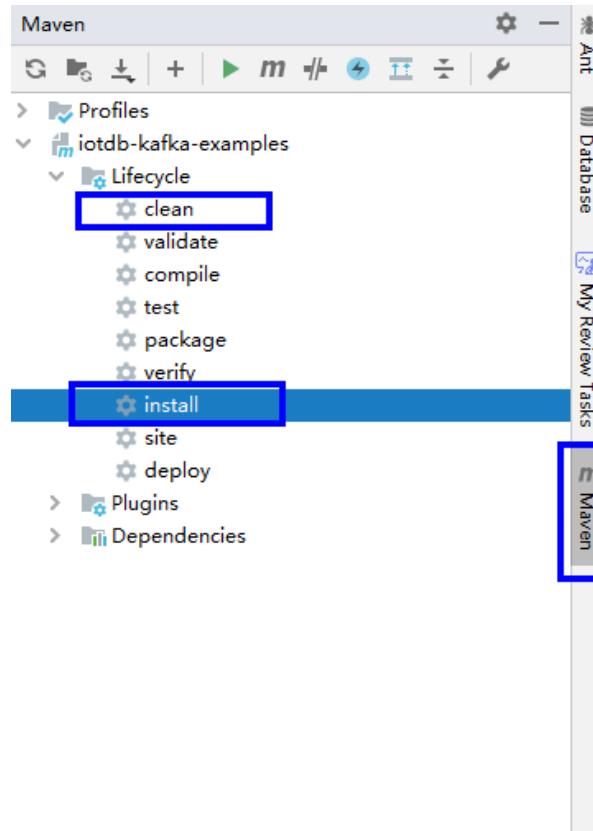

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven** > *Sample project name* > **Lifecycle** > **clean** and double-click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **install** and double-click **install** to run the **install** command of Maven.

**Figure 1-190** Maven clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window of IDEA, and run the **mvn clean install** command to build the file.

**Figure 1-191** Entering **mvn clean install** in the IDEA Terminal text box

```
[INFO] -----  
[INFO] BUILD SUCCESS  
[INFO] -----  
[INFO] Total time: 1.594 s  
[INFO] Finished at: 2022-01-15T17:58:02+08:00  
[INFO] -----  
D:\IoTDB\二次开发\v18\sample_project\src\iotdb-examples\iotdb-kafka-example>mvn clean install
```

After the build is completed, message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

## Step 2 Prepare the dependent JAR file.

- Go to the client installation directory, create the **lib** directory, and import the JAR package generated in **Step 1** to the **lib** directory, for example, **/opt/hadoopclient/lib**.
- Go to the Kafka client and copy the JAR package on which Kafka depends to the **lib** directory in **Step 2.1**. The following is an example directory:

```
cp /opt/hadoopclient/Kafka/kafka/libs/*.jar /opt/hadoopclient/lib
```

3. Go to the IoTDB client and copy the JAR package on which IoTDB depends to the **lib** directory in **Step 2.1**. The following is an example directory:  

```
cp /opt/hadoopclient/IoTDB/iotdb/lib/*.jar/opt/hadoopclient/lib
```
4. Copy all files in the **src/main/resources** directory of the IntelliJ IDEA project to the **src/main/resources** directory at the same level as the **lib** folder, that is, **/opt/hadoopclient/src/main/resources**.

**Step 3** Go to the **/opt/hadoopclient** directory and ensure that the current user has the read permission on all files in the **src/main/resources** directory and the dependency library folder. In addition, ensure that JDK has been installed and Java environment variables have been set. Then, run the following command to run the sample project:

```
java -cp /opt/hadoopclient/lib/*:/opt/hadoopclient/src/main/resources  
com.huawei.bigdata.iotdb.KafkaConsumerMultThread
```

----End

#### 1.14.4.4.2 Viewing Commissioning Results

If the application running is successful, the following information is displayed.

```
[2022-01-17 14:43:57,511] INFO Consumer Thread-1 partitions:1 record:sensor_89,1642401919971,1.000000

```

#### 1.14.4.5 Using a UDF

##### 1.14.4.5.1 Registering a UDF

1. Build a JAR file.

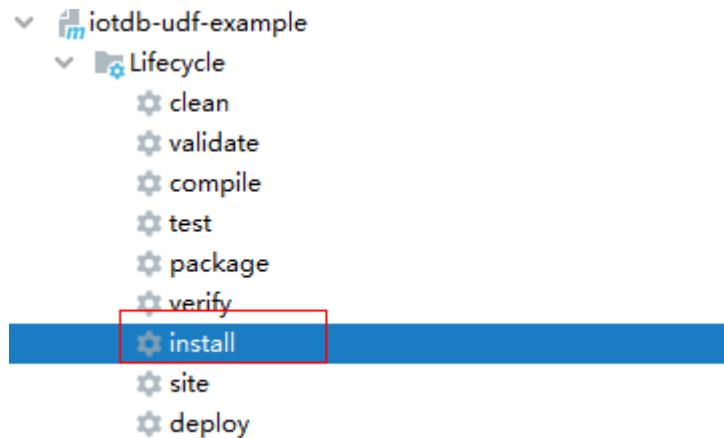

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven**, locate the target project name, and double-click **clean** under **Lifecycle** to run the **clean** command of Maven.

Choose **Maven**, locate the target project name, and double-click **install** under **Lifecycle** to run the **install** command of Maven.

Figure 1-192 Maven clean and install

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window of IDEA, and run the **mvn clean install** command to build the file.

Figure 1-193 Building result after mvn clean install is entered

```
[INFO] --- maven-install-plugin:2.4:install (default-install) @ iotdb-udf-example ---
[INFO] Installing D:\code\lib\sample_project\src\iotdb-examples\iotdb-udf-example\target\iotdb-udf-example-0.12.0-hw-ei-312005.jar to D:\repo1\com\huawei\mrs\iotdb-udf-example\0.12.0-hw-ei-312005\iot
[INFO] Installing D:\code\lib\sample_project\src\iotdb-examples\iotdb-udf-example\pom.xml to D:\repo1\com\huawei\mrs\iotdb-udf-example\0.12.0-hw-ei-312005\iotdb-udf-example-0.12.0-hw-ei-312005.pom
[INFO] -----
[INFO] BUILD SUCCESS
[INFO] -----
[INFO] Total time: 01:19 min
[INFO] Finished at: 2022-02-14T15:51:35+08:00
[INFO] -----
```

After the build is complete, message "BUILD SUCCESS" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

2. Import the dependent JAR file.

Log in to the node where IoTDBServer is located as user **root**, run **su - omm** to switch to user **omm**, and import the JAR file generated in 1 to the **\$BIGDATA\_HOME/FusionInsight\_IoTDB\_\*/install/FusionInsight-IoTDB-\*/iotdb/ext/udf** directory.

**NOTICE**

During cluster deployment, ensure that a corresponding JAR package exists in the UDF JAR package path of each IoTDBServer node. You can modify IoTDB configuration **udf\_root\_dir** to specify the root path for the UDF to load JAR files.

3. Run the following SQL statement to register the UDF:

**CREATE FUNCTION <UDF-NAME> AS '<UDF-CLASS-FULL-PATHNAME>'**

For example, you can run the following statement to register a UDF named **example**:

```
CREATE FUNCTION example AS 'com.huawei.bigdata.iotdb.UDTFExample'
```

### 1.14.4.5.2 Querying a UDF

#### Basic SQL Syntax Supported

- SLIMIT / SOFFSET
- LIMIT / OFFSET
- NON ALIGN
- Queries with value filters
- Queries with time filters

Currently, aligned time series are not supported in UDF queries. An error message is reported if you use UDF queries with aligned time series selected.

#### Queries with an Asterisk (\*)

Assume that there are two time series (`root.sg.d1.s1` and `root.sg.d1.s2`).

- Execute the **SELECT example(s1) from root.sg.d1** statement.  
The result set contains the result of **example(root.sg.d1.s1)**.
- Execute the **SELECT example(s1, s2) from root.sg.d1** statement.  
The result set contains the result of **example(root.sg.d1.s1, root.sg.d1.s2)**.

#### Queries with key-value pair attributes in UDF parameters

You can pass any number of key-value pair parameters to the UDF when constructing a UDF query. The key and value in a key-value pair must be enclosed in single or double quotation marks.

---

#### NOTICE

The key-value pair parameters can be passed in only after the time series have been passed in.

---

For example:

```
SELECT example(s1, 'key1'='value1', 'key2'='value2'), example(*, 'key3'='value3') FROM root.sg.d1;  
SELECT example(s1, s2, 'key1'='value1', 'key2'='value2') FROM root.sg.d1;
```

#### Showing All Registered UDFs

Run the following SQL statement on the IoTDB client to view the registered UDFs:

```
SHOW FUNCTIONS
```

### 1.14.4.5.3 Deregistering a UDF

#### Syntax

```
DROP FUNCTION <UDF-NAME>
```

## Example

Run the following command on the IoTDB client to deregister the UDF named **example**:

```
DROP FUNCTION example
```

## 1.14.5 More Information

### 1.14.5.1 Common APIs

#### 1.14.5.1.1 Java API

IoTDB provides a connection pool (SessionPool) for native APIs. When using the APIs, you only need to specify the pool size to obtain connections from the pool. If you cannot get a connection in 60 seconds, a warning log will be printed, but the program continues to wait.

When a connection is used, it automatically returns to the pool and waits to be used next time. When a connection is damaged, it is deleted from the pool and a new connection is created to perform user operations again.

For query operations:

1. When SessionPool is used for query, the result set is SessionDataSetWrapper, the encapsulation class of SessionDataSet.
2. If a query result set is not traversed and you do not want to continue traversing, you need to call **closeResultSet** to release the connection.
3. If an exception is reported when you traverse a query result set, you need to call **closeResultSet** to release the connection.
4. You can call the **getColumnName()** method of SessionDataSetWrapper to obtain the column names in the result set.

**Table 1-131** Sessions APIs and corresponding parameters

| Method   | Description            |
|--|------------------------|
| <ul style="list-style-type: none"><li>• Session(String host, int rpcPort)</li><li>• Session(String host, String rpcPort, String username, String password)</li><li>• Session(String host, int rpcPort, String username, String password)</li></ul> | Initializes a session. |
| Session.open()   | Opens a session.       |
| Session.close()  | Closes a session.      |
| void createDatabase(String database)   | Creates a database.    |

| Method   | Description   |
|--|---|
| <ul style="list-style-type: none"><li>• void deleteDatabase(String storageGroup)</li><li>• void deleteDatabases(List&lt;String&gt; storageGroups)</li></ul>  | Deletes one or more databases.  |
| <ul style="list-style-type: none"><li>• void createTimeseries(String path, TSDataType dataType, TSEncoding encoding, CompressionType compressor, Map&lt;String, String&gt; props, Map&lt;String, String&gt; tags, Map&lt;String, String&gt; attributes, String measurementAlias)</li><li>• void createMultiTimeseries(List&lt;String&gt; paths, List&lt;TSDataType&gt; dataTypes, List&lt;TSEncoding&gt; encodings, List&lt;CompressionType&gt; compressors, List&lt;Map&lt;String, String&gt;&gt; propsList, List&lt;Map&lt;String, String&gt;&gt; tagsList, List&lt;Map&lt;String, String&gt;&gt; attributesList, List&lt;String&gt; measurementAliasList)</li></ul> | Creates one or more time series.  |
| <ul style="list-style-type: none"><li>• void deleteTimeseries(String path)</li><li>• void deleteTimeseries(List&lt;String&gt; paths)</li></ul>   | Deletes one or more time series.  |
| <ul style="list-style-type: none"><li>• void deleteData(String path, long time)</li><li>• void deleteData(List&lt;String&gt; paths, long time)</li></ul>   | Deletes the data of one or more time series before or at a specific time point.   |
| void insertRecord(String deviceId, long time, List<String> measurements, List<String> values)  | Inserts a record, which contains the data of multiple measurement points of a device at a timestamp. Servers need to perform type inference, which may take extra time. |
| void insertTablet(Tablet tablet)   | Inserts a tablet, which contains multiple rows of non-empty data blocks. The columns in each row are the same.  |
| void insertTablets(Map<String, Tablet> tablet)   | Inserts multiple tablets.   |
| void insertRecords(List<String> deviceIds, List<Long> times, List<List<String>> measurementsList, List<List<String>> valuesList)   | Inserts multiple records. Servers need to perform type inference, which may take extra time.  |

| Method  | Description  |
|---|--|
| void insertRecord(String deviceld, long time, List<String> measurements, List<TSDDataType> types, List<Object> values)  | Inserts a record, which contains the data of multiple measurement points of a device at a timestamp. With the data type information, servers do not need to perform type inference, improving the performance. |
| void insertRecords(List<String> devicelds, List<Long> times, List<List<String>> measurementsList, List<List<TSDDataType>> typesList, List<List<Object>> valuesList)     | Inserts multiple records. With the data type information, servers do not need to perform type inference, improving the performance.  |
| submitApplication(SubmitApplicationRequest request)   | Used by the client to submit a new application to ResourceManager.   |
| void insertRecordsOfOneDevice(String deviceld, List<Long> times, List<List<String>> measurementsList, List<List<TSDDataType>> typesList, List<List<Object>> valuesList) | Inserts multiple records of the same device.   |
| SessionDataSet executeRawDataQuery(List<String> paths, long startTime, long endTime)  | Queries raw data. The interval includes the start time but does not include the end time.  |
| SessionDataSet executeQueryStatement(String sql)  | Executes query statements.   |
| void executeNonQueryStatement(String sql)   | Executes non-query statements.   |

**Table 1-132** Test APIs

| Method   | Description  |
|--|--|
| <ul style="list-style-type: none"><li>• void testInsertRecords(List&lt;String&gt; devicelds, List&lt;Long&gt; times, List&lt;List&lt;String&gt;&gt; measurementsList, List&lt;List&lt;String&gt;&gt; valuesList)</li><li>• void testInsertRecords(List&lt;String&gt; devicelds, List&lt;Long&gt; times, List&lt;List&lt;String&gt;&gt; measurementsList, List&lt;List&lt;TSDDataType&gt;&gt; typesList, List&lt;List&lt;Object&gt;&gt; valuesList)</li></ul> | Tests testInsertRecords. A response is returned immediately after data is transmitted to the server. No data is written. |

| Method  | Description   |
|---|---|
| <ul style="list-style-type: none"><li>• void testInsertRecord(String deviceld, long time, List&lt;String&gt; measurements, List&lt;String&gt; values)</li><li>• void testInsertRecord(String deviceld, long time, List&lt;String&gt; measurements, List&lt;TSDataType&gt; types, List&lt;Object&gt; values)</li></ul> | Tests insertRecord. A response is returned immediately after data is transmitted to the server. No data is written. |
| void testInsertTablet(Tablet tablet)  | Tests insertTablet. A response is returned immediately after data is transmitted to the server. No data is written. |

## 1.15 Kafka Development Guide

### 1.15.1 Overview

#### 1.15.1.1 Development Environment Preparation

##### Kafka Introduction

Kafka is a distributed message release and subscription system. With features similar to JMS, Kafka processes active streaming data.

Kafka is applicable to message queuing, behavior tracing, operation & maintenance (O&M) data monitoring, log collection, streaming processing, event tracing, and log persistence.

Kafka features:

- High throughput
- Message persistence to disks
- Scalable distributed system
- Fault-tolerant
- Support for online and offline scenarios

##### Interface Type Introduction

APIs provided by Kafka can be divided into two types: Producer API and Consumer API. Both the types of APIs contain Java API. For details, see section [Java API](#).

#### 1.15.1.2 Common Concepts

- **Topic**

A same type of messages maintained by Kafka.

- **Partition**  
One topic can be divided into multiple partitions, and each partition corresponds to an appendant and log file whose sequence is fixed.
- **Producer**  
Role in a Kafka topic to which messages are sent.
- **Consumer**  
Role that obtains messages from Kafka topics.
- **Broker**  
A node server in a Kafka cluster.
- **keytab file**  
A key file for storing user information. Applications use the key file for API authentication in the cluster.

### 1.15.1.3 Development Process

Kafka client roles include Producer and Consumer, which share the same application development process.

[Figure 1-194](#) and [Table 1-133](#) show each phase of the development process.

Figure 1-194 Kafka client application development process

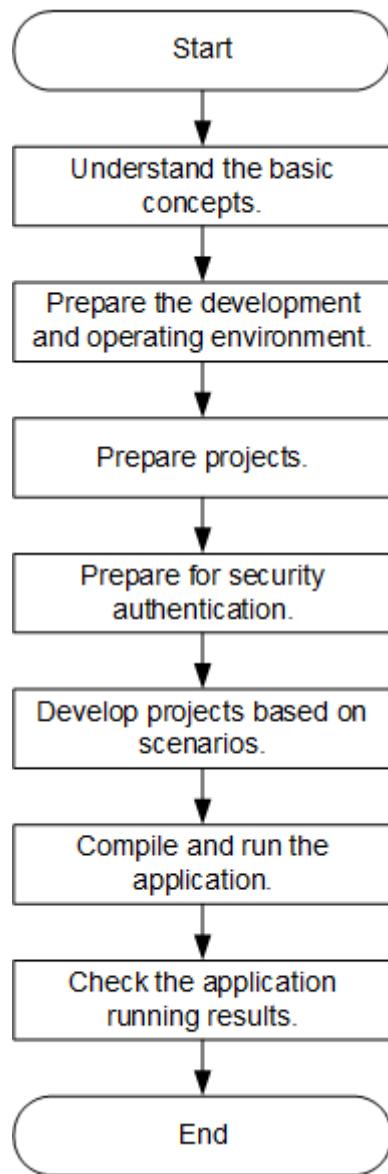

Table 1-133 Kafka client application development process description

| Phase                          | Description   | Reference Document              |
|--------------------------------|---|---------------------------------|
| Understand the basic concepts. | Before developing an application, learn basic concepts of Kafka, and determine whether the desired role is Producer or Consumer based on the actual scenario. | <a href="#">Common Concepts</a> |

| Phase  | Description   | Reference Document  |
|--|---|---|
| Prepare the development and operating environment. | The Java language is recommended for the development of Java applications. The IntelliJ IDEA tool can be used.<br><br>The Kafka running environment is the Kafka client. Install and configure the client according to the guide. | <a href="#">Preparing for Development and Operating Environment</a> |
| Prepare projects                                   | Kafka provides program samples for different scenarios. You can import the program samples for learning.  | <a href="#">Configuring and Importing Sample Projects</a>           |
| Prepare for security authentication.               | If you use a security cluster, you need to perform security authentication.   | <a href="#">Preparing for Security Authentication</a>               |
| Develop projects based on scenarios.               | Producer and Consumer API usage samples are provided and cover API, and multi-thread usage scenarios, helping you quickly know Kafka interfaces well.   | <a href="#">Developing an Application</a>                           |
| Compile and run the application.                   | Compile the developed application and submit it for running.  | <a href="#">Application Commissioning</a>                           |
| View application running results.                  | Program running results will be written to and printed on the console. You can use a Linux client to consume topic data to check whether data has been successfully written.  | <a href="#">Application Commissioning</a>                           |

## 1.15.2 Environment Preparation

### 1.15.2.1 Preparing for Development and Operating Environment

#### Preparing Development Environment

[Table 1-134](#) describes the environment required for secondary development.

**Table 1-134** Development environment

| Item   | Description   |
|--|---|
| OS   | <ul style="list-style-type: none"><li>• Development environment: Windows OS. Windows 7 or later is supported.</li><li>• Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul>   |
| IntelliJ IDEA installation and configuration | <p>It is the basic configuration for the development environment. JDK 1.8 is used. IntelliJ IDEA 2019.1 or other compatible versions are used.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li></ul> |

| Item                          | Description   |
|-------------------------------|---|
| Installing JDK                | <p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>Oracle JDK 1.8</li><li>IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>For security purposes, the server supports only TLS V1.2 or later.</li><li>By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <code>com.ibm.jsse2.overrideDefaultTLS</code> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls</a>.</li><li>For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul> |
| Maven installation            | Basic configuration of the development environment for project management throughout the lifecycle of software development.   |
| Developer account preparation | See <a href="#">Preparing a Developer Account</a> for configuration.  |
| 7-zip                         | It is a tool used to decompress <b>.zip</b> and <b>.rar</b> packages. The 7-Zip 16.04 is supported.   |

## Preparing an Operating Environment

During application development, you need to prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#) and choose **Homepage > Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the

client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.

For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.

- b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Kafka\config**. Obtain the Kafka-related configuration file.

**Table 1-135** describes the main configuration files.

**Table 1-135** Configuration file

| Document Name       | Function  |
|---------------------|---|
| server.properties   | Configures the Kafka server.  |
| client.properties   | Configures the Kafka client.  |
| producer.properties | Configures producer of kafka parameters.                              |
| consumer.properties | Configures consumer of kafka parameters.                              |
| user.keytab         | Provides user information for Kerberos security authentication.       |
| krb5.conf           | Kerberos server configuration information                             |
| kafkaSecurityMode   | Indicates whether the security mode is enabled for the Kafka service. |

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

#### NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.
- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.

Ensure that the difference between the client time and the cluster time is less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).

- b. **Accessing FusionInsight Manager of an MRS Cluster.** Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all JAR package in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/Kafka/install\_files/kafka/libs** directory to the **lib** directory where the compiled JAR package is stored for subsequent commissioning, for example, **/opt/hadoopclient/Kafka/kafka/libs**.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Kafka/install_files/kafka/libs/* root@IP address of the client node:/opt/hadoopclient/Kafka/kafka/libs
```

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

### 1.15.2.2 Configuring and Importing Sample Projects

**Step 1** Obtain the sample project folder **kafka-examples** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

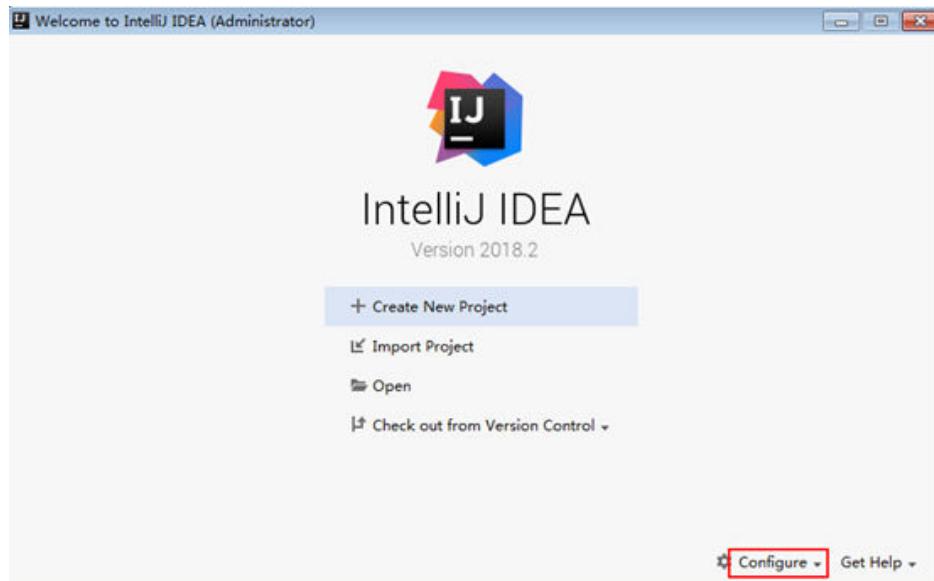

**Step 2** Configure the **krb5.conf** and **user.keytab** files.

Copy the **krb5.conf** and **keytab** files obtained in [Preparing a Developer Account](#) section and all the cluster configuration file obtained in section [Preparing an Operating Environment](#) to the **kafka-examples\src\main\resources** directory of the sample project.

**Step 3** After installing the IntelliJ IDEA and JDK tools, configure JDK in IntelliJ IDEA.

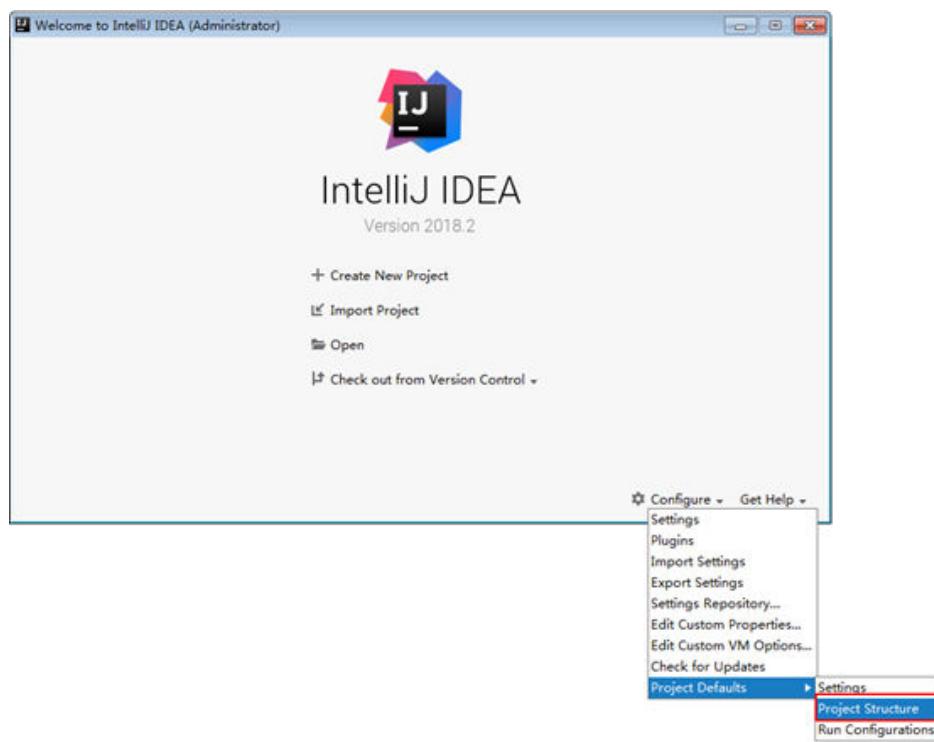

1. Open IntelliJ IDEA and click **Configure**.

Figure 1-195 Quick Start

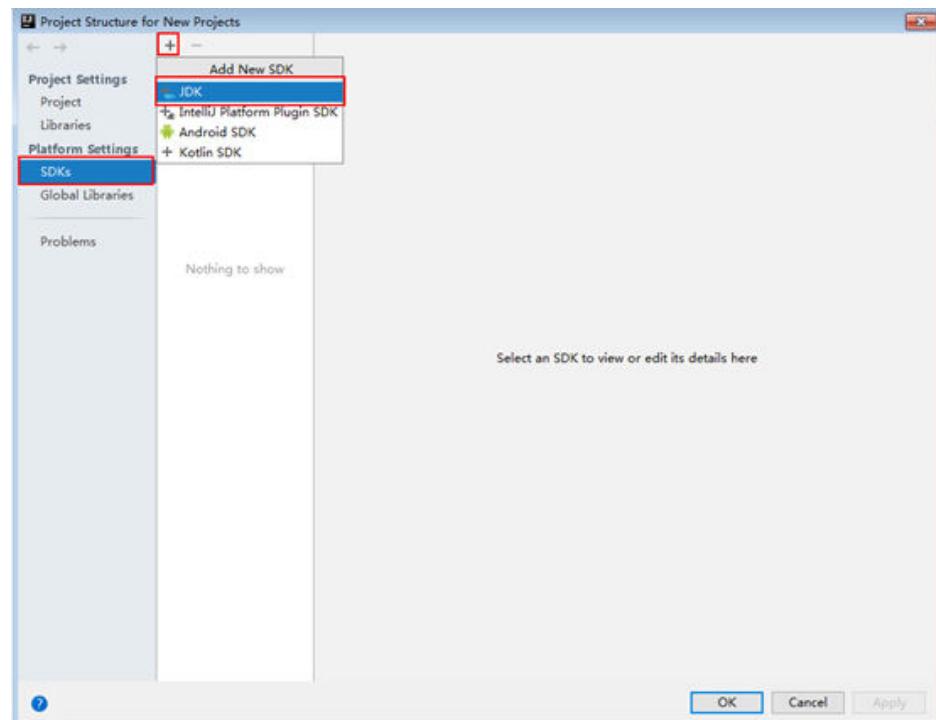

2. Choose **Project Defaults > Project Structure**.

Figure 1-196 Configure

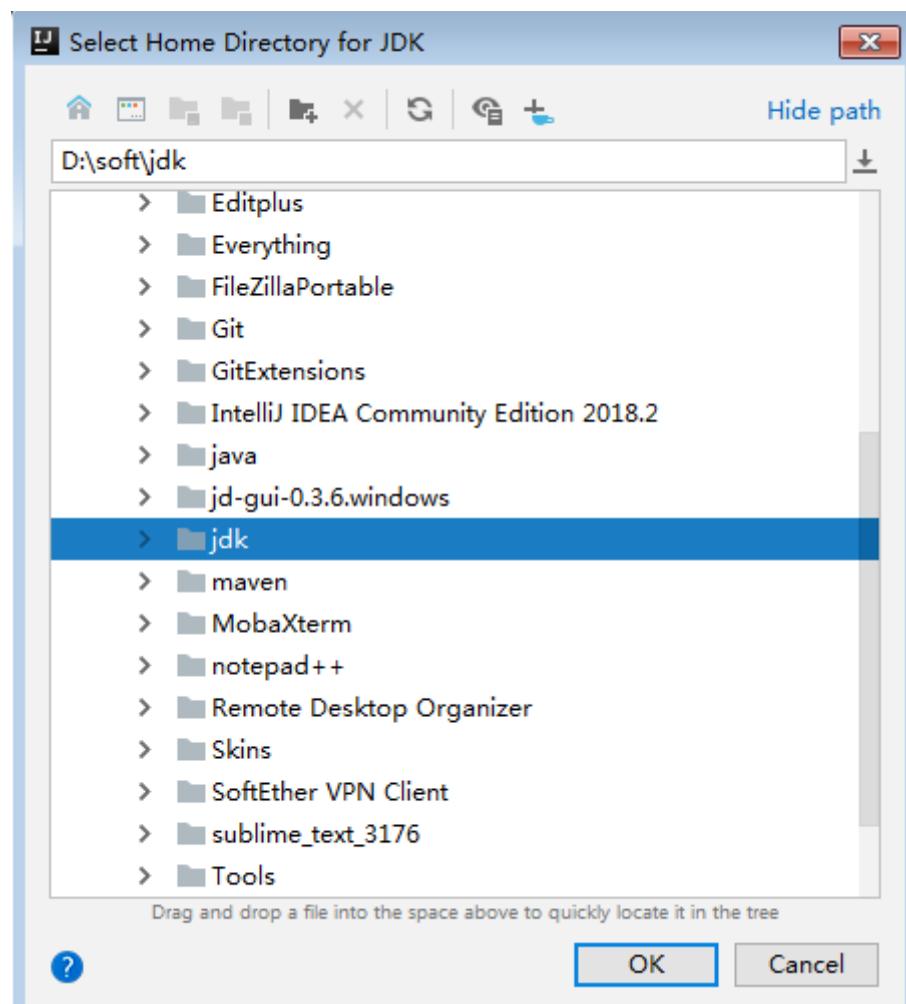

3. In the displayed **Project Structure for New Projects** interface, click **SDKs**. Then click the plus sign (+) and choose **JDK**.

Figure 1-197 Project Structure for New Projects

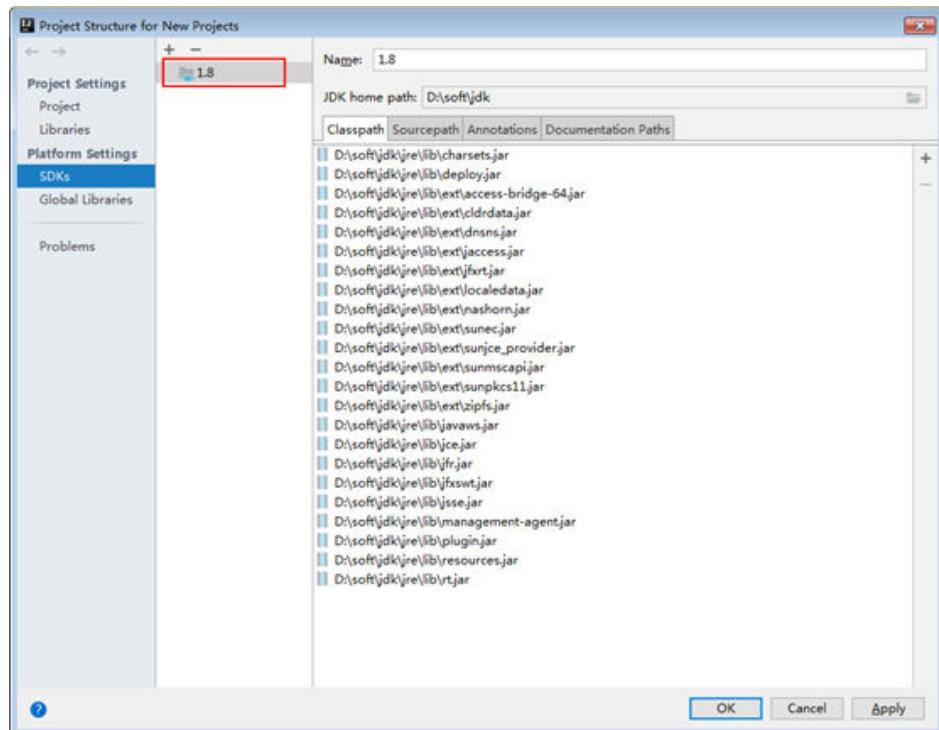

4. In the displayed **Select Home Directory for JDK** interface, select the JDK directory, and click **OK**.

Figure 1-198 Select Home Directory for JDK

5. Click OK.

Figure 1-199 Completing the JDK configuration

**Step 4** Import the sample project into the IntelliJ IDEA development environment.

1. Choose **Open**.

The dialog box for browsing directories is displayed.

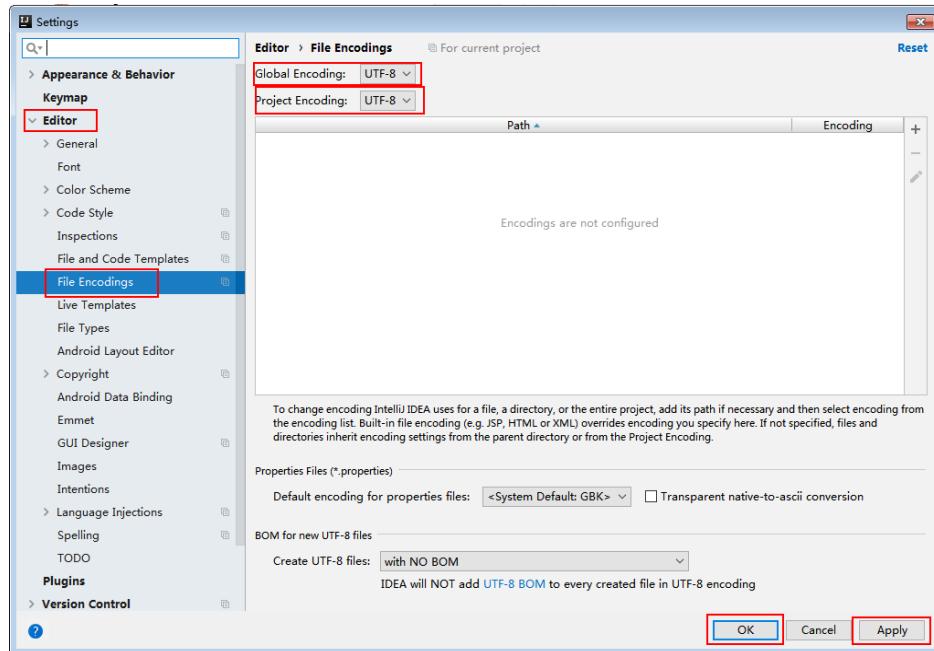

2. Select the sample project folder and click **OK**.

**Step 5** Set the IntelliJ IDEA text file coding format to prevent invalid characters.

1. On the IntelliJ IDEA menu bar, choose **File > Settings**.

The **Settings** window is displayed.

2. Choose **Editor > File Encodings** in the navigation tree. In the **Project Encoding** area and **Global Encoding** area, set the parameter to **UTF-8**, click **Apply**, and then click **OK**, as shown in [Figure 1-200](#).

**Figure 1-200** Setting the IntelliJ IDEA coding format

----End

### 1.15.2.3 Preparing for Security Authentication

#### 1.15.2.3.1 Sasl Kerberos authentication

In a secure cluster environment, components must perform mutual authentication before communicating with each other to ensure communication security. Kafka application development requires Kafka, ZooKeeper and Kerberos security authentication. To perform the security authentication, a **jaas** file needs to be generated, and related environment variables need to be configured. **LoginUtil** related interfaces are provided for the configuration. As shown in the following code sample, only the machine-machine user account applied by the user and the keytab file name need to be configured. For details about the code, reference may be made to the **LoginUtil** class in **com.huawei.bigdata.kafka.example.security** of the sample project.

Code sample:

```
/**  
 * keytab file name of the machine-machine account that a user applies for  
 */  
private static final String USER_KEYTAB_FILE = "keytab file name of the machine-machine account that a user applies for";  
  
/**  
 * Machine-machine account that a user applies for  
 */  
private static final String USER_PRINCIPAL = "Machine-machine account that a user applies for ";  
  
public static void securityPrepare() throws IOException  
{  
    String filePath = System.getProperty("user.dir") + File.separator + "src" + File.separator + "main" +  
    File.separator + "resources" + File.separator;  
    String krbFile = filePath + "krb5.conf";  
    String userKeyTableFile = filePath + USER_KEYTAB_FILE;
```

```
//Replace separators in Windows.  
userKeyTableFile = userKeyTableFile.replace("\\", "\\\\";  
krbFile = krbFile.replace("\\", "\\\\";  
  
LoginUtil.setKrb5Config(krbFile);  
LoginUtil.setZookeeperServerPrincipal("zookeeper/hadoop.<system domain name>");  
LoginUtil.setJaasFile(USER_PRINCIPAL, userKeyTableFile);  
}
```

#### NOTE

You can log in to the FusionInsight Manager, choose **System > Permission > Domain and Mutual Trust**, and check the value of **Local Domain**, which is the current system domain name.

### 1.15.2.3.2 SASL/PLAINTEXT Authentication

#### Scenario

Kafka supports SASL/PLAINTEXT authentication for clusters in security mode.

#### Configuring SASL/PLAINTEXT Authentication on the Kafka Server

- Step 1 Log in to FusionInsight Manager.
  - Step 2 Choose **Cluster > Services > Kafka** and choose **Configurations > All Configurations**. Search for **sasl.enabled.mechanisms**, change the value to **GSSAPI,PLAIN**, and click **Save**.
  - Step 3 Click **Dashboard**, click **More**, and select **Restart Service** to make the configuration take effect.
- End

#### Configuring SASL/PLAINTEXT Authentication on the Kafka Client

You only need to configure dynamic **jaas.conf** and set related authentication attributes on the Kafka client. For example, only set the username and password of the human-machine account that you have applied for in the following sample code. For details, see the authentication sample code in **Producer** of the **com.huawei.bigdata.kafka.example.security** package.

```
public static Properties initProperties() {  
    .....  
    props.put("sasl.mechanism", "PLAIN");  
    props.put("sasl.jaas.config", "org.apache.kafka.common.security.plain.PlainLoginModule required  
username=manager_user password=Password");  
}
```

#### NOTE

- *manager\_user* is a human-machine user created on FusionInsight Manager and must have the production and consumption permissions for the topic that is being used.
- *Password* is the password of *manager\_user*.
  - If the open-source **kafka-client** JAR package is used, the special characters in the password can only be the dollar sign (\$).
  - If the MRS **kafka-client** JAR package is used, the special characters in the password are those supported by FusionInsight Manager (for example, ~`!?,.;-\_()'[]/<>@#\$%^&\*+|=).

## 1.15.3 Developing an Application

### 1.15.3.1 Typical Scenario Description

#### Scenario

Kafka is a distributed message system, in which messages can be publicized or subscribed. A Producer is to be developed to send a message to a topic of a Kafka cluster every second, and a Consumer is to be implemented to ensure that the topic is subscribed and that messages of the topic are consumed in real time.

#### Development Idea

1. Use a Linux client to create a topic. For details, see [Shell](#).
2. Develop a Producer to produce data to the topic.
3. Develop a Consumer to consume the data of the topic.

#### Suggestions on Performance Tuning

1. Create a topic and plan its partitions based on service requirements. The number of partitions limits the number of concurrent consumers.
2. The key value of a message must be variable to ensure even message distribution.
3. Consumers are advised to proactively submit the offset to avoid repeated consumption.
4. For details about other tuning suggestions, see section "Kafka" in MapReduce Service (MRS) 3.3.1-LTS Performance Tuning Guide (for Huawei Cloud Stack 8.3.1).

### 1.15.3.2 Typical Scenario Sample Code Description

#### 1.15.3.2.1 Producer API Usage Sample

#### Function Description

The following code snippet belongs to the **run** method of the **com.huawei.bigdata.kafka.example.Producer** class. It is used by the Producer APIs to produce messages for the security topic.

#### Code Sample

```
/*
 * The Producer thread executes a function to send messages periodically.
 */
public void run() {
    LOG.info("New Producer: start.");
    int messageNo = 1;

    while (messageNo <= MESSAGE_NUM) {
        String messageStr = "Message_" + messageNo;
        long startTime = System.currentTimeMillis();
```

```
// Construct message records.  
ProducerRecord<Integer, String> record = new ProducerRecord<Integer, String>(topic, messageNo,  
messageStr);  
  
if (isAsync) {  
    // Sending in asynchronous mode  
    producer.send(record, new DemoCallBack(startTime, messageNo, messageStr));  
} else {  
    try {  
        // Sending in synchronous mode  
        producer.send(record).get();  
        long elapsedTime = System.currentTimeMillis() - startTime;  
        LOG.info("message(" + messageNo + ", " + messageStr + ") sent to topic(" + topic + ") in " +  
elapsedTime + " ms.");  
    } catch (InterruptedException ie) {  
        LOG.info("The InterruptedException occurred : {}.", ie);  
    } catch (ExecutionException ee) {  
        LOG.info("The ExecutionException occurred : {}.", ee);  
    }  
}  
messageNo++;  
}
```

### 1.15.3.2.2 Consumer API Usage Sample

#### Function Description

The following code sample belongs to the **com.huawei.bigdata.kafka.example.Consumer** class. It is used to enable the Consumer API to subscribe a secure topic and consume messages.

#### Code Sample

```
/**  
 * Consumer constructor.  
 * @param topic Name of the subscribed topic  
 */  
  
public Consumer(String topic) {  
    super("KafkaConsumerExample", false);  
    // Initializes the configuration parameters required for starting the consumer. For details, see the code.  
    Properties props = initProperties();  
    consumer = new KafkaConsumer<Integer, String>(props);  
    this.topic = topic;  
}  
  
public void doWork() {  
    // Subscribe  
    consumer.subscribe(Collections.singletonList(this.topic));  
    // Message consumption request  
    ConsumerRecords<Integer, String> records = consumer.poll(waitTime);  
    // Message Processing  
    for (ConsumerRecord<Integer, String> record : records) {  
        LOG.info("[ConsumerExample], Received message: (" + record.key() + ", " + record.value() + ") at  
offset " + record.offset());  
    }  
}
```

### 1.15.3.2.3 Multi-thread Producer Sample

#### Function Description

The multi-thread producer function is implemented based on the code sample described in section [Producer API Usage Sample](#). Multiple producer threads can

be started. Each thread sends messages to the partition whose key is the same as the thread ID.

The following code snippet belongs to the run method in the **com.huawei.bigdata.kafka.example.ProducerMultThread** class, and these code snippets are used to enable multiple threads to produce data.

## Code Sample

```
/*
 * Specify the current ThreadID as the key value and send data.
 */
public void run()
{
LOG.info("Producer: start.");

    // Record the number of messages.
int messageCount = 1;

    // Specify the number of messages sent by each thread.
int messagesPerThread = 5;
while (messageCount <= messagesPerThread)
{
    // Specify the content of messages to be sent.
    String messageStr = new String("Message_" + sendThreadId + "_" + messageCount);

    // Specify a key value for each thread to enable the thread to send messages to only a specified
partition.
    String key = String.valueOf(sendThreadId);

    // Send messages.
    producer.send(new KeyedMessage<String, String>(sendTopic, key, messageStr));
LOG.info("Producer: send " + messageStr + " to " + sendTopic + " with key: " + key);
    messageCount++;
}
}
```

### 1.15.3.2.4 Multi-thread Consumer Sample

## Function Description

The multi-thread consumer function is implemented based on the code sample described in section [Consumer API Usage Sample](#). The number of consumer threads that can be started to consume the messages in partitions is the same as the number of partitions in the topic.

The following code snippet belongs to the run method in the **com.huawei.bigdata.kafka.example.ConsumerMultThread** class, and these code snippets are used to implement concurrent consumption of messages in a specified topic.

## Code Sample

```
/*
 * Start the concurrent multi-thread consumer.
 */
public void run() {
    LOG.info("Consumer: start.");
    Properties props = Consumer.initProperties();
    // Start a specified number of consumer threads to consume.
    // Note: When this parameter is larger than the number of partitions of the topic to be consumed, the
extra threads fails to consume data.
}
```

```
for (int threadNum = 0; threadNum < CONCURRENCY_THREAD_NUM; threadNum++) {
    new ConsumerThread(threadNum, topic, props).start();
    LOG.info("Consumer Thread " + threadNum + " Start.");
}
}

private class ConsumerThread extends ShutdownableThread {
    private int threadNum = 0;
    private String topic;
    private Properties props;
    private KafkaConsumer<String, String> consumer = null;

    /**
     * Construction method of the consumer thread class
     *
     * @param threadNum Thread number
     * @param topic      topic
     */
    public ConsumerThread(int threadNum, String topic, Properties props) {
        super("ConsumerThread" + threadNum, true);
        this.threadNum = threadNum;
        this.topic = topic;
        this.props = props;
        this.consumer = new KafkaConsumer<String, String>(props);
    }

    public void doWork() {
        consumer.subscribe(Collections.singleton(this.topic));
        ConsumerRecords<String, String> records = consumer.poll(waitTime);
        for (ConsumerRecord<String, String> record : records) {
            LOG.info("Consumer Thread-" + this.threadNum + " partitions:" + record.partition() + " record: "
                    + record.value() + " offsets: " + record.offset());
        }
    }
}
```

### 1.15.3.3 Kafka Streams Scenario Description

#### Scenario Description

Kafka Streams is a lightweight stream processing framework provided by Apache Kafka. The input and output of Kafka Streams are stored in the Kafka cluster.

The following describes the most common WordCount samples.

#### Development Guideline

1. Create two topics on the Linux client to serve as the input and output topics.
2. Develop a Kafka Streams to implement the word count function. The system collects statistics on the number of words in each message by reading the message in the input topic, consumes data from the output topic, and outputs the statistical result in the form of a key-value pair.

### 1.15.3.4 Kafka Streams Sample Code Description

### 1.15.3.4.1 High level KafkaStreams API Usage Sample

#### Function Description

The following code snippets are used in the **createWordCountStream** method of the **com.huawei.bigdata.kafka.example.WordCountDemo** class to implement the following function:

Collects statistics on input records. Same words are divided into a group, which is used as a key value. The occurrence times of each word are calculated as a value and are output in the form of a key-value pair.

#### Code Sample

```
static void createWordCountStream(final StreamsBuilder builder) {  
    // Receive the input records from input-topic.  
    final KStream<String, String> source = builder.stream(INPUT_TOPIC_NAME);  
  
    // Aggregate the calculation result of the key-value pair.  
    final KTable<String, Long> counts = source  
        // Process the received records and split according to the regular expression REGEX_STRING.  
        .flatMapValues(value ->  
            Arrays.asList(value.toLowerCase(Locale.getDefault()).split(REGEX_STRING)))  
        // Aggregate the calculation result of the key-value pair.  
        .groupBy((key, value) -> value)  
        // The final calculation result  
        .count();  
  
    // Output the key-value pair of the calculation result from the output topic.  
    counts.toStream().to(OUTPUT_TOPIC_NAME, Produced.with(Serdes.String(), Serdes.Long()));  
}
```

### 1.15.3.4.2 Low level KafkaStreams API Usage Sample

#### Function Description

The following code snippets are used in the **com.huawei.bigdata.kafka.example.WordCountProcessorDemo** class to implement the following function:

Collects statistics on input records. Same words are divided into a group, which is used as a key value. The occurrence times of each word are calculated as a value and are output in the form of a key-value pair.

#### Code Sample

```
private static class MyProcessorSupplier implements ProcessorSupplier<String, String> {  
    @Override  
    public Processor<String, String> get() {  
        return new Processor<String, String>() {  
            // ProcessorContext instance, which provides the access of the metadata of the records being  
            processed  
            private ProcessorContext context;  
            private KeyValueStore<String, Integer> kvStore;  
  
            @Override  
            @SuppressWarnings("unchecked")  
            public void init(ProcessorContext context) {  
                // Save processor context in the local host, because it will be used for punctuate() and commit().  
                this.context = context;  
                // Execute punctuate() once every second.  
                this.context.schedule(Duration.ofSeconds(1), PunctuationType.STREAM_TIME, timestamp -> {
```

```
try (final KeyValueIterator<String, Integer> iter = kvStore.all()) {
    System.out.println("----- " + timestamp + " -----");
    while (iter.hasNext()) {
        final KeyValue<String, Integer> entry = iter.next();
        System.out.println("[" + entry.key + ", " + entry.value + "]");
        // Send the new records to the downstream processor as key-value pairs.
        context.forward(entry.key, entry.value.toString());
    }
}
});
// Search for the key-value states storage area named KEY_VALUE_STATE_STORE_NAME to
memorize the recently received input records.
this.kvStore = (KeyValueStore<String, Integer>)
context.getStateStore(KEY_VALUE_STATE_STORE_NAME);
}

// Process the receiving records of input topic. Split the records into words, and count the words.
@Override
public void process(String dummy, String line) {
    String[] words = line.toLowerCase(Locale.getDefault()).split(REGEX_STRING);

    for (String word : words) {
        Integer oldValue = this.kvStore.get(word);

        if (oldValue == null) {
            this.kvStore.put(word, 1);
        } else {
            this.kvStore.put(word, oldValue + 1);
        }
    }
}

@Override
public void close() {
}
};

}
```

### 1.15.3.5 Kafka Token Authentication Mechanism Scenario

#### Scenario

The token authentication mechanism is a lightweight authentication mechanism that does not require Kerberos authentication. It can be used in APIs.

#### Development Guideline

1. Use a Linux client to create a token. For details, see "Kafka Token Authentication Mechanism Tool Usage" in MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1) in the MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1).
2. Use the token mechanism for authentication in the secondary development sample.

### 1.15.3.6 Sample Code for Kafka Token Authentication

#### Function

This example shows how to use Kafka user token for authentication.

## Prerequisite

The following parameters of the user token have been added to the *Sample project folder\src\main\resources\producer.properties* file:

- **sasl.mechanism**: SASL framework for user authentication. Set this parameter to **SCRAM-SHA-512**.
- **sasl.jaas.config**: token configuration used by the user

For example, add the following content. Set the parameters in the **producer.properties** file. Ensure that the semicolons (;) and colons (:) are correct.

```
sasl.mechanism = SCRAM-SHA-512
sasl.jaas.config = org.apache.kafka.common.security.scram.ScramLoginModule required username="Token
ID generated by the user" password="HMAC of the token generated by the user" tokenauth=true;
```

## Sample Code

Initialize the configuration in the **Producer()** method and load the token configuration from a file. Do not hardcode the password.

```
public static Properties initProperties() {
    Properties props = new Properties();
    KafkaProperties kafkaProc = KafkaProperties.getInstance();

    // Broker address list
    props.put(BOOTSTRAP_SERVER, kafkaProc.getValues(BOOTSTRAP_SERVER, "localhost:21007"));
    // Client ID
    props.put(CLIENT_ID, kafkaProc.getValues(CLIENT_ID, "DemoProducer"));
    // Key serialization class
    props.put(KEY_SERIALIZER,
        kafkaProc.getValues(KEY_SERIALIZER, "org.apache.kafka.common.serialization.StringSerializer"));
    // Value serialization class
    props.put(VALUE_SERIALIZER,
        kafkaProc.getValues(VALUE_SERIALIZER, "org.apache.kafka.common.serialization.StringSerializer"));
    // Protocol type: Currently, the SASL_PLAINTEXT or PLAINTEXT protocol types can be used.
    props.put(SECURITY_PROTOCOL, kafkaProc.getValues(SECURITY_PROTOCOL, "SASL_PLAINTEXT"));
    // Service name
    props.put(SASL_KERBEROS_SERVICE_NAME, "kafka");
    // Domain name
    props.put(KERBEROS_DOMAIN_NAME, kafkaProc.getValues(KERBEROS_DOMAIN_NAME,
    "hadoop.hadoop.com"));
    // Partition class name
    props.put(PARTITIONER_NAME,
        kafkaProc.getValues(PARTITIONER_NAME, "com.huawei.bigdata.kafka.example.SimplePartitioner"));
    return props;
}
```

 NOTE

When using the token authentication mechanism, you need to comment out the Kerberos authentication mechanism to ensure that only one authentication mechanism is used during code running, as shown in the following:

```
public static void main(String[] args)
{
    if (isSecurityModel())
    {
        // try
        //{
        //     LOG.info("Securitymode start.");
        //
        //     //!!!Note: When using security authentication, you need to change the account to a
        // machine-machine one.
        //     securityPrepare();
        //}
        // catch (IOException e)
        //{
        //     LOG.error("Security prepare failure.");
        //     LOG.error("The IOException occurred.", e);
        //     return;
        //}
        // LOG.info("Security prepare success.");
    }

    // Specify whether to use the asynchronous sending mode.
    final boolean asyncEnable = false;
    Producer producerThread = new Producer(KafkaProperties.TOPIC, asyncEnable);
    producerThread.start();
}
```

### 1.15.3.7 Sample Code for Connecting Kafka to Spring Boot

#### Function

Spring Boot is used to produce and consume Kafka clusters.

#### Sample Code

Use Spring Boot to implement Kafka production and consumption.

```
@RestController
public class MessageController {
    private final static Logger LOG = LoggerFactory.getLogger(MessageController.class);
    @Autowired
    private KafkaProperties kafkaProperties;
    @GetMapping("/produce")
    public String produce() {
        Producer producerThread = new Producer();
        producerThread.init(this.kafkaProperties);
        producerThread.start();
        String message = "Start to produce messages";
        LOG.info(message);
        return message;
    }
    @GetMapping("/consume")
    public String consume() {
        Consumer consumerThread = new Consumer();
        consumerThread.init(this.kafkaProperties);
        consumerThread.start();
        LOG.info("Start to consume messages");
        // Wait for 180s and close the consumer. Modification can be made during actual execution.
        try {
            Thread.sleep(consumerThread.getThreadAliveTime());
        }
```

```
        } catch (InterruptedException e) {
            LOG.info("Occurred InterruptedException: ", e);
        } finally {
            consumerThread.close();
        }
        return String.format("Finished consume messages");
    }
}
```

**Produce** indicates the message production interface, **consume** indicates the message consumption interface, and **KafkaProperties** indicates the client parameter. The parameters need to be modified based on the actual service.

#### NOTE

The **KafkaProperties** parameter in the sample code can be configured in **springboot > kafka-examples > src > main > resources > application.properties** or manually compiled in the **application.properties** file in the sample running environment. If no default value is specified, the configuration is mandatory.

- **bootstrap.servers**: Broker address list of the Kafka cluster. The format is **IP address: Port, IP address: Port, IP address: Port**. In the IPv6 environment, add **[]** to the IP address, for example, **[1:2:3:4:5:6:7:8]:21007**.
- **security.protocol**: authentication protocol used by the Kafka client. The default value is **SASL\_PLAINTEXT**. The **SASL\_SSL** protocol is supported.
- **sasl.mechanism**: authentication mechanism used by the client. The default value is **PLAIN**.
- **manager\_username**: user of the cluster. The value must be enclosed in double quotation marks, for example, **"username"**.
- **manager\_password**: password of the cluster user. Passwords stored in plaintext pose security risks. Store them in ciphertext in configuration files or environment variables. The value must be enclosed in double quotation marks, for example, **"password"**.
- **topic**: name of the production and consumption topic. The default value is **example-metric1**.
- **isAsync**: whether to use asynchronous production. The default value is **false**.
- **consumer.alive.time**: lifetime of the consumer thread. The default value is **180000**, in milliseconds.
- **server.port**: port for accessing the Spring Boot server. The default value is **8080**, which can be customized.
- **server.address**: IP address bound to the Spring Boot server during the startup. The default value is **0.0.0.0**, which needs to be changed to the IP address of the node where Spring Boot is deployed.
- **is.security.mode**: whether the client connects to the cluster in security mode. The default value is **true**.

## Sample Running

### Step 1 Enable Kafka Plain authentication.

Log in to FusionInsight Manager, choose **Cluster > Services > Kafka** and choose **Configurations > All Configurations**. Search for **sasl.enabled.mechanisms**, change the value to **GSSAPI,PLAIN**, Click **Save**, click **Dashboard**, click **More**, and select **Restart Service** to make the configuration take effect.

### Step 2 Obtain the **huawei-spring-boot-kafka-examples-\*jar** package.

Find the POM file in the **springboot/kafka-examples** directory of the sample code, and use the Maven install tool to compile the Spring Boot sample in the

same directory as the POM file. A target folder is generated, and **huawei-spring-boot-kafka-examples-\*jar** is obtained from the **target** folder.

**Step 3** Create a directory on Windows or Linux as the running directory.

- Create the **D:\Spring** directory in the Windows OS and upload the **huawei-spring-boot-kafka-examples-\*jar** and **application.properties** files to the current directory.
- Create the **/opt/spring** directory on the Linux OS and upload the **huawei-spring-boot-kafka-examples-\*jar** and **application.properties** files to the current directory.

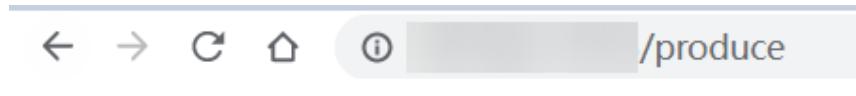

**Step 4** Run the corresponding command to start Spring Boot:

- In Windows, open the CLI in the **D:\Spring** directory and run the following command:  
**java -jar huawei-spring-boot-kafka-examples-\*jar**
- In Linux, run the following command in the **/opt/spring** directory:  
**java -jar huawei-spring-boot-kafka-examples-\*jar**

**Step 5** Produce data.

- For a Windows OS, open a browser and enter **http://IP address bound during Spring Boot startup:Port bound during Spring Boot startup/produce** to generate data to Broker, as shown in the following figure.

**Figure 1-201** Producing data

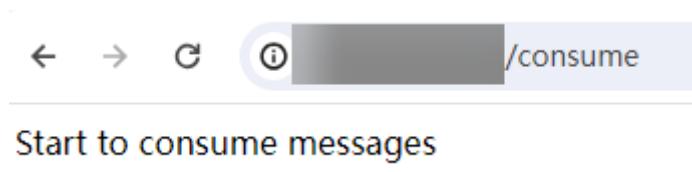

- For a Linux OS, run the **curl** command to access Spring Boot.  
**curl http://IP address bound during Spring Boot startup:Port bound during Spring Boot startup/produce**

**Step 6** Consume data.

- For a Windows OS, open a browser and enter **http://IP address bound during Spring Boot startup:Port bound during Spring Boot startup/consume** to consume data from broker, as shown in the following figure.

**Figure 1-202** Consuming data

- For a Linux OS, run the **curl** command to access Spring Boot.  
**curl http://IP address bound during Spring Boot startup:Port bound during Spring Boot startup/consume**

----End

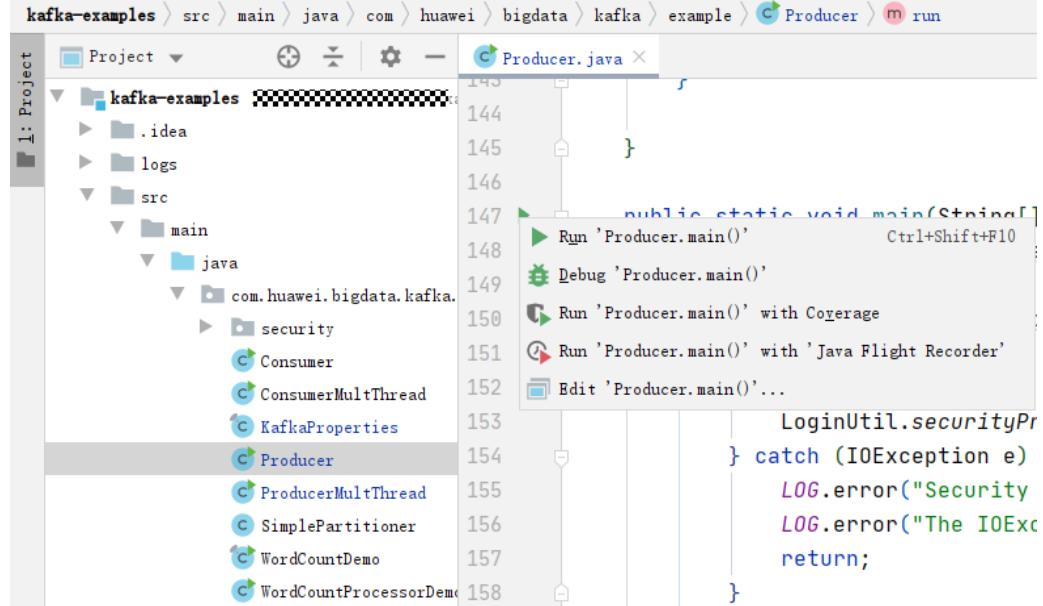

## 1.15.4 Application Commissioning

### 1.15.4.1 Commissioning an Application in Windows

#### Starting Producer

- Step 1** Ensure that the mappings between the host names and service IP addresses of all the hosts in the remote cluster are configured in the local **hosts** file.
- Step 2** Run **Producer.java** on IntelliJ IDEA, as shown in [Figure 1-203](#).

**Figure 1-203** Run **Producer.java** on IntelliJ IDEA

- Step 3** The console window appears. You can find that Producer is sending messages to the default topic (example-metric1). One piece of log is printed when every 10 messages are sent.

**Figure 1-204** Procedurer running window

```
[2019-06-12 10:31:37,865] INFO Updated cluster metadata version 2 to Cluster(id = 1cPugjn8Q4ernMH8RS_~JA, nodes = [187.
[2019-06-12 10:31:51,729] INFO Updated cluster metadata version 3 to Cluster(id = 1cPugjn8Q4ernMH8RS_~JA, nodes = [187.
[2019-06-12 10:31:53,140] INFO The Producer have send 10 messages. (com.huawei.bigdata.kafka.example.NewProducer)
[2019-06-12 10:31:54,516] INFO The Producer have send 20 messages. (com.huawei.bigdata.kafka.example.NewProducer)
[2019-06-12 10:31:55,906] INFO The Producer have send 30 messages. (com.huawei.bigdata.kafka.example.NewProducer)
[2019-06-12 10:31:57,299] INFO The Producer have send 40 messages. (com.huawei.bigdata.kafka.example.NewProducer)
[2019-06-12 10:31:58,686] INFO The Producer have send 50 messages. (com.huawei.bigdata.kafka.example.NewProducer)
[2019-06-12 10:32:00,070] INFO The Producer have send 60 messages. (com.huawei.bigdata.kafka.example.NewProducer)
```

----End

#### Starting Consumer

- Step 1** Run the **Consumer.java** file.

**Step 2 Click Run.** In the console window that appears, you can find that Producer starts after Consumer successfully starts, and then you can view messages received in real time.

**Figure 1-205 Consumer.java running window**

```
[2019-06-23 17:49:48,609] INFO [Consumer clientId=consumer-1, groupId=DemoConsumer] (Re-)joining group (org.apache.kafka.clients.consumer.internals.AbstractCoordinator)
[2019-06-23 17:49:51,865] INFO [Consumer clientId=consumer-1, groupId=DemoConsumer] Successfully joined group with generation 5 (org.apache.kafka.clients.consumer.internals.ConsumerCoordinator)
[2019-06-23 17:49:51,866] INFO [Consumer clientId=consumer-1, groupId=DemoConsumer] Setting newly assigned partitions [example-metric1-0, example-metric1-1] (org.apache.kafka.clients.consumer.internals.ConsumerCoordinator)
[2019-06-23 17:49:56,670] INFO [NewConsumerExample], Received message: (1, Message_1) at offset 188 (com.huawei.bigdata.kafka.example.NewConsumer)
[2019-06-23 17:49:56,670] INFO [NewConsumerExample], Received message: (5, Message_5) at offset 189 (com.huawei.bigdata.kafka.example.NewConsumer)
[2019-06-23 17:49:56,670] INFO [NewConsumerExample], Received message: (8, Message_8) at offset 190 (com.huawei.bigdata.kafka.example.NewConsumer)
[2019-06-23 17:49:56,670] INFO [NewConsumerExample], Received message: (9, Message_9) at offset 191 (com.huawei.bigdata.kafka.example.NewConsumer)
[2019-06-23 17:49:56,670] INFO [NewConsumerExample], Received message: (15, Message_15) at offset 192 (com.huawei.bigdata.kafka.example.NewConsumer)
[2019-06-23 17:49:56,670] INFO [NewConsumerExample], Received message: (18, Message_18) at offset 193 (com.huawei.bigdata.kafka.example.NewConsumer)
```

----End

## Starting Other Code Samples

The procedures for starting other code samples are similar to the procedures for starting Producer and Consumer in this section.

### 1.15.4.2 Commissioning an Application in Linux

#### Scenario

Run a sample program in Linux after code development is complete.

#### Procedure

**Step 1 Export a JAR package.**

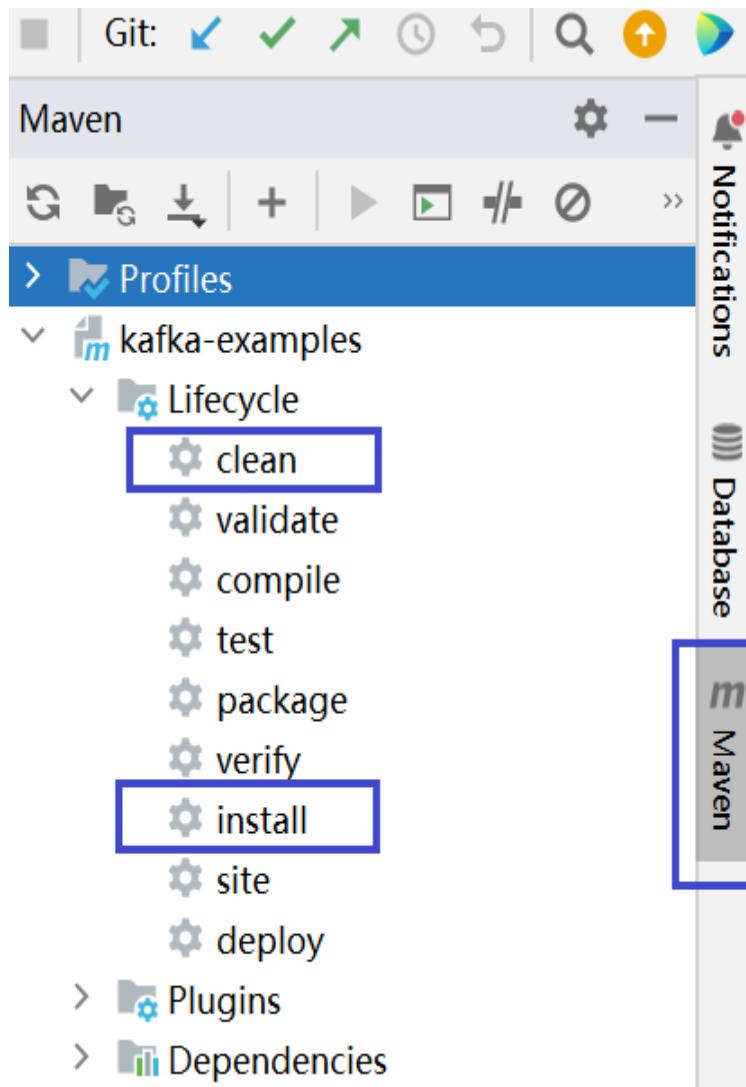

You can build a JAR file in either of the following ways:

- Method 1:

Choose **Maven** > *Sample projectname* > **Lifecycle** > **clean**, double click **clean** to run the **clean** command of Maven.

Choose **Maven** > *Sample project name* > **Lifecycle** > **install**, double click **install** to run the **install** command of Maven.

Figure 1-206 Maven tools: clean and install

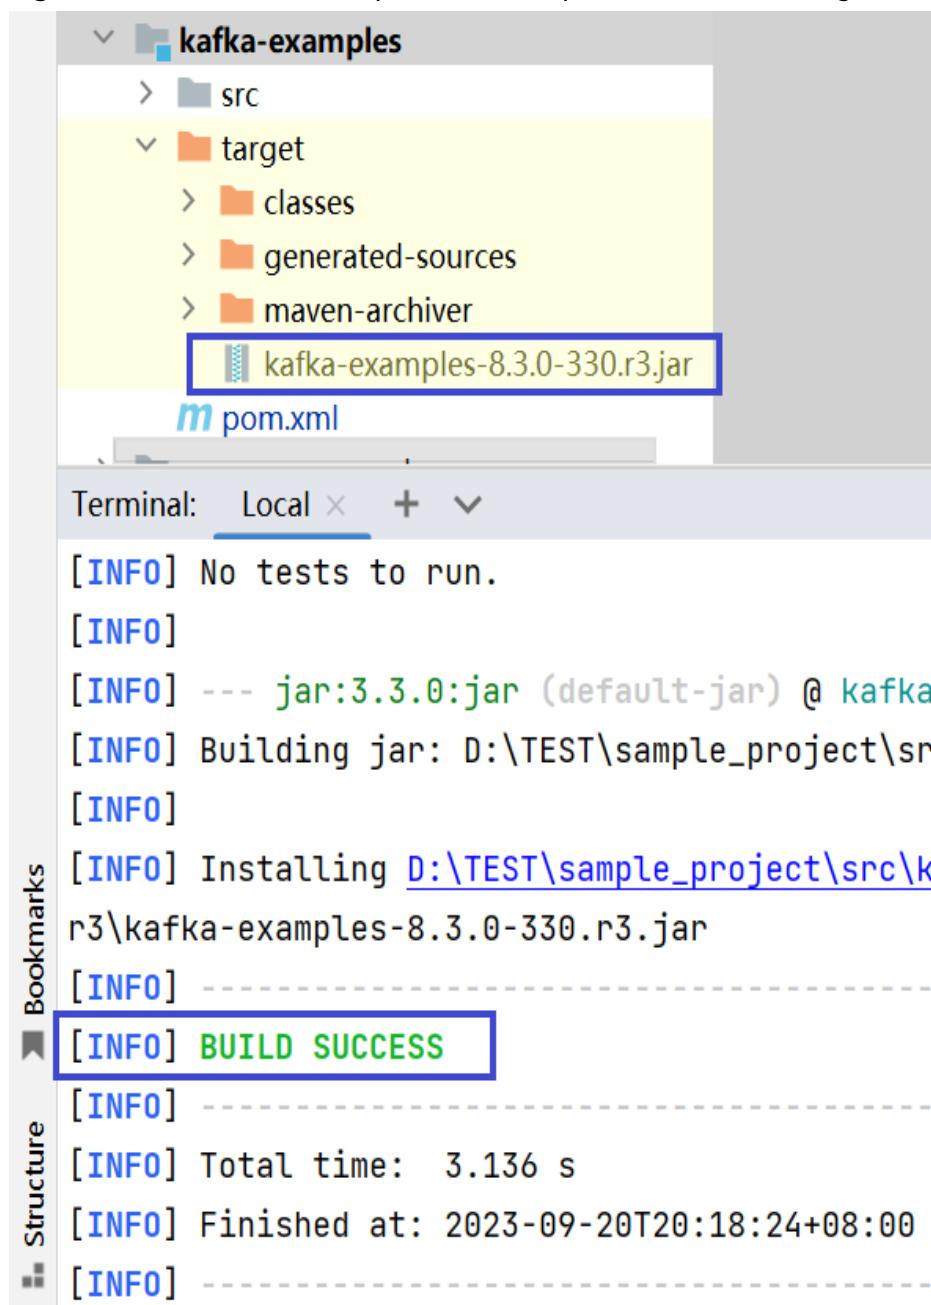

- Method 2: Go to the directory where the **pom.xml** file is located in the **Terminal** window in the lower part of the IDEA, and run the **mvn clean install** command to compile the **pom.xml** file.

Figure 1-207 Enter mvn clean compile in the IDEA Terminal text box.

The screenshot shows the IntelliJ IDEA terminal window with the command `mvn clean install` entered. The terminal output area is currently empty.

After the compilation is completed, the message "Build Success" is displayed, the **target** directory is generated, and the generated JAR file is stored in the **target** directory.

Figure 1-208 When the compilation is completed, the JAR file is generated.

- Step 2** Copy the JAR file generated during project compilation to the `/opt/hadoopclient/Kafka/kafka/libs` directory.
- Step 3** Copy all files in the `src/main/resources` directory of the IntelliJ IDEA project to the `src/main/resources` directory at the same level as the `lib` folder, that is, `/opt/hadoopclient/src/kafka-examples/src/main/resources`.
- Step 4** Ensure that the current user has read permission of all the files in the `src/main/resources` and `libs` folders in `/opt/hadoopclient/src/kafka-examples/`, jdk has been installed, and java environment variables are set. Then, run the command, for example, `java -cp /opt/hadoopclient/Kafka/kafka/libs/*:src/main/resources com.huawei.bigdata.kafka.example.Producer` to run the example project.

----End

## 1.15.4.3 Kafka Streams Sample Running Guide

### 1.15.4.3.1 High level Streams API Sample Usage Guide

1. Open sample code **WordCountDemo.java** in the IDE and change the following two variables to the machine-machine account name and keytab file that you apply for.

```
// Use the machine-machine account keytab file that you apply for.  
private static final String USER_KEYTAB_FILE = "Change it to the real-world keytab file name.;"  
// Use the machine-machine account name that you apply for.  
private static final String USER_PRINCIPAL = "Change it to the real-world username.;"
```

2. Use the Linux client to create the input and output topics. Ensure that the topic names are the same as those in the sample code, set the policy for clearing the output topic to compact, and run the sample code.

```
// source-topic name created by the user, that is, input topic  
private static final String INPUT_TOPIC_NAME = "streams-wordcount-input";  
// sink-topic name created by the user, that is, output topic  
private static final String OUTPUT_TOPIC_NAME = "streams-wordcount-output";
```

- Create the input topic:

```
kafka-topics.sh --create --bootstrap-server  
192.168.0.11:21007,192.168.0.12:21007,192.168.0.13:21007 --  
command-config config/client.properties --replication-factor 1 --  
partitions 1 --topic streams-wordcount-input
```

- Create the output topic:

```
kafka-topics.sh --create --bootstrap-server  
192.168.0.11:21007,192.168.0.12:21007,192.168.0.13:21007 --  
command-config config/client.properties --replication-factor 1 --  
partitions 1 --topic streams-wordcount-output --config  
cleanup.policy=compact
```

- Run sample code **WordCountDemo.java**. For details, see [Commissioning an Application in Windows](#) and [Commissioning an Application in Linux](#).

3. Use the Linux client to write messages and view the statistics result.

Run the **kafka-console-producer.sh** command to write messages to the input topic.

```
# kafka-console-producer.sh --broker-list 192.168.0.11:21007,192.168.0.12:21007,192.168.0.13:21007 --  
topic streams-wordcount-input --producer.config /opt/hadoopclient/Kafka/kafka/config/  
producer.properties  
>This is Kafka Streams test  
>test starting  
>now Kafka Streams is running  
>test end  
>
```

Run the **kafka-console-consumer.sh** command to consume data from the output topic and view the statistics result.

```
# kafka-console-consumer.sh --topic streams-wordcount-output --bootstrap-server  
192.168.0.11:21007,192.168.0.12:21007,192.168.0.13:21007 --consumer.config /opt/hadoopclient/  
Kafka/kafka/config/consumer.properties --from-beginning --property print.key=true --property  
print.value=true --property key.deserializer=org.apache.kafka.common.serialization.StringDeserializer --  
property value.deserializer=org.apache.kafka.common.serialization.LongDeserializer --formatter  
kafka.tools.DefaultMessageFormatter  
this 1  
is 6  
kafka 12  
streams 8  
test 8
```

```
test 9
starting 1
now 1
kafka 13
streams 9
is 7
running 1
test 10
end 1
```

#### 1.15.4.3.2 Low level Streams API Sample Usage Guide

1. Open sample code **WordCountProcessorDemo.java** in the IDE and change the following two variables to the machine-machine account name and keytab file that you apply for.

```
// Use the machine-machine account keytab file that you apply for.
private static final String USER_KEYTAB_FILE = "Change it to the real-world keytab file name";
// Use the machine-machine account name that you apply for.
private static final String USER_PRINCIPAL = "Change it to the real-world username. ";
```

2. Use the Linux client to create the input and output topics. Ensure that the topic names are the same as those in the sample code, set the policy for clearing the output topic to compact, and run the sample code.

```
// source-topic name created by the user, that is, input topic
private static final String INPUT_TOPIC_NAME = "streams-wordcount-processor-input";
```

```
// sink-topic name created by the user, that is, output topic
private static final String OUTPUT_TOPIC_NAME = "streams-wordcount-processor-output";
```

- Create the input topic:

```
kafka-topics.sh --create --bootstrap-server
192.168.0.11:21007,192.168.0.12:21007,192.168.0.13:21007 --
command-config config/client.properties --replication-factor 1 --
partitions 1 --topic streams-wordcount-processor-input
```

- Create the output topic:

```
kafka-topics.sh --create --bootstrap-server
192.168.0.11:21007,192.168.0.12:21007,192.168.0.13:21007 --
command-config config/client.properties --replication-factor 1 --
partitions 1 --topic streams-wordcount-processor-output --config
cleanup.policy=compact
```

- Run sample code **WordCountProcessorDemo.java**. For details, see [Commissioning an Application in Windows](#) and [Commissioning an Application in Linux](#).

3. Use the Linux client to write messages and view the statistics result.

Run the **kafka-console-producer.sh** command to write messages to the input topic.

```
# kafka-console-producer.sh --broker-list 192.168.0.11:21007,192.168.0.12:21007,192.168.0.13:21007 --
topic streams-wordcount-processor-input --producer.config /opt/hadoopclient/Kafka/kafka/config/
producer.properties
>This is Kafka Streams test
>now Kafka Streams is running
>test end
>
```

Run the **kafka-console-consumer.sh** command to consume data from the output topic and view the statistics result.

```
# kafka-console-consumer.sh --topic streams-wordcount-processor-output --bootstrap-server
192.168.0.11:21007,192.168.0.12:21007,192.168.0.13:21007 --consumer.config /opt/hadoopclient/
Kafka/kafka/config/consumer.properties --from-beginning --property print.key=true --property
print.value=true
```

```
is 1
kafka 1
streams 1
test 1
this 1
end 1
is 2
kafka 2
now 1
running 1
streams 2
test 2
this 1
```

#### 1.15.4.4 Sample Code Running Guide for the Kafka Token Authentication Mechanism

### Procedure

#### Kafka Server Configuration

**Step 1** On the FusionInsight Manager portal, choose **Cluster**, click the name of the desired cluster, and choose **Service > Kafka**. On the displayed page, click **Configuration** to go to the Kafka service configuration page.

**Step 2** Enable the token authentication mechanism.

Find the **delegation.token.master.key** parameter, which specifies the master key used to generate and verify tokens. Check whether the parameter has been configured. If it has been configured, and the value is not **null**, the token authentication mechanism has been enabled and does not need to be reconfigured. If the token authentication mechanism is configured again, the original token cannot be used.

The value of **delegation.token.master.key** can be customized, for example, **Tokentest**.

**Step 3** Specify the SASL authentication mechanism used for the service.

Find the **sasl.enabled.mechanisms** parameter and set it to **GSSAPI,SCRAM-SHA-256,SCRAM-SHA-512**. Use commas (,) to separate the three items.

**Step 4** Log in to a component using Scram.

Find the custom parameter **kafka.config.expandor** and set its name to **listener.name.sasl\_plaintext.scram-sha-512.sasl.jaas.config**. Set the value to **org.apache.kafka.common.security.scram.ScramLoginModule required;**

**Step 5** Log in to FusionInsight Manager and restart all Broker instances of the Kafka service.

#### Kafka Client Configuration

**Step 6** Generate a token for the user. For details, see "Kafka Token Authentication Mechanism Tool Usage" in *MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1)* in the *MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1)*.

#### Secondary Development Sample Code Project Configuration

The token authentication mechanism can be used for APIs. Therefore, you can configure the token authentication mechanism in **Producer()** and **Consumer()** of the secondary development sample.

**Step 7** Enable the token authentication mechanism.

Set **tokenauth** to **true** on the client.

**Step 8** Specify the SASL authentication mechanism used for the service.

Set **sasl.mechanism** to **SCRAM-SHA-512** on the client.

**Step 9** Configure the Java Authentication and Authorization Service (JAAS) file.

Configure **sasl.jaas.config** on the client as follows:

```
org.apache.kafka.common.security.scram.ScramLoginModule required  
username="TOKENID"  
password="HMAC";
```

**TOKENID** and **HMAC** are generated when tokens are generated in **Step 6**.

#### NOTE

For details about how to enable the token authentication mechanism, specify the SASL authentication mechanism for a specified service, and configure the JAAS file, see [Sample Code for Kafka Token Authentication](#).

**Step 10** Run the sample code based on the running environment. For details, see [Commissioning an Application in Windows](#) and [Commissioning an Application in Linux](#).

----End

## 1.15.5 More Information

### 1.15.5.1 External Interfaces

#### 1.15.5.1.1 Shell

1. Query the list of topics in current clusters.

```
bin/kafka-topics.sh --list --bootstrap-server <Kafka cluster IP  
address:21007> --command-config config/client.properties
```

2. Query the details of a topic.

```
bin/kafka-topics.sh --describe --bootstrap-server <Kafka cluster IP  
address:21007> --command-config config/client.properties --topic <Topic  
name>
```

3. Delete a topic (this operation can be performed by an administrator).

```
bin/kafka-topics.sh --delete --bootstrap-server <Kafka cluster IP  
address:21007> --command-config config/client.properties --topic <Topic  
name>
```

4. Create a topic (this operation can be performed by an administrator).

```
bin/kafka-topics.sh --create --bootstrap-server <Kafka cluster IP  
address:21007> --command-config config/client.properties --partitions 6  
--replication-factor 2 --topic <Topic name>
```

5. Assign permissions to the Consumer (this operation is performed by an administrator).

```
bin/kafka-acls.sh --authorizer-properties zookeeper.connect=<ZooKeeper cluster IP address:24002/kafka> --add --allow-principal User:<User name> --consumer --topic <Topic name> --group <Consumer group name>
```

```
bin/kafka-acls.sh --bootstrap-server <Kafka cluster IP address:21007> --command-config config/client.properties --add --allow-principal User:<User name> --consumer --topic <Topic name> --group <Consumer group name>
```

6. Assign permissions to the Producer (this operation is performed by an administrator).

```
bin/kafka-acls.sh --authorizer-properties zookeeper.connect=<ZooKeeper cluster IP address:24002/kafka> --add --allow-principal User:<User name> --producer --topic <Topic name>
```

```
bin/kafka-acls.sh --bootstrap-server <Kafka cluster IP address:21007> --command-config config/client.properties --add --allow-principal User:<User name> --producer --topic <Topic name>
```

7. Produce messages (this operation requires the producer permission of the desired topic).

```
bin/kafka-console-producer.sh --broker-list <KafkaCluster IP address:21007> --topic <Topic name> --producer.config config/producer.properties
```

8. Consume data (the producer permission of the topic is required).

```
bin/kafka-console-consumer.sh --topic <Topic name> --bootstrap-server <KafkaCluster IP address:21007> --consumer.config config/consumer.properties
```

For details, see the MapReduce Service (MRS) 3.3.1-LTS Shell O&M Commands (for Huawei Cloud Stack 8.3.1).

### 1.15.5.1.2 Java API

Versions of interfaces adopted by Kafka are consistent with those in Open Source Community. For details, see <https://kafka.apache.org/24/documentation.html>.

## Major Interfaces of a Producer

**Table 1-136** Major parameters of a Producer

| Parameter         | Description         | Remarks   |
|-------------------|---------------------|---|
| bootstrap.servers | Broker address list | The Producer creates connections with the Broker based on this parameter. |

| Parameter                  | Description                             | Remarks   |
|----------------------------|---|---|
| security.protocol          | Security protocol type                  | The Producer uses the security protocol of the type specified by this parameter. In security mode, only the SASL protocol is supported, so this parameter needs to be configured as <b>SASL_PLAINTEXT</b> . |
| sasl.kerberos.service.name | Service name                            | This parameter specifies the Kerberos user name used by the Kafka cluster for running. This parameter needs to be configured as <b>kafka</b> .  |
| key.serializer             | Serialization of key values in messages | This parameter specifies how to serialize the key values in messages.   |
| value.serializer           | Serialization of messages               | This parameter specifies how to serialize transmitted messages.   |

**Table 1-137** Major interface functions of a Producer

| Return Value                                | Interface Function                                   | Description  |
|---|--|--|
| java.util.concurrent.Future<RecordMetadata> | send(ProducerRecord<K, V> record)                    | Indicates a TX interface without a callback function. Generally, the get() function of Future is used for synchronous transmission.                                      |
| java.util.concurrent.Future<RecordMetadata> | send(ProducerRecord<K, V> record, Callback callback) | Indicates a TX interface with a callback function. Generally, this interface uses the callback function to process transmission results after asynchronous transmission. |

| Return Value | Interface Function  | Description   |
|--------------|---|---|
| void         | onCompletion(RecordMe tadata metadata,<br>Exception exception); | Indicates the interface method for a callback function. This method is used to process asynchronous transmission results. |

## Major Interfaces of a Consumer

**Table 1-138** Major parameters of a Consumer

| Parameter                  | Description                               | Remarks   |
|----------------------------|---|---|
| bootstrap.servers          | Broker address list                       | The Consumer creates connections with the Broker based on this parameter.   |
| security.protocol          | Security protocol type                    | The Consumer uses the security protocol of the type specified by this parameter. In security mode, only the SASL protocol is supported, so this parameter needs to be configured as <b>SASL_PLAINTEXT</b> . |
| sasl.kerberos.service.name | Service name                              | This parameter specifies the Kerberos user name used by the Kafka cluster for running. This parameter needs to be configured as <b>kafka</b> .  |
| key.deserializer           | Deserialization of key values in messages | This parameter specifies how to deserialize the key values in messages.   |
| value.deserializer         | Deserialization of messages               | This parameter specifies how to deserialize received messages.  |

**Table 1-139** Major interface functions of a Consumer

| Return Value         | Interface Function                                       | Description  |
|----------------------|--|--|
| void                 | close()  | Indicates the interface method for closing the Consumer. |
| void                 | subscribe(java.util.Collection<java.lang.String> topics) | Indicates the interface method for subscribing topics.   |
| ConsumerRecords<K,V> | poll(final Duration timeout)                             | Indicates the interface method for requesting messages.  |

### 1.15.5.1.3 Security Ports

1. By default, port 21007 is used for access to secure Kafka clusters, and port 21005 is used for access to normal Kafka clusters.
2. API supports access via both ports 21005 and 21007.

### 1.15.5.1.4 SSL Encryption Function Used by a Client

#### Prerequisites

1. Before enabling the SSL function on the client, ensure that the SSL service function on the server has been enabled (**ssl.mode.enable** of the server has been set to **true**).
2. The SSL function requires APIs. For details, see "Component Operation Guide > Using Kafka > Safety Instruction on Using Kafka" in MapReduce Service (MRS) 3.3.1-LTS User Guide (for Huawei Cloud Stack 8.3.1) in the MapReduce Service (MRS) 3.3.1-LTS Usage Guide (for Huawei Cloud Stack 8.3.1).

#### Description

- **SSL used by a Linux client**
  - a. Change the value of **security.protocol** in the **client installation directory/Kafka/kafka/config/producer.properties** and **client installation directory/Kafka/kafka/config/consumer.properties** directories to **SASL\_SSL** or **SSL**.
  - b. When using the Shell commands, enter a port ID corresponding to the protocol set in Step 1. For example, if **security.protocol** is set to **SASL\_SSL**, an SASL\_SSL protocol port ID is required, which is **21009** by default:  
**bin/kafka-console-producer.sh --broker-list </P address of a Kafka cluster:21009> --topic <Topic name> --producer.config config/producer.properties**  
**bin/kafka-console-consumer.sh --topic <Topic name> --bootstrap-server </P address of a Kafka cluster:21009> --consumer.config config/consumer.properties**

- **SSL used by a Windows client**
  - a. Download the Kafka client, decompress the client, and find the **ca.crt** file in the root directory.
  - b. Use the **ca.crt** file to generate the TrustStore file of the client.  
Run the **keytool -noprompt -import -alias myservercert -file ca.crt -keystore truststore.jks** command in the Java running environment.
  - c. Create the **conf** directory in the **kafka-examples** directory of the IntelliJ IDEA project (at the same level as the **src** directory), and copy the generated **truststore.jks** file to the **conf** directory. Add the following codes to the client codes (**initProperties ()** method of **Producer.java** and **Consumer.java**):

```
//truststore file address  
props.put("ssl.truststore.location", System.getProperty("user.dir") + File.separator + "conf" +  
File.separator + "truststore.jks");  
//truststore file password (password when the TrustStore file is generated)  
props.put("ssl.truststore.password", "XXXXX");
```
  - d. Change the values of **security.protocol** in **producer.properties** and **consumer.properties** in the **src/main/resources** directory of the IntelliJ IDEA project as required, and change the value of **bootstrap.servers** in the **producer.properties** file to ensure that the type of **security.protocol** matches with the port ID of **bootstrap.servers**.

### 1.15.5.2 FAQ

#### 1.15.5.2.1 Topic Authentication Fails During Sample Running and "example-metric1=TOPIC\_AUTHORIZATION\_FAILED" Is Displayed

##### Troubleshooting Procedure

- Step 1** Apply to the administrator for the access permission for the related topic.
- Step 2** If the topic cannot be logged in after the access permission is assigned, log in to FusionInsight Manager, go to the Kafka service configuration page, search for **allow.everyone.if.no.acl.found**, and change the value to **true**. Then, run the sample again.
- End

#### 1.15.5.2.2 Running the Producer.java Sample to Obtain Metadata Fails and "ERROR fetching topic metadata for topics..." Is Displayed, Even the Access Permission for the Related Topic

##### Troubleshooting Procedure

- Step 1** Find **bootstrap.servers** in **producer.properties** under the **conf** directory of the project, and check whether the IP address and port ID are configured correctly.
- If the IP address is inconsistent with the service IP address of the Kafka cluster, change the IP address to the correct one.
  - If the port ID is 21007 (security mode port), change it to 21005 (normal mode port).

**Step 2** Check whether network connections are correct to ensure that the current device can access the Kafka cluster normally.

----End

## 1.16 MapReduce Development Guide

### 1.16.1 Overview

#### 1.16.1.1 MapReduce Overview

##### MapReduce Introduction

Hadoop MapReduce is an easy-to-use parallel computing software framework. Applications developed based on MapReduce can run on large clusters consisting of thousands of servers and process data sets larger than 1 TB in fault tolerance (FT) mode.

A MapReduce job (application or job) splits an input data set into several data blocks which then are processed by Map tasks in parallel mode. The framework sorts output results of the Map task, sends the results to Reduce tasks, and returns a result to the client. Input and output information is stored in the Hadoop Distributed File System (HDFS). The framework schedules and monitors tasks and re-executes failed tasks.

MapReduce supports the following features:

- Large-scale parallel computing
- Large data set processing
- High FT and reliability
- Reasonable resource scheduling

#### 1.16.1.2 Basic Concepts

##### Hadoop shell command

Basic hadoop shell commands include commands that are used to submit MapReduce jobs, kill MapReduce jobs, and perform operations on the HDFS.

##### MapReduce InputFormat and OutputFormat

Based on the specified InputFormat, the MapReduce framework splits data sets, reads data, provides key-value pairs for Map tasks, and determines the number of Map tasks that are started in parallel mode. Based on the OutputFormat, the MapReduce framework outputs the generated key-value pairs to data in a specific format.

Map and Reduce tasks are running based on <key,value> pairs. In other words, the framework regards the input information about a job as a group of key-value pairs and outputs a group of key-value pairs. Two groups of key-value pairs may

be of different types. For a single Map or Reduce task, key-value pairs are processed in single-thread serial mode.

The framework needs to perform serialized operations on key and value classes. Therefore, the classes must support the Writable interface. To facilitate sorting operations, key classes must support the WritableComparable interface.

The input and output types of a MapReduce job are as follows:

(input) <k1,v1> -> Map -> <k2,v2> -> Summary data -> <k2, List(v2)> -> Reduce -> <k3,v3> (output)

## Job Core

In normal cases, an application only needs to inherit Mapper and Reducer classes and rewrite map and reduce methods to implement service logic. The map and reduce methods constitute the core of jobs.

## MapReduce WebUI

Allows users to monitor running or historical MapReduce jobs, view logs, and implement fine-grained job development, configuration, and optimization.

## Keytab file

A key file for storing user information. Applications use the key file for application programming interface (API) authentication on product.

## Reduce

A processing model function that merges all intermediate values associated with the same intermediate key.

## Shuffle

A process of outputting data from a Map task to a Reduce task.

## Map

A method used to map a group of key-value pairs into a new group of key-value pairs.

### 1.16.1.3 Development Process

All stages of the development process are shown and described in [Figure 1-209](#) and [Table 1-140](#).

Figure 1-209 MapReduce development process

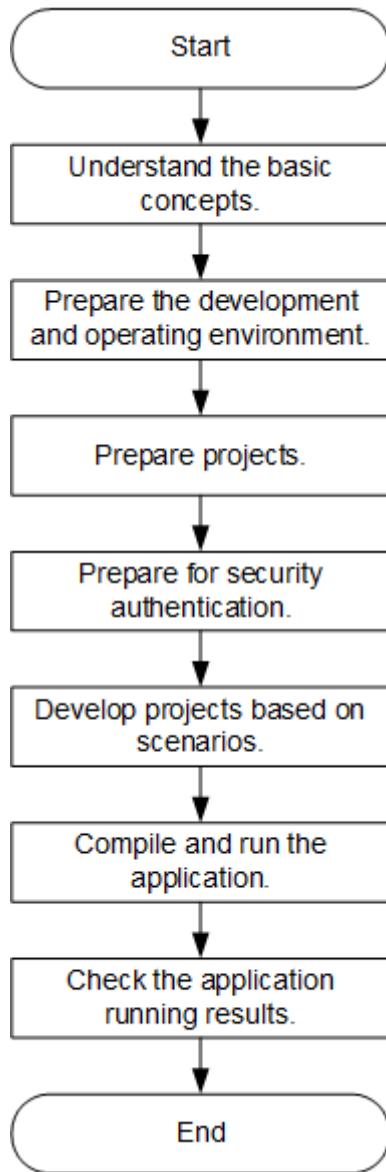

Table 1-140 Description of MapReduce development process

| Stage  | Description   | Reference   |
|--|---|---|
| Understand the basic concepts.                     | Before the application development, the basic concepts of MapReduce are required to be understood.  | <a href="#">Basic Concepts</a>                                      |
| Prepare the development and operating environment. | Use IntelliJ IDEA and configure the development environment based on the reference.<br>The running environment of MapReduce is the MapReduce client. Install and configure the client based on the reference. | <a href="#">Preparing for Development and Operating Environment</a> |

| Stage                                  | Description  | Reference  |
|--|--|--|
| Prepare projects                       | MapReduce provides sample projects in various scenarios. Sample projects can be imported for studying. Or you can create a new MapReduce project based on the reference. | <a href="#">Configuring and Importing Sample Projects</a><br><a href="#">Creating a New Project (Optional)</a> |
| Prepare for safety certification.      | If a safe cluster is used, the safety certification must be performed.   | <a href="#">Preparing the Authentication Mechanism</a>   |
| Develop projects based on scenarios.   | Provide the example project.<br>This helps users to learn about the programming interfaces of all Spark components quickly.  | <a href="#">Developing the Project</a>   |
| Compile and run the application.       | Users compile the developed application and deliver it for running based on the reference.   | <a href="#">Commissioning the Application</a>  |
| Check the application running results. | Application running results are stored in the directory specified by users. Users can also check the running results through the UI.                                     | <a href="#">Commissioning the Application</a>  |

## 1.16.2 Environment Preparation

### 1.16.2.1 Preparing for Development and Operating Environment

#### Preparing Development Environment

[Table 1-141](#) describes the environment required for application development.

**Table 1-141** Development environment

| Preparation Item | Description   |
|------------------|---|
| OS               | <ul style="list-style-type: none"><li>Development environment: Windows OS. Windows 7 or later is supported.</li><li>Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the running environment must be able to communicate with the cluster service plane network.</li></ul> |

| Preparation Item                             | Description   |
|--|---|
| IntelliJ IDEA installation and configuration | <p>It is the basic configuration for the development environment. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If the IBM JDK is used, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>  |
| Maven installation                           | Basic configuration of the development environment for project management throughout the lifecycle of software development.   |
| Installing JDK                               | <p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– Oracle JDK 1.8</li><li>– IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>– OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>– BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-jav 技术/8?topic=customization-matching-behavior-sslcontextgetinstance#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul> |
| Developer account preparation                | See <a href="#">Preparing a Developer Account</a> for configuration.  |
| 7-zip  | Used to decompress <b>.zip</b> and <b>.rar</b> packages. The 7-Zip 16.04 is supported.  |

| Preparation Item          | Description   |
|---------------------------|---|
| checkJarsCrossPlatform.sh | In a cluster with both the x86 and TaiShan platforms, if a third-party JAR package not supported on the x86 and TaiShan platforms is required in the MapReduce program, you need to check whether this JAR package supports cross-platform deployment. If it does not support, resolve this problem following instructions provided in <a href="#">Cross-Platform Compatibility of JAR Packages</a> . |

## Preparing an Operating Environment

During application development, you need to prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning program; configure the network connection, and commission the program in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#). In the upper right corner of the home page, click **Download Client**. Set **Select Client Type** to **Complete Client**. Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file. Then, decompress **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.
  - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Yarn\config** and obtain the cluster configuration file. The configuration file will be imported to the configuration file directory (usually the **conf** folder) of the MapReduce sample project.
  - c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

### NOTE

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.

- If you use the Linux environment for commissioning, you need to prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client on the node. For example, the client installation directory is **/opt/hadoopclient**.  
Ensure that the difference between the client time and the cluster time is less than 5 minutes.  
For details about how to install a cluster client, see [Installing a Client](#).
  - b. **Accessing FusionInsight Manager of an MRS Cluster**. Download the cluster client software package to the active management node and decompress it. Then, log in to the active management node as user **root**. Go to the decompression path of the cluster client and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Yarn\config** directory to the **conf** directory where the compiled JAR package is stored for subsequent commissioning, for example, **/opt/hadoopclient/conf**.  
For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following command:  

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Yarn/config/* root@IP address of the client node:/opt/  
hadoopclient/conf
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory.
  - c. Check the network connection of the client node.  
During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client resides, to ensure that the local host can communicate with each host in the cluster.

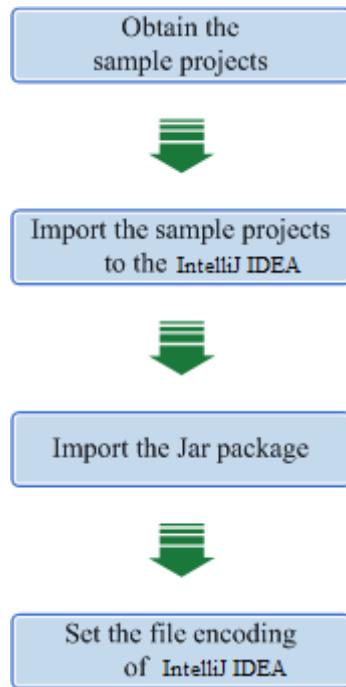

## 1.16.2.2 Configuring and Importing Sample Projects

### Scenario

MapReduce provides sample projects for multiple scenarios to help you quickly learn MapReduce projects.

The procedure of importing MapReduce example code is described as follows: [Figure 1-210](#) shows the procedure.

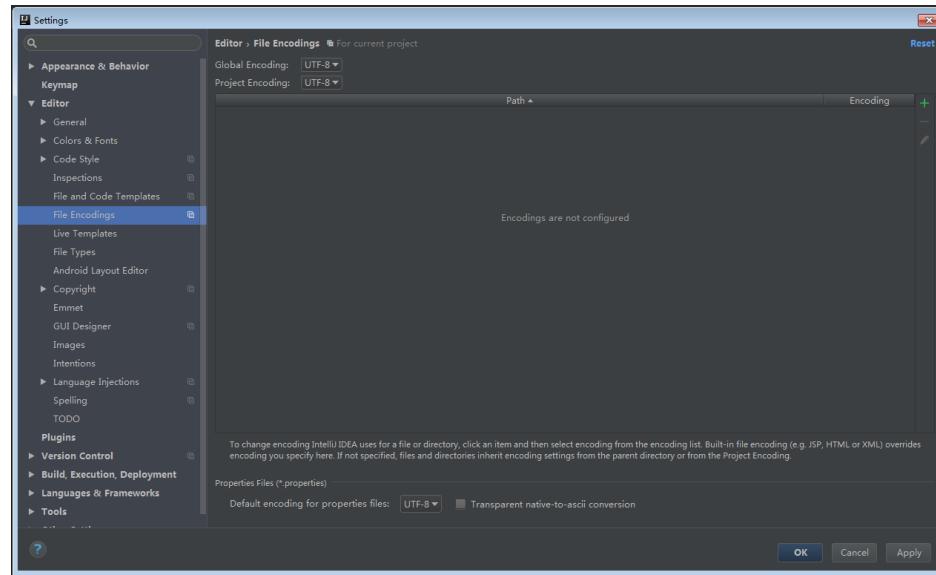

Figure 1-210 Procedure of importing sample projects

## Procedure

- Step 1** Obtain the sample project folder **mapreduce-example-security** in the **src** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Copy the **user.keytab** and **krb5.conf** files obtained during [Preparing a Developer Account](#) and the cluster configuration file obtained during running environment preparation in [Preparing an Operating Environment](#) to the **conf** directory of the sample project.
- Step 3** Import the sample project to the IntelliJ IDEA development environment.
  1. Open IntelliJ IDEA and choose **File > Open**.
  2. Choose the directory of the example project **mapreduce-example-security**. Click **OK**.
- Step 4** Set the IntelliJ IDEA text file coding format to prevent garbled characters.
  1. On the IntelliJ IDEA menu bar, choose **File > Settings**.  
The **Settings** window is displayed.
  2. Choose **Editor > File Encodings** from the navigation tree. In the "Global Encoding" and "Project Encodings" area, set the value to **UTF-8**, click **Apply**, and click **OK**, as shown in [Figure 1-211](#)

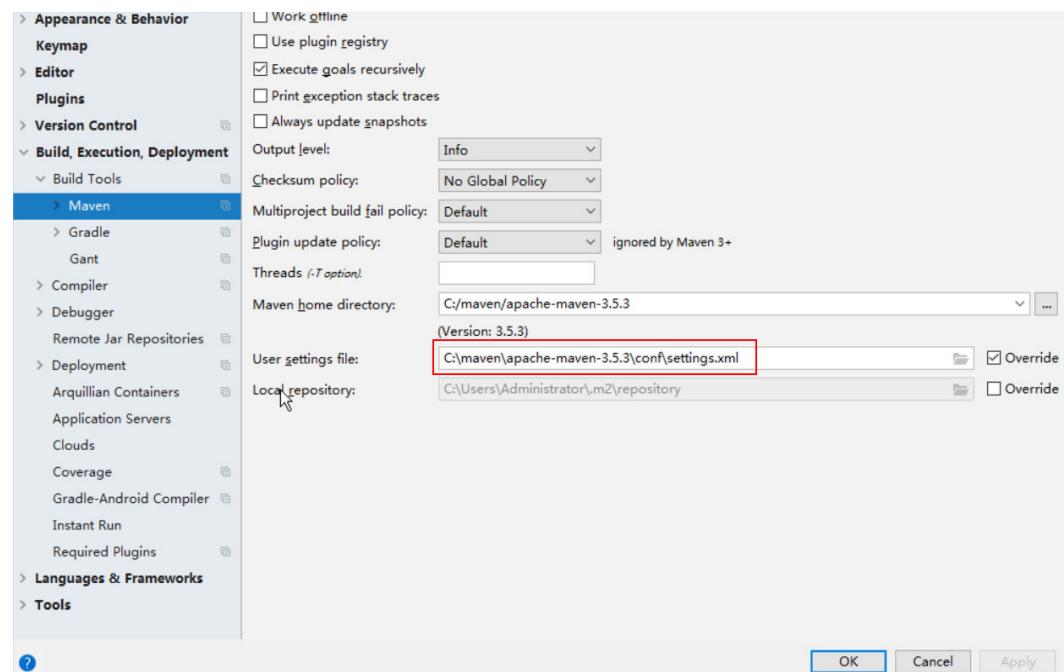

Figure 1-211 Setting the IntelliJ IDEA coding format

**Step 5** Add the configuration information such as the address of the open-source image repository to the **setting.xml** configuration file of the local Maven by referring to [Configuring Huawei Open-Source Mirrors](#).

On the IntelliJ IDEA page, select **File > Settings > Build, Execution, Deployment > Build Tools > Maven**, select **Override** next to **User settings file**, and change the value of **User settings file** to the directory where the **settings.xml** file is stored. Ensure that the directory is **<Local Maven installation directory>\conf\settings.xml**.

Figure 1-212 Directory for storing the **settings.xml** file

----End

## References

The dependency packages mapped to the sample projects of MapReduce are as follows:

- MapReduce statistics sample project  
No additional jars.
- MapReduce accessing multi-components sample project

 NOTE

- If you want to use the multi-component accessing sample project after importing a sample project, ensure that the Hive and HBase services have been installed in the cluster.
- If you do not use the multi-components accessing sample project, you can ignore errors about the multi-components accessing sample project as long as the compilation of the statistics sample project is not affected. Otherwise, delete the files about the multi-components accessing sample project after importing the sample projects.

### 1.16.2.3 Creating a New Project (Optional)

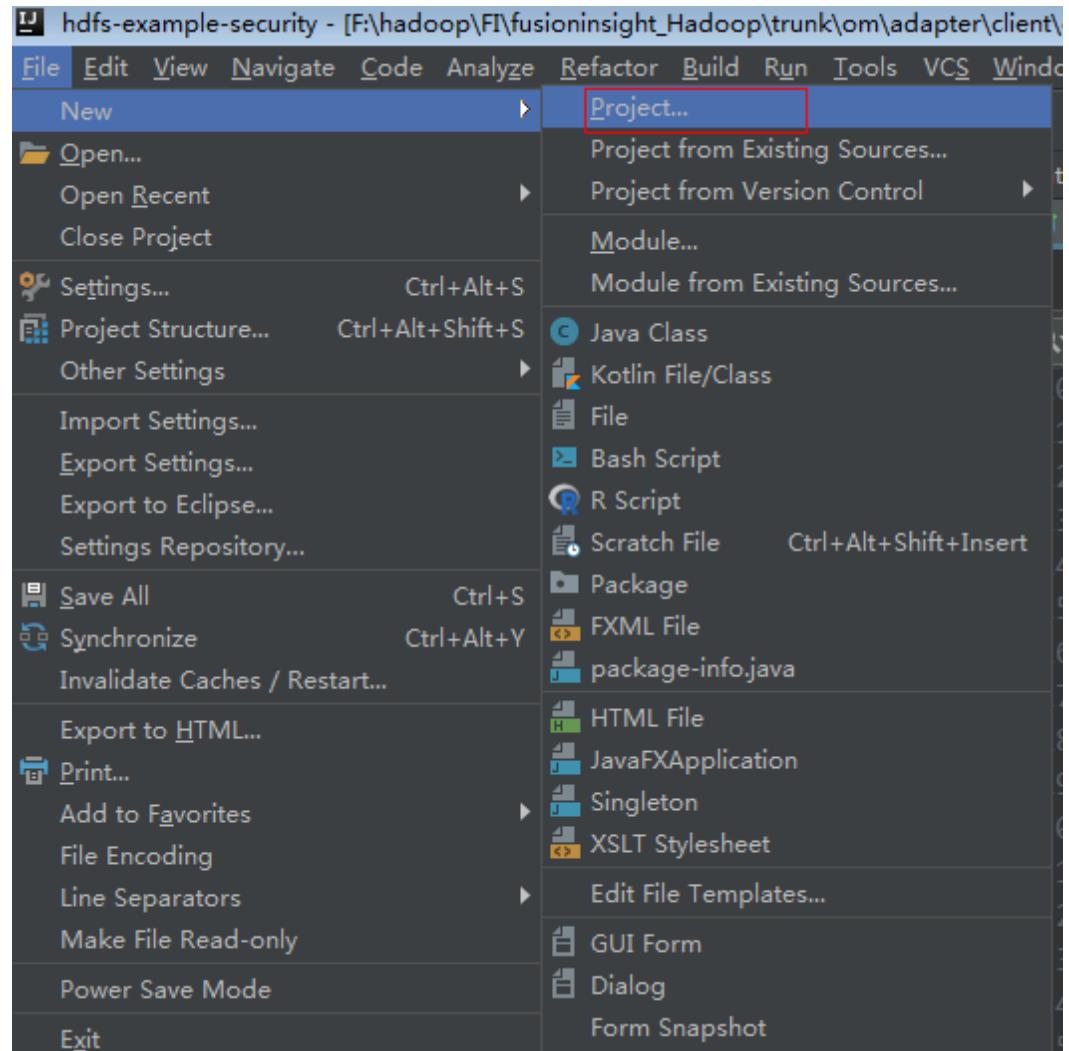

#### Scenario

Apart from importing MapReduce sample projects, you can also create a new MapReduce project using IntelliJ IDEA.

#### Procedure

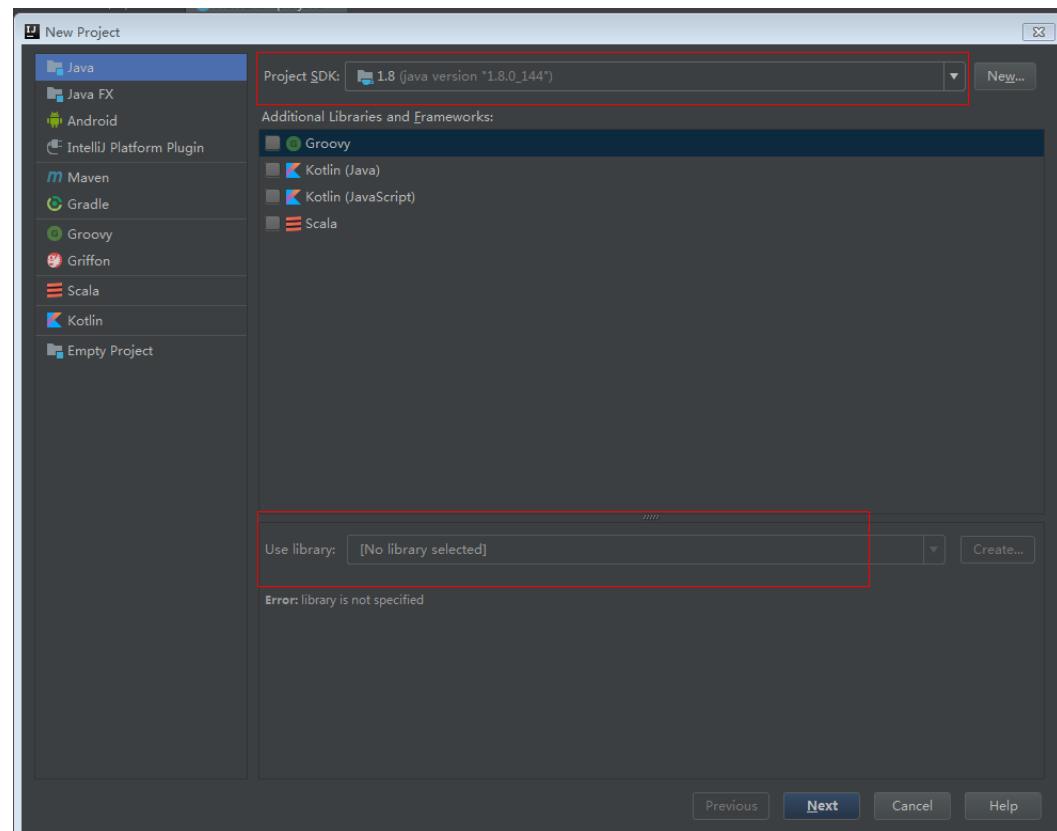

**Step 1** Open IntelliJ IDEA and choose **File > New > Project**, as shown in [Figure 1-213](#).

Figure 1-213 Creating a project

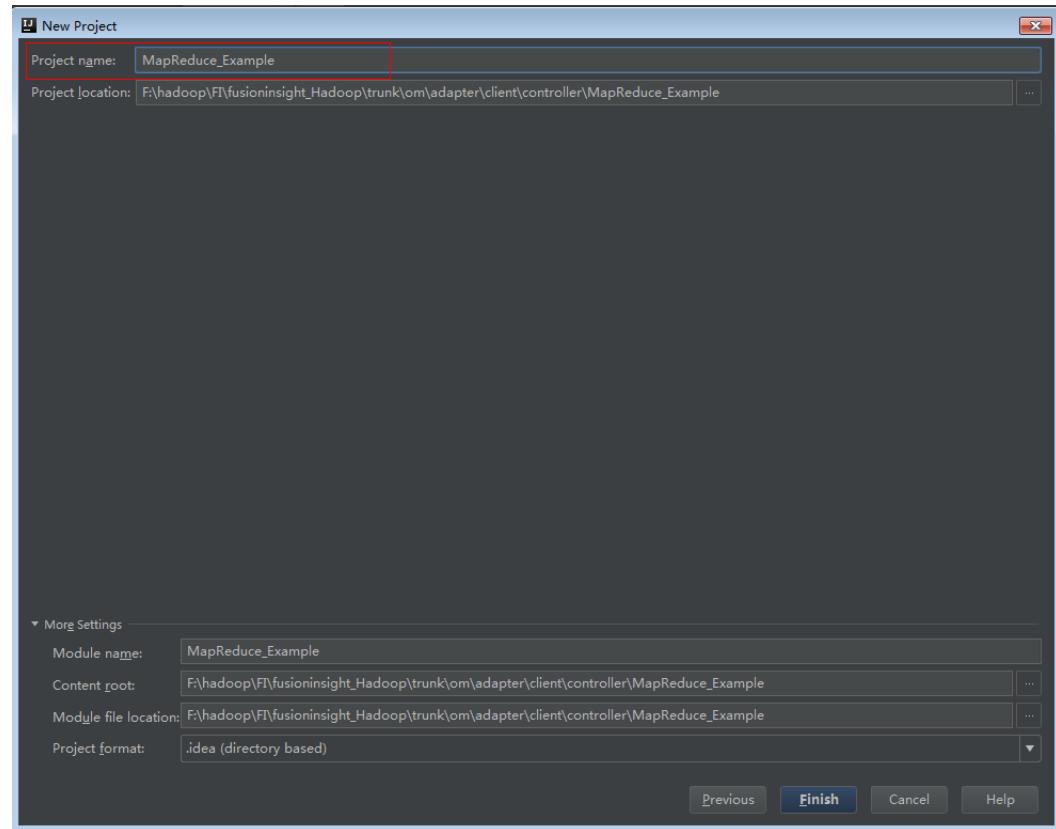

**Step 2** On the **New Project** page, select **Java**, and then configure the JDK and other Java libraries required by the project. As shown in the following figure. After the configuration is complete, click **Next**.

Figure 1-214 Configuring sdk information required by the project

**Step 3** Enter the name of the new project in the dialog box. Click **Finish**.

Figure 1-215 Enter the project name

----End

#### 1.16.2.4 Preparing the Authentication Mechanism

##### Scenario

In a safe cluster environment, the communication among components cannot be a simple communication. Components must be authorized by each other before the communication to ensure the security of the communication.

When users are developing the MapReduce application, the MapReduce is required to interwork with Yarn and HDFS in certain scenarios. Therefore, security authentication code must be written into the MapReduce application to ensure that the MapReduce application can run properly.

Two security authentication methods are described as follows:

- Authentication by running command lines:

Before submitting the MapReduce application for running, run the following command in the MapReduce client to obtain authentication:

***kinit component service user***

- Authentication by adding code:

Authenticate by obtaining principal and keytab files of the client.

## MapReduce Security Authentication Code

The security authentication is completed by calling the LoginUtil class.

In the code of the **FemaleInfoCollector** class in the **com.huawei.bigdata.mapreduce.examples** package of the sample project **MapReduce**, test@<system domain name>, user.keytab, and krb5.conf are examples. In practice, contact the admin to obtain your keytab and krb5.conf files and place them in the conf directory.):

```
public static final String PRINCIPAL= "test@<system domain name>";
public static final String KEYTAB =
FemaleInfoCollector.class.getClassLoader().getResource("user.keytab").getPath();
public static final String KRB =
FemaleInfoCollector.class.getClassLoader().getResource("krb5.conf").getPath();
...
// Security login
LoginUtil.login(PRINCIPAL, KEYTAB, KRB, conf);
```

## 1.16.3 Developing the Project

### 1.16.3.1 MapReduce Statistics Sample Project

#### 1.16.3.1.1 Typical Scenarios

##### Scenario

Develop a MapReduce application to perform the following operations on logs about dwell durations of netizens for shopping online:

- Collect statistics on female netizens who dwell on online shopping for more than 2 hours at a weekend.
- The first column in the log file records names, the second column records genders, and the third column records the dwell duration in the unit of minute. Three attributes are separated by commas (,).

**log1.txt:** logs collected on Saturday

```
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,5
CaiXuyu,female,50
Liyuan,male,20
FangBo,female,50
LiuYang,female,20
YuanJing,male,10
GuoYijun,male,50
CaiXuyu,female,50
FangBo,female,60
```

**log2.txt:** logs collected on Sunday

```
LiuYang,female,20
YuanJing,male,10
CaiXuyu,female,50
FangBo,female,50
GuoYijun,male,5
CaiXuyu,female,50
Liyuan,male,20
CaiXuyu,female,50
```

```
FangBo,female,50  
LiuYang,female,20  
YuanJing,male,10  
FangBo,female,50  
GuoYijun,male,50  
CaiXuyu,female,50  
FangBo,female,60
```

## Data Preparation

Save log files in the Hadoop distributed file system (HDFS).

1. Create text files input\_data1.txt and input\_data2.txt on the Linux operating system, and copy log1.txt to input\_data1.txt and log2.txt to input\_data2.txt.
2. Create **/tmp/input** on the HDFS, and run the following commands to upload input\_data1.txt and input\_data2.txt to **/tmp/input**:
  - a. On the Linux client, run **hdfs dfs -mkdir /tmp/input**.
  - b. On the Linux client, run **hdfs dfs -put local\_file\_path /tmp/input**.

## Development Idea

Collects the information about female netizens who spend more than 2 hours in online shopping on the weekend from the log files.

The process includes:

- Read the source file data.
- Filter the data information about the time that female netizens spend online.
- Aggregate the total time that each female netizen spends online.
- Filter the information about female netizens who spend more than 2 hours online.

### 1.16.3.1.2 Example Code

#### Function

Collect statistics on female netizens who dwell on online shopping for more than 2 hours at a weekend.

The operation is performed in three steps:

- Filter the online time of female netizens in original files using the CollectionMapper class inherited from the Mapper abstract class.
- Count the online time of each female netizen, and output information about female netizens who dwell online for more than 2 hours using the CollectionReducer class inherited from the Reducer abstract class.
- The main method creates a MapReduce job and submits the MapReduce job to the Hadoop cluster.

#### Example Code

The following code snippets are used as an example. For complete code, see the com.huawei.bigdata.mapreduce.examples.FemaleInfoCollector class.

Example 1: The CollectionMapper class defines the map() and setup() methods of the Mapper abstract class.

```
public static class CollectionMapper extends  
    Mapper<Object, Text, Text, IntWritable> {  
  
    // Delimiter.  
    String delim;  
    // Filter sex.  
    String sexFilter;  
  
    // Name.  
    private Text nameInfo = new Text();  
  
    // Output <key,value> must be serialized.  
    private IntWritable timeInfo = new IntWritable(1);  
  
    /**  
     * Distributed computing  
     *  
     * @param key Object: location offset of the source file.  
     * @param value Text: a row of characters in the source file.  
     * @param context Context: output parameter.  
     * @throws IOException , InterruptedException  
     */  
    public void map(Object key, Text value, Context context)  
        throws IOException, InterruptedException  
    {  
  
        String line = value.toString();  
  
        if (line.contains(sexFilter))  
        {  
  
            // A character string that has been read.  
            String name = line.substring(0, line.indexOf(delim));  
            nameInfo.set(name);  
            // Obtain the dwell duration.  
            String time = line.substring(line.lastIndexOf(delim) + 1,  
                line.length());  
            timeInfo.set(Integer.parseInt(time));  
  
            // The Map task outputs a key-value pair.  
            context.write(nameInfo, timeInfo);  
        }  
    }  
    /**  
     * map use to init.  
     *  
     * @param context Context.  
     */  
    public void setup(Context context) throws IOException,  
        InterruptedException  
    {  
  
        // Obtain configuration information using Context.  
        delim = context.getConfiguration().get("log.delimiter", ",");  
  
        sexFilter = delim  
            + context.getConfiguration()  
            .get("log.sex.filter", "female") + delim;  
    }  
}
```

Example 2: The CollectionReducer class defines the reduce() method of the Reducer abstract class.

```

public static class CollectionReducer extends
    Reducer<Text, IntWritable, Text, IntWritable>
{
    // Statistical results.
    private IntWritable result = new IntWritable();

    // Total time threshold.
    private int timeThreshold;

    /**
     * @param key Text : key after Mapper.
     * @param values Iterable : all statistical results with the same key.
     * @param context Context
     * @throws IOException , InterruptedException
     */
    public void reduce(Text key, Iterable<IntWritable> values,
                      Context context) throws IOException, InterruptedException
    {
        int sum = 0;
        for (IntWritable val : values) {
            sum += val.get();
        }

        // No results are output if the time is less than the threshold.
        if (sum < timeThreshold)
        {
            return;
        }
        result.set(sum);

        // In the output information, key indicates netizen information, and value indicates the total online
        // time of the netizen.
        context.write(key, result);
    }

    /**
     * The setup() method is invoked for only once before the map() method or reduce() method.
     *
     * @param context Context
     * @throws IOException , InterruptedException
     */
    public void setup(Context context) throws IOException,
                           InterruptedException
    {
        // Context obtains configuration information.
        timeThreshold = context.getConfiguration().getInt(
            "log.time.threshold", 120);
    }
}

```

**Example 3:** Use the main() method to create a job, set parameters, and submit the job to the hadoop cluster.

```

public static void main(String[] args) throws Exception {
    // Initialize environment variables.
    Configuration conf = new Configuration();

    // Security login.
    LoginUtil.login(PRINCIPAL, KEYTAB, KRB, conf);

    // Obtain input parameters.
    String[] otherArgs = new GenericOptionsParser(conf, args)
        .getRemainingArgs();
    if (otherArgs.length != 2) {
        System.err.println("Usage: collect female info <in> <out>");
        System.exit(2);
    }
}

```

```
// Initialize the job object.  
@SuppressWarnings("deprecation")  
Job job = new Job(conf, "Collect Female Info");  
job.setJarByClass(FemaleInfoCollector.class);  
  
// Set map and reduce classes to be executed, or specify the map and reduce classes using configuration  
files.  
job.setMapperClass(CollectionMapper.class);  
job.setReducerClass(CollectionReducer.class);  
  
// Set the Combiner class. The combiner class is not used by default. Classes same as the reduce class are  
used.  
// Exercise caution when using the Combiner class. You can specify it using configuration files.  
job.setCombinerClass(CollectionReducer.class);  
  
// Set the output type of the job.  
job.setOutputKeyClass(Text.class);  
job.setOutputValueClass(IntWritable.class);  
FileInputFormat.addInputPath(job, new Path(otherArgs[0]));  
FileOutputFormat.setOutputPath(job, new Path(otherArgs[1]));  
  
// Submit the job to a remote environment for execution.  
System.exit(job.waitForCompletion(true) ? 0 : 1);  
}
```

Example 4: CollectionCombiner class combines the mapped data on the map side to reduce the amount of data transmitted from map to reduce.

```
/**  
 * Combiner class  
 */  
public static class CollectionCombiner extends  
Reducer<Text, IntWritable, Text, IntWritable> {  
  
    // Intermediate statistical results  
    private IntWritable intermediateResult = new IntWritable();  
  
    /**  
     * @param key    Text : key after Mapper  
     * @param values Iterable : all results with the same key in this map task  
     * @param context Context  
     * @throws IOException , InterruptedException  
     */  
    public void reduce(Text key, Iterable<IntWritable> values,  
Context context) throws IOException, InterruptedException {  
int sum = 0;  
for (IntWritable val : values) {  
sum += val.get();  
}  
  
intermediateResult.set(sum);  
  
// In the output information, key indicates netizen information,  
// and value indicates the total online time of the netizen in this map task.  
context.write(key, intermediateResult);  
}  
}
```

### 1.16.3.2 MapReduce Accessing Multi-Component Example Project

### 1.16.3.2.1 Instance

#### Scenario

The sample project illustrates how to compile MapReduce jobs to visit multiple service components in HDFS, HBase, and Hive, helping users to understand key actions such as certificating and configuration loading.

The logic of the sample project is as follows:

The input data is HDFS text file and the input file is **log1.txt**.

```
YuanJing,male,10  
GuoYijun,male,5
```

Map:

1. Obtain one row of the input data and extract the user name.
2. Query one piece of data from HBase.
3. Query one piece of data from Hive.
4. Combine the data queried from HBase and that from Hive as the output of Map as the output of Map.

Reduce:

1. Obtain the last piece of data from Map output.
2. Import the data to HBase.
3. Save the data to HDFS.

#### Data Planning

1. Create an HDFS data file.
  - a. Create a text file named **data.txt** in the Linux-based HDFS and copy the content of **log1.txt** to **data.txt**.
  - b. Run the following commands to create a directory **/tmp/examples/multi-components/mapreduce/input/** and copy the **data.txt** to the directory:
    - i. **hdfs dfs -mkdir -p /tmp/examples/multi-components/mapreduce/input/**
    - ii. **hdfs dfs -put data.txt /tmp/examples/multi-components/mapreduce/input/**
2. Create a HBase table and insert data into it.
  - a. Run the **source bigdata\_env** command on a Linux-based HBase client and run the **hbase shell** command.
  - b. Run the **create 'table1', 'cf'** command in the HBase shell to create table1 with column family cf.
  - c. Run the **put 'table1', '1', 'cf:cid', '123'** command to insert data whose rowkey is 1, column name is **cid**, and data value is **123**.
  - d. Run the **quit** command to exit the table.
3. Create a Hive table and load data to it.

- a. Run the **beeline** command on a Linux-based Hive client.
  - b. In the Hive beeline interaction window, run the **CREATE TABLE person(name STRING, gender STRING, stayTime INT) ROW FORMAT DELIMITED FIELDS TERMINATED BY ',' stored as textfile;** command to create data table **person** with three fields.
  - c. In the Hive beeline interaction window, run the **LOAD DATA INPATH '/tmp/examples/multi-components/mapreduce/input/' OVERWRITE INTO TABLE person;** command to load data files to the **person** table.
  - d. Run **!q** to exit the table.
4. The data of HDFS is cleared in the preceding step. Therefore, perform 1 again.

### 1.16.3.2.2 Example Code

## Function

The functions of the sample project are as follows:

- Collect the name information from HDFS source files, query and combine data of HBase and Hive using the MultiComponentMapper class inherited from the Mapper abstract class.
- Obtain the last piece of mapped data and output to HBase and HDFS, using the MultiComponentMapper class inherited from the Reducer abstract class.
- The main function creates a MapReduce job and submits the MapReduce job to Hadoop clusters.

## Example Code

For details about code, see the class  
`com.huawei.bigdata.mapreduce.examples.MultiComponentExampl`.

Example code of the map function used by MultiComponentMapper class to define the Mapper abstract class.

```
private static class MultiComponentMapper extends Mapper<Object, Text, Text, Text> {  
    Configuration conf;  
  
    @Override protected void map(Object key, Text value, Context context) throws IOException,  
    InterruptedException {  
        conf = context.getConfiguration();  
  
        // for components that depend on Zookeeper, need provide the conf of jaas and krb5  
        // Notice, no need to login again here, will use the credentials in main function  
        String krb5 = "krb5.conf";  
        String jaas = "jaas_mr.conf";  
        // These files are uploaded at main function  
        File jaasFile = new File(jaas);  
        File krb5File = new File(krb5);  
        System.setProperty("java.security.auth.login.config", jaasFile.getCanonicalPath());  
        System.setProperty("java.security.krb5.conf", krb5File.getCanonicalPath());  
        System.setProperty("zookeeper.sasl.client", "true");  
  
        LOG.info("UGI :" + UserGroupInformation.getCurrentUser());  
  
        String name = "";  
        String line = value.toString();  
        if (line.contains("male")) {
```

```
// A character string that has been read
    name = line.substring(0, line.indexOf(","));
}
// 1. read from HBase
String hbaseData = readHBase();

// 2. read from Hive
String hiveData = readHive(name);

// The Map task outputs a key-value pair.
context.write(new Text(name), new Text("hbase:" + hbaseData + ", hive:" + hiveData));
}
```

Example code of the readHBase function.

```
private String readHBase() {
    String tableName = "table1";
    String columnFamily = "cf";
    String hbaseKey = "1";
    String hbaseValue;

    Configuration hbaseConfig = HBaseConfiguration.create(conf);
    org.apache.hadoop.hbase.client.Connection conn = null;
    try {
        // Create a HBase connection
        conn = ConnectionFactory.createConnection(hbaseConfig);
        // get table
        Table table = conn.getTable(Table.Name.valueOf(tableName));
        // Instantiate a Get object.
        Get get = new Get(hbaseKey.getBytes());
        // Submit a get request.
        Result result = table.get(get);
        hbaseValue = Bytes.toString(result.getValue(columnFamily.getBytes(), "cid".getBytes()));

        return hbaseValue;
    } catch (IOException e) {
        LOG.warn("Exception occur ", e);
    } finally {
        if (conn != null) {
            try {
                conn.close();
            } catch (Exception e1) {
                LOG.error("Failed to close the connection ", e1);
            }
        }
    }
    return "";
}
```

Example of the readHive function.

```
private String readHive(String name) throws IOException {
    //Load the configuration file
    Properties clientInfo = null;
    String userdir = System.getProperty("user.dir") + "/";
    InputStream fileInputStream = null;
    try {
        clientInfo = new Properties();
        String hiveclientProp = userdir + "hiveclient.properties";
        File propertiesFile = new File(hiveclientProp);
        fileInputStream = new FileInputStream(propertiesFile);
        clientInfo.load(fileInputStream);
    } catch (Exception e) {
        throw new IOException(e);
    } finally {
        if (fileInputStream != null) {
            fileInputStream.close();
        }
    }
}
```

```
        }
    }
String zkQuorum = clientInfo.getProperty("zk.quorum");
String zooKeeperNamespace = clientInfo.getProperty("zooKeeperNamespace");
String serviceDiscoveryMode = clientInfo.getProperty("serviceDiscoveryMode");
// Read this carefully:
// MapReduce can only use Hive through JDBC.
// Hive will submit another MapReduce Job to execute query.
// So we run Hive in MapReduce is not recommended.
final String driver = "org.apache.hive.jdbc.HiveDriver";

String sql = "select name,sum(stayTime) as " + "stayTime from person where name = '" + name + "'"
group by name";

StringBuilder sBuilder = new StringBuilder("jdbc:hive2://").append(zkQuorum).append("/");
// in map or reduce, use 'auth=delegationToken'
sBuilder
.append(";serviceDiscoveryMode=")

.append(serviceDiscoveryMode)
.append(";zooKeeperNamespace=")
.append(zooKeeperNamespace)
.append(";auth=delegationToken;");
String url = sBuilder.toString();
Connection connection = null;
PreparedStatement statement = null;
ResultSet resultSet = null;
try {
    Class.forName(driver);
    connection = DriverManager.getConnection(url, "", "");
    statement = connection.prepareStatement(sql);
    resultSet = statement.executeQuery();

    if (resultSet.next()) {
        return resultSet.getString(1);
    }
} catch (ClassNotFoundException e) {
    LOG.warn("Exception occur ", e);
} catch (SQLException e) {
    LOG.warn("Exception occur ", e);
} finally {
    if (null != resultSet) {
        try {
            resultSet.close();
        } catch (SQLException e) {
            // handle exception
        }
    }
    if (null != statement) {
        try {
            statement.close();
        } catch (SQLException e) {
            // handle exception
        }
    }
    if (null != connection) {
        try {
            connection.close();
        } catch (SQLException e) {
            // handle exception
        }
    }
}
return "";
}
```

Example code of the reduce function used by MultiComponentReducer class to define the Reducer abstract class.

```
private static class MultiComponentReducer extends Reducer<Text, Text, Text, Text> {
    Configuration conf;

    public void reduce(Text key, Iterable<Text> values, Context context) throws IOException,
    InterruptedException {
        conf = context.getConfiguration();

        // for components that depend on Zookeeper, need provide the conf of jaas and krb5
        // Notice, no need to login again here, will use the credentials in main function
        String krb5 = "krb5.conf";
        String jaas = "jaas_mr.conf";
        // These files are uploaded at main function
        File jaasFile = new File(jaas);
        File krb5File = new File(krb5);
        System.setProperty("java.security.auth.login.config", jaasFile.getCanonicalPath());
        System.setProperty("java.security.krb5.conf", krb5File.getCanonicalPath());
        System.setProperty("zookeeper.sasl.client", "true");

        Text finalValue = new Text("");
        // just pick the last value as the data to save
        for (Text value : values) {
            finalValue = value;
        }

        // write data to HBase
        writeHBase(key.toString(), finalValue.toString());

        // save result to HDFS
        context.write(key, finalValue);
    }
}
```

Example of the writeHBase function.

```
private void writeHBase(String rowKey, String data) {
    String tableName = "table1";
    String columnFamily = "cf";

    try {
        LOG.info("UGI read :" + UserGroupInformation.getCurrentUser());
    } catch (IOException e1) {
        // handler exception
    }

    Configuration hbaseConfig = HBaseConfiguration.create(conf);
    org.apache.hadoop.hbase.client.Connection conn = null;
    try {
        // Create a HBase connection
        conn = ConnectionFactory.createConnection(hbaseConfig);
        // get table
        Table table = conn.getTable(TableName.valueOf(tableName));

        // create a Put to HBase
        List<Put> list = new ArrayList<Put>();
        byte[] row = Bytes.toBytes("row" + rowKey);
        Put put = new Put(row);
        byte[] family = Bytes.toBytes(columnFamily);
        byte[] qualifier = Bytes.toBytes("value");
        byte[] value = Bytes.toBytes(data);
        put.addColumn(family, qualifier, value);
        list.add(put);
        // execute Put
        table.put(list);
    } catch (IOException e) {
        LOG.warn("Exception occur ", e);
    } finally {
        if (conn != null) {
            try {

```

```
        conn.close();
    } catch (Exception e1) {
        LOG.error("Failed to close the connection ", e1);
    }
}
```

Example code: the main() function creates a job, configures the dependency and permission, and submits the job to Hadoop clusters.

```

public static void main(String[] args) throws Exception {
    //Load the hiveclient.properties configuration file
    Properties clientInfo = null;
    try {
        clientInfo = new Properties();

clientInfo.load(MultiComponentExample.class.getClassLoader().getResourceAsStream("hiveclient.properties"));
    } catch (Exception e) {
        throw new IOException(e);
    } finally {
    }

    String zkQuorum = clientInfo.getProperty("zk.quorum");
    String zooKeeperNamespace = clientInfo.getProperty("zooKeeperNamespace");
    String serviceDiscoveryMode = clientInfo.getProperty("serviceDiscoveryMode");
    String principal = clientInfo.getProperty("principal");
    String auth = clientInfo.getProperty("auth");
    String sasl_qop = clientInfo.getProperty("sasl.qop");
    String hbaseKeytab =
MultiComponentExample.class.getClassLoader().getResource("user.keytab").getPath();
    String hbaseJaas =
MultiComponentExample.class.getClassLoader().getResource("jaas_mr.conf").getPath();
    String hiveClientProperties =
MultiComponentExample.class.getClassLoader().getResource("hiveclient.properties").getPath();
    // a list of files, separated by comma
    String files = "file://" + KEYTAB + "," + "file://" + KRB + "," + "file://" + JAAS;
    files = files + "," + "file://" + hbaseKeytab;
    files = files + "," + "file://" + hbaseJaas;
    files = files + "," + "file://" + hiveClientProperties;
    // this setting will ask Job upload these files to HDFS
    config.set("tmpfiles", files);

    // clean control files before job submit
    MultiComponentExample.cleanupBeforeRun();

    // Security login
    LoginUtil.setJaasConf(ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME, PRINCIPAL, hbaseKeytab);
    LoginUtil.setZookeeperServerPrincipal(ZOOKEEPER_DEFAULT_SERVER_PRINCIPAL);
    LoginUtil.login(PRINCIPAL, KEYTAB, KRB, config);

    // find dependency jars for hive
    Class hiveDriverClass = Class.forName("org.apache.hive.jdbc.HiveDriver");
    Class thriftClass = Class.forName("org.apache.thrift.TException");
    Class serviceThriftCLIClass = Class.forName("org.apache.hive.service.rpc.thrift.TCLIService");
    Class hiveConfClass = Class.forName("org.apache.hadoop.hive.conf.HiveConf");
    Class hiveTransClass = Class.forName("org.apache.thrift.transport.HiveTSaslServerTransport");
    Class hiveMetaClass = Class.forName("org.apache.hadoop.hive.metastore.api.MetaException");
    Class hiveShimClass =
Class.forName("org.apache.hadoop.hive.metastore.security.HadoopThriftAuthBridge23");
    Class thriftCLIClass = Class.forName("org.apache.hive.service.cli.thrift.ThriftCLIService");

    // add dependency jars to Job
    JarFinderUtil.addDependencyJars(config, hiveDriverClass, serviceThriftCLIClass, thriftCLIClass, thriftClass,
        hiveConfClass, hiveTransClass, hiveMetaClass, hiveShimClass);

    // add hive config file
    config.addResource("hive-site.xml");
}

```

```
// add hbase config file
Configuration conf = HBaseConfiguration.create(config);

// Initialize the job object.
Job job = Job.getInstance(conf);
job.setJarByClass(MultiComponentExample.class);

// set mapper&reducer class
job.setMapperClass(MultiComponentMapper.class);
job.setReducerClass(MultiComponentReducer.class);

//set job input&output
FileInputFormat.addInputPath(job, new Path(baseDir, INPUT_DIR_NAME + File.separator + "data.txt"));
FileOutputFormat.setOutputPath(job, new Path(baseDir, OUTPUT_DIR_NAME));

// Set the output type of the job.
job.setOutputKeyClass(Text.class);
job.setOutputValueClass(Text.class);

// HBase use this utility class to add dependency jars of hbase to MR job
TableMapReduceUtil.addDependencyJars(job);

// this is mandatory when access to security HBase cluster
// HBase add security credentials to Job, and will use in map and reduce
TableMapReduceUtil.initCredentials(job);

// create Hive security credentials

StringBuilder sBuilder = new StringBuilder("jdbc:hive2://").append(zkQuorum).append("/");

sBuilder.append(";serviceDiscoveryMode=").append(serviceDiscoveryMode).append(";zooKeeperNamespace=")
.append(zooKeeperNamespace)
.append(";sasl.qop=")
.append(sasl_qop)
.append(";auth=")
.append(auth)
.append(";principal=")
.append(principal)
.append(";");
String url = sBuilder.toString();
Connection connection = DriverManager.getConnection(url, "", "");
String tokenStr = ((HiveConnection) connection)
    .getDelegationToken(UserGroupInformation.getCurrentUser().getShortUserName(), PRINCIPAL);
connection.close();
Token<DelegationTokenIdentifier> hive2Token = new Token<DelegationTokenIdentifier>();
hive2Token.decodeFromUrlString(tokenStr);
// add Hive security credentials to Job
job.getCredentials().addToken(new Text("hive.server2.delegation.token"), hive2Token);
job.getCredentials().addToken(new Text(HiveAuthConstants.HS2_CLIENT_TOKEN), hive2Token);

// Submit the job to a remote environment for execution.
System.exit(job.waitForCompletion(true) ? 0 : 1);

}
```

 **NOTE**

Replace all the zkQuorum objects with the actual information about the ZooKeeper cluster nodes.

## 1.16.4 Commissioning the Application

### 1.16.4.1 Commissioning the Application in the Windows Environment

### 1.16.4.1.1 Compiling and Running the Application

#### Scenario

After the code development is complete, you can run an application in the Windows development environment. If the network between the local and the cluster service plane is normal, you can perform the commissioning on the local host.

##### NOTE

- If IBM JDK is used in the Windows environment, the application cannot be run in the Windows environment.
- Do not restart HDFS service while MapReduce application is in running status, otherwise the application will fail.

#### Running MapReduce Statistics Sample Project

**Step 1** Ensure that all JAR packages on which the sample project depends have been obtained.

**Step 2** In the IntelliJ IDEA development environment, select the LocalRunner.java project.

Right-click the project and choose **Run > LocalRunner.main()** from the shortcut menu to run the project. Click to run the related application project.

----End

#### Running MapReduce Accessing Multi-Component Example Project

**Step 1** Save the **user.keytab**, **hive-site.xml**, **hbase-site.xml**, and **hiveclient.properties** files to the **conf** directory of the project.

Create the **jaas\_mr.conf** file in the **conf** directory and add the following content (**test** is the user corresponding to **user.keytab**):

```
Client {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=true  
    keyTab="user.keytab"  
    principal="test@<system domain name>"  
    useTicketCache=false  
    storeKey=true  
    debug=true;  
};
```

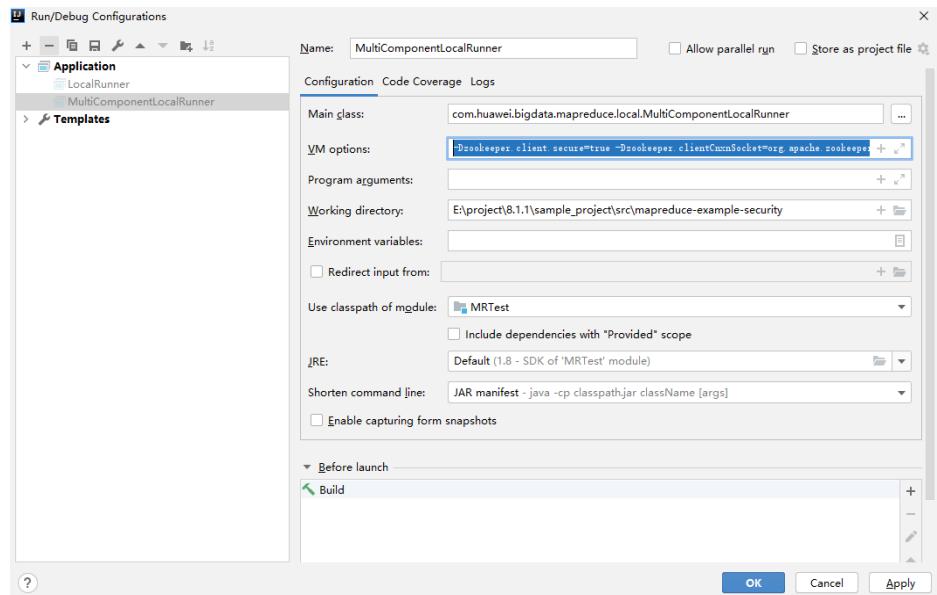

**Step 2** Ensure that all Hive and HBase JAR packages on which the sample project depends have been obtained.

**Step 3** In the IntelliJ IDEA development environment, click **MultiComponentLocalRunner.java** to run the application project. You can also right-click the project and choose **Run MultiComponentLocalRunner.main()** from the shortcut menu to run the project.

If ZooKeeper SSL is enabled for the cluster, add the -

**Dzookeeper.client.secure=true -**

**Dzookeeper.clientCnxnSocket=org.apache.zookeeper.ClientCnxnSocketNetty** parameter to the position shown in the following figure before running this example.

----End

#### 1.16.4.1.2 Checking the Commissioning Result

##### Scenario

After a MapReduce application is run, you can check the running result through one of the following methods:

- Viewing the program running status in IntelliJ IDEA.
- Viewing MapReduce logs.
- Logging in to the MapReduce WebUI.
- Logging in to the Yarn WebUI.

##### NOTE

You must have permission to access WebUI. If not, contact the admin to obtain an account and password.

##### Procedure

- **Check the running result by obtaining the MapReduce log.**

As shown below, the console outputs the application running result.

```
1848 [main] INFO org.apache.hadoop.security.UserGroupInformation - Login successful for user

```

#### NOTE

In the Windows environment, the following exception occurs but does not affect services.

java.io.IOException: Could not locate executable null\bin\winutils.exe in the Hadoop binaries.

- **Check the running result by using MapReduce WebUI.**

Log in to FusionInsight Manager as a user who has the permission to view tasks and choose **Cluster > Name of the desired cluster > Services > Mapreduce > JobHistoryServer**. On the web page that is displayed, view the task execution status.

**Figure 1-216 JobHistory Web UI**

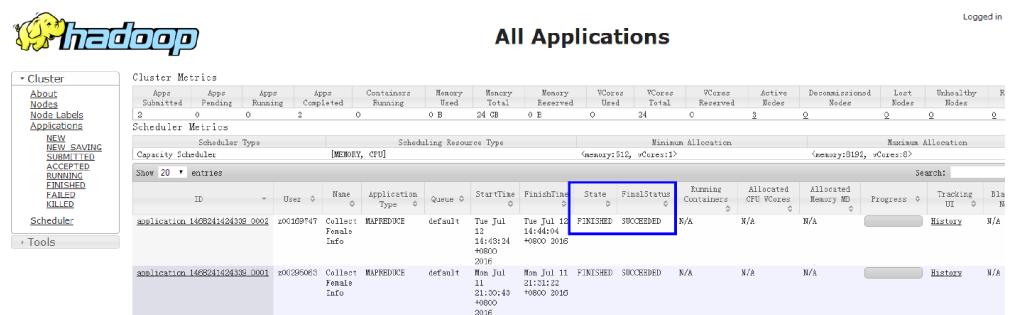

The screenshot shows a table of completed MapReduce jobs. The columns include Submit Time, Start Time, Finish Time, Job ID, Name, User, Queue, State, Maps Total, Maps Completed, Reduces Total, and Reduces Completed. Two rows are highlighted with blue boxes around their 'State' and 'Maps Completed' columns. The first row's state is 'SUCCEEDED' and maps completed are 2. The second row's state is also 'SUCCEEDED' and maps completed are 3.

| Submit Time             | Start Time              | Finish Time             | Job ID                 | Name           | User      | Queue   | State     | Maps Total | Maps Completed | Reduces Total | Reduces Completed |
|-------------------------|-------------------------|-------------------------|------------------------|----------------|-----------|---------|-----------|------------|----------------|---------------|-------------------|

- **View MapReduce logs to learn application running conditions.**

MapReduce logs offers immediate visibility into application running conditions. You can adjust application programs based on the logs.

## 1.16.4.2 Commissioning an Application in the Linux Environment

### 1.16.4.2.1 Compiling and Running the Application

#### Scenario

After the code development is complete, you can run an application in the Linux development environment.

#### Prerequisites

You have installed the Yarn client.

#### Procedure

- Step 1** Go to the local root directory of the project and run the following command in Windows cmd to compress the package:

```
mvn -s "{maven_setting_path}" clean package
```

- In the preceding command, {maven\_setting\_path} is the path of the setting.xml file of the local maven.  
• After the package is successfully packed, obtain the JAR package, for example, *MRTTest-XXX.jar*, from the **target** subdirectory in the root directory of the project. The name of the JAR package varies according to the actual package.

- Step 2** Upload **MRTTest-XXX.jar** to the Linux client, such as **/opt/hadoopclient/conf**, the same directory where the configuration files are located in.

- Step 3** Run the sample project in the Linux environment.

- Run the following command for MapReduce statistics sample project to configure parameters and submit jobs:

```
yarn jar MRTTest-XXX.jar  
com.huawei.bigdata.mapreduce.examples.FemaleInfoCollector  
<inputPath> <outputPath>  
<inputPath> indicates the input path and <outputPath> indicates the output path in HDFS.
```

- Before running the **yarn jar MRTTest-XXX.jar com.huawei.bigdata.mapreduce.examples.FemaleInfoCollector <inputPath> <outputPath>** command, upload the **log1.txt** and **log2.txt** files to the **<inputPath>** directory in HDFS.
- Before running the **yarn jar MRTTest-XXX.jar com.huawei.bigdata.mapreduce.examples.FemaleInfoCollector <inputPath> <outputPath>** command, ensure that the **<outputPath>** directory is deleted. Otherwise, an error will occur.
- Do not restart the HDFS service during the running of MapReduce tasks. Otherwise, the tasks may fail.

- In MapReduce accessing multi-components sample project, perform the following operations:
  - a. Obtain the **user.keytab**, **krb5.conf**, **hbase-site.xml**, **hiveclient.properties**, and **hive-site.xml** configuration files, create a folder for example **/opt/hadoopclient/conf**, and save the configurations files.

 NOTE

The account permission files **user.keytab** and **krb5.conf** are acquired from the administrator. The account permission file **hbase-site.xml** is acquired from the HBase client, **hiveclient.properties** and **hive-site.xml** are acquired from the Hive client.

- b. Create the **jaas\_mr.conf** file in the created folder. The content of the **jaas\_mr.conf** file is as follows:

```
Client {  
    com.sun.security.auth.module.Krb5LoginModule required  
    useKeyTab=true  
    keyTab="user.keytab"  
    principal="test@<system domain name>"  
    useTicketCache=false  
    storeKey=true  
    debug=true;  
};
```

 NOTE

The **test@<system domain name>** in the preceding file content is an example of user. Modify it as required.

- c. Add the classpath required for sample projects in the Linux environment, Example of classpath:

**export YARN\_USER\_CLASSPATH=/opt/hadoopclient/conf:/opt/hadoopclient/HBase/hbase/lib/\*:/opt/hadoopclient/HBase/hbase/lib/client-facing-thirdparty/\*:/opt/hadoopclient/Hive/Beeline/lib/\***

- d. Submit MapReduce jobs. Run the following command to run the sample project:

**yarn jar MRTTest-XXX.jar  
com.huawei.bigdata.mapreduce.examples.MultiComponentExample**

----End

### 1.16.4.2.2 Checking the Commissioning Result

#### Scenario

After a MapReduce application is run, you can check the running result through one of the following methods:

- Viewing the command output.
- Logging in to the MapReduce WebUI
- Logging in to the Yarn WebUI
- Viewing MapReduce logs

### NOTE

You must have permission to access WebUI. If not, contact the admin to obtain an account and password.

## Procedure

- Check the running result by using MapReduce WebUI.

Log in to FusionInsight Manager as a user who has the permission to view tasks and choose **Cluster > Name of the desired cluster > Services > Mapreduce > JobHistoryServer**. On the web page that is displayed, view the task execution status.

Figure 1-218 JobHistory Web UI

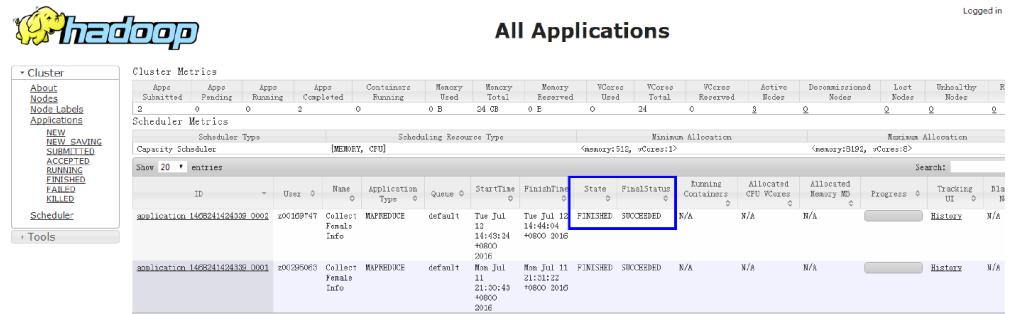

| Submit Time             | Start Time              | Finish Time             | Job ID                 | Name           | User      | Queue   | State     | Maps Total | Maps Completed | Reduces Total | Reduces Completed |
|-------------------------|-------------------------|-------------------------|------------------------|----------------|-----------|---------|-----------|------------|----------------|---------------|-------------------|
| 2016-07-11 14:14:34 CST | 2016-07-11 14:43:30 CST | 2016-07-11 14:43:30 CST | job_1408241424339_0002 | Collect Female | x00109747 | default | SUCCEEDED | 2          | 2              | 1             | 1                 |
| 2016-07-11 20:05:17 CST | 2016-07-11 20:05:17 CST | 2016-07-11 20:13:22 CST | job_1408241424339_0001 | Info           | x00295069 | default | SUCCEEDED | 2          | 2              | 1             | 1                 |

- Check the running result by using YARN WebUI.

Log in to FusionInsight Manager as a user who has the permission to view tasks and choose **Cluster > Name of the desired cluster > Services > Yarn > ResourceManager(Active)**. On the web page that is displayed, view the task execution status.

Figure 1-219 ResourceManager Web UI

| ID                             | User      | Num Apps | Application Type | Queue   | StartTime                | FinishTime               | State    | FinalStatus | Running Containers | Allocated CPU | Allocated Memory MB | Progress | Tracking UI | Logs | History | W/A |
|--------------------------------|-----------|----------|------------------|---------|--------------------------|--------------------------|----------|-------------|--------------------|---------------|---------------------|----------|-------------|------|---------|-----|

```

- **View MapReduce logs to learn application running conditions.**

MapReduce logs offers immediate visibility into application running conditions. You can adjust application programs based on the logs.

## 1.16.5 More Information

### 1.16.5.1 Cross-Platform Compatibility of JAR Packages

#### Scenarios

This section describes how to configure a third-party JAR package in the MapReduce program if the package is not supported by x86 and TaiShan platforms in the cluster.

#### Procedure

- Step 1** On the Linux client, use the `checkJarsCrossPlatform.sh` script to check the cross-platform compatibility of all used JAR packages.

Run the following command to configure the cross-platform compatibility:

```
sh /opt/hadoopClient/checkJarsCrossPlatform.sh {path}
```

 NOTE

*path* is the client directory that contains all third-party JAR packages in the program.

```
sh /opt/hadoopClient/checkJarsCrossPlatformCompatibility.sh /opt/hadoopClient/lib/
4]: Succeed to check cross-platform compatibility for jars in dir.
4]: Not Compatibility For Cross-Platform Jars List is
4]: /opt/hadoopClient/lib/jansi-1.4.jar
```

- Step 2** Based on the command output in [Step 1](#), download the JAR packages not supported on the x86 and TaiShan platforms.

For example, as shown in the command output in [Step 1](#), the **jansi-1.4.jar** package is not supported by the x86 and TaiShan platforms and you need to download this package on both platforms.

- Step 3** Classify all used JAR packages shown in [Step 1](#) into following three types and compress these three types of JAR packages into .zip packages.
- public: JAR packages belonging to this type can run across platforms. Compress all JAR packages of this type to a **job-public.zip** package.
  - x86: JAR packages belonging to this type can run only on the x86 platform. Compress all JAR packages of this type to a **job-x86.zip** package.
  - TaiShan: JAR packages belonging to this type can run only on the TaiShan platform. Compress all JAR packages of this type to a **job-arm.zip** package.

- Step 4** [Accessing FusionInsight Manager of an MRS Cluster](#).

- Step 5** Choose **Cluster > Name of the desired cluster > Services > HDFS**.

- Step 6** Click **NameNode (Active)** to enter the WebUI page.

- Step 7** On the WebUI page, choose **Utilities > Browse the file system**.

- Step 8** Upload the three .zip packages **job-public.zip**, **job-x86.zip**, and **job-arm.zip** generated in [Step 3](#) to the **/tmp** directory of HDFS, as shown in [Figure 1-220](#).

**Figure 1-220** Uploading .zip packages

| -rw-r--r--       | super  | hadoop | 147.26 KB | Jan 04 14:33  | 3           | 128 MB     | job-x86.zip       |  |  |  |
| drwxrwxrwt       | yarn   | hadoop | 0 B       | Jan 04 10:16  | 0           | 0 B        | logs              |  |  |  |
| drwxrwxrwx       | spark  | hadoop | 0 B       | Jan 02 16:28  | 0           | 0 B        | spark             |  |  |  |
| drwxrwxrwx       | spark  | hadoop | 0 B       | Jan 02 16:27  | 0           | 0 B        | sparkhive-scratch |  |  |  |

Showing 1 to 10 of 10 entries

Previous 1 Next

- Step 9** Add the **mapreduce.job.cache.archives** to the **mapred-site.xml** file in the **/conf** directory of the program.

```
<property>
<name>mapreduce.job.cache.archives</name>
<value>hdfs://hacluster/tmp/job-public.zip#public,hdfs://hacluster/tmp/job-x86.zip#x86,hdfs://
hacluster/tmp/job-arm.zip#arm</value>
</property>
```

- Step 10** Modify the **yarn.application.classpath** of the **yarn-site.xml** file in the **/conf** directory of the program. Specifically, add **\$PWD/public/\*,\$PWD/\$CPU\_TYPE/\*** to the value and separate them with a comma (,).

```
<property>
<name>yarn.application.classpath</name>
<value>$PWD/public/*,$PWD/$CPU_TYPE/*,$HADOOP_CONF_DIR,$HADOOP_COMMON_HOME/share/
hadoop/common/*,$HADOOP_COMMON_HOME/share/hadoop/common/lib/*,$HADOOP_HDFS_HOME/
share/hadoop/hdfs/*,$HADOOP_HDFS_HOME/share/hadoop/hdfs/lib/*,$HADOOP_YARN_HOME/share/
hadoop/mapreduce/*,$HADOOP_YARN_HOME/share/hadoop/mapreduce/lib/*,$HADOOP_YARN_HOME/
share/hadoop/yarn/*,$HADOOP_YARN_HOME/share/hadoop/yarn/lib/*,$HADOOP_YARN_HOME/share/
hadoop/tools/lib/*</value>
</property>
```

- Step 11** Compile and run the program.

----End

## 1.16.5.2 Common APIs

### 1.16.5.2.1 Java API

Directly consult official website for detailed API of MapReduce:

<http://hadoop.apache.org/docs/r3.3.1/api/index.html>

#### Common Interfaces

Common classes in MapReduce are as follows:

- org.apache.hadoop.mapreduce.Job: an interface for users to submit MR jobs and used to set job parameters, submit jobs, control job executions, and query job status.
- org.apache.hadoop.mapred.JobConf: configuration class of a MapReduce job and major configuration interface for users to submit jobs to Hadoop.

**Table 1-142** Common interfaces of org.apache.hadoop.mapreduce.Job

Interface	Description
Job(Configuration conf, String jobName), Job(Configuration conf)	Creates a MapReduce client for configuring job attributes and submitting the job.
setMapperClass(Class<extends Mapper> cls)	A core interface used to specify the Mapper class of a MapReduce job. The Mapper class is empty by default. You can also configure <b>mapreduce.job.map.class</b> in <b>mapred-site.xml</b> .
setReducerClass(Class<extends Reducer> cls)	A core interface used to specify the Reducer class of a MapReduce job. The Reducer class is empty by default. You can also configure <b>mapreduce.job.reduce.class</b> in <b>mapred-site.xml</b> .

Interface	Description
setCombinerClass(Class<extends Reducer> cls)	Specifies the Combiner class of a MapReduce job. The Combiner class is empty by default. You can also configure <b>mapreduce.job.combine.class</b> in <b>mapred-site.xml</b> . The Combiner class can be used only when the input and output key and value types of the reduce task are the same.
setInputFormatClass(Class <extends InputFormat> cls)	A core interface used to specify the InputFormat class of a MapReduce job. The default InputFormat class is <b>TextInputFormat</b> . You can also configure <b>mapreduce.job.inputformat.class</b> in <b>mapred-site.xml</b> . This interface can be used to specify the InputFormat class for processing data in different formats, reading data, and splitting data into data blocks.
setJarByClass(Class< > cls)	A core interface used to specify the local location of the JAR package of a class. Java locates the JAR package based on the class file and uploads the JAR package to the Hadoop distributed file system (HDFS).
setJar(String jar)	Specifies the local location of the JAR package of a class. You can directly set the location of a JAR package and upload the JAR package to the HDFS. Use either setJar(String jar) or setJarByClass(Class< > cls). You can also configure <b>mapreduce.job.jar</b> in <b>mapred-site.xml</b> .
setOutputFormatClass(Class<extends OutputFormat> theClass)	A core interface used to specify the OutputFormat class of a MapReduce job. The default OutputFormat class is <b>TextOutputFormat</b> . You can also configure <b>mapred.output.format.class</b> in <b>mapred-site.xml</b> . In the default <b>TextOutputFormat</b> , each key and value are recorded in text. <b>OutputFormat</b> is not specified usually.
setOutputKeyClass(Class< > theClass)	A core interface used to specify the output key type of a MapReduce job. You can also configure <b>mapreduce.job.output.key.class</b> in <b>mapred-site.xml</b> .
setOutputValueClass(Class < > theClass)	A core interface used to specify the output value type of a MapReduce job. You can also configure <b>mapreduce.job.output.value.class</b> in <b>mapred-site.xml</b> .

Interface	Description
setPartitionerClass(Class<extends Partitioner> theClass)	Specifies the Partitioner class of a MapReduce job. You can also configure <b>mapred.partitionner.class</b> in <b>mapred-site.xml</b> . This method is used to allocate Map output results to reduce classes. <b>HashPartitioner</b> is used by default, which evenly allocates the key-value pairs of a map task. For example, in HBase applications, different key-value pairs belong to different regions. In this case, you must specify the Partitioner class to allocate map output results.
setSortComparatorClass(Class<extends RawComparator> cls)	Specifies the compression class for output results of a map task. Compression is not implemented by default. You can also configure <b>mapreduce.map.output.compress</b> and <b>mapreduce.map.output.compress.codec</b> in <b>mapred-site.xml</b> . You can compress data for transmission when the map task outputs a large amount of data.
setPriority(JobPriority priority)	Specifies the priority of a MapReduce job. Five priorities can be set: <b>VERY_HIGH</b> , <b>HIGH</b> , <b>NORMAL</b> , <b>LOW</b> , and <b>VERY_LOW</b> . The default priority is <b>NORMAL</b> . You can also configure <b>mapreduce.job.priority</b> in <b>mapred-site.xml</b> .

**Table 1-143** Common interfaces of org.apache.hadoop.mapred.JobConf

Interface	Description
setNumMapTasks(int n)	A core interface used to specify the number of map tasks in a MapReduce job. You can also configure <b>mapreduce.job.maps</b> in <b>mapred-site.xml</b> . <b>NOTE</b> The InputFormat class controls the number of map tasks. Ensure that the InputFormat class supports setting the number of map tasks on the client.

Interface	Description
setNumReduceTasks(int n)	A core interface used to specify the number of reduce tasks in a MapReduce job. Only one reduce task is started by default. You can also configure <b>mapreduce.job.reduces</b> in <b>mapred-site.xml</b> . The number of reduce tasks is controlled by users. In most cases, the number of reduce tasks is one-fourth the number of map tasks.
setQueueName(String queueName)	Specifies the queue where a MapReduce job is submitted. The default queue is used by default. You can also configure <b>mapreduce.job.queuename</b> in <b>mapred-site.xml</b> .

### 1.16.5.2.2 REST API

#### Function Description

Use the HTTP REST API to view more information about MapReduce tasks. Currently, the REST API of MapResuce can be used to query the status of completed tasks. For details about the API, see the official website:

<http://hadoop.apache.org/docs/r3.3.1/hadoop-mapreduce-client/hadoop-mapreduce-client-hs/HistoryServerRest.html>

#### Preparing the Running Environment

1. Install the client, for example, to the **/opt/hadoopclient** directory on the node. For details, see section "Installing a Client."
2. Go the client installation directory and run the following commands to configure the environment variables:

```
source bigdata_env  
kinit service user
```

##### NOTE

The validity duration of kinit authentication is 24 hours. If you run the sample again 24 hours later, you need to run the kinit command again.

3. HTTPS-based access is different from HTTP-based access. When you access MapReduce using HTTPS, you must ensure that the SSL protocol supported by the curl command is supported by the cluster because SSL security encryption is used. If the cluster does not support the SSL protocol, change the SSL protocol in the cluster. For example, if the cURL supports only the TLSv1 protocol, perform the following steps:

Log in to FusionInsight Manager, choose **Cluster > Name of the desired cluster > Services > Yarn > Configurations > All Configurations**, search for

**hadoop.ssl.enabled.protocols** in the search box, and check whether the parameter value contains **TLSv1**. If the parameter value does not contain **TLSv1**, add **TLSv1** in the **hadoop.ssl.enabled.protocols** configuration item. Clear the value of **ssl.server.exclude.cipher.list**. Otherwise, you cannot access Yarn using HTTPS. Click **Save**, and click **More > Restart Service** to restart the service.

 NOTE

- The values of MapReduce configuration items **hadoop.ssl.enabled.protocols** and **ssl.server.exclude.cipher.list** directly reference the values of the corresponding configuration items in Yarn. Therefore, you need to change the values of the corresponding configuration items in Yarn and restart the Yarn and MapReduce services.
- TLSv1 has security vulnerabilities. Exercise caution when using it.

## Procedure

Obtain detailed information about tasks that have been completed on MapReduce.

- Commands for the operation:

```
curl -k -i --negotiate -u : "https://10.120.85.2:26014/ws/v1/history/mapreduce/jobs"
```

In the preceding command, **10.120.85.2** indicates the value of **JHS\_FLOAT\_IP** for MapReduce, and **26014** indicates the port ID of the JobHistoryServer node.

 NOTE

In RedHat 6.x and CentOS 6.x, a compatibility problem occurs when the curl command is used to access the JobHistoryServer. As a result, the correct result cannot be returned.

- You can view the status information about historical tasks, such as the task IDs, start time, end time, and task execution status.

- Execution result

```
{
  "jobs": [
    "job": [
      {
        "submitTime":1525693184360,
        "startTime":1525693194840,
        "finishTime":1525693215540,
        "id":"job_1525686535456_0001",
        "name":"QuasiMonteCarlo",
        "queue":"default",
        "user":"mapred",
        "state":"SUCCEEDED",
        "mapsTotal":1,
        "mapsCompleted":1,
        "reducesTotal":1,
        "reducesCompleted":1
      }
    ]
  }
}
```

- Result analysis:

Using this API, you can query the completed MapReduce tasks in the current cluster and obtain information listed in **Table 1**.

**Table 1-144** Common information

Parameter	Description
submitTime	Time when a task is submitted
startTime	Start time
finishTime	End time
queue	Task queue
user	User who submits the task
state	Task state, success or failure

### 1.16.5.3 FAQ

#### 1.16.5.3.1 No Response from the Client When Submitting the MapReduce Application

##### Question

After the MapReduce task is submitted to the YARN server, the client is prompted with following information without response for a long time.

```
16/03/03 16:44:56 INFO hdfs.DFSClient: Created HDFS_DELEGATION_TOKEN token 44 for admin on ha-hdfs:hacluster
16/03/03 16:44:56 INFO security.TokenCache: Got dt for hdfs://hacluster; Kind: HDFS_DELEGATION_TOKEN, Service: ha-hdfs:hacluster, Ident: (HDFS_DELEGATION_TOKEN token 44 for admin)
16/03/03 16:44:56 INFO client.ConfiguredRMFailoverProxyProvider: Failing over to 53
16/03/03 16:44:57 INFO input.FileInputFormat: Total input files to process : 200
16/03/03 16:44:57 INFO mapreduce.JobSubmitter: number of splits:200
16/03/03 16:44:57 INFO mapreduce.JobSubmitter: Submitting tokens for job: job_1456738266914_0005
16/03/03 16:44:57 INFO mapreduce.JobSubmitter: Kind: HDFS_DELEGATION_TOKEN, Service: ha-hdfs:hacluster, Ident: (HDFS_DELEGATION_TOKEN token 44 for admin)
16/03/03 16:44:57 INFO impl.YarnClientImpl: Submitted application application_1456738266914_0005
16/03/03 16:44:57 INFO mapreduce.Job: The url to track the job: https://linux2:26001/proxy/application_1456738266914_0005/
16/03/03 16:44:57 INFO mapreduce.Job: Running job: job_1456738266914_0005
```

##### Answer

For the above problem, ResourceManager provides the key diagnosis information about MapReduce operating status on the WebUI. For the MapReduce application that is submitted to the YARN, users can obtain the current application status and the reason to be in the status with the diagnosis information.

Procedures:

Log in to FusionInsight Manager, and select **Cluster > Name of the desired cluster > Services > Yarn > ResourceManager (Active)**. Enter the WebUI, click the submitted MapReduce application on the WebUI of ResourceManager (Active), check the diagnosis information on the WebUI, and take measures according to the diagnosis information.

MapReduce logs offers immediate visibility into application running conditions. You can adjust application programs based on the logs.

### 1.16.5.3.2 When an Application Is Run, An Abnormality Occurs Due to Network Faults

#### Question

When an application is run in the Windows environment, the application fails to connect the cluster. While the application running in the Linux environment (the same network with the host that is installed with the MRS Cluster) works properly.

#### Answer

Kerberos authentication requires the UDP protocol. But the firewall disables the required UDP ports with special operations, resulting in that the network of the application running in the Windows environment fails to connect with the MRS Cluster. Reset the firewall, and open the UDP ports that are required, to ensure that the host running the application in the Windows environment can connect with the MRS.

### 1.16.5.3.3 How to Perform Remote Debugging During MapReduce Secondary Development?

#### Question

During the secondary development of MapReduce, how to perform remote debugging?

#### Answer

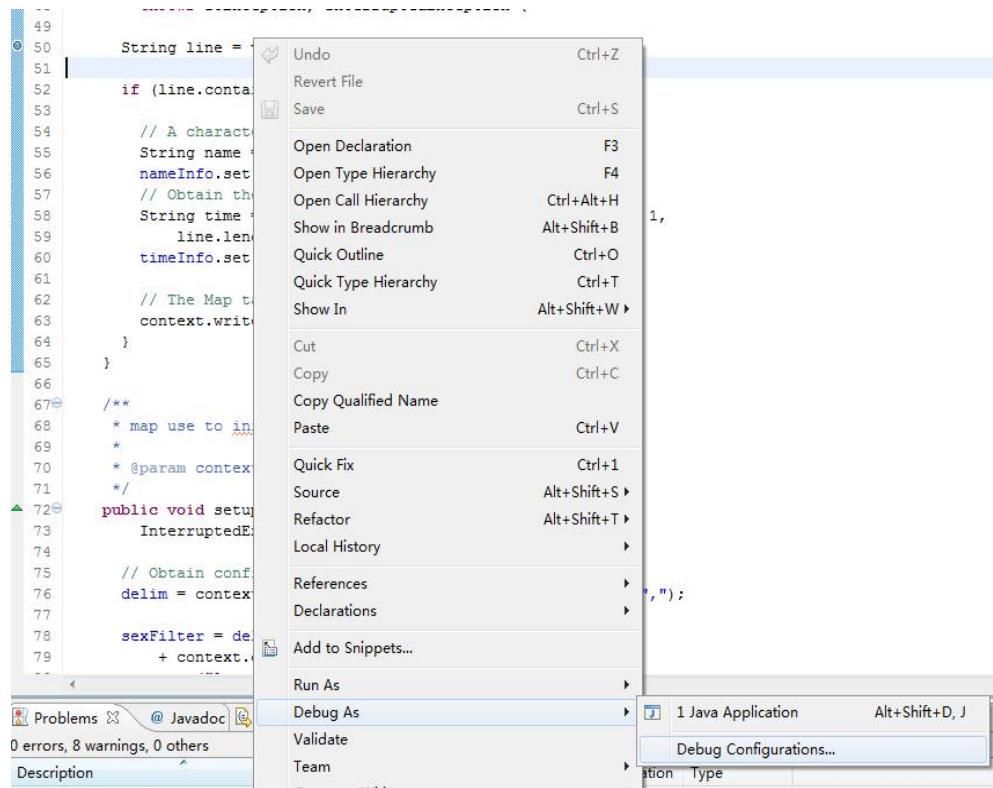

MapReduce adopts Java remote debugging mechanism. Run Java remote debugging commands when starting the Map or Reduce tasks.

- Step 1** The **mapreduce.map.java.opts** and **mapreduce.reduce.java.opts** parameters specify the JVM startup parameters of Map and Reduce tasks respectively. In the **mapred-site.xml** configuration file on the client, add the command **-agentlib:jdwp=transport=dt\_socket,server=y,suspend=y,address=8000** to the **mapreduce.map.java.opts** and **mapreduce.reduce.java.opts** parameters.
- Step 2** MapReduce is a distributed computing framework, and the node where Map or Reduce tasks are running are not fixed. It is advisable to keep only one NodeManager running in the cluster to ensure that the task is executed in the running NodeManager.
- Step 3** Submit MapReduce tasks on the client, then the Map or Reduce tasks will be suspended and listen to the port 8000 to wait for remote debugging.
- Step 4** In IDE, select the implementation class of MapReduce tasks and configure the remote debugging information to perform debugging.
  1. Double-click the area in the blue box to configure or cancel the break point.

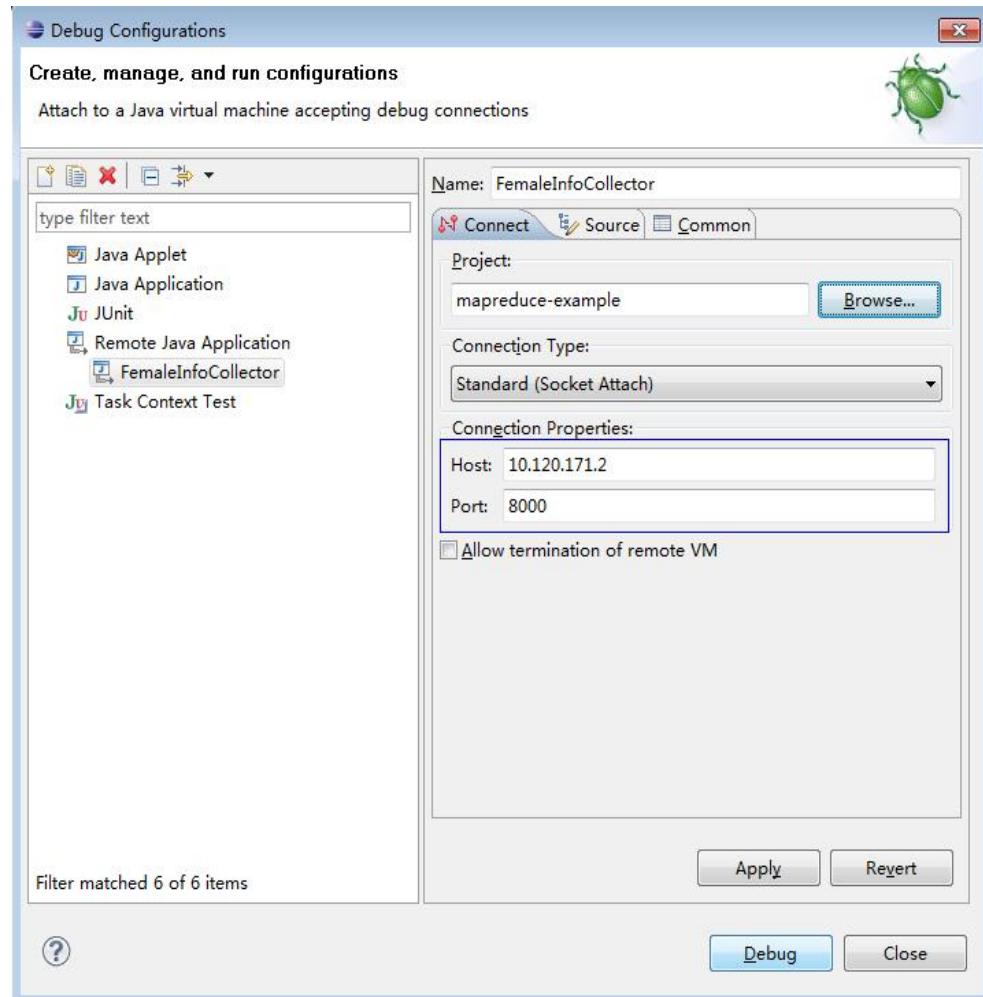

```

39    /**
40     * Distributed computing
41     *
42     * @param key      Object : location offset of the source file
43     * @param value    Text : a row of characters in the source file
44     * @param context Context : output parameter
45     * @throws IOException , InterruptedException
46     */
47     public void map(Object key, Text value, Context context)
48         throws IOException, InterruptedException {
49
50         String line = value.toString();
51
52         if (line.contains(sexFilter)) {
53
54             // A character string that has been read
55             String name = line.substring(0, line.indexOf(delim));
56             nameInfo.set(name);
57             // Obtain the dwell duration.
58             String time = line.substring(line.lastIndexOf(delim) + 1,
59                 line.length());
60             timeInfo.set(Integer.parseInt(time));
61
62             // The Map task outputs a key-value pair.
63             context.write(nameInfo, timeInfo);
64         }
65     }
66 
```

- Right-click the break point and choose **Debug As->Debug Configurations...** from the shortcut menu.

3. On the displayed page, double-click **Remote Java Application** and configure the **Connection Properties** area. Set **Host** to the IP address of the NodeManager and **Port** to **8000**, and then click **Debug**.

----End

**NOTE**

If you use IDE to submit MapReduce tasks, the IDE is the client. Modify the **mapred-site.xml** file of the secondary development project by referring to [Step 1](#).

## 1.17 Oozie Development Guide

### 1.17.1 Overview

#### 1.17.1.1 Application Development Overview

##### Oozie Introduction

Oozie is a workflow engine used to manage Hadoop jobs. Oozie workflows are defined and described based on the directed acyclic graph (DAG). Oozie supports

multiple types of workflow modes and workflow scheduled triggering mechanisms. Oozie features easy extensibility, convenient maintenance, and high reliability and works closely with each component in the Hadoop ecosystem.

Oozie workflows are classified into three types:

- Workflow  
Provides a complete basic service workflow.
- Coordinator  
Built on workflows, triggers workflows in a scheduled manner or based on conditions.
- Bundle  
Built on coordinators, centrally schedules, controls, and manages coordinators.

Oozie provides the following features:

- Supports distribution, merging, and choice workflow modes.
- Works closely with each component in the Hadoop ecosystem.
- Supports parameterized workflow variables.
- Supports scheduled workflow triggering.
- Provides a web console that allows users to view and monitor workflows and view logs.

### 1.17.1.2 Common Concepts

- **Workflow definition file**

Workflow definition files refer to XML files that describe service logic, including **workflow.xml**, **coordinator.xml**, and **bundle.xml**. Workflow definition files are parsed and executed by the Oozie engine.

- **Workflow property file**

The workflow property file refers to the parameter configuration file named **job.properties** for workflow execution. Each workflow has only one property file.

- **keytab file**

The keytab file is a key file that stores user information. In security mode, applications use the key file for API authentication.

- **Client**

Users can access the server from the client through the Java API, Shell API, REST API, or WebUI to access the Oozie server. The client in this document includes the example code used for accessing Oozie through the Java API.

- **Oozie WebUI**

Log in to the Oozie WebUI via <https://Oozie server IP address:21003/oozie>.

### 1.17.1.3 Development Process

This document describes Oozie application development based on the Java API.

For information about each phase in the development process, see [Figure 1-221](#) and [Table 1-145](#).

Figure 1-221 Oozie application development process

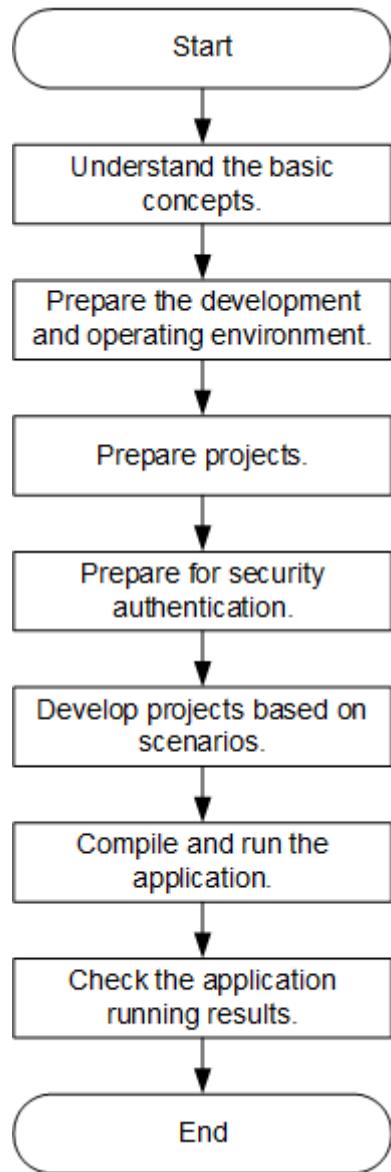

Table 1-145 Description of Oozie development process

Phase	Description	Reference Document
Understand the basic concepts.	Before developing an application, learn basic concepts of Oozie and understand the scenario requirements and design tables.	<a href="#">Common Concepts</a>

Phase	Description	Reference Document
Prepare the development and operating environment.	The Java language is recommended for the development of Oozie applications. The IDEA tool can be used.	<a href="#">Preparing Development and Operating Environment</a>
Prepare projects.	Oozie provides example projects for different scenarios. You can import an example project to learn the application.	<a href="#">Downloading and Importing Sample Projects</a>
Prepare for security authentication.	If you use a security cluster, you need to perform security authentication.	<a href="#">Preparing Authentication Mechanism Code</a>
Develop projects based on scenarios.	An example project based on the Java language is provided.	<a href="#">Developing the Project</a>
Compile and run the application.	Compile the developed application and submit it for running.	<a href="#">Commissioning the Application</a>
View application running results.	Application running results are written into a specified path. You can also view the application running status on the UI.	<a href="#">Commissioning the Application</a>

## 1.17.2 Environment Preparation

### 1.17.2.1 Preparing Development and Operating Environment

[Table 1-146](#) describes the environment required for secondary development.

**Table 1-146** Development environment

Item	Description
OS	Windows OS. Windows 7 or later is supported. If the program needs to be commissioned locally, the development and running environment must be able to communicate with the cluster service plane network.

Item	Description
Installing JDK	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>● For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>● For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>● For security purposes, the server supports only TLS V1.2 or later.</li><li>● By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>● For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IDEA installation and configuration	<p>It is the basic configuration for the development environment. The version must be 2019.1 or other compatible version.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>● If the IBM JDK is used, ensure that the JDK configured in IDEA is the IBM JDK.</li><li>● If the Oracle JDK is used, ensure that the JDK configured in IDEA is the Oracle JDK.</li><li>● If the Open JDK is used, ensure that the JDK configured in IDEA is the Open JDK.</li><li>● Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>
Maven installation	Basic configuration of the development environment for project management throughout the lifecycle of software development.
User development preparation	See <a href="#">Preparing a Developer Account</a> for configuration.

Item	Description
7-zip	Used to decompress .zip and .rar packages. The 7-zip 16.04 is supported.

### 1.17.2.2 Downloading and Importing Sample Projects

#### Scenario

Download sample projects and import them to the IDEA on Windows for learning.

#### Prerequisites

- If the active Oozie node and Solr are deployed on the same node, the Oozie IP address needs to be replaced with the host name to submit an Oozie task. Otherwise, the task fails to be submitted.
- A developer account, for example, **developuser**, has been prepared by following instructions in [Preparing Development and Operating Environment](#), and the user authentication credential file has been downloaded to the local host.  
The user has the common user permission of Oozie, HDFS access permission, Hive table read and write permission, HBase read and write permission, and Yarn queue submission permission.
- A complete cluster client has been installed in the Linux environment.
- The URL of a running Oozie server (any node) has been obtained. The URL is the target address to which the client submits a workflow job.

The URL format is `https://Oozie node service IP address:21003/oozie`. The port number is the value of **OOZIE\_HTTPS\_PORT**, which is **21003** by default.  
for example, `https://10.10.10.176:21003/oozie`.

#### Procedure

- Step 1** Obtain the **OozieMapReduceExample**, **OozieSparkHBaseExample**, and **OozieSparkHiveExample** sample projects from the sample project folder **ooziesecurity-examples** in the **src\oozie-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Copy the keytab file **user.keytab** and user authentication credential file **krb5.conf** obtained in [Preparing a Developer Account](#) to the **\src\main\resources** directory of the **OozieMapReduceExample**, **OozieSparkHBaseExample**, and **OozieSparkHiveExample** sample projects.
- Step 3** In an application development environment, import the sample projects to the IDEA development environment.
1. Choose **File > Open**.  
The **Browse** dialog box is displayed.
  2. Select a sample project folder, and click **OK**.

**Step 4** Modify the parameters in the sample project. For details, see [Table 1-147](#).

**Table 1-147** Parameters to be modified

File Name	Parameter	Value	Example Value
\src\main\resources\job.properties	userName	User who submits a job.	developuser
\src\main\resources\application.properties	submit_user	User who submits a job.	developuser
	oozie_url_default	https://Oozie service IP address:21003/oozie	https://10.10.10.176:21003/oozie

**Step 5** Select the sample project to be run.

- For the **OozieMapReduceExample** sample project, go to [Step 6](#).
- For the **OozieSparkHBaseExample** and **OozieSparkHiveExample** sample projects, see [Scheduling Spark to Access HBase and Hive Using Oozie](#).

**Step 6** Use the client to upload the **examples** folder of Oozie to HDFS.

- Log in to the node where the client is installed, and switch to the directory of the client, for example **/opt/hadoopclient**.

**cd /opt/hadoopclient**

- Run the following command to configure environment variables:

**source bigdata\_env**

- Run the following command to perform user authentication. Change the password upon the first login.

**kinit developuser**

- Run the following commands to create a directory in HDFS and upload the sample project to the directory:

**hdfs dfs -mkdir /user/developuser**

**hdfs dfs -put -f /opt/hadoopclient/Oozie/oozie-client-\*/\* /examples /user/developuser**

In the preceding command, **oozie-client-\*** indicates the version number. Replace it with the actual version number.

----End

### 1.17.2.3 Preparing Authentication Mechanism Code

#### Scenario

In a secure cluster environment, components must perform mutual authentication before communicating with each other to ensure communication security.

In some cases, Oozie needs to communicate with Hadoop and Hive when users develop Oozie applications. Codes for security authentication need to be written into the Oozie applications to ensure that the applications can work properly.

Two security authentication modes are available:

- Command line authentication:

Before running the Oozie applications, run the following command on the Oozie client to obtain authentication:

**kinit Component service user**

- Code authentication (Kerberos security authentication):

You can contact the administrator to create and obtain keytab and krb5.conf files used for Kerberos security authentication. For details, see the sample codes.

The sample codes invoke the LoginUtil class for security authentication and support the Oracle JAVA platform and the IBM JAVA platform.

Set **userName** to the actual user name based on the actual situation, for example, **developeruser**.

```
private static void login(String keytabFilePath, String krb5FilePath, String user) throws IOException {
    Configuration conf = new Configuration();
    conf.set(KERBEROS_PRINCIPAL, user);
    conf.set(KEYTAB_FILE, keytabFilePath);
    conf.set(HADOOP_SECURITY_AUTHENTICATION, "kerberos");
    conf.set(HADOOP_SECURITY_AUTHORIZATION, "true");

    /*
     * if need to connect zk, please provide jaas info about zk. of course,
     * you can do it as below:
     * System.setProperty("java.security.auth.login.config", confDirPath +
     * "jaas.conf"); but the demo can help you more : Note: if this process
     * will connect more than one zk cluster, the demo may be not proper. you
     * can contact us for more help
     */
    LoginUtil.setJaasConf(ZOOKEEPER_DEFAULT_LOGIN_CONTEXT_NAME, user, keytabFilePath);
    LoginUtil.setZookeeperServerPrincipal(ZOOKEEPER_DEFAULT_SERVER_PRINCIPAL);
    LoginUtil.login(user, keytabFilePath, krb5FilePath, conf);
}
```

## 1.17.3 Developing the Project

### 1.17.3.1 Development of Configuration Files

#### 1.17.3.1.1 Description

#### Development Process

1. Configure the **workflow.xml** workflow configuration file (**coordinator.xml** schedules the workflow, and **bundle.xml** manages a pair of Coordinators) and **job.properties**.
2. If you want to implement codes, develop relevant jar packages, for example, Java Action. If you want to use Hive, develop SQL files.
3. Upload the configuration file and jar packages (including dependent jar packages) to the HDFS. The upload path is **oozie.wf.application.path** in **workflow.xml**.

4. The workflow can be implemented by using the following three methods. For details, see [More Information](#).
  - Shell command
  - Java API
  - Hue
5. The Oozie client provides examples for your reference, involving various Actions and how to use Coordinator and Bundle. For example, if the installation directory of the Oozie client is /opt/hadoopclient, the examples directory is **/opt/hadoopclient/Oozie/oozie-client-\*/examples**.

The following example shows you how to configure a configuration file by using the Mapreduce workflow and invoke the configuration file by running the Shell command.

## Description

Provides that a user needs to analyze website logs offline every day, and collect statistics on the access frequency of each module of the website. Log files are stored in the HDFS.

Jobs are submitted through templates and configuration files in the client.

### 1.17.3.1.2 Development Procedure

#### Step 1 Analyze the service.

1. Analyze and process logs using Mapreduce in the client example directory.
2. Move Mapreduce analysis results to the data analysis result directory, and set the data file access permission to **660**.
3. To analyze data every day, perform [Step 1.1](#) and [Step 1.2](#) every day.

#### Step 2 Implement the service.

1. Log in to the node where the client is located, and create the **dataLoad** directory, for example, **/opt/hadoopclient/Oozie/oozie-client-\*/examples/apps/dataLoad/**. This directory is used as a program running directory to store files that are edited subsequently.

#### NOTE

You can directly copy the content in the **map-reduce** directory of the example directory to the **dataLoad** directory and edit the content.

Replace **oozie-client-\*** in the directory with the actual version number.

2. Compile a workflow job property file **job.properties**.  
For details, see [job.properties](#).
3. Compile a workflow job using **workflow.xml**.

**Table 1-148** Actions in a Workflow

No.	Procedure	Description
1	Define the start action.	For details, see <a href="#">Start Action</a>

No.	Procedure	Description
2	Define the MapReduce action.	For details, see <a href="#">MapReduce Action</a>
3	Define the FS action.	For details, see <a href="#">FS Action</a>
4	Define the end action.	For details, see <a href="#">End Action</a>
5	Define the kill action.	For details, see <a href="#">Kill Action</a>

### NOTE

Dependent or newly developed JAR packages must be saved in **dataLoad/lib**.

The following provides an example workflow file:

```
<workflow-app xmlns="uri:oozie:workflow:1.0" name="data_load">
  <start to="mr-dataLoad"/>
  <action name="mr-dataLoad">
    <map-reduce> <resource-manager>${resourceManager}</resource-manager>
      <name-node>${nameNode}</name-node>
      <prepare>
        <delete path="${nameNode}/user/${wf:user()}/${dataLoadRoot}/output-data/map-reduce"/>
      </prepare>
      <configuration>
        <property>
          <name>mapred.job.queue.name</name>
          <value>${queueName}</value>
        </property>
        <property>
          <name>mapred.mapper.class</name>
          <value>org.apache.oozie.example.SampleMapper</value>
        </property>
        <property>
          <name>mapred.reducer.class</name>
          <value>org.apache.oozie.example.SampleReducer</value>
        </property>
        <property>
          <name>mapred.map.tasks</name>
          <value>1</value>
        </property>
        <property>
          <name>mapred.input.dir</name>
          <value>/user/oozie/${dataLoadRoot}/input-data/text</value>
        </property>
        <property>
          <name>mapred.output.dir</name>
          <value>/user/${wf:user()}/${dataLoadRoot}/output-data/map-reduce</value>
        </property>
      </configuration>
    </map-reduce>
    <ok to="copyData"/>
    <error to="fail"/>
  </action>

  <action name="copyData">
    <fs>
      <delete path='${nameNode}/user/oozie/${dataLoadRoot}/result' />
      <move source='${nameNode}/user/${wf:user()}/${dataLoadRoot}/output-data/map-reduce'
            target='${nameNode}/user/oozie/${dataLoadRoot}/result' />
      <chmod path='${nameNode}/user/oozie/${dataLoadRoot}/result' permissions='rwxrw-rw-' dir-files='true' />
    </fs>
  </action>
</workflow-app>
```

```
</fs>
<ok to="end"/>
<error to="fail"/>
</action>

<kill name="fail">
    <message>This workflow failed, error message[$wf:errorMessage(wf:lastErrorNode())]</
message>
    </kill>
    <end name="end"/>
</workflow-app>
```

#### 4. Compile a Coordinator job using **coordinator.xml**.

The Coordinator job is used to analyze data every day. For details, see [coordinator.xml](#).

#### Step 3 Upload the workflow file.

1. Use or switch to the user account that is granted with rights to upload files to the HDFS. For details about developer account preparation, see [Preparing Development and Operating Environment](#).
2. Implement Kerberos authentication for the user account.
3. Run the HDFS upload command to upload the **dataLoad** folder to a specified directory on the HDFS (user **developuser** must have the read/write permission for the directory).

##### NOTE

The specified directory must be the same as **oozie.coord.application.path** and **workflowAppUri** defined in **job.properties**.

#### Step 4 Execute the workflow file.

1. Log in to the client node, implement Kerberos authentication for user **developuser**.

```
cd /opt/hadoopclient
source bigdata_env
kinit developuser
```

2. Run the following command to start the workflow:

Command:

```
oozie job -oozie https://oozie server hostname:port/oozie -config
job.propertiesfile path -run
```

Parameter list:

**Table 1-149** Parameters

Parameter	Description
job	Indicates that a job is to be executed.
-oozie	Indicates the (any instance) Oozie server address.
-config	Indicates the path of <b>job.properties</b> .
-run	Indicates the starts workflow.

For example:

```
oozie job -oozie https://10-1-130-10:21003/oozie -config job.properties -run  
----End
```

### 1.17.3.2 Example Codes

#### 1.17.3.2.1 job.properties

##### Function

**job.properties** is a workflow property file that defines external parameters used for workflow execution.

##### Parameter Description

**Table 1-150** describes parameters in **job.properties**.

**Table 1-150** Parameters

Parameter	Meaning
nameNode	Indicates the Hadoop distributed file system (HDFS) NameNode cluster address.
resourceManager	Indicates the Yarn ResourceManager address.
queueName	Identifies the MapReduce queue where a workflow job is executed.
dataLoadRoot	Identifies the folder where the workflow job resides.
oozie.coord.application.path	Indicates the storage path of a Coordinator job in the HDFS.
start	Indicates the time when a scheduled workflow job is started.
end	Indicates the time when a scheduled workflow job is stopped.
workflowAppUri	Indicates the storage path of a workflow job in the HDFS.

##### NOTE

You can define parameters in the key=value format based on service requirements.

## Example Codes

```
nameNode=hdfs://hacluster  
  
resourceManager=10.1.130.10:26004  
queueName=QueueA  
dataLoadRoot=examples  
  
oozie.coord.application.path=${nameNode}/user/oozie_cli/${dataLoadRoot}/apps/dataLoad  
start=2013-04-02T00:00Z  
end=2014-04-02T00:00Z  
workflowAppUri=${nameNode}/user/oozie_cli/${dataLoadRoot}/apps/dataLoad
```

### 1.17.3.2.2 workflow.xml

#### Function

**workflow.xml** describes a complete service workflow. A workflow consists of a start node, an end node, and multiple action nodes.

#### Parameter Description

**Table 1-151** describes parameters in **workflow.xml**.

**Table 1-151** Parameters

Parameter	Meaning
name	Identifies a workflow file.
start	Indicates the workflow start node.
end	Indicates the workflow end node.
action	Indicates nodes (one or multiple) that are used to implement a service.

## Example Codes

```
<workflow-app xmlns="uri:oozie:workflow:1.0" name="data_load">  
  <start to="copyData"/>  
  <action name="copyData">  
    </action>  
    .....  
  <end name="end"/>  
</workflow-app>
```

### 1.17.3.2.3 Start Action

#### Function

The Start Action node indicates the start point of a workflow job. Each workflow job has only one Start Action node.

#### Parameter Description

**Table 1-152** describes the parameter used on the Start Action node.

**Table 1-152** Parameters

Parameter	Meaning
to	Identifies a subsequent action node.

## Example Codes

```
<start to="mr-dataLoad"/>
```

### 1.17.3.2.4 End Action

#### Function

The End Action node indicates the end point of a workflow job. Each workflow job has only one End Action node.

#### Parameter Description

[Table 1-153](#) describes the parameter used on the End Action node.

**Table 1-153** Parameters

Parameter	Meaning
name	Identifies an end action.

## Example Codes

```
<end name="end"/>
```

### 1.17.3.2.5 Kill Action

#### Function

The Kill Action node indicates the end point of a workflow job when an error occurs.

#### Parameter Description

[Table 1-154](#) describes parameters used on the Kill Action node.

**Table 1-154** Parameters

Parameter	Meaning
name	Identifies a kill action.
message	Provides error messages.

Parameter	Meaning
\$ {wf:errorMessage(wf:lastErrorNode())}	Indicates the internal error message function in the Oozie system.

## Example Codes

```
<kill name="fail">
  <message>
    This workflow failed, error message[${wf:errorMessage(wf:lastErrorNode())}]
  </message>
</kill>
```

### 1.17.3.2.6 FS Action

#### Function

The FS Action node is a Hadoop distributed file system (HDFS) operation node. You can create and delete HDFS files and folders and grant permissions for HDFS files and folders using this node.

#### Parameter Description

[Table 1-155](#) describes parameters used on the FS Action node.

**Table 1-155** Parameters

Parameter	Meaning
name	Identifies an FS action.
delete	Deletes a specified file or folder.
move	Moves a file from the source directory to the target directory.
chmod	Modifies file or folder access rights.
path	Indicates the current file path.
source	Indicates the source file path.
target	Indicates the target file path.
permissions	Indicates permissions.

**\${variable name}**  indicates the value defined in  **job.properties** .

For example,  **\${nameNode}**  indicates  **hdfs://hacluster** . (See  [job.properties](#) .)

## Example Codes

```
<action name="copyData">
  <fs>
    <delete path='${nameNode}/user/oozie_cli/${dataLoadRoot}/result' />
    <move source='${nameNode}/user/${wf:user()}/${dataLoadRoot}/output-data/map-reduce' target='${nameNode}/user/oozie_cli/${dataLoadRoot}/result' />
    <chmod path='${nameNode}/user/oozie_cli/${dataLoadRoot}/result' permissions='rwxrw-rw-' dir-files='true' /></chmod>
  </fs>
  <ok to="end"/>
  <error to="fail"/>
</action>
```

### 1.17.3.2.7 MapReduce Action

#### Function

The MapReduce Action node is used to execute a map-reduce job.

#### Parameter Description

**Table 1-156** describes parameters used on the MapReduce Action node.

**Table 1-156** Parameters

Parameter	Meaning
name	Identifies a map-reduce action.
resourceManager	Indicates the MapReduce ResourceManager address.
name-node	Indicates the Hadoop distributed file system (HDFS) NameNode address.
queueName	Identifies the MapReduce queue where a job is executed.
mapred.mapper.class	Identifies the Mapper class.
mapred.reducer.class	Identifies the Reducer class.
mapred.input.dir	Indicates the input directory of MapReduce processed data.
mapred.output.dir	Indicates the output directory of MapReduce processing results.
mapred.map.tasks	Indicates the number of map tasks.

#### NOTE

**\${variable name}** indicates the value defined in **job.properties**.

For example,  **\${nameNode}** indicates **hdfs://hacluster**. (See [job.properties](#).)

## Example Codes

```
<action name="mr-dataLoad">
    <map-reduce>
        <resource-manager>${resourceManager}</resource-manager>
        <name-node>${nameNode}</name-node>
        <prepare>
            <delete path="${nameNode}/user/${wf:user()}/${dataLoadRoot}/output-data/map-reduce"/>
        </prepare>
        <configuration>
            <property>
                <name>mapred.job.queue.name</name>
                <value>${queueName}</value>
            </property>
            <property>
                <name>mapred.mapper.class</name>
                <value>org.apache.oozie.example.SampleMapper</value>
            </property>
            <property>
                <name>mapred.reducer.class</name>
                <value>org.apache.oozie.example.SampleReducer</value>
            </property>
            <property>
                <name>mapred.map.tasks</name>
                <value>1</value>
            </property>
            <property>
                <name>mapred.input.dir</name>
                <value>/user/oozie/${dataLoadRoot}/input-data/text</value>
            </property>
            <property>
                <name>mapred.output.dir</name>
                <value>/user/${wf:user()}/${dataLoadRoot}/output-data/map-reduce</value>
            </property>
        </configuration>
    </map-reduce>
    <ok to="copyData"/>
    <error to="fail"/>
</action>
```

### 1.17.3.2.8 coordinator.xml

#### Function

**coordinator.xml** is used to periodically execute a workflow job.

#### Parameter Description

[Table 1-157](#) describes parameters in **coordinator.xml**.

**Table 1-157** Parameters

Parameter	Meaning
frequency	Indicates the workflow execution interval.
start	Indicates the time when a scheduled workflow job is started.
end	Indicates the time when a scheduled workflow job is stopped.

Parameter	Meaning
workflowAppUri	Indicates the storage path of a workflow job in the HDFS.
resourceManager	Indicates the MapReduce ResourceManager address.
queueName	Identifies the MapReduce queue where a job is executed.
nameNode	Indicates the Hadoop distributed file system (HDFS) NameNode address.

#### NOTE

**\${variable name}** indicates the value defined in **job.properties**.

For example,  **\${nameNode}** indicates **hdfs://hacluster**. (See [job.properties](#).)

## Example Codes

```
<coordinator-app name="cron-coord" frequency ="${coord:days(1)}" start ="${start}" end ="${end}"  
timeZone ="UTC" xmlns="uri:oozie:coordinator:0.2">  
    <action>  
        <workflow>  
            <app-path>${workflowAppUri}</app-path>  
            <configuration>  
                <property>  
                    <name>resourceManager</name>  
                    <value>${resourceManager}</value>  
                </property>  
                <property>  
                    <name>nameNode</name>  
                    <value>${nameNode}</value>  
                </property>  
                <property>  
                    <name>queueName</name>  
                    <value>${queueName}</value>  
                </property>  
            </configuration>  
        </workflow>  
    </action>  
</coordinator-app>
```

### 1.17.3.3 Development of Java

#### 1.17.3.3.1 Description

These typical scenarios help you quickly understand the development procedure of Oozie and learn key API functions.

This example shows you how to submit a MapReduce job and query the job status by using the Java API. The sample code relates to the MapReduce job only, but the API invocation codes of other jobs are the same. The difference is that the configuration of **job.properties** in a job and that of **workflow.xml** in a workflow is different.

 NOTE

After the operations in [Downloading and Importing Sample Projects](#) are complete, you can submit MapReduce jobs and query job status through Java APIs.

### 1.17.3.3.2 Sample Code

## Function

Oozie submits a job from the run method of `org.apache.oozie.client.OozieClient` and obtains job information from `getJobInfo`.

## Sample Code

Change `OOZIE_URL_DEFALUT` in the code example to the actual host name of any Oozie node, for example, `https://10-1-131-131:21003/oozie/`.

```
public void test(String filePath) {
    try {
        UserGroupInformation.getLoginUser()
            .doAs(
                new PrivilegedExceptionAction<Void>() {
                    /**
                     * run job
                     *
                     * @return null
                     * @throws Exception exception
                     */
                    public Void run() throws Exception {
                        runJob(filePath);
                        return null;
                    }
                });
    } catch (Exception e) {
        e.printStackTrace();
    }
}

private void runJob(String filePath) throws OozieClientException, InterruptedException {
    Properties conf = getJobProperties(filePath);

    // submit and start the workflow job
    String jobId = wc.run(conf);

    logger.info("Workflow job submitted : {}" , jobId);

    // wait until the workflow job finishes printing the status every 10 seconds
    while (wc.getJobInfo(jobId).getStatus() == WorkflowJob.Status.RUNNING) {
        logger.info("Workflow job running ... {}" , jobId);
        Thread.sleep(10 * 1000);
    }

    // print the final status of the workflow job
    logger.info("Workflow job completed ... {}" , jobId);
    logger.info(String.valueOf(wc.getJobInfo(jobId)));
}

/**
 * Get job.properties File in filePath
 *
 * @param filePath file path
 * @return job.properties
 * @since 2020-09-30
 */
```

```
public Properties getJobProperties(String filePath) {
    File configFile = new File(filePath);
    if (!configFile.exists()) {
        logger.info(filePath, "{} is not exist.");
    }

    InputStream inputStream = null;

    // create a workflow job configuration
    Properties properties = wc.createConfiguration();
    try {
        inputStream = new FileInputStream(filePath);
        properties.load(inputStream);

    } catch (Exception e) {
        e.printStackTrace();
    } finally {
        if (inputStream != null) {
            try {
                inputStream.close();
            } catch (IOException e) {
                e.printStackTrace();
            }
        }
    }

    return properties;
}
```

## Precautions

Implement the security authentication when you use the Java API to access the Oozie. For details, see section "Preparing for the Development Environment". Upload the dependent configuration file (For details about how to develop the **Workflow.xml** configuration file, see [workflow.xml](#)) and the jar package to the HDFS, and ensure that users who have passed the security authentication are granted the rights to access the relevant directory on the HDFS. (The owner of the directory is the authenticated users, or is in the same user group with the users).

### 1.17.3.4 Scheduling Spark to Access HBase and Hive Using Oozie

#### Prerequisites

Prerequisites in [Downloading and Importing Sample Projects](#) have been met.

#### Preparing a Development Environment

**Step 1** Obtain the **OozieSparkHBaseExample** and **OozieSparkHiveExample** sample projects from the sample project folder **ooziesecurity-examples** in the **src\oozie-examples** directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).

Currently, MRS Spark uses Scala 2.12.14.

**Step 2** Copy the keytab file **user.keytab** and user authentication credential file **krb5.conf** obtained in [Preparing a Developer Account](#) to the **\src\main\resources** directory of the **OozieSparkHBaseExample** and **OozieSparkHiveExample** sample projects.

**Step 3** Modify the parameters in each sample project. For details, see [Table 1-158](#).

**Table 1-158** Parameters to be modified

File Name	Parameter	Value	Example Value
src\main\resources\application.properties	submit_user	User who submits a job.	developuser
	oozie_url_default	https://Oozie service IP address:21003/oozie/	https://10.10.10.176:21003/oozie/
src\main\resources\job.properties	userName	User who submits a job.	developuser
	examplesRoot	Use the default value or change the value based on the site requirements.	myjobs
	oozie.wf.application.path	Use the default value or change the value based on the site requirements.	<p><b>NOTICE</b> \${nameNode}/user/\${userName}/\${examplesRoot}/apps/spark Ensure that the path is the same as the path with the &lt;jar&gt; and &lt;spark-opts&gt; tags in the src\main\resources\workflow.xml file.</p>
src\main\resources\workflow.xml	<jar> </jar>	Change <b>OoizeSparkHBase-1.0.jar</b> to the actual JAR package name.	<jar>\${nameNode}/user/\${userName}/\${examplesRoot}/apps/spark/lib/OoizeSparkHBase-1.0.jar</jar>

#### NOTE

Go to the root directory of the project, for example, D:\sample\_project\src\oozie-examples\oozie-security-examples\OozieSparkHBaseExample, and run the **mvn clean package -DskipTests** command. After the operation is successful, the package is in the target directory.

**Step 4** Create the following folders on the HDFS client in the configured path:

**hdfs dfs -mkdir -p /user/developuser/myjobs/apps/spark/lib**

**hdfs dfs -mkdir -p /user/developuser/myjobs/apps/spark/hbase**

**hdfs dfs -mkdir -p /user/developuser/myjobs/apps/spark/hive**

**Step 5** Upload the files listed in **Table 1-159** to the corresponding path.

**Table 1-159** Files to be uploaded

Initial File Path	File	Destination Path
Spark client directory (for example, /opt/hadoopclient/Spark/spark/conf)	hive-site.xml	/user/developuser/myjobs/apps/spark directory in the HDFS.
	hbase-site.xml	
Keytab file obtained in <a href="#">Preparing a Developer Account</a>	user.keytab	
	krb5.conf	
Spark client directory (for example, /opt/hadoopclient/Spark/spark/jars)	JAR package	Share HDFS /user/oozie/share/lib/spark/ directory of Oozie.
JAR package of the sample projects to be used, for example, <b>OoizeSparkHBase-1.0.jar</b>	JAR package	/user/developuser/myjobs/apps/spark/lib/ directory in the HDFS.
OozieSparkHiveExample sample project directory <b>src\main\resources</b>	workflow.xml	/user/developuser/myjobs/apps/spark/hive/ directory in the HDFS. <b>NOTE</b> Change the path of <b>spark-archive.zip</b> in <spark-opts> based on the actual HDFS file path.
OozieSparkHBaseExample sample project directory <b>src\main\resources</b>	workflow.xml	/user/developuser/myjobs/apps/spark/hbase/ directory in the HDFS. <b>NOTE</b> Change the path of <b>spark-archive.zip</b> in <spark-opts> based on the actual HDFS file path.

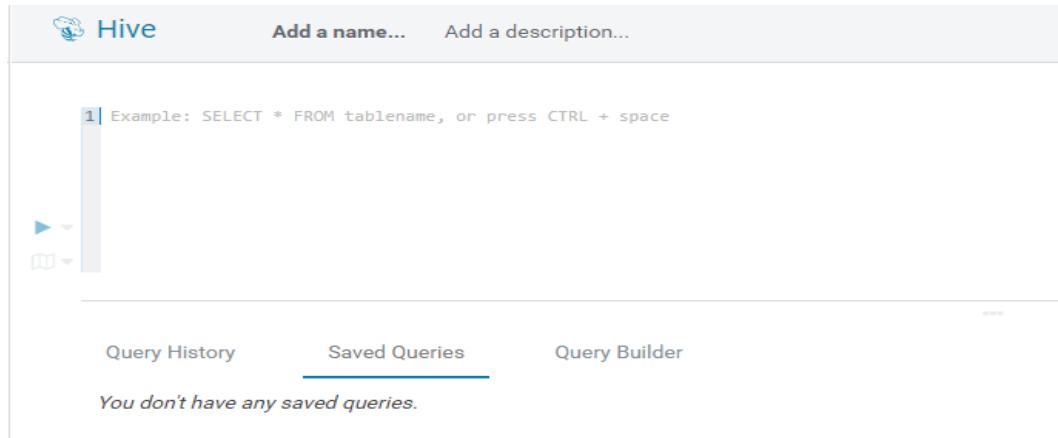

**Step 6** Change the value of **hive.security.authenticator.manager** in the **hive-site.xml** file in the **/user/developuser/myjobs/apps/spark** directory of HDFS from **org.apache.hadoop.hive ql.security.SessionStateUserMSGroupAuthenticator** to **org.apache.hadoop.hive ql.security.SessionStateUserGroupAuthenticator**.

**Step 7** If ZooKeeper SSL is enabled, add the following content to the **hbase-site.xml** file in the **/user/developuser/myjobs/apps/spark** directory of the HDFS:

```
<property>
<name>HBASE_ZK_SSL_ENABLED</name>
<value>true</value>
</property>
```

**Step 8** Run the following commands to create a Hive table:

You can enter the following SQL statements in the Hive panel on the Hue UI:

```
CREATE DATABASE test;  
  
CREATE TABLE IF NOT EXISTS `test`.`usr` (user_id int comment  
'userID',user_name string comment 'userName',age int comment  
'age')PARTITIONED BY (country string)STORED AS PARQUET;  
  
CREATE TABLE IF NOT EXISTS `test`.`usr2` (user_id int comment  
'userID',user_name string comment 'userName',age int comment  
'age')PARTITIONED BY (country string)STORED AS PARQUET;  
  
INSERT INTO TABLE test.usr partition(country='CN') VALUES(1,'maxwell',45),  
(2,'minwell',30),(3,'mike',22);  
  
INSERT INTO TABLE test.usr partition(country='USA') VALUES(4,'minbin',35);
```

**Step 9** Use HBase Shell to run the following commands to create an HBase table:

```
create 'SparkHBase',{NAME=>'cf1'}  
put 'SparkHBase','01','cf1:name','Max'  
put 'SparkHBase','01','cf1:age','23'  
----End
```

## 1.17.4 Commissioning the Application

### 1.17.4.1 Commissioning an Application in the Windows Environment

#### 1.17.4.1.1 Compiling and Running Applications

##### Scenario

After the code development is complete using Java APIs, you can run applications in the Windows development environment. If the local and cluster service planes can communicate with each other, you can perform the commissioning on the local host.

## Procedure

- The HTTPS SSL certificate is required for running applications in Windows.
  - a. Log in to any node in the cluster and go to the following directory to download the **ca.crt** file.  
**cd \${BIGDATA\_HOME}/om-agent\_8.3.1/nodeagent/security/cert/subcert/certFile/**
  - b. Download the **ca.crt** file to a local directory and open the CLI as the administrator.  
Run the following command:  
**keytool -import -v -trustcacerts -alias ca -file "D:\xx\ca.crt" -storepass JRE truststore password -keystore "%JAVA\_HOME%\jre\lib\security\cacerts"**  
In the preceding command, **D:\xx\ca.crt** is the path for storing the **ca.crt** file. **%JAVA\_HOME %** indicates the JDK installation path. Obtain the JRE truststore password by following the instructions provided in [Huawei Cloud Stack 8.3.1 Account List](#).
- In the development environment (such as IDEA), right-click **OozieRestApiMain.java**, and choose **Run 'OozieRestApiMain.main()'** to run the application project.
- Run the following command on the Oozie client:  
**oozie job -oozie https://Oozie service IP:21003/oozie -config job.properties -run**  
You need to copy the **job.properties** file in the **src\main\resources** directory of the sample project to the directory where the Oozie client is located in advance.

### 1.17.4.1.2 Checking the Commissioning Result

#### Scenario

The results can be viewed on the console after the Oozie sample project is completed.

#### Procedure

The following information is displayed if the sample project is successful:

```
log4j:WARN No appenders could be found for logger (com.huawei.hadoop.security.LoginUtil).
log4j:WARN Please initialize the log4j system properly.
log4j:WARN See http://logging.apache.org/log4j/1.2/faq.html#noconfig for more info.
SLF4J: Class path contains multiple SLF4J bindings.
SLF4J: Found binding in [jar:file:/D:/temp/newClientSec/oozie-example/lib/slf4j-log4j12-1.7.5.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: Found binding in [jar:file:/D:/temp/newClientSec/oozie-example/lib/slf4j-simple-1.7.1.jar!/org/slf4j/impl/StaticLoggerBinder.class]
SLF4J: See http://www.slf4j.org/codes.html#multiple_bindings for an explanation.
SLF4J: Actual binding is of type [org.slf4j.impl.Log4jLoggerFactory]
current user is developuser@<system domain name> (auth:KERBEROS)
login user is developuser@<system domain name> (auth:KERBEROS)
cluset status is true
Warning: Could not get charToByteConverterClass!
Workflow job submitted: 0000071-160729120057089-oozie-omm-W
Workflow job running ...0000071-160729120057089-oozie-omm-W
```

```
Workflow job running ...0000071-160729120057089-oozie-omm-W
Workflow job completed ...0000071-160729120057089-oozie-omm-W
Workflow id[0000071-160729120057089-oozie-omm-W] status[SUCCEEDED]
-----finish Oozie -----
```

Directory **/user/developuser/examples/output-data/map-reduce** is generated on the HDFS. The directory contains the following two files:

- `_SUCCESS`
- `part-00000`

You can view the files by using the file browser of the Hue or running the following commands on the HDFS:

```
hdfs dfs -ls /user/developuser/examples/output-data/map-reduce
```

#### 📖 NOTE

In the Windows environment, the following exception may occur but does not affect services.

```
java.io.IOException: Could not locate executable null\bin\winutils.exe in the Hadoop binaries.
```

## 1.17.5 More Information

### 1.17.5.1 Common API Introduce

#### 1.17.5.1.1 Shell

**Table 1-160** Interface parameters

Command	Parameter	Meaning
oozie version	-	The version information
oozie job	-config <arg>	Indicates the path to the job configuration file <b>job.properties</b> .
	-oozie <arg>	Indicates the Oozie server address.
	-haconfig <arg>	Indicates the path to the Oozie service configuration file <b>oozie-site.xml</b> .
	-run	Runs a job.
	-start <arg>	Starts a specified job.

Command	Parameter	Meaning
	-submit	Submits a job.
	-kill <arg>	Deletes a specified job.
	-suspend <arg>	Suspends a specified job.
	-resume <arg>	Resumes a specified job.
	-D <property=value>	Sets a property.
oozie admin	-oozie <arg>	Indicates the Oozie server address.
	-status	Indicates the service status of the Oozie service.

The Oozie command and other parameters can be found in the following address:  
[https://oozie.apache.org/docs/5.1.0/DG\\_CommandLineTool.html](https://oozie.apache.org/docs/5.1.0/DG_CommandLineTool.html).

#### 1.17.5.1.2 Java

Java APIs are provided by `org.apache.oozie.client.OozieClient`.

**Table 1-161 API**

Item	Description
public String run(Properties conf)	Runs a job.
public void start(String jobId)	Starts the specified job.
public String submit(Properties conf)	Submits a job.
public void kill(String jobId)	Delete the specified job.
public void suspend(String jobId)	Suspends the specified job.
public void resume(String jobId)	Resumes the specified job.
public WorkflowJob getJobInfo(String jobId)	Obtains job information.

#### 1.17.5.1.3 REST

The common APIs of REST are the same as the APIs of Java. For details, see  
<http://oozie.apache.org/docs/5.1.0/WebServicesAPI.html>.

## 1.18 Redis Development Guide

## 1.18.1 Overview

### 1.18.1.1 Application Development Overview

#### Redis Introduction

Redis is an open-source, high-performance key-value distributed storage database. It supports a variety of data types, making up storage limitations of Memcached and meeting requirements for real-time and high-concurrency processing. In certain application scenarios, Redis is a good supplement to relational databases.

Redis is similar to Memcached. Besides, it supports data persistence and diverse data types. Redis supports union, intersection, and complement of mathematical sets on the server side and a wide range of sorting functions.

Redis applies to the following application scenarios:

- High performance.
- Low latency.
- Enriching data structure.
- Supporting persistence.

#### Interface Type Introduction

Redis server is developed on the basis of C language. The community provides clients with common development languages and using Java language to develop Redis applications is recommended.

Redis employs the same interfaces as Jedis. For details, see <https://github.com/xetorthio/jedis>.

Redis can invoke the interfaces to provide diverse functions, as shown in **Table 1-162**.

**Table 1-162** Functions provided by Redis interfaces

Function	Description
String type access	Common operations of String in class java are: set, get, append, and strlen.
List type access	Common operations of List data structures are: lpush, rpush, lpop, rpop, llen, lindex, lrange, and lrem.
Hash type access	Common operations of Map data structures.
Set type access	Common operations of Set data structures.
Sorted Set type access	Sorted set operations

Function	Description
GEO (Geographical location)	Geographical location information can be added to the stored data

### 1.18.1.2 Common Concepts

- **keytab file**

The keytab file is a key file that stores user information. In security mode, applications use the key file for API authentication.

- **Client**

Users can access the server from the client through Java API and Redis-cli to read and write the data in Redis. The client in this document includes the example code used for accessing Redis through the Java API.

### 1.18.1.3 Development Process

This document describes Redis application development based on the Java API.

For information about each phase in the development process, see [Figure 1-222](#) and [Table 1-163](#).

Figure 1-222 Redis application development process

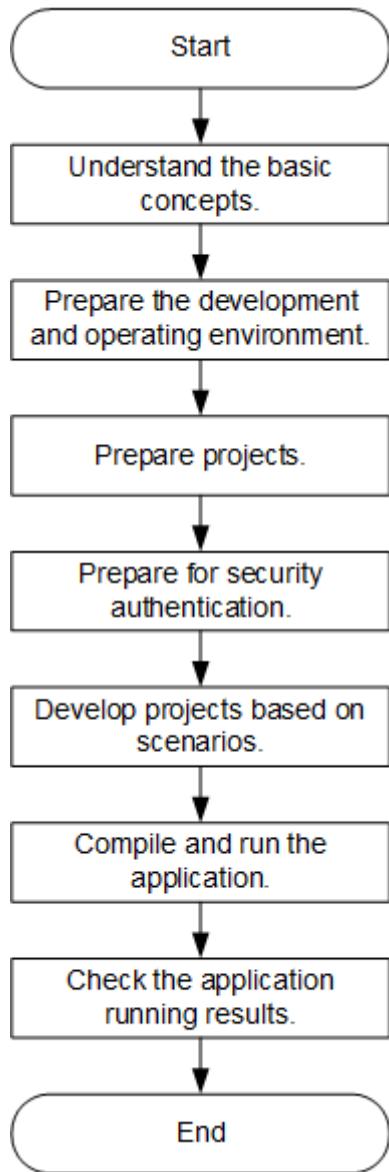

Table 1-163 Redis application development process description

Phase	Description	Reference Document
Understand the basic concepts.	Before developing an application, learn basic concepts of Redis and understand the scenario requirements.	<a href="#">Common Concepts</a>

Phase	Description	Reference Document
Prepare the development and operating environment.	The Java language is recommended for the development of Redis applications. The IntelliJ IDEA tool can be used. The Redis running environment is the client. Install and configure the client according to the guide.	<a href="#">Development and Operating Environment</a>
Prepare projects.	Redis provides example projects for different scenarios. You can import an example project to learn the application.	<a href="#">Configuring and Importing Sample Projects</a>
Prepare for security authentication.	If you use a security cluster, you need to perform security authentication.	<a href="#">Preparing for Security Authentication</a>
Develop projects based on scenarios.	Providing the example projects of the Java language, covering Redis cluster initialization and a variety of data types access.	<a href="#">Developing an Application</a>
Compile and run the application.	Compile the developed application and submit it for running.	<a href="#">Application Commissioning</a>
View application running results.	Application running results will be written and output to the console.	<a href="#">Application Commissioning</a>

## 1.18.2 Environment Preparation

### 1.18.2.1 Development and Operating Environment

[Table 1-164](#) describes the development and running environment to be prepared for secondary development.

**Table 1-164** Development environment

Item	Description
OS	<ul style="list-style-type: none"><li>• Development environment: Windows OS. Windows 7 or later is supported.</li><li>• Operating environment: Windows OS or Linux OS. If the program needs to be commissioned locally, the runtime environment must be able to communicate with the cluster service plane network.</li></ul>
JDK installation	<p>Basic configuration of the development and running environment. The version requirements are as follows:</p> <p>The server and client support only the built-in OpenJDK. Other JDKs cannot be used.</p> <p>If the JAR packages of the SDK classes that need to be referenced by the customer applications run in the application process, the JDK requirements are as follows:</p> <ul style="list-style-type: none"><li>• For x86 nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- Oracle JDK 1.8</li><li>- IBM JDK 1.8.0.7.20 and 1.8.0.6.15</li></ul></li><li>• For Arm nodes that run clients, use the following JDKs:<ul style="list-style-type: none"><li>- OpenJDK 1.8.0_402 (built-in JDK, which can be obtained from the <b>JDK</b> folder in the cluster client installation directory.)</li><li>- BiSheng JDK 1.8.0_402</li></ul></li></ul> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• For security purposes, the server supports only TLS V1.2 or later.</li><li>• By default, the IBM JDK supports only TLS V1.0. If the IBM JDK is used, set the startup parameter <b>com.ibm.jsse2.overrideDefaultTLS</b> to <b>true</b>. After the setting, the IBM JDK supports TLS V1.0, V1.1, and V1.2. For details, see <a href="https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls">https://www.ibm.com/docs/en/sdk-java-technology/8?topic=customization-matching-behavior-sslcontextgetinstance-tls-oracle#matchsslcontext_tls</a>.</li><li>• For details about the BiSheng JDK, see <a href="https://www.hikunpeng.com/en/developer/devkit/compiler/jdk">https://www.hikunpeng.com/en/developer/devkit/compiler/jdk</a>.</li></ul>
IntelliJ IDEA installation and configuration	<p>Basic configuration of the development environment. The version must be 2019.1 or other compatible versions.</p> <p><b>NOTE</b></p> <ul style="list-style-type: none"><li>• If you use the IBM JDK, ensure that the JDK configured in IntelliJ IDEA is the IBM JDK.</li><li>• If the Oracle JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Oracle JDK.</li><li>• If the Open JDK is used, ensure that the JDK configured in IntelliJ IDEA is the Open JDK.</li><li>• Do not use the same workspace and the sample project in the same path for different IntelliJ IDEA programs.</li></ul>

Item	Description
Maven installation	Basic configuration of the development environment for project management throughout the lifecycle of software development.
Redis cluster creation	<ol style="list-style-type: none"><li>1. Log in to FusionInsight Manager.</li><li>2. Click <b>Cluster</b>, click the name of the desired cluster, choose <b>Services &gt; Redis</b>, and click <b>Redis Manager</b>.</li><li>3. Click <b>Create Redis Cluster</b>.</li><li>4. Enter a cluster name and click <b>Next</b>.</li><li>5. Select all the available Redis instances contained in the Redis cluster.</li><li>6. Click <b>Submit</b>. In the displayed <b>Create Redis Cluster</b> window, enter the administrator password and click <b>OK</b>.</li></ol> <p><b>NOTE</b> Skip these steps if such a cluster containing all the Redis instances already exists.</p>
User development preparation	Prepare a cluster user for application development and grant permissions to the user by referring to <a href="#">Preparing a Developer Account</a> .
7-Zip	Used to decompress <b>.zip</b> and <b>.rar</b> packages. The 7-Zip 16.04 version is supported.

## Preparing Operating Environment

During application development, prepare the code running and commissioning environment to verify that the application is running properly.

- If the local Windows development environment can communicate with the cluster service plane network, download the cluster client to the local host; obtain the cluster configuration file required by the commissioning application; configure the network connection, and commission the application in Windows.
  - a. [Accessing FusionInsight Manager of an MRS Cluster](#) ,In the upper right corner of the home page, click **Download Client**.Select the platform type based on the type of the node where the client is to be installed (select **x86\_64** for the x86 architecture and **aarch64** for the Arm architecture) and click **OK**. After the client files are packaged and generated, download the client to the local PC as prompted and decompress it.  
For example, if the client file package is **FusionInsight\_Cluster\_1\_Services\_Client.tar**, decompress it to obtain the **FusionInsight\_Cluster\_1\_Services\_ClientConfig.tar** file, and then decompress it to the **D:\FusionInsight\_Cluster\_1\_Services\_ClientConfig** directory on the local PC. The directory name cannot contain spaces.
  - b. Go to the client decompression path **FusionInsight\_Cluster\_1\_Services\_ClientConfig\Redis\FusionInsight-redis-\*.tar.gz\redis\config** and manually import the configuration file to

the configuration file directory (usually the **resources\config** folder) of the Redis sample project.

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. [Table 1-165](#) describes the main configuration files.

**Table 1-165** Configuration files

File	Function
redis.conf	Configures Redis parameters.
log4j.xml	Configures logs.
auth.conf	Provides authentication configuration when Redis is connected.
aof-backup.properties	Provides configuration for backing up Redis data.
user.keytab	Provides user information for Kerberos security authentication.
krb5.conf	Provides Kerberos server configuration information.

- c. During application development, if you need to commission the application in the local Windows system, copy the content in the **hosts** file in the decompression directory to the **hosts** file of the node where the client is located. Ensure that the local host can communicate correctly with the hosts listed in the **hosts** file in the decompression directory.

 **NOTE**

- If the host where the client is installed is not a node in the cluster, configure network connections for the client to prevent errors when you run commands on the client.
- The local **hosts** file in a Windows environment is stored in, for example, **C:\WINDOWS\system32\drivers\etc\hosts**.
- When configuring IPv6 hosts on the local PC running Windows, add **%** and **InterfaceIndex** of the network interface card (NIC) to the end of the IPv6 address. The **InterfaceIndex** can be obtained by running the **ipconfig** command.

Example:

fec1:0:0:e505:8:99:5:1%10

- If you use the Linux environment for commissioning, prepare the Linux node where the cluster client is to be installed and obtain related configuration files.
  - a. Install the client in a directory, for example, **/opt/hadoopclient**, on the node.

Ensure that the difference between the client time and the cluster time is less than 5 minutes.

For details about how to install a cluster client, see [Installing a Client](#).

- b. **Accessing FusionInsight Manager of an MRS Cluster.** Download the cluster client software package to the active management node and decompress it. Then log in to the active management node as user **root**. Go to the decompression directory of the cluster client, and copy all configuration files in the **FusionInsight\_Cluster\_1\_Services\_ClientConfig/Redis/FusionInsight-redis-\*.tar.gz/redis/config** directory to the client node to the **config** directory where the compiled JAR package is stored, for example, **/opt/hadoopclient/config**, for subsequent commissioning.

For example, if the client software package is **FusionInsight\_Cluster\_1\_Services\_Client.tar** and the download path is **/tmp/FusionInsight-Client** on the active management node, run the following commands:

```
cd /tmp/FusionInsight-Client  
tar -xvf FusionInsight_Cluster_1_Services_Client.tar  
tar -xvf FusionInsight_Cluster_1_Services_ClientConfig.tar  
cd FusionInsight_Cluster_1_Services_ClientConfig  
scp Redis/FusionInsight-redis-*.tar.gz/redis/config/* root@IP address of the client node::/opt/hadoopclient/config
```

The keytab file obtained during the [Preparing a Developer Account](#) is also stored in this directory. [Table 1-166](#) describes the main configuration files.

**Table 1-166** Configuration files

File	Function
redis.conf	Configures Redis parameters.
log4j.xml	Configures logs.
auth.conf	Provides authentication configuration when jedisclient is connected.
aof-backup.properties	Provides configuration for backing up Redis data.
user.keytab	Provides user information for Kerberos security authentication.
krb5.conf	Provides Kerberos server configuration information.

- c. Check the network connection of the client node.

During the client installation, the system automatically configures the **hosts** file on the client node. You are advised to check whether the **/etc/hosts** file contains the host names of the nodes in the cluster. If no, manually copy the content in the **hosts** file in the decompression directory to the **hosts** file on the node where the client is located, to ensure that the local host can communicate with each host in the cluster.

## 1.18.2.2 Configuring and Importing Sample Projects

### Background

The Redis development example project is included in the client installation directory. Import the project to IntelliJ IDEA for learning.

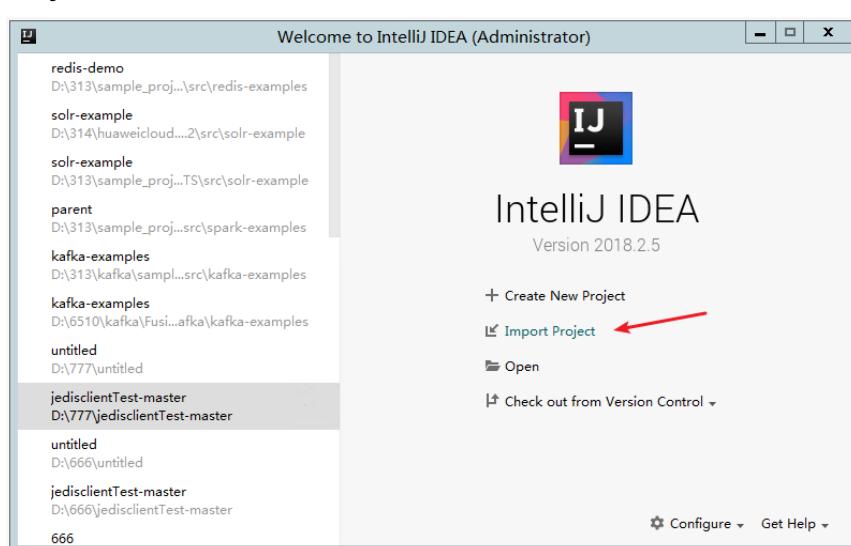

### Prerequisites

Ensure that the difference between the local PC time and the MRS cluster time is less than 5 minutes. If the time difference cannot be determined, contact the system administrator.

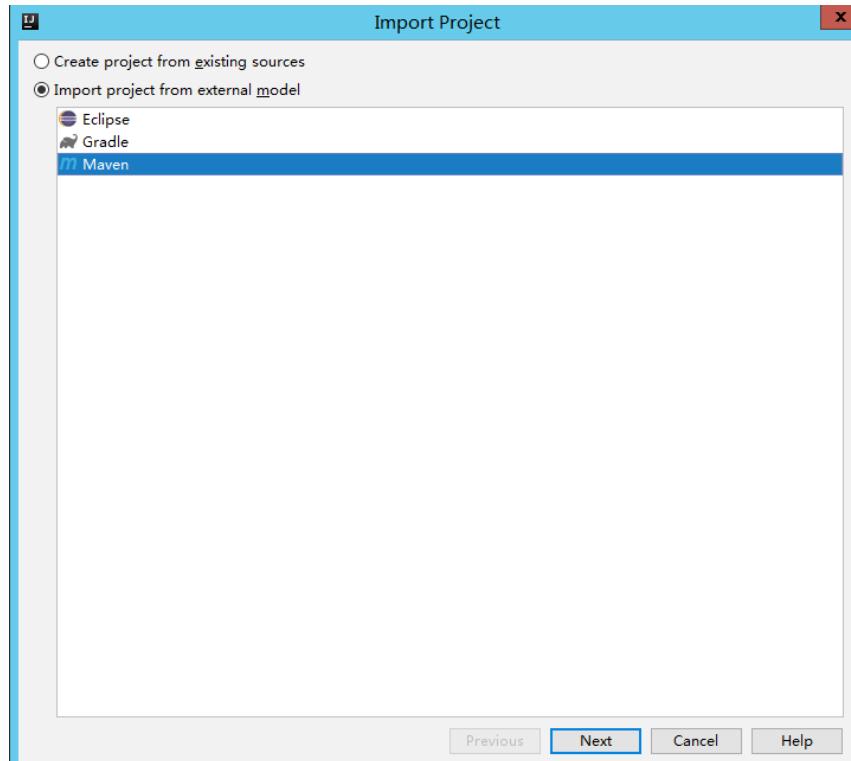

You can view the MRS cluster time in the lower-right corner on FusionInsight Manager.

### Procedure

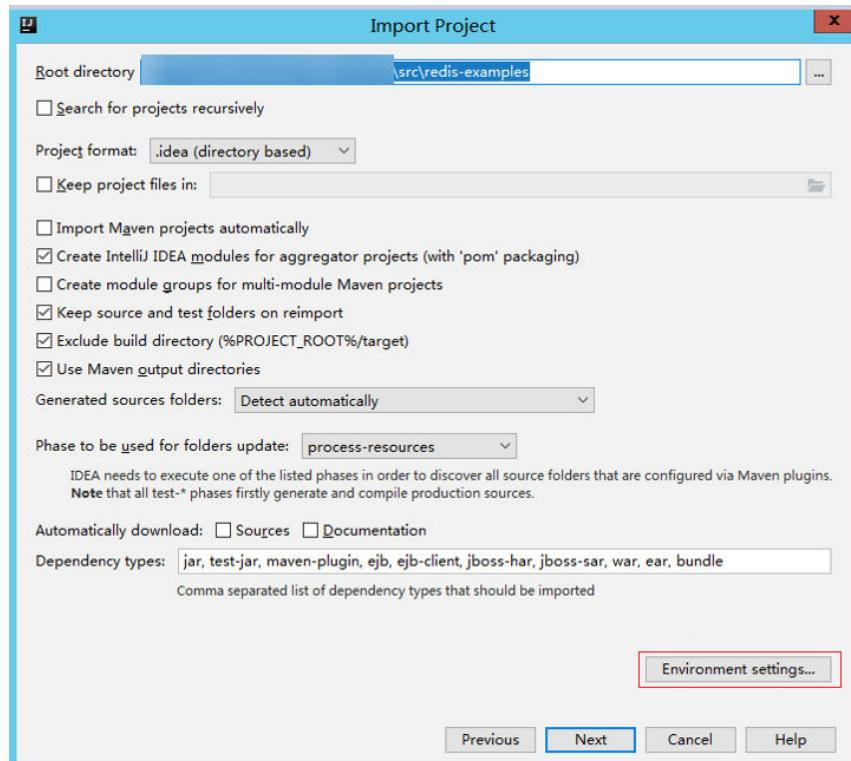

- Step 1** Obtain the sample project folder in the `/src/redis-examples` directory where the sample code is decompressed. For details, see [Obtaining Sample Projects from Huawei Mirrors](#).
- Step 2** Copy the `user.keytab` and `krb5.conf` files obtained in [Preparing a Developer Account](#) section to the `/src/main/resources/config` directory of the sample project.
- Step 3** Import the example project to the IntelliJ IDEA development environment.
  1. Start the IntelliJ IDEA, select **Import Project** on the **Quick Start** page.  
Or, for the used IDEA tool, add projects directly from the IDEA homepage. Select **File > Close Project** back to the **Quick Start** page and select **Import Project** .

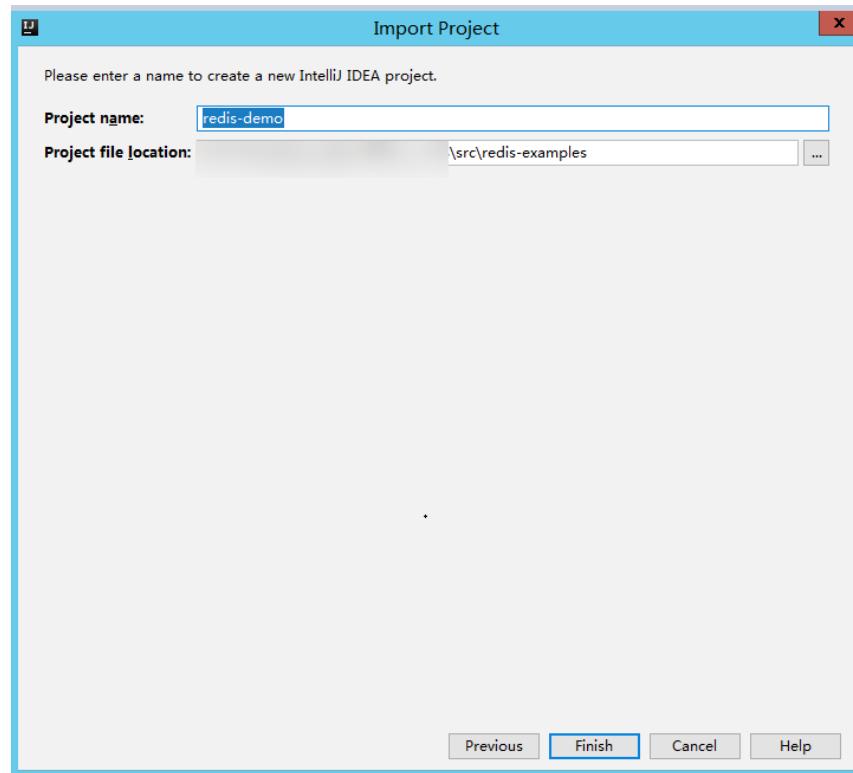

2. Select the example project folder, and click **OK**.
3. On the **Import Project** page that is displayed, select **Import project from external model and Maven**, and click **Next**.

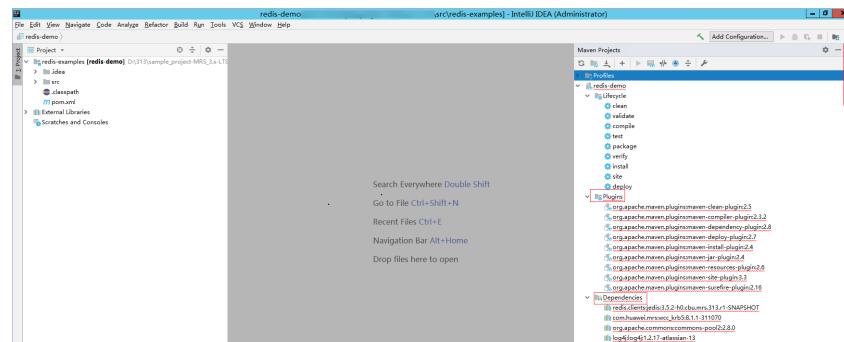

4. Click **Environment settings** to configure the environment information. Select the local Maven version. Set **User settings file** and **Local repository** based on the site requirements, click **OK**, and then click **Next**.

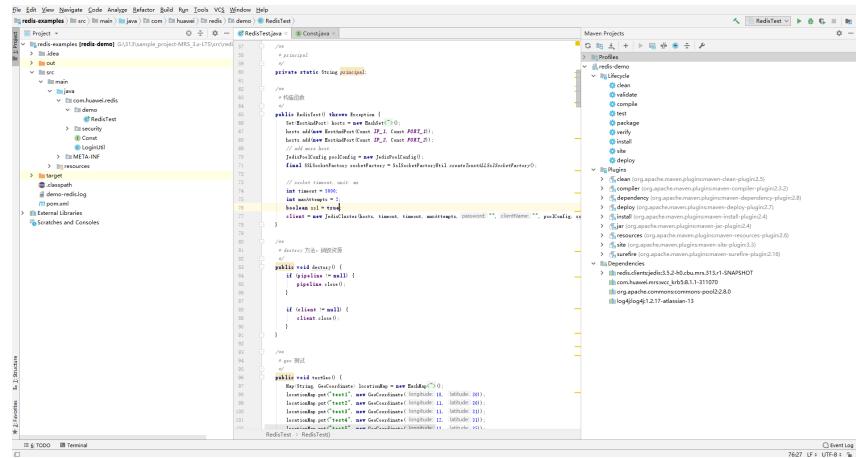

5. Confirm the subsequent configurations and click **Next**. Retain the default values unless otherwise required.
6. Enter the **project name**, select the **Project file location**, and click **Finish**.

**Step 4** In the menu bar on the right, click **Maven Project** and check whether the plug-in is loaded.

**Step 5** Click **Install** under the current project to execute the program.

----End

## 1.18.2.3 Preparing for Security Authentication

### 1.18.2.3.1 Preparing Authentication Mechanism Code

#### Scenario

In a secure cluster environment, components must perform mutual authentication before communicating with each other to ensure communication security. Redis application development requires Kerberos security authentication. You can contact the administrator to create and obtain keytab and krb5.conf files used for Kerberos security authentication. For details about how to use, see the description in the example codes.

Security authentication uses the code authentication mode. This example project applies to the Oracle Java platform and the IBM Java platform.

#### Initializing security configurations

Set system properties **redis.authentication.jaas** to **true**.

Set **principal** to the actual user name based on the actual situation, for example, **redisuser1@**.

The following code snippet belongs to the **init** method in the **RedisTest** class of the **com.huawei.redis.demo** package.

```
public static void init() throws IOException {
    System.setProperty("redis.authentication.jaas", "true");
    if (System.getProperty("redis.authentication.jaas", "false").equals("true")) {
        LoginUtil.setKrb5Config(getResource("config/krb5.conf"));
        principal = "redisuser1@" + KerberosUtil.getKrb5DomainRealm();
        LoginUtil.setJaasFile(principal, getResource("config/user.keytab"));
    }
}
```

## 1.18.3 Developing an Application

### 1.18.3.1 Typical Scenario Description

Based on typical scenarios, users can quickly learn and master the Redis development process and know important interface functions.

## Scenarios

The service operation object of the Redis is key. Operations covered by example codes include access operations for keys of the String, List, Hash, Set, and Sorted Set types.

Example codes are described in the following sequence:

- Redis cluster initialization
- String type access
- List type access
- Hash type access
- Set type access
- Sorted Set type access
- Usage of Basic GEO APIs
- Use of Pipelines in the Single-thread Scenario
- Use of Pipelines in the Multi-thread Scenario
- Use of Pipelines in the bytes data Scenario

### 1.18.3.2 Example Code Description

#### 1.18.3.2.1 Redis Cluster Initialization

## Function

Create JedisCluster instances by specifying the IP addresses and port IDs of one or more instances in a cluster.

## Example Code

The following code snippet belongs to the **RedisTest** method in the **RedisTest** class of the **com.huawei.redis.demo** package.

```
public RedisTest() {  
  
    Set<HostAndPort> hosts = new HashSet<HostAndPort>();  
    hosts.add(new HostAndPort(Const.IP_1, Const.PORT_1));  
    hosts.add(new HostAndPort(Const.IP_2, Const.PORT_2));  
    // add more host...  
  
    // socket timeout(connect, read), unit: ms  
  
    JedisPoolConfig poolConfig = new JedisPoolConfig();  
    final SSLSocketFactory socketFactory = SslSocketFactoryUtil.createTrustAllSslSocketFactory();  
    int timeout = 5000;  
    int maxAttempts = 2;  
    // Enabling channel encryption for Redis, the value of boolean SSL is changed to true  
    boolean ssl = false;  
    client = new JedisCluster(hosts, timeout, timeout, maxAttempts, "", "", poolConfig, ssl, socketFactory,
```

```
null, null, null);  
}
```

#### NOTE

- On FusionInsight Manager, users can view the Redis instances included in the Redis clusters.
- In the Redis cluster, the port ID corresponding to role Redis\_1 is 22400, and the port ID corresponding to role Redis\_2 is 22401. The others follow the same rule.
- Set the values, such as Const.IP\_1, Const.IP\_2, Const.PORT\_1, and Const.PORT\_2 in the **Const** class of the **com.huawei.redis** package, to the IP addresses and port IDs in the actual environment.
- Enabling channel encryption for Redis

Log in to FusionInsight Manager, choose **Cluster > Services > Redis > Configurations > All Configurations**, search for **REDIS\_SSL\_ON**, and set the parameter value to **true** to enable SSL channel encryption for Redis.

```
public interface Const {  
  
    String IP_1 = "Redis_1 node IP address";  
    String IP_2 = "Redis_2 node IP address";  
  
    int PORT_1 = 22400;  
    int PORT_2 = 22401;  
}
```

### 1.18.3.2.2 String Type Access

#### Function

Implement setting and obtaining data of simple String type in Redis, through the methods such as **set** and **get** in the JedisCluster instance.

#### Example Code

The following code snippets belong to the **testString** method in the RedisTest class of the **com.huawei.redis.demo** package.

```
public void testString() {  
    String key = "sid-user01";  
  
    // Save user's session ID, and set expire time  
    client.setex(key, 5, "A0BC9869FBC92933255A37A1D21167B2");  
    String sessionId = client.get(key);  
    LOGGER.info("User " + key + ", session id: " + sessionId);  
    try {  
        Thread.sleep(10000);  
    } catch (InterruptedException e) {  
        LOGGER.warn("InterruptedException");  
    }  
  
    sessionId = client.get(key);  
    LOGGER.info("User " + key + ", session id: " + sessionId);  
  
    key = "message";  
  
    client.set(key, "hello");  
    String value = client.get(key);  
    LOGGER.info("Value: " + value);  
  
    client.append(key, " world");  
    value = client.get(key);  
    LOGGER.info("After append, value: " + value);  
}
```

```
    client.del(key);  
}
```

## Precautions

- All types of key in Redis are case-sensitive.
- **sessionId** is a variable name. In actual use, sensitive data may be stored in Redis. Therefore, you are not advised to directly print the data read from Redis.

### 1.18.3.2.3 List Type Access

#### Function

Implement setting and obtaining data of List type in the Redis, through the methods such as rpush and lpop in the JedisCluster instance.

#### Example Code

The following code snippet belongs to the **testList** method in the **RedisTest** class of the **com.huawei.redis.demo** package.

```
public void testList() {  
    String key = "messages";  
  
    // Right push  
    client.rpush(key, "Hello how are you?");  
    client.rpush(key, "Fine thanks. I'm having fun with redis.");  
    client.rpush(key, "I should look into this NOSQL thing ASAP");  
  
    // Fetch all data  
    List<String> messages = client.lrange(key, 0, -1);  
    LOGGER.info("All messages: " + messages);  
  
    long len = client.llen(key);  
    LOGGER.info("Message count: " + len);  
  
    // Fetch the first element and delete it from list  
    String message = client.lpop(key);  
    LOGGER.info("First message: " + message);  
    len = client.llen(key);  
    LOGGER.info("After one pop, message count: " + len);  
  
    client.del(key);  
}
```

### 1.18.3.2.4 Hash Type Access

#### Function

Implement setting and obtaining data of Hash type in the Redis, through the methods such as hset, hget, hmset and hgetall in the JedisCluster instance.

#### Example Code

The following code snippet belongs to the **testHash** method in the **RedisTest** class of the **com.huawei.redis.demo** package.

```
public void testHash() {
    String key = "userinfo-001";

    // like Map.put()
    client.hset(key, "id", "J001");
    client.hset(key, "name", "John");
    client.hset(key, "gender", "male");
    client.hset(key, "age", "35");
    client.hset(key, "salary", "1000000");

    // like Map.get()
    String id = client.hget(key, "id");
    String name = client.hget(key, "name");
    LOGGER.info("User " + id + "'s name is " + name);

    Map<String, String> user = client.hgetAll(key);
    LOGGER.info(user);
    client.del(key);

    key = "userinfo-002";
    Map<String, String> user2 = new HashMap<String, String>();
    user2.put("id", "L002");
    user2.put("name", "Lucy");
    user2.put("gender", "female");
    user2.put("age", "25");
    user2.put("salary", "200000");
    client.hmset(key, user2);
    client.hincrBy(key, "salary", 50000);
    id = client.hget(key, "id");
    String salary = client.hget(key, "salary");
    LOGGER.info("User " + id + "'s salary is " + salary);

    // like Map.keySet()
    Set<String> keys = client.hkeys(key);
    LOGGER.info("all fields: " + keys);
    // like Map.values()
    List<String> values = client.hvals(key);
    LOGGER.info("all values: " + values);

    // Fetch some fields
    values = client.hmget(key, "id", "name");
    LOGGER.info("partial field values: " + values);

    // like Map.containsKey()
    boolean exist = client.hexists(key, "gender");
    LOGGER.info("Exist field gender? " + exist);

    // like Map.remove();
    client.hdel(key, "age");
    keys = client.hkeys(key);
    LOGGER.info("after del field age, rest fields: " + keys);

    client.del(key);
}
```

### 1.18.3.2.5 Set Type Access

#### Function

Implement setting and obtaining of Set type in the Redis, through the methods such as sadd and smember in the JedisCluster instance.

#### Example Code

The following code snippet belongs to the **testSet** method in the **RedisTest** class of the **com.huawei.redis.demo** package.

```
public void testSet() {
    String key = "sets";

    client.sadd(key, "HashSet");
    client.sadd(key, "SortedSet");
    client.sadd(key, "TreeSet");

    // like Set.size()
    long size = client.scard(key);
    LOGGER.info("Set size: " + size);

    client.sadd(key, "SortedSet");
    size = client.scard(key);
    LOGGER.info("Set size: " + size);

    Set<String> sets = client.smembers(key);
    LOGGER.info("Set: " + sets);

    client.srem(key, "SortedSet");
    sets = client.smembers(key);
    LOGGER.info("Set: " + sets);

    boolean ismember = client.sismember(key, "TreeSet");
    LOGGER.info("TreeSet is set's member: " + ismember);

    client.del(key);
}
```

### 1.18.3.2.6 Sorted Set Type Access

#### Function

Implement setting and obtaining data of Sorted Set type in the Redis, through the methods such as zadd and zrange in the JedisCluster instance.

#### Example Code

The following code snippet belongs to the **testSortedSet** method in the **RedisTest** class of the **com.huawei.redis.demo** package.

```
public void testSortedSet() {
    String key = "hackers";

    // Score: age
    client.zadd(key, 1940, "Alan Kay");
    client.zadd(key, 1953, "Richard Stallman");
    client.zadd(key, 1965, "Yukihiro Matsumoto");
    client.zadd(key, 1916, "Claude Shannon");
    client.zadd(key, 1969, "Linus Torvalds");
    client.zadd(key, 1912, "Alan Turing");

    // sort by score, ascending order
    Set<String> setValues = client.zrange(key, 0, -1);
    LOGGER.info("All hackers: " + setValues);

    long size = client.zcard(key);
    LOGGER.info("Size: " + size);

    Double score = client.zscore(key, "Linus Torvalds");
    LOGGER.info("Score: " + score);

    long count = client.zcount(key, 1960, 1969);
    LOGGER.info("Count: " + count);

    // sort by score, descending order
```

```
Set<String> setValues2 = client.zrevrange(key, 0, -1);
LOGGER.info("All hackers 2: " + setValues2);

client.zrem(key, "Linus Torvalds");
setValues = client.zrange(key, 0, -1);
LOGGER.info("All hackers: " + setValues);

client.del(key);
}
```

### 1.18.3.2.7 Usage of Basic GEO APIs

#### Function

This section describes how to use basic GEO APIs, such as the geoadd, geodist, and georadius methods of the `JedisCluster` instance.

#### Example Code

The following code snippet belongs to the `testGeo` method in the `RedisTest` class of the `com.huawei.redis.demo` package.

```
public void testGeo() {
    Map<String,GeoCoordinate> locationMap = new HashMap<String, GeoCoordinate>();
    locationMap.put("test1",new GeoCoordinate(10,30));
    locationMap.put("test2",new GeoCoordinate(11,30));
    locationMap.put("test3",new GeoCoordinate(11,31));
    locationMap.put("test4",new GeoCoordinate(12,32));
    locationMap.put("test5",new GeoCoordinate(13,35));

    client.geoadd("location",locationMap);

    double dis = client.geodist("location","test1","test2", GeoUnit.KM);
    LOGGER.info("The distance between test1 and test2 is " + dis + " KM.");

    List<GeoCoordinate> geoCoordinateList = client.geopos("location","test1","test2");
    LOGGER.info("Geo location info is " + geoCoordinateList.toString());

    List<String> hashInfo = client.geohash("location" , "test1" , "test2");
    LOGGER.info("geohash info of test1 and test2 is " + hashInfo.toString());

    List<GeoRadiusResponse> memberInfoByNumber = client.georadius("location" , 11 , 31 , 500 ,
GeoUnit.KM, GeoRadiusParam.geoRadiusParam().withDist());
    LOGGER.info("Get location info by longitude and latitude : ");
    for(GeoRadiusResponse geoRadiusResponse : memberInfoByNumber){
        LOGGER.info(geoRadiusResponse.getMemberByString() + ":" + geoRadiusResponse.getDistance());
    }

    List<GeoRadiusResponse> memberInfoByLocation = client.georadiusByMember("location" , "test3" ,
500 , GeoUnit.KM, GeoRadiusParam.geoRadiusParam().sortAscending().withDist().count(3));
    LOGGER.info("Get location info by member : ");
    for(GeoRadiusResponse geoRadiusResponse : memberInfoByLocation){
        LOGGER.info(geoRadiusResponse.getMemberByString() + ":" + geoRadiusResponse.getDistance());
    }
}
```

### 1.18.3.2.8 Use of Pipelines in the Single-thread Scenario

#### Function

The pipeline (pipeline) function of Redis can achieve the efficient operation in Redis, and `JedisCluster` can read and write cluster data.

#### Example Code

For scenarios that do not require return values and require all return values and some return values, use the corresponding interface in the sample code. The example code is applicable to single-thread scenarios.

```
public void testPipeline() {
    HostAndPort host1 = new HostAndPort(IP_1,PORT_1);
    HostAndPort host2 = new HostAndPort(IP_2,PORT_2);
    HashSet<HostAndPort> set = new HashSet<HostAndPort>();
    set.add(host1);
    set.add(host2);
    JedisCluster cluster = null;
    try{
        cluster = new JedisCluster(set);
        ClusterBatch pipeline = cluster.getPipeline();
        pipeline.set("key1","value1");
        pipeline.set("key2","value2");
        pipeline.set("key3","value3");

        // none returned value
        pipeline.sync();

        // all returned value
        List<Object> syncAndReturnAll = pipeline.syncAndReturnAll();

        //part returned value
        List<Object> syncAndReturn = pipeline.syncAndReturn(new String[]{"key1"});
    }catch(Exception e){
        e.printStackTrace();
    }finally{
        if(cluster != null){
            cluster.close();
        }
    }
}
```

### 1.18.3.2.9 Use of Pipelines in the Multi-thread Scenario

#### Function

The pipeline (pipeline) function of Redis can achieve the efficient operation in Redis, and JedisCluster can read and write cluster data.

#### Example Code

For scenarios that do not require return values and require all return values and some return values, use the corresponding interface in the sample code. The example code is applicable to multi-thread scenarios.

```
public void testPipeline() {
    public static void main(String[] args){
        HostAndPort host1 = new HostAndPort(IP_1,PORT_1);
        HostAndPort host2 = new HostAndPort(IP_2,PORT_2);
        HashSet<HostAndPort> set = new HashSet<HostAndPort>();
        set.add(host1);
        set.add(host2);

        myThread t1 = new myThread(set);
        myThread t2 = new myThread(set);
        myThread t3 = new myThread(set);

        t1.start();
        t2.start();
        t3.start();
    }

    public static class myThread extends Thread{
        private JedisCluster cluster;
```

```
myThread(Set<HostAndPort> set){
    cluster = new JedisCluster(set);
}

public void run(){
    try{
        ClusterBatch pipeline = cluster.getPipeline();
        pipeline.set("key1","value1");
        pipeline.set("key2","value2");
        pipeline.set("key3","value3");

        // none returned value
        pipeline.sync();

        // all returned value
        List<Object> syncAndReturnAll = pipeline.syncAndReturnAll();

        //part returned value
        List<Object> syncAndReturn = pipeline.syncAndReturn(new String[]{"key1"});
    }catch (Exception e){
        e.printStackTrace();
    }finally {
        if(cluster != null){
            cluster.close();
        }
    }
}
```

### 1.18.3.2.10 Use of Pipelines in the bytes data Scenario

#### Function

The pipeline function of Redis can achieve the efficient operation in Redis, and JedisCluster can read and write cluster data.

#### Example Code

For scenarios that do not require return values and require all return values and some return values, use the corresponding interface in the sample code. This example applies to scenarios where input and output parameters are bytes data.

```
public void testBinaryPipeline() {
    HostAndPort host1 = new HostAndPort(IP_1,PORT_1);
    HostAndPort host2 = new HostAndPort(IP_2,PORT_2);
    HashSet<HostAndPort> set = new HashSet<HostAndPort>();
    set.add(host1);
    set.add(host2);
    JedisCluster cluster = null;
    try{
        cluster = new JedisCluster(set);
        BinaryClusterBatch pipeline = cluster.getBinaryPipeline();
        pipeline.set("key1".getBytes(),"value1".getBytes());
        pipeline.set("key2".getBytes(),"value2".getBytes());
        pipeline.set("key3".getBytes(),"value3".getBytes());

        // none returned value
        pipeline.sync();

        // all returned value
        List<Object> syncAndReturnAll = pipeline.syncAndReturnAll();

        //part returned value
        byte[][] part = new byte[][]{"key1".getBytes(), "key2".getBytes()};
        List<Object> syncAndReturn = pipeline.syncAndReturn(part);
    }
```

```
        }catch(Exception e){
            e.printStackTrace();
        }finally{
            if(cluster != null){
                cluster.close();
            }
        }
    }
```

### 1.18.3.2.11 Connection to a Redis Logical ClusterUsing Spring Boot

#### Function

Spring Boot is used to connect to a Redis logical cluster and read and write data in this cluster.

#### Example Code

The example code is used to connect to a Redis logical cluster to realize read and write in Redis.

```
@Repository
public class CustomerRedisTemplateUtil {
    protected static final Logger logger =
LoggerFactory.getLogger(CustomerRedisTemplateUtil.class.getName());
    private static JedisCluster client;
    /**
     * Default connection timeout
     */
    private static final Integer TIMEOUT = 3000;
    /**
     * Maximum retries
     */
    private static final Integer MAX_ATTEMPTS = 1;
    @Value("${spring.redis.cluster.nodes}")
    private String nodes;
    @Value("${redis.keytab}")
    private String keytab;
    @Value("${redis.user}")
    private String user;
    @Value("${redis.krb5}")
    private String krb5;
    @Value("${redis.realm}")
    private String realm;
    @Value("${redis.ssl}")
    private boolean ssl;
    @PostConstruct
    private void init() throws NoSuchAlgorithmException, KeyManagementException {
        if (Objects.isNull(client)) {
            System.setProperty("redis.authentication.jaas", "true");
            AuthConfiguration authConfig = new AuthConfiguration(krb5, keytab, user);
            GlobalConfig.setAuthConfiguration(authConfig);
            authConfig.setServerRealm(realm);
            authConfig.setLocalRealm(realm);
            logger.info("user={}, realm={}", user, realm);
            //Configure the connection pool.
            JedisPoolConfig jedisPoolConfig = new JedisPoolConfig();
            jedisPoolConfig.setMaxTotal(5);
            jedisPoolConfig.setMaxIdle(3);
            jedisPoolConfig.setMinIdle(2);
            Set<HostAndPort> hosts = new HashSet<HostAndPort>();
            for (String node : nodes.split(",")) {
                HostAndPort hp = getIpAndPort(node);
                if (hp == null) {
                    logger.warn("{} not valid", node);
                    continue;
                }
                jedisPoolConfig.addServer(hp.getHost(), hp.getPort());
            }
        }
    }
}
```

```
        }
        hosts.add(hp);
    }
    final SSLSocketFactory socketFactory = SslSocketFactoryUtil.createTrustALLSslSocketFactory();
    client = new JedisCluster(hosts, TIMEOUT, TIMEOUT, TIMEOUT, MAX_ATTEMPTS, jedisPoolConfig,
ssl,
        socketFactory, authConfig);
}
}
public static HostAndPort getIpAndPort(String hostAndPortStr) {
    if (StringUtils.isBlank(hostAndPortStr)) {

}
```

The values of **spring.redis.cluster.nodes**, **redis.user**, **redis.keytab**, **redis.krb5** and **redis.realm** need to be read from the **/src/main/resources/application.properties** configuration file of the sample project. Modify the parameters based on the site requirements.

#### NOTE

- **spring.redis.cluster.nodes** indicates the IP address and port number of the logical cluster. Multiple IP addresses and ports are separated by commas (,), for example, **IP address 1:Port number 1,IP address 2:Port number 2,IP address 3:Port number 3**.
- Obtaining the instance service IP address: Log in to FusionInsight Manager, choose **Cluster > Services > Redis**, and click **Instance** to view the IP addresses of instances running in the cluster.
- Obtaining the port number: On Redis nodes, the port number used by role **Redis\_1** is **22400**, and that used by role **Redis\_2** is **22401**. The others follow the same rule.
- **redis.user** indicates the username for connecting to the Redis logical cluster. The recommended format is **Username@Domain name**, for example, **redis\_user@HADOOP.COM**.
- **redis.keytab** and **redis.krb5** indicate the authentication credentials of the user for connecting to the Redis logical cluster, which can be obtained from the downloaded authentication credentials.
- **redis.realm** indicates the current cluster domain name. You can log in to FusionInsight Manager and choose **System > Permission > Domain** and **Mutual Trust** to view the actual domain name of the cluster.
- **redis.ssl** indicates whether to enable the channel encryption. If the channel encryption is enabled, set this parameter to **true**. Otherwise, set this parameter to **false**. To check whether channel encryption has been enabled for a cluster, perform the following operations:  
Log in to FusionInsight Manager, choose **Cluster > Services > Redis**. On the page that is displayed, click the **Configurations** tab then the **All Configurations** sub-tab. On this sub-tab page, search for **REDIS\_SSL\_ON**. If its value is **true**, SSL channel encryption has been enabled for Redis. Otherwise, channel encryption has been disabled for the Redis cluster.
- **server.port** indicates the port for accessing the Spring Boot server. The default value is **9093** and can be customized.

### 1.18.3.3 Redis Client Authentication Mode

#### 1.18.3.3.1 Usage Instruction

You can access the Redis service in security mode through the Java client provided by Huawei. Currently, four authentication modes are provided. Before the authentication, you need to create a Redis role and user on the FusionInsight Manager management page, for example, create user **redisuser**. For details, see [Development and Operating Environment](#). Then, download the authentication file of the user.

#### 1.18.3.3.2 Authentication Through the auth.conf File

You can use the **auth.conf** configuration file to access the Redis service in security mode. The sample code is as follows:

```
public class SecureJedisClusterDemo {  
    /*  
     * Entry method  
     *  
     * @param args args  
     */  
    public static void main(String[] args) {  
        Set<HostAndPort> hosts = new HashSet<HostAndPort>();  
        hosts.add(new HostAndPort(Const.IP_1, Const.PORT_1));  
        hosts.add(new HostAndPort(Const.IP_2, Const.PORT_2));  
    }  
}
```

```
// add host...
// System.setProperty("SERVER_REALM","HADOOP.COM");

JedisCluster client = new JedisCluster(hosts, 15000);
System.out.println(client.set("SecureJedisClusterDemo", "value"));
System.out.println(client.get("SecureJedisClusterDemo"));
client.del("SecureJedisClusterDemo");
client.close();
}
```

#### NOTE

- Change the values of **Const.IP\_1**, **Const.IP\_2**, **Const.PORT\_1**, and **Const.PORT\_2** in the sample code to the actual IP addresses and port numbers.
